8 WTA	Write Transfer Active: This status bit indicates a write transfer is active. If this bit is 0, it means no valid write data exists in the ESDHC. This bit is set in either of the following cases: • After the end bit of the write command. • When writing 1 to the Continue Request bit in the Protocol Control register to restart a write transfer. This bit is cleared in either of the following cases: • After getting the CRC status of the last data block as specified by the transfer count (Single and Multiple). • After getting the CRC status of any block where data transmission is about to be stopped by a Stop At Block Gap Request.

Table continues on the next page...

ESDHCV2x_PRSSTAT field descriptions (continued)

Field	Description
	During a write transaction, a Block Gap Event interrupt is generated when this bit is changed to 0, as result of the Stop At Block Gap Request being set. This status is useful for the Host Driver in determining when to issue commands during Write Busy state. 1 Transferring data 0 No valid data
7 SDOFF	SD Clock Gated Off Internally: This status bit indicates that the SD Clock is internally gated off, because of buffer over/under-run or read pause without read wait assertion, or the driver has cleared SDCLKEN bit to stop the SD clock. This bit is for the Host Driver to debug data transaction on the SD bus. 1 SD Clock is gated off 0 SD Clock is active
6 PEROFF	ipg_perclk Gated Off Internally: This status bit indicates that the ipg_perclk is internally gated off. This bit is for the Host Driver to debug transaction on the SD bus. When INITA bit is set, ESDHC sending 80 clock cycles to the card, the SDCLKEN bit must be '1' to enable the output card clock, otherwise the ipg_perclk will never be gate off, so ipg_perclk and ipg_clk will be always active. 1 ipg_perclk is gated off 0 ipg_perclk is active
5 HCKOFF	hclk Gated Off Internally: This status bit indicates that the hclk is internally gated off. This bit is for the Host Driver to debug during a data transfer. 1 hclk is gated off 0 hclk is active
4 IPGOFF	ipg_clk Gated Off Internally: This status bit indicates that the ipg_clk is internally gated off. This bit is for the Host Driver to debug. 1 ipg_clk is gated off 0 ipg_clk is active
3 SDSTB	SD Clock Stable This status bit indicates that the internal card clock is stable. This bit is for the Host Driver to poll clock status when changing the clock frequency. It is recommended to clear SDCLKEN bit in System Control register to remove glitch on the card clock when the frequency is changing. 1 clock is stable 0 clock is changing frequency and not stable
2 DLA	Data Line Active This status bit indicates whether one of the DAT lines on the SD Bus is in use. In the case of read transactions: This status indicates if a read transfer is executing on the SD Bus. Changes in this value from 1 to 0, between data blocks, generates a Block Gap Event interrupt in the Interrupt Status register. This bit will be set in either of the following cases:

Table continues on the next page...

ESDHCV2x_PRSSTAT field descriptions (continued)

Field	Description
	• After the end bit of the read command. • When writing a 1 to the Continue Request bit in the Protocol Control register to restart a read transfer. This bit will be cleared in either of the following cases: (1) When the end bit of the last data block is sent from the SD Bus to the ESDHC. (2) When the Read Wait state is stopped by a Suspend command and the DAT2 line is released. The ESDHC will wait at the next block gap by driving Read Wait at the start of the interrupt cycle. If the Read Wait signal is already driven (data buffer cannot receive data), the ESDHC can wait for a current block gap by continuing to drive the Read Wait signal. It is necessary to support Read Wait in order to use the suspend / resume function. This bit will remain 1 during Read Wait. In the case of write transactions: This status indicates that a write transfer is executing on the SD Bus. Changes in this value from 1 to 0 generate a Transfer Complete interrupt in the Interrupt Status register. This bit will be set in either of the following cases: • After the end bit of the write command. • When writing to 1 to the Continue Request bit in the Protocol Control register to continue a write transfer. This bit will be cleared in either of the following cases: • When the SD card releases Write Busy of the last data block, the ESDHC will also detect if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, the ESDHC will assume the card drive "Not Busy". • When the SD card releases write busy, prior to waiting for write transfer, and as a result of a Stop At Block Gap Request. In the case of command with busy pending: This status indicates that a busy state follows the command and the data line is in use. This bit will be cleared when the DAT0 line is released. 1 DAT Line Active 0 DAT Line Inactive
1 CDIHB	Command Inhibit (DAT): This status bit is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this bit is 0, it indicates that the ESDHC can issue the next SD/MMC Command. Commands with a busy signal belong to Command Inhibit (DAT) (for example, R1b, R5b type). Except in the case when the command busy is finished, changing from 1 to 0 generates a Transfer Complete interrupt in the Interrupt Status register. **NOTE:** The SD Host Driver can save registers for a suspend transaction after this bit has changed from 1 to 0. 1 Cannot issue command which uses the DAT line 0 Can issue command which uses the DAT line
0 CIHB	Command Inhibit (CMD): If this status bit is 0, it indicates that the CMD line is not in use and the ESDHC can issue a SD/MMC Command using the CMD line.

Table continues on the next page...

ESDHCV2x_PRSSTAT field descriptions (continued)

Field	Description
	This bit is set also immediately after the Transfer Type register is written. This bit is cleared when the command response is received. Even if the Command Inhibit (DAT) is set to 1, Commands using only the CMD line can be issued if this bit is 0. Changing from 1 to 0 generates a Command Complete interrupt in the Interrupt Status register. If the ESDHC cannot issue the command because of a command conflict error (Refer to Command CRC Error) or because of a Command Not Issued By Auto CMD12 Error, this bit will remain 1 and the Command Complete is not set. The Status of issuing an Auto CMD12 does not show on this bit. 1 Cannot issue command 0 Can issue command using only CMD line

26.7.11 Protocol Control (ESDHCV2x_PROCTL)

There are three cases to restart the transfer after stop at the block gap. The appropriate case depends on whether ESDHC issues a Suspend command or the SD card accepts the Suspend command.

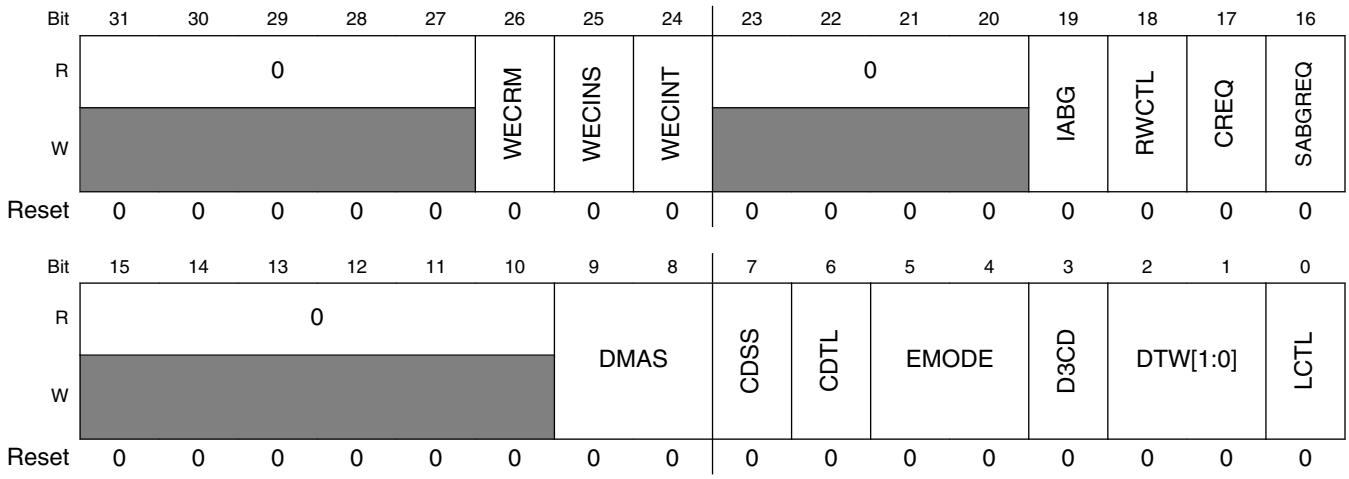
1. If the Host Driver does not issue a Suspend command, the Continue Request will be used to restart the transfer.
2. If the Host Driver issues a Suspend command and the SD card accepts it, a Resume command will be used to restart the transfer.
3. If the Host Driver issues a Suspend command and the SD card does not accept it, the Continue Request will be used to restart the transfer.

Any time Stop At Block Gap Request stops the data transfer, the Host Driver will wait for a Transfer Complete (in the Interrupt Status register), before attempting to restart the transfer. When restarting the data transfer by Continue Request, the Host Driver will clear the Stop At Block Gap Request before or simultaneously.

Addresses: ESDHCV2-1_PROCTL is 5000_4000h base + 28h offset = 5000_4028h

ESDHCV2-2_PROCTL is 5000_8000h base + 28h offset = 5000_8028h

ESDHCV2-4_PROCTL is 5002_4000h base + 28h offset = 5002_4028h



ESDHCV2x_PROCTL field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved
26 WECRM	Wakeup Event Enable On SD Card Removal: This bit enables a wakeup event, through a Card Removal, in the Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, the Card Removal Status and the ESDHC interrupt can be asserted without SD_CLK toggling. When the wakeup feature is not enabled, the SD_CLK must be active in order to assert the Card Removal Status and the ESDHC interrupt. 1 Enable 0 Disable
25 WECINS	Wakeup Event Enable On SD Card Insertion: This bit enables a wakeup event, through a Card Insertion, in the Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, the Card Insertion Status and the ESDHC interrupt can be asserted without SD_CLK toggling. When the wakeup feature is not enabled, the SD_CLK must be active in order to assert the Card Insertion Status and the ESDHC interrupt. 1 Enable 0 Disable
24 WECINT	Wakeup Event Enable On Card Interrupt: This bit enables a wakeup event, through a Card Interrupt, in the Interrupt Status register. This bit can be set to 1 if FN_WUS (Wake Up Support) in CIS is set to 1. When this bit is set, the Card Interrupt Status and the ESDHC interrupt can be asserted without SD_CLK toggling. When the wakeup feature is not enabled, the SD_CLK must be active in order to assert the Card Interrupt Status and the ESDHC interrupt. 1 Enable 0 Disable
23–20 Reserved	This read-only field is reserved and always has the value zero. Reserved

Table continues on the next page...

ESDHCV2x_PROCTL field descriptions (continued)

Field	Description
19 IABG	Interrupt At Block Gap: This bit is valid only in 4-bit mode, of the SDIO card, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SDIO card cannot signal an interrupt during a multiple block transfer, this bit should be set to 0 to avoid an inadvertent interrupt. When the Host Driver detects an SDIO card insertion, it sets this bit according to the CCCR of the card. 1 Enabled 0 Disabled
18 RWCTL	Read Wait Control: The read wait function is optional for SDIO cards. If the card supports read wait, set this bit to enable use of the read wait protocol to stop read data using the DAT[2] line. Otherwise the ESDHC has to stop the SD Clock to hold read data, which restricts commands generation. When the Host Driver detects an SDIO card insertion, it sets this bit according to the CCCR of the card. If the card does not support read wait, this bit will never be set to 1, otherwise DAT line conflicts may occur. If this bit is set to 0, stop at block gap during read operation is also supported, but the ESDHC will stop the SD Clock to pause reading operation. 1 Enable Read Wait Control, and assert Read Wait without stopping SD Clock at block gap when SABGREQ bit is set 0 Disable Read Wait Control, and stop SD Clock at block gap when SABGREQ bit is set
17 CREQ	Continue Request: This bit is used to restart a transaction which was stopped using the Stop At Block Gap Request. When a Suspend operation is not accepted by the card, it is also by setting this bit to restart the paused transfer. To cancel stop at the block gap, set Stop At Block Gap Request to 0 and set this bit to 1 to restart the transfer. The ESDHC automatically clears this bit, therefore it is not necessary for the Host Driver to set this bit to 0. If both Stop At Block Gap Request and this bit are 1, the continue request is ignored. 1 Restart 0 No effect
16 SABGREQ	Stop At Block Gap Request: This bit is used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the Transfer Complete is set to 1, indicating a transfer completion, the Host Driver will leave this bit set to 1. Clearing both the Stop At Block Gap Request and Continue Request does not cause the transaction to restart. Read Wait is used to stop the read transaction at the block gap. The ESDHC will honor the Stop At Block Gap Request for write transfers, but for read transfers it requires that the SDIO card support Read Wait. Therefore, the Host Driver will not set this bit during read transfers unless the SDIO card supports Read Wait and has set the Read Wait Control to 1, otherwise the ESDHC will stop the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the Host Driver writes data to the Data Port register, the Host Driver will set this bit after all block data is written. If this bit is set to 1, the Host Driver will not write data to the Data Port register after a block is sent. Once this bit is set, the Host Driver will not clear this bit before the Transfer Complete bit in Interrupt Status Register is set, otherwise the ESDHCs behavior is undefined. This bit effects Read Transfer Active, Write Transfer Active, DAT Line Active and Command Inhibit (DAT) in the Present State register. 1 Stop 0 Transfer

ESDHCV2x_PROCTL field descriptions (continued)

Field	Description
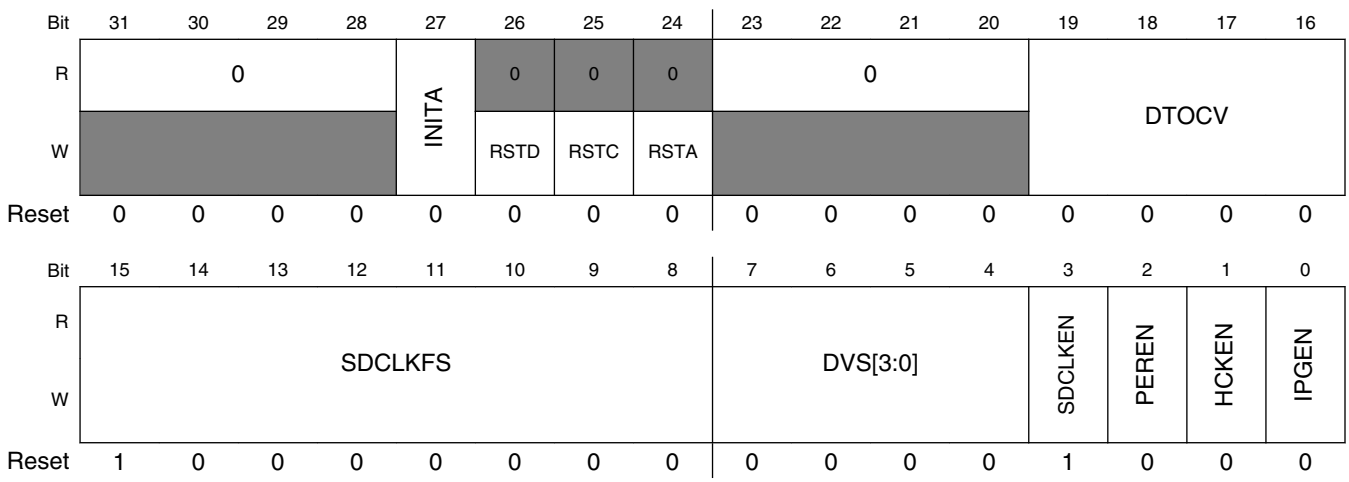
	This bit, fully controlled by the Host Driver, is used to caution the user not to remove the card while the card is being accessed. If the software is going to issue multiple SD commands, this bit can be set during all these transactions. It is not necessary to change for each transaction. When the software issues multiple SD commands, setting the bit once before the first command is sufficient; it is not necessary to reset the bit between commands. 1 LED on 0 LED off

26.7.12 System Control (ESDHCV2x_SYSCTL)

Addresses: ESDHCV2-1_SYSCTL is 5000_4000h base + 2Ch offset = 5000_402Ch
ESDHCV2-2_SYSCTL is 5000_8000h base + 2Ch offset = 5000_802Ch
ESDHCV2-4_SYSCTL is 5002_4000h base + 2Ch offset = 5002_402Ch



ESDHCV2x_SYSCTL field descriptions

Field	Description
31–28 Reserved	This read-only field is reserved and always has the value zero. Reserved
27 INITA	Initialization Active: When this bit is set, 80 SD-Clocks are sent to the card. After the 80 clocks are sent, this bit is self cleared. This bit is very useful during the card power-up period when 74 SD-Clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this bit is already 1 has no effect. Writing 0 to this bit at any time has no effect. When either of the CIHB and CDIHB bits in the Present State Register are set, writing 1 to this bit is ignored (that is, when command line or data lines are active, write to this bit is not allowed). On the other hand, when this bit is set, that is, during initialization active period, it is allowed to issue commands, and the command bit stream will appear on the CMD pad after all 80 clock cycles are completer. When this command ends, the driver can make sure that the 80 clock cycles are sent out, which is very useful when the driver needs to send 80 cycles to the card and does not want to wait until this bit is self cleared.

Table continues on the next page...

ESDHCV2x_SYSCTL field descriptions (continued)

Field	Description
26 RSTD	Software Reset For DAT Line: Only part of the data circuit is reset. DMA circuit is also reset. The following registers and bits are cleared by this bit: • Data Port register • Buffer is cleared and initialized.Present State register • Buffer Read Enable • Buffer Write Enable • Read Transfer Active • Write Transfer Active • DAT Line Active • Command Inhibit (DAT) Protocol Control register • Continue Request • Stop At Block Gap Request Interrupt Status register • Buffer Read Ready • Buffer Write Ready • DMA Interrupt • Block Gap Event • Transfer Complete 1 Reset 0 No Reset
25 RSTC	Software Reset For CMD Line: Only part of the command circuit is reset. The following registers and bits are cleared by this bit: • Present State register Command Inhibit (CMD) • Interrupt Status register Command Complete 1 Reset 0 No Reset
24 RSTA	Software Reset For ALL: This reset effects the entire Host Controller except for the card detection circuit. Register bits of type ROC, RW, RW1C, RWAC are cleared. During its initialization, the Host Driver will set this bit to 1 to reset the ESDHC. The ESDHC will reset this bit to 0 when the capabilities registers are valid and the Host Driver can read them. Additional use of Software Reset For All does not affect the value of the Capabilities registers. After this bit is set, it is recommended that the Host Driver reset the external card and re-initialize it. b Reset 0 No Reset
23–20 Reserved	This read-only field is reserved and always has the value zero. Reserved
19–16 DTOCV	Data Timeout Counter Value: This value determines the interval by which DAT line timeouts are detected. Refer to the Data Timeout Error bit in the Interrupt Status register for information on factors that dictate time-out generation. Time-out clock frequency will be generated by dividing the base clock SDCLK value by this value. The Host Driver can clear the Data Timeout Error Status Enable (in the Interrupt Status Enable register) to prevent inadvertent time-out events.

Table continues on the next page...

ESDHCV2x_SYSCTL field descriptions (continued)

Field	Description
	1111 Reserved 1110 SDCLK x 2^{27} 0001 SDCLK x 2^{14} 0000 SDCLK x 2^{13}
15–8 SDCLKFS	SDCLK Frequency Select: This register is used to select the frequency of the SDCLK pin. The frequency is not programmed directly, rather this register holds the prescaler (this register) and divisor (next register) of the Base Clock Frequency register. Setting 00h bypasses the frequency prescaler of the SD Clock. Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of ipg_perclk and the following Divisor bits. The frequency of SDCLK is set by the following formula: Clock Frequency = (Base Clock) / (prescaler x divisor) For example, if the Base Clock Frequency is 96 MHz, and the target frequency is 25 MHz, then choosing the prescaler value of 01h and divisor value of 1h will yield 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 08h and divisor value of eh yields the exact clock value of 400 kHz. The reset value of this bit field is 80h, so if the input Base Clock (ipg_perclk) is about 96 MHz, the default SD Clock after reset is 375 kHz. According to the SD Physical Specification Version 1.1 and the SDIO Card Specification Version 1.2, the maximum SD Clock frequency is 50 MHz and will never exceed this limit. Only the following settings are allowed: 0x80 Base clock divided by 256 0x40 Base clock divided by 128 0x20 Base clock divided by 64 0x10 Base clock divided by 32 0x08 Base clock divided by 16 0x04 Base clock divided by 8 0x02 Base clock divided by 4 0x01 Base clock divided by 2 0x00 Base clock (10 MHz-63 MHz)
7–4 DVS[3:0]	Divisor: This register is used to provide a more exact divisor to generate the desired SD clock frequency. **NOTE:** The divider can even support odd divisor without deterioration of duty cycle. The setting are as following: 0x0 Divisor by 1 0x1 Divisor by 2 0xe Divisor by 15 0xf Divisor by 16

Table continues on the next page...

ESDHCV2x_SYSCTL field descriptions (continued)

Field	Description
3 SDCLKEN	SD Clock Enable The Host Controller will stop SDCLK when writing this bit to 0. SDCLK Frequency can be changed when this bit is 0. Then, the Host Controller will maintain the same clock frequency until SDCLK is stopped (Stop at SDCLK=0). If the Card Inserted in the Present State register is cleared, this bit should be cleared by the Host Driver to save power.
2 PEREN	Peripheral Clock Enable: If this bit is set, ipg_perclk will always be active and no automatic gating is applied. Thus the SDCLK is active except when auto gating-off during buffer danger (buffer about to over-run or under-run). When this bit is cleared, the ipg_perclk will be automatically off when there is no transaction on the SD bus. As this bit is only a feature enabling bit, clearing this bit does not stop SDCLK immediately. The ipg_perclk will be internally gated off, if none of the following factors are met: • The cmd part is reset, or • Data part is reset, or • A soft reset, or • The cmd is about to send, or • Clock divisor is just updated, or • Continue request is just set, or • This bit is set, or • Card insertion is detected, or • Card removal is detected, or • Card external interrupt is detected, or • 80 clocks for initialization phase is ongoing 1 ipg_perclk will not be automatically gated off 0 ipg_perclk will be internally gated off
1 HCKEN	HCLK Enable: If this bit is set, hclk will always be active and no automatic gating is applied. When this bit is cleared, hclk will be automatically off when no data transfer is on the SD bus. 1 hclk will not be automatically gated off 0 hclk will be internally gated off
0 IPGEN	IPG Clock Enable: If this bit is set, ipg_clk will always be active and no automatic gating is applied. The ipg_clk will be internally gated off, if none of the following factors are met: • The cmd part is reset, or • Data part is reset, or • Soft reset, or • The cmd is about to send, or • Clock divisor is just updated, or • Continue request is just set, or • This bit is set, or • Card insertion is detected, or • Card removal is detected, or • Card external interrupt is detected, or • The ipg_perclk is not gated off **NOTE:** The ipg_clk will not be auto gated off if the ipg_perclk is not gated off. Clearing only this bit has no effect unless the PEREN bit is also cleared.

Table continues on the next page...

Field	Description
	1 ipg_clk will not be automatically gated off 0 ipg_clk will be internally gated off

26.7.13 Interrupt Status (ESDHCV2x_IRQSTAT)

An interrupt is generated when the Normal Interrupt Signal Enable is enabled and at least one of the status bits is set to 1. For all bits, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. Before clearing the Card Interrupt, make sure that the card stops asserting the interrupt, that is, the Card Driver stops servicing the interrupt condition. Otherwise, the CINT bit will be asserted again.

Interrupt Status (ESDHCV2_IRQSTAT) below shows the relationship between the Command Timeout Error and the Command Complete.

Table 26-54. ESDHC Status for Command Timeout Error/Command Complete Bit Combinations

Command Complete	Command Timeout Error	Meaning of the Status
0	0	X
X	1	Response not received within 64 SDCLK cycles
1	0	Response received

Table below shows the relationship between the Transfer Complete and the Data Timeout Error.

Table 26-55. ESDHC Status for Data Timeout Error/Transfer Complete Bit Combinations

Transfer Complete	Data Timeout Error	Meaning of the Status
0	0	X
0	1	Timeout occurred during transfer
1	X	Data Transfer Complete

Table below shows the relationship between the Command CRC Error and Command Timeout Error.

Table 26-56. ESDHC Status for Command CRC Error/Command Timeout Error Bit Combinations

Command Complete	Command Timeout Error	Meaning of the Status
0	0	No error
0	1	Response Timeout Error
1	0	Response CRC Error
1	1	CMD line conflict

Addresses: ESDHCV2-1_IRQSTAT is 5000_4000h base + 30h offset = 5000_4030h
ESDHCV2-2_IRQSTAT is 5000_8000h base + 30h offset = 5000_8030h
ESDHCV2-4_IRQSTAT is 5002_4000h base + 30h offset = 5002_4030h

ESDHCV2*x*_IRQSTAT field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value zero. Reserved
28 DMAE	DMA Error: Occurs when an Internal DMA transfer has failed. This bit is set to 1, when some error occurs in the data transfer. This error can be caused by either Simple DMA or ADMA, depending on which DMA is in use. The value in DMA System Address register is the next fetch address where the error occurs. As any error corrupts the whole data block, the Host Driver will re-start the transfer from the corrupted block boundary. The address of the block boundary can be calculated either from the current DS_ADDR value or from the remaining number of blocks and the block size. 1 Error 0 No Error
27–25 Reserved	This read-only field is reserved and always has the value zero. Reserved

Table continues on the next page...

ESDHCV2x_IRQSTAT field descriptions (continued)

Field	Description
24 AC12E	Auto CMD12 Error: Occurs when detecting that one of the bits in the Auto CMD12 Error Status register has changed from 0 to 1. This bit is set to 1, not only when the errors in Auto CMD12 occur, but also when the Auto CMD12 is not executed due to the previous command error. 1 Error 0 No Error
23 Reserved	This read-only field is reserved and always has the value zero. Reserved
22 DEBE	Data End Bit Error: Occurs either when detecting 0 at the end bit position of read data, which uses the DAT line, or at the end bit position of the CRC. 1 Error 0 No Error
21 DCE	Data CRC Error: Occurs when detecting a CRC error when transferring read data, which uses the DAT line, or when detecting the Write CRC status having a value other than 010. 1 Error 0 No Error
20 DTOE	Data Timeout Error: Occurs when detecting one of following time-out conditions. • Busy time-out for R1b,R5b type • Busy time-out after Write CRC status • Read Data time-out. 1 Time out 0 No Error
19 CIE	Command Index Error: Occurs if a Command Index error occurs in the command response. 1 Error 0 No Error
18 CEBE	Command End Bit Error: Occurs when detecting that the end bit of a command response is 0. 1 End Bit Error Generated 0 No Error
17 CCE	Command CRC Error: Command CRC Error is generated in two cases. • If a response is returned and the Command Timeout Error is set to 0 (indicating no time-out), this bit is set when detecting a CRC error in the command response. • The ESDHC detects a CMD line conflict by monitoring the CMD line when a command is issued. If the ESDHC drives the CMD line to 1, but detects 0 on the CMD line at the next SDCLK edge, then

Table continues on the next page...

ESDHCV2x_IRQSTAT field descriptions (continued)

Field	Description
	the ESDHC will abort the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error will also be set to 1 to distinguish CMD line conflict. 1 CRC Error Generated. 0 No Error
16 CTOE	Command Timeout Error: Occurs only if no response is returned within 64 SDCLK cycles from the end bit of the command. If the ESDHC detects a CMD line conflict, in which case a Command CRC Error will also be set (as shown in Interrupt Status (ESDHCV2_IRQSTAT)), this bit will be set without waiting for 64 SDCLK cycles. Because the command will be aborted by the ESDHC. 1 Time out 0 No Error
15–9 Reserved	This read-only field is reserved and always has the value zero. Reserved
8 CINT	Card Interrupt: This status bit is set when an interrupt signal is detected from the external card. In 1-bit mode, the ESDHC will detect the Card Interrupt without the SD Clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so the interrupt from card can only be sampled during interrupt cycle, introducing some delay between the interrupt signal from the SDIO card and the interrupt to the Host System. Writing 1 to this bit will clear it, but as the interrupt factor from the SDIO card is not clear, this bit is set again. In order to clear this bit, reset the interrupt factor from the external card and then clear this bit. When this status bit is set, and the Host Driver needs to service this interrupt, the Card Interrupt Signal Enable in the Interrupt Signal Enable register should be cleared to deactivate the interrupt signal to the Host System. After completion of the card interrupt service, (it should reset the interrupt factors in the SDIO card and the interrupt signal should not be asserted), write 1 to clear this bit, enable the Card Interrupt Signal Enable and start sampling the interrupt signal again. 1 Generate Card Interrupt 0 No Card Interrupt
7 CRM	Card Removal: This status bit is set if the Card Inserted bit (PRSSTNT[CINS]) changes from 1 to 0. When the Host Driver writes this bit to 1 to clear this status, the status of CINS should be confirmed, because the card state may possibly change when the Host Driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if no card is inserted. In order to leave it cleared, clear the Card Removal Status Enable bit IRQSTATEN[CRMSEN]in Interrupt Status Enable register. 1 Card removed 0 Card state unstable or inserted
6 CINS	Card Insertion: This status bit is set if the Card Inserted bit in the Present State register changes from 0 to 1. When the Host Driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state may possibly be changed when the Host Driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if a card is inserted. In order to leave it cleared, clear the Card Inserted Status Enable bit in Interrupt Status Enable register.

Table continues on the next page...

ESDHCV2x_IRQSTAT field descriptions (continued)

Field	Description
	1 Card inserted 0 Card state unstable or removed
5 BRR	Buffer Read Ready: This status bit is set if the Buffer Read Enable bit, in the Present State register, changes from 0 to 1. Refer to the Buffer Read Enable bit in the Present State register for additional information. 1 Ready to read buffer 0 Not ready to read buffer
4 BWR	Buffer Write Ready: This status bit is set if the Buffer Write Enable bit, in the Present State register, changes from 0 to 1. Refer to the Buffer Write Enable bit in the Present State register for additional information. 1 Ready to write buffer: 0 Not ready to write buffer
3 DINT	DMA Interrupt: Occurs only when the internal DMA finishes the data transfer successfully. When errors occur during data transfer, this bit will not be set. Instead, the DMAE bit will be set. Either Simple DMA or ADMA finishes data transferring, this bit will be set. 1 DMA Interrupt is generated 0 No DMA Interrupt
2 BGE	Block Gap Event: If the Stop At Block Gap Request bit in the Protocol Control register is set, this bit is set when a read or write transaction is stopped at a block gap. If Stop At Block Gap Request is not set to 1, this bit is not set to 1. In the case of a Read Transaction: This bit is set at the falling edge of the DAT Line Active Status (When the transaction is stopped at SD Bus timing). The Read Wait must be supported in order to use this function. In the case of Write Transaction: This bit is set at the falling edge of Write Transfer Active Status (After getting CRC status at SD Bus timing). 1 Transaction stopped at block gap 0 No block gap event
1 TC	Transfer Complete: This bit is set when a read or write transfer is completed. In the case of a Read Transaction: This bit is set at the falling edge of the Read Transfer Active Status. There are two cases in which this interrupt is generated. The first is when a data transfer is completed as specified by the data length (after the last data has been read to the Host System). The second is when data has stopped at the block gap and completed the data transfer by setting the Stop At Block Gap Request bit in the Protocol Control register (after valid data has been read to the Host System). In the case of a Write Transaction: This bit is set at the falling edge of the DAT Line Active Status. There are two cases in which this interrupt is generated. The first is when the last data is written to the SD card as specified by the data length and the busy signal is released. The second is when data transfers are stopped at the block gap, by setting the Stop At Block Gap Request bit in the Protocol Control register, and the data transfers are completed. (After valid data is written to the SD card and the busy signal released.)

Table continues on the next page...

ESDHCV2x_IRQSTAT field descriptions (continued)

Field	Description
	1 Transfer complete 0 Transfer not complete
0 CC	Command Complete: This bit is set when you receive the end bit of the command response (except Auto CMD12). Refer to the Command Inhibit (CMD) in the Present State register. 1 Command complete 0 Command not complete

26.7.14 Interrupt Status Enable (ESDHCV2x_IRQSTATEN)

Setting the bits in this register to 1 enables the corresponding Interrupt Status to be set by the specified event. If any bit is cleared, the corresponding Interrupt Status bit is also cleared (that is, when the bit in this register is cleared, the corresponding bit in Interrupt Status Register is always 0).

- Depending on IABG bit setting, ESDHC may be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There will be some delays on the Card Interrupt, asserted from the card, to the time the Host System is informed.
- To detect a CMD line conflict, the Host Driver must set both Command Timeout Error Status Enable and Command CRC Error Status Enable to 1.

Addresses: ESDHCV2-1_IRQSTATEN is 5000_4000h base + 34h offset = 5000_4034h
ESDHCV2-2_IRQSTATEN is 5000_8000h base + 34h offset = 5000_8034h

26.7.15 Interrupt Signal Enable (ESDHCV2x_IRQSIGEN)

This register is used to select which interrupt status is indicated to the Host System as the interrupt. These status bits all share the same interrupt line. Setting any of these bits to 1 enables interrupt generation. The corresponding Status register bit will generate an interrupt when the corresponding interrupt signal enable bit is set.

Addresses: ESDHCV2-1_IRQSIGEN is 5000_4000h base + 38h offset = 5000_4038h
ESDHCV2-2_IRQSIGEN is 5000_8000h base + 38h offset = 5000_8038h

26.7.16 Auto CMD12 Status (ESDHCV2x_AUTOC12ERR)

When the Auto CMD12 Error Status bit in the Status register is set, the Host Driver will check this register to identify what kind of error the Auto CMD12 indicated. This register is valid only when the Auto CMD12 Error status bit is set.

Table below shows the relationship between the Auto CMGD12 CRC Error and the Auto CMD12 Command Timeout Error.

Table 26-60. Relationship Between Command CRC Error and Command Timeout Error for Auto CMD12

Auto CMD12 CRC Error	Auto CMD12 Timeout Error	Type of Error
0	0	No Error
0	1	Response Timeout Error
1	0	Response CRC Error
1	1	CMD line conflict

Changes in Auto CMD12 Error Status register can be classified in three scenarios:

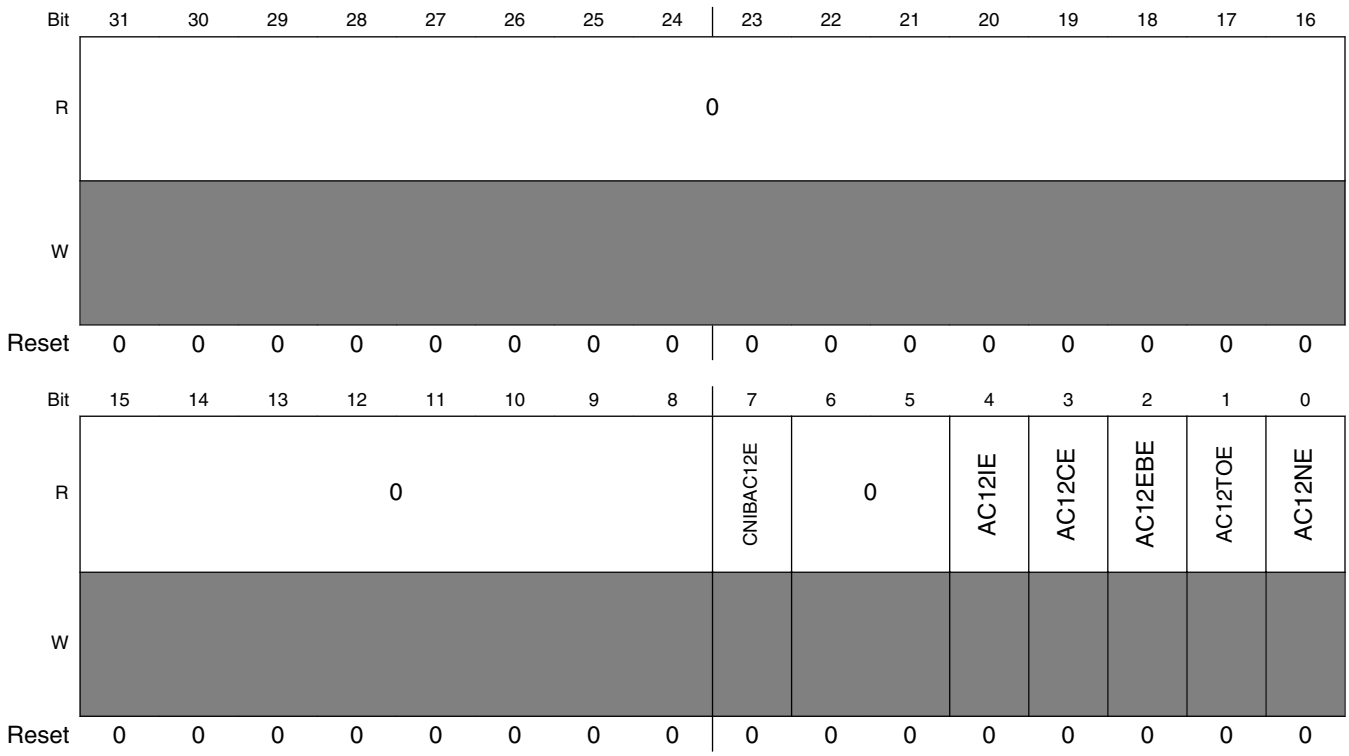
1. When the ESDHC is going to issue an Auto CMD12.
2. Set bit 0 to 1 if the Auto CMD12 cannot be issued due to an error in the previous command
3. Set bit 0 to 0 if the Auto CMD12 is issued
4. At the end bit of an Auto CMD12 response:
    - Check errors correspond to bits 1-4.

- Set bits 1-4 corresponding to detected errors.
- Clear bits 1-4 corresponding to detected errors

5. Before reading the Auto CMD12 Error Status bit 7:
   - Set bit 7 to 1 if there is a command that cannot be issued
   - Clear bit 7 if there is no command to issue

The timing for generating the Auto CMD12 Error and writing to the Command register are asynchronous. After that, bit 7 will be sampled when the driver is not writing to the Command register. It is suggested to read this register only when the AC12E bit in Interrupt Status register is set. An Auto CMD12 Error Interrupt is generated when one of the error bits (0-4) is set to 1. The Command Not Issued By Auto CMD12 Error does not generate an interrupt.

Addresses: ESDHCV2-1_AUTOC12ERR is 5000_4000h base + 3Ch offset = 5000_403Ch
ESDHCV2-2_AUTOC12ERR is 5000_8000h base + 3Ch offset = 5000_803Ch
ESDHCV2-4_AUTOC12ERR is 5002_4000h base + 3Ch offset = 5002_403Ch



ESDHCV2x_AUTOC12ERR field descriptions

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7 CNIBAC12E	Command Not Issued By Auto CMD12 Error: Setting this bit to 1 means CMD_wo_DAT is not executed due to an Auto CMD12 Error (D04-D01) in this register.

Table continues on the next page...

ESDHCV2x_AUTOC12ERR field descriptions (continued)

Field	Description
	1 Not Issued 0 No error
6–5 Reserved	This read-only field is reserved and always has the value zero. Reserved
4 AC12IE	Auto CMD12 Index Error: Occurs if the Command Index error occurs in response to a command. 1 Error, the CMD index in response is not CMD12 0 No error
3 AC12CE	Auto CMD12 CRC Error: Occurs when detecting a CRC error in the command response. 1 CRC Error Met in Auto CMD12 Response 0 No CRC error
2 AC12EBE	Auto CMD12 End Bit Error: Occurs when detecting that the end bit of command response is 0 which should be 1. 1 End Bit Error Generated 0 No error
1 AC12TOE	Auto CMD12 Timeout Error: Occurs if no response is returned within 64 SDCLK cycles from the end bit of the command. If this bit is set to1, the other error status bits (2-4) have no meaning. 1 Time out 0 No error
0 AC12NE	Auto CMD12 Not Executed: If memory multiple block data transfer is not started, due to a command error, this bit is not set because it is not necessary to issue an Auto CMD12. Setting this bit to 1 means the ESDHC cannot issue the Auto CMD12 to stop a memory multiple block data transfer due to some error. If this bit is set to 1, other error status bits (1-4) have no meaning. 1 Not executed 0 Executed

26.7.17 Host Controller Capabilities (ESDHCV2x_HOSTCAPBLT)

This register provides the Host Driver with information specific to the ESDHC implementation. The value in this register is the power-on-reset value, and does not change with a software reset. Any write to this register is ignored.

Addresses: ESDHCV2-1_HOSTCAPBLT is 5000_4000h base + 40h offset = 5000_4040h
ESDHCV2-2_HOSTCAPBLT is 5000_8000h base + 40h offset = 5000_8040h

Field	Description
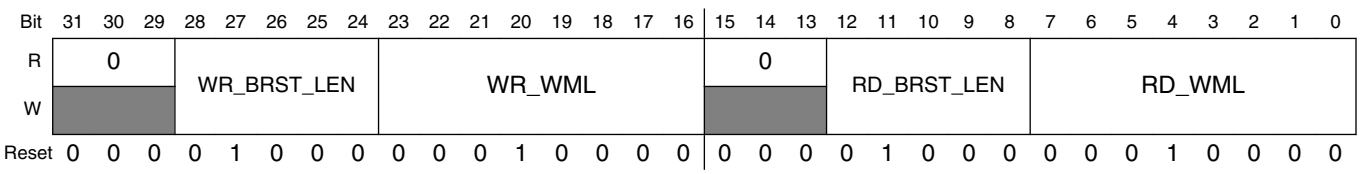
23 SRS	Suspend / Resume Support: This bit indicates whether the ESDHC supports Suspend / Resume functionality. If this bit is 0, the Suspend and Resume mechanism, as well as the Read Wait, are not supported, and the Host Driver will not issue either Suspend or Resume commands. 1 Supported 0 Not supported
22 DMAS	DMA Support: This bit indicates whether the ESDHC is capable of using the internal DMA to transfer data between system memory and the data buffer directly. 1 DMA Supported 0 DMA not supported
21 HSS	High Speed Support: This bit indicates whether the ESDHC supports High Speed mode and the Host System can supply a SD Clock frequency from 25 MHz to 50 MHz. 1 High Speed Supported 0 High Speed Not Supported
20 ADMAS	ADMA Support: This bit indicates whether the ESDHC supports the ADMA feature. 1 Advanced DMA Supported 0 Advanced DMA Not supported
19 Reserved	This read-only field is reserved and always has the value zero. Reserved
18–16 MBL[2:0]	Max Block Length: This value indicates the maximum block size that the Host Driver can read and write to the buffer in the ESDHC. The buffer will transfer block size without wait cycles. 000 512 bytes 001 1024 bytes 010 2048 bytes 011 4096 bytes
15–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

26.7.18 Watermark Level (ESDHCV2*x*_WML)

Both write and read watermark levels (FIFO threshold) are configurable. There value can range from 1 to 128 words. Both write and read burst lengths are also configurable. There value can range from 1 to 31 words.

Addresses: ESDHCV2-1_WML is 5000_4000h base + 44h offset = 5000_4044h
ESDHCV2-2_WML is 5000_8000h base + 44h offset = 5000_8044h
ESDHCV2-4_WML is 5002_4000h base + 44h offset = 5002_4044h



ESDHCV2*x*_WML field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value zero. Reserved
28–24 WR_BRST_LEN	Write Burst Length:[1] The number of words the ESDHC writes in a single burst. The write burst length must be less than or equal to the write watermark level, and all bursts within a watermark level transfer will be in back-to-back mode. On reset, this field will be 8. Writing 0 to this field will result in '01000' (that is, it is not able to clear this field).
23–16 WR_WML	Write Watermark Level: The number of words used as the watermark level (FIFO threshold) in a DMA write operation. Also the number of words as a sequence of write bursts in back-to-back mode. The maximum legal value for the write watermark level is 128.
15–13 Reserved	This read-only field is reserved and always has the value zero. Reserved
12–8 RD_BRST_LEN	Read Burst Length:[2] The number of words the ESDHC reads in a single burst. The read burst length must be less than or equal to the read watermark level, and all bursts within a watermark level transfer will be in back-to-back mode. On reset, this field will be 8. Writing 0 to this field will result in '01000' (that is, it is not able to clear this field.
7–0 RD_WML	Read Watermark Level: The number of words used as the watermark level (FIFO threshold) in a DMA read operation. Also the number of words as a sequence of read bursts in back-to-back mode. The maximum legal value for the read water mark level is 128.

1. Due to system restriction, the actual burst length may not exceed 16.
2. Due to system restriction, the actual burst length may not exceed 16.

26.7.19 Force Event (ESDHCV2x_FEVT)

The Force Event Register is not a physically implemented register. Rather, it is an address at which the Interrupt Status Register can be written if the corresponding bit of the Interrupt Status Enable Register is set. This register is a write only register and writing 0 to it has no effect. Writing 1 to this register sets the corresponding bit of Interrupt Status Register. A read from this register always results in 0's. In order to change the corresponding status bits in the Interrupt Status Register, set IPGEN bit in System Control Register so that ipg_clk is always active.

Forcing a card interrupt will generate a short pulse on the DAT[1] line, and the driver will treat this interrupt as a normal interrupt. The interrupt service routine will skip polling the card interrupt factor as the interrupt is self cleared.

Addresses: ESDHCV2-1_FEVT is 5000_4000h base + 50h offset = 5000_4050h
ESDHCV2-2_FEVT is 5000_8000h base + 50h offset = 5000_8050h
ESDHCV2-4_FEVT is 5002_4000h base + 50h offset = 5002_4050h

0 FEVTAC12NE	Force Event Auto Command 12 Not Executed: Forces the AC12NE bit in the Auto Command12 Error Status Register to be set

26.7.20 ADMA Error Status Register (ESDHCV2x_ADMAES)

When an ADMA Error Interrupt occurrs, the ADMA Error States field (ADMAES) in this register holds the ADMA state and the ADMA System Address register (ADSADDR) holds the address of the error descriptor.

To recover from this error, the Host Driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address
- ST_FDS: Current location set in the ADMA System Address register is the error descriptor address
- ST_CADR: This state is never set because it only increments the descriptor pointer and doesn't generate an ADMA error
- ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address

In case of a write operation, the Host Driver should use ACMD22 command (see field descriptions table) to get the number of the written block, because unwritten data may exist in the Host Controller.

The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) in the ST_FDS state. The Host Driver can distinguish this error by reading the Valid bit of the error descriptor.

Table 26-65. ADMA Error State Coding

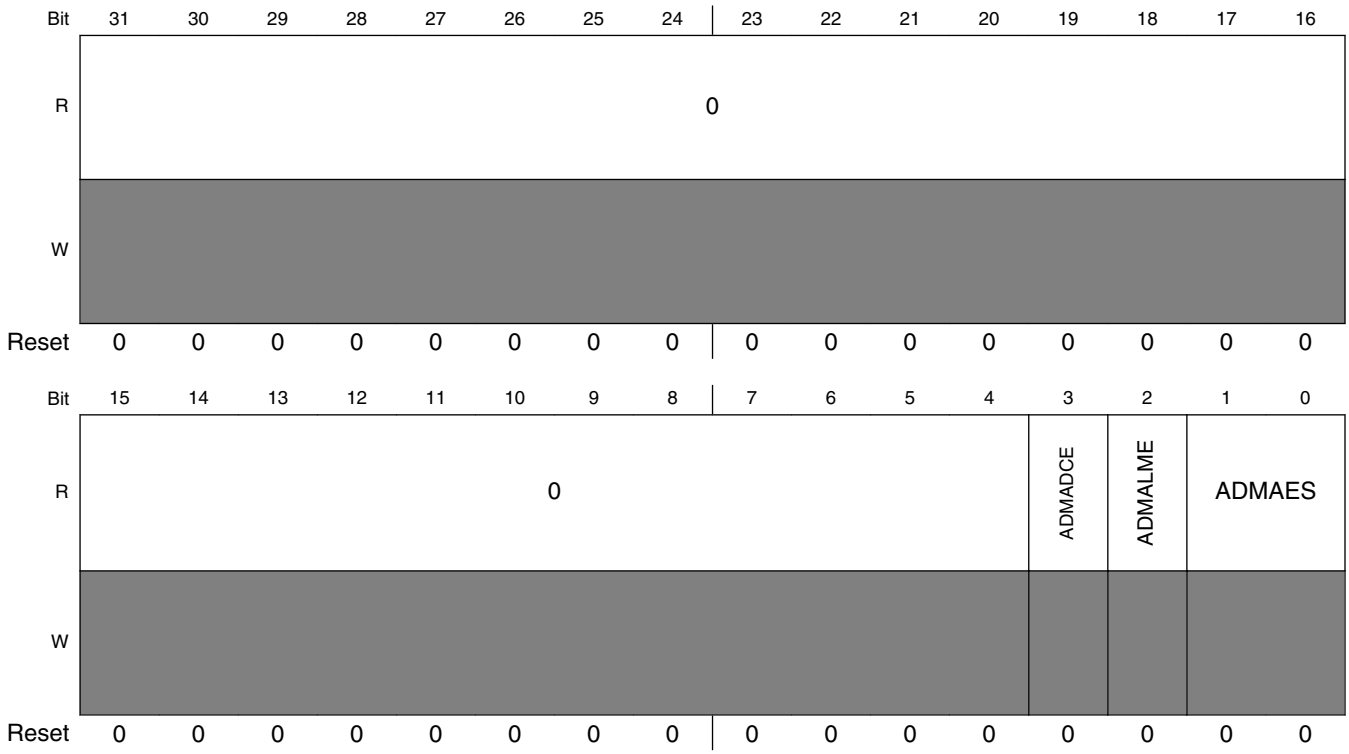
D01-D00	ADMA Error State (when error has occurred)	Contents of ADMA System Address Register
00	ST_STOP (Stop DMA)	Holds the address of the next executable Descriptor command
01	ST_FDS (Fetch Descriptor)	Holds the valid Descriptor address

Table continues on the next page...

Table 26-65. ADMA Error State Coding (continued)

D01-D00	ADMA Error State (when error has occurred)	Contents of ADMA System Address Register
10	ST_CADR (Change Address)	No ADMA Error is generated
11	ST_TFR (Transfer Data)	Holds the address of the next executable Descriptor command

Addresses: ESDHCV2-1_ADMAES is 5000_4000h base + 54h offset = 5000_4054h
ESDHCV2-2_ADMAES is 5000_8000h base + 54h offset = 5000_8054h
ESDHCV2-4_ADMAES is 5002_4000h base + 54h offset = 5002_4054h



ESDHCV2*x*_ADMAES field descriptions

Field	Description
31–4 Reserved	This read-only field is reserved and always has the value zero. Reserved
3 ADMADCE	ADMA Descritor Error: This error occurs when invalid descriptor fetched by ADMA: 1 Error 0 No Error
2 ADMALME	ADMA Length Mismatch Error: This error occurs in the following 2 cases:

Table continues on the next page...

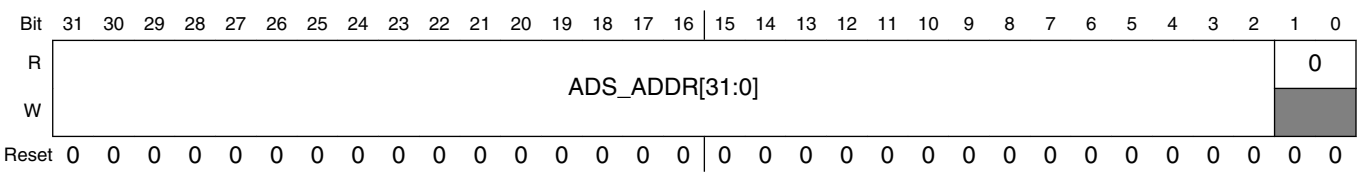
ESDHCV2x_ADMAES field descriptions (continued)

Field	Description
	• While the Block Count Enable is being set, the total data length specified by the Descriptor table is different from that specified by the Block Count and Block Length • Total data length can not be divided by the block length 1 Error 0 No Error
1–0 ADMAES	ADMA Error State (when ADMA Error is occurred.): This field indicates the state of the ADMA when an error has occurred during an ADMA data transfer. Refer to ADMA Error Status Register (ESDHCV2_ADMAES) for more details.

26.7.21 ADMA System Address (ESDHCV2x_ADSADDR)

This register contains the physical system memory address used for ADMA transfers.

Addresses: ESDHCV2-1_ADSADDR is 5000_4000h base + 58h offset = 5000_4058h
ESDHCV2-2_ADSADDR is 5000_8000h base + 58h offset = 5000_8058h
ESDHCV2-4_ADSADDR is 5002_4000h base + 58h offset = 5002_4058h



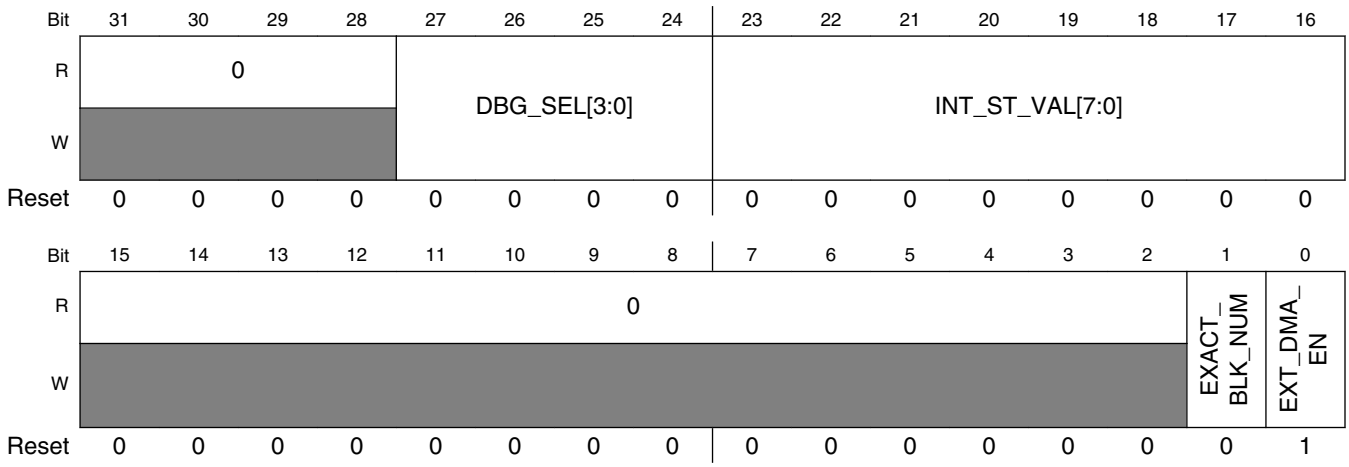
ESDHCV2x_ADSADDR field descriptions

Field	Description
31–2 ADS_ ADDR[31:0]	ADMA System Address: This register holds the word address of the executing command in the Descriptor table. At the start of ADMA, the Host Driver will set the start address of the Descriptor table. The ADMA engine increments this register address whenever fetching a Descriptor command. When the ADMA is stopped at the Block Gap, this register indicates the address of the next executable Descriptor command. When the ADMA Error Interrupt is generated, this register will hold the valid Descriptor address depending on the ADMA state. The lower 2 bits of this register is tied to '0' so the ADMA address is always word aligned. As this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so this register value cannot be changed when the TC bit is set. Such restriction is also listed in Software Restrictions.
1–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

26.7.22 Vendor Specific Register (ESDHCV2x_VENDOR)

This register contains the vendor specific control/status register.

Addresses: ESDHCV2-1_VENDOR is 5000_4000h base + C0h offset = 5000_40C0h
ESDHCV2-2_VENDOR is 5000_8000h base + C0h offset = 5000_80C0h
ESDHCV2-4_VENDOR is 5002_4000h base + C0h offset = 5002_40C0h



ESDHCV2x_VENDOR field descriptions

Field	Description
31–28 Reserved	This read-only field is reserved and always has the value zero. Reserved
27–24 DBG_SEL[3:0]	Debug Select Select the internal sub-block to show its internal state value.
23–16 INT_ST_VAL[7:0]	Internal State Value Internal state value, reflecting the corresponding state value selected by Debug Select field. This field is read-only and write to this field does not have effect.
15–2 Reserved	This read-only field is reserved and always has the value zero. Reserved
1 EXACT_BLK_NUM	Exact block number block read enable for SDIO CMD53 This bit should be set before S/W issues CMD53 multi-block read with exact block number. This bit should not be set if the CMD53 multi-block read is not exact block number. 0 none exact block read 1 exact block read for SDIO CMD53
0 EXT_DMA_EN	External DMA Request Enable Enable the request to external DMA. When the internal DMA (either Simple DMA or Advanced DMA) is not in use, and this bit is set, ESDHC will send out DMA request when the internal buffer is ready. This bit is particularly useful when transferring data by ARM platform polling mode, and it is not allowed to send out the external DMA request. By default, this bit is set. 0 In any scenario, ESDHC does not send out external DMA request 1 When internal DMA is not active, the external DMA request will be sent out

26.7.23 MMC Boot Register (ESDHCV2x_MMCBOOT)

This register contains the MMC Fast Boot control register.

Addresses: ESDHCV2-1_MMCBOOT is 5000_4000h base + C4h offset = 5000_40C4h
ESDHCV2-2_MMCBOOT is 5000_8000h base + C4h offset = 5000_80C4h
ESDHCV2-4_MMCBOOT is 5002_4000h base + C4h offset = 5002_40C4h

Chapter 27
Enhanced Secured Digital Host Controller (eSDHCv3)

27.1 Overview

The Enhanced Secured Digital Host Controller Version 3 (ESDHCV3, referred to as ESDHC hereafter) provides the interface between the host system and the SD/SDIO/MMC cards, as depicted in Figure 27-1. The ESDHC acts as a bridge, passing host bus transactions to the SD/SDIO/MMC cards by sending commands and performing data accesses to/from the cards. It handles the SD/SDIO/MMC protocols at the transmission level.

The types of cards supported by the ESDHC are described briefly as follows:

The Multi Media Card (MMC) is a universal low cost data storage and communication media that is designed to cover a wide area of applications including mobile video and gaming. Old MMC cards are based on a 7-pin serial bus with a single data pin, while the new high speed MMC communication is based on an advanced 11-pin serial bus designed to operate in the low voltage range.

The Secure Digital Card (SD) is an evolution of the old MMC technology. It is specifically designed to meet the security, capacity, performance, and environment requirements inherent in newly emerging audio and video consumer electronic devices. The physical form factor, pin assignment and data transfer protocol are forward compatible with the old MMC (with some additions).

Under the SD protocol, it can be categorized into Memory card, I/O card and Combo card, which has both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI standard. The I/O card, which is also known as SDIO card, provides high-speed data I/O with low power consumption for mobile electronic devices. For the sake of simplicity, Figure 27-1 does not show cards with reduced size or mini cards.

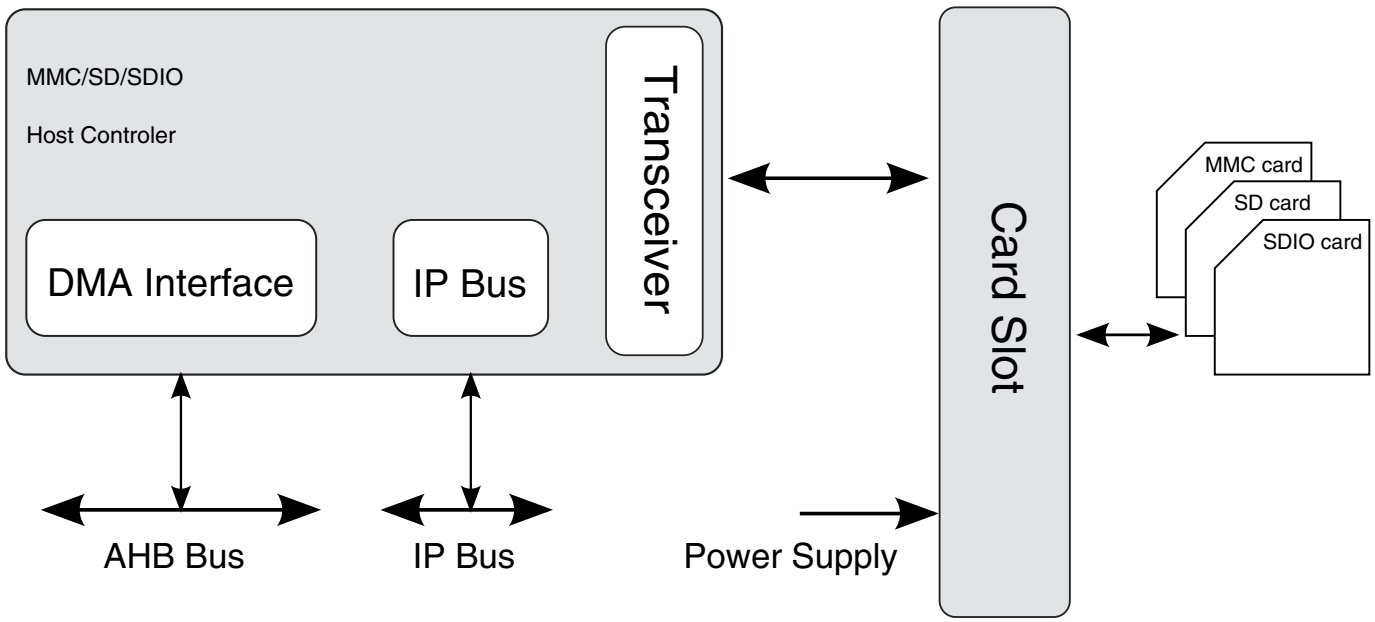

Figure 27-1. System Connection of the ESDHC

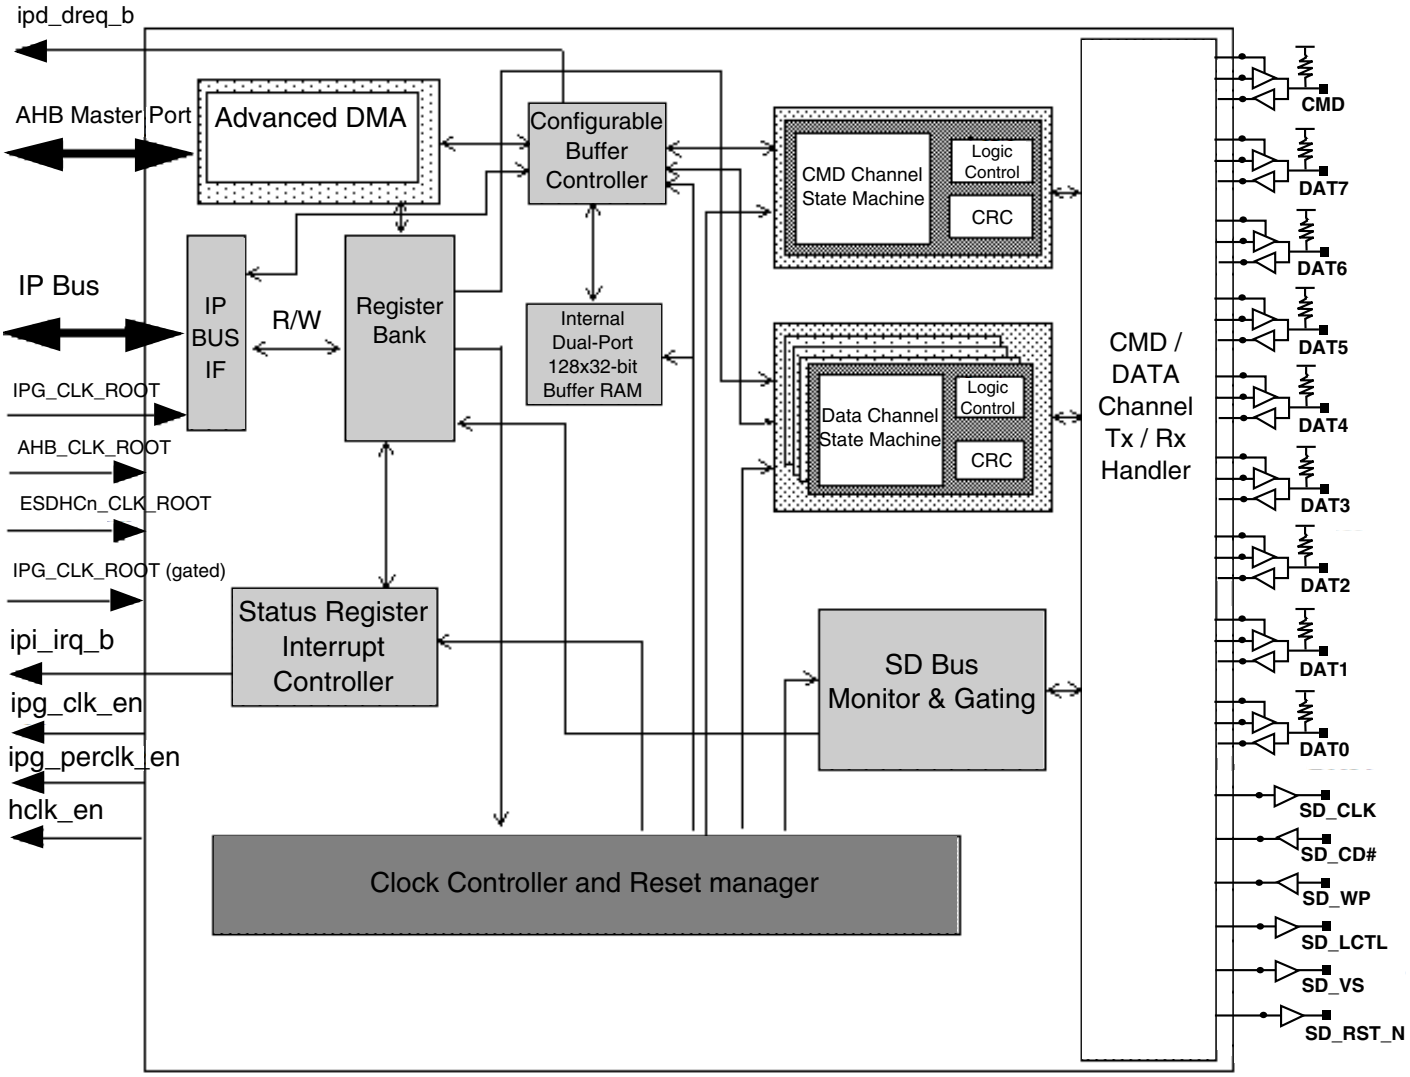

Figure 27-2. enhanced Secure Digital Host Controller Block Diagram

27.1.1 Features

The features of the ESDHC include the following:

- Conforms to the SD Host Controller Standard Specification version 2.0 including Test Event register support
- Compatible with the MMC System Specification version 4.2/4.3/4.4
- Compatible with the SD Memory Card Specification version 2.0 and supports the High Capacity SD Memory Card
- Compatible with the SDIO Card Specification version 2.0
- Designed to work with SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, MMC, MMC plus, and MMC RS cards

- Card bus clock frequency up to 52 MHz
- Supports 1-bit / 4-bit SD and SDIO modes, 1-bit / 4-bit / 8-bit MMC modes devices
  - Up to 200 Mbps of data transfer for SD/SDIO cards using 4 parallel data lines
  - Up to 416 Mbps of data transfer for MMC cards using 8 parallel data lines in SDR (Single Data Rate) mode
  - Up to 832 Mbps of data transfer for MMC cards using 8 parallel data lines in DDR (Dual Data Rate) mode
- Supports Single Block, Multi Block read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports the write protection switch for write operations
- Supports both synchronous and asynchronous abort
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports Auto CMD12 for multi-block transfer
- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes, also supports interrupt period
- Embodies a fully configurable 128x32-bit FIFO for read/write data
- Supports internal and external DMA capabilities
- Supports Advanced DMA to perform linked memory access

27.1.2 Modes and Operations

27.1.2.1 Data transfer Modes

The ESDHC can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- MMC 1-bit
- MMC 4-bit
- MMC 8-bit
- Identification Mode (up to 400 kHz)
- MMC full speed mode (up to 20 MHz)
- MMC high speed mode (up to 52 MHz)
- MMC DDR mode (up to 52MHz, sampled on both clock edges)
- SD/SDIO full speed mode (up to 25 MHz)
- SD/SDIO high speed mode (up to 50 MHz)

27.2 External Signals

27.2.1 Signals Overview

The ESDHC has 15 associate I/O signals.

- The SD_CLK is an internally generated clock used to drive the MMC, SD, SDIO cards.
- The CMD I/O is used to send commands and receive responses to/from the card. Eight data lines (DAT7~DAT0) are used to perform data transfers between the ESDHC and the card.
- The SD_CD# and SD_WP are card detection and write protection signals directly routed from the socket. A low on SD_CD# means that a card is inserted and a high on SD_WP means that the write protect switch is active.
- SD_OD is an output signal generated in SoC level outside ESDHC and is used to select the external open drain resistor.
- SD_LCTL is an output signal used to drive an external LED to indicate that the SD interface is busy.
- SD_RST_N is an output signal used to reset MMC card. This should be supported by card.

SD_CD#, SD_WP, SD_OD, SD_LCTL and SD_RST_N are all optional for system implementation. If the ESDHC is desired to support a 4-bit data transfer, DAT7~DAT4 can also be optional and tied to high.

27.2.2 Ports Table

See Table 26-1 for the signal properties of the I/Os.

Table 27-1. Properties of I/O Signals

Name	Port	Function	Reset State	Pull up
SD_CLK	O	Clock for MMC/SD/SDIO card	0	N/A
SD_CMD	I/O	CMD line connect to card	1	Pull up
SD_DAT7	I/O	DAT7 line in 8-bit mode Not used in other modes	1	Pull up
SD_DAT6	I/O	DAT6 line in 8-bit mode Not used in other modes	1	Pull up

Table continues on the next page...

Table 27-1. Properties of I/O Signals (continued)

Name	Port	Function	Reset State	Pull up
SD_DAT5	I/O	DAT5 line in 8-bit mode Not used in other modes	1	Pull up
SD_DAT4	I/O	DAT4 line in 8-bit mode Not used in other modes	1	Pull up
SD_DAT3	I/O	DAT3 line in 4/8-bit mode or configured as card detection pin May be configured as card detection pin in 1-bit mode	0	Should be pull-up/pull-down configurable as this port may be used for card detection
SD_DAT2	I/O	DAT2 line or Read Wait in 4-bit mode Read Wait in 1-bit mode	1	Pull up
SD_DAT1	I/O	DAT1 line in 4/8-bit mode Also used to detect interrupt in 1/4-bit mode	1	Pull up
SD_DAT0	I/O	DAT0 line in all modes Also used to detect busy state	1	Pull up
SD_CD#	I	Card detection pin If not used tie high	N/A	N/A
SD_WP	I	Card write protect detect If not used tie low	N/A	N/A
SD_OD	O	Open drain select (not generated within the ESDHC). Optional output	N/A	N/A
SD_LCTL	O	LED control used to drive an external LED Active high Fully controlled by the driver Optional output	0	N/A
SD_RST_N	O	Card hardware reset signal, active LOW	1	N/A

27.3 Functional Description

The following sections provide a brief functional description of the major system blocks, including the Data Buffer, DMA AHB interface, register bank as well as IP Bus interface, dual-port memory wrapper, data/command controller, clock & reset manager and clock generator.

27.3.1 Data Buffer

The ESDHC uses one configurable data buffer, so that data can be transferred between the system bus (IP Bus or AHB Bus) and the SD card, with an optimized manner to maximize throughput between the two clock domains (that is, the IP peripheral clock, and the master clock). See the table below for illustration of the buffer scheme. The buffer is used as temporary storage for data being transferred between the host system and the card. The watermark levels for read and write are both configurable, and can be any number from 1 to 128 words. The burst lengths for read and write are also configurable, and can be any number from 1 to 31 words.

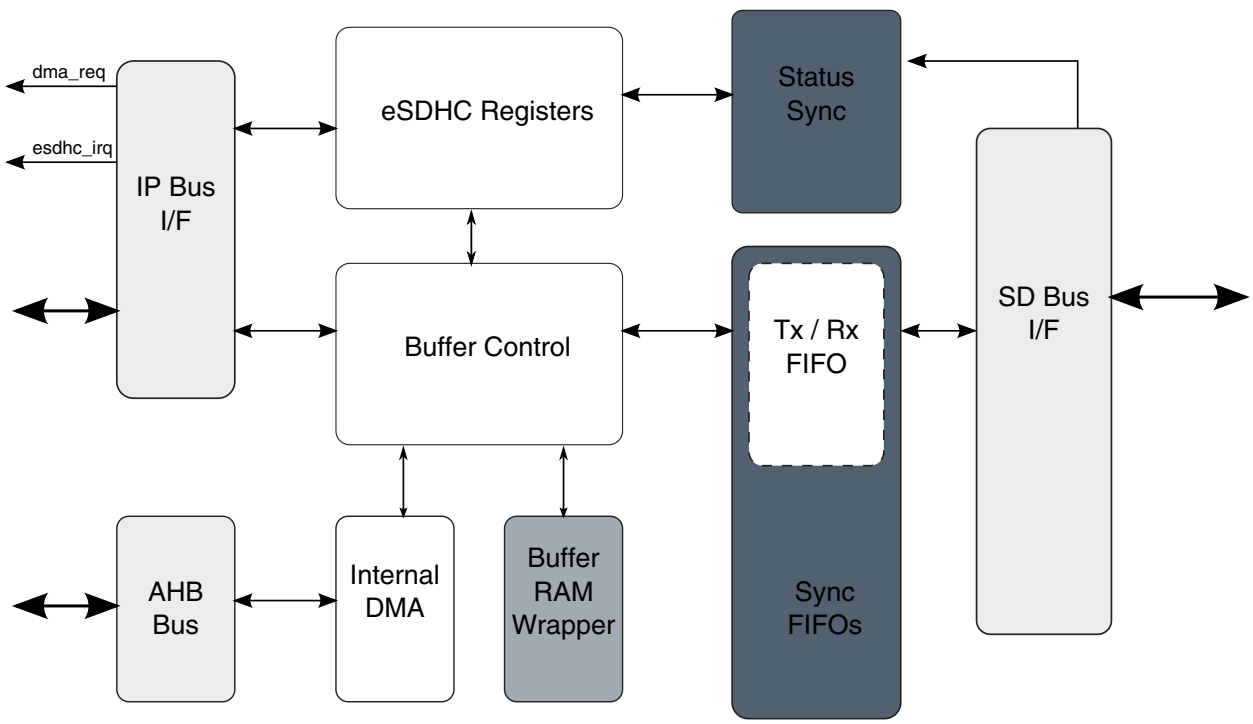

Figure 27-3. ESDHC Buffer Scheme

There are 3 transfer modes to access the data buffer:

- ARM platform polling mode:
  - For a host read operation, when the number of words received in the buffer meets or exceeds the RD_WML watermark value, then by polling the BRR bit the Host Driver can read the Buffer Data Port register to fetch the amount of words set in the RD_WML register from the buffer. The write operation is similar.
- External DMA mode:
  - For a read operation, when there are more words received in the buffer than the amount set in the RD_WML register, a DMA request is sent out to inform the external DMA to fetch the data. The request will be immediately de-asserted

when there is an access on the Buffer Data Port register. If the number of words in the buffer after the current burst meets or exceeds RD_WML value, then the DMA request is asserted again. For instance, if there are twice as many words in the buffer than the RD_WML value, there are two successive DMA requests with only one cycle of de-assertion between. The write operation is similar.

NOTE

Data buffer accesses by the ARM platform polling mode and external DMA mode both use the IP Bus. In these mode, if the external DMA is enabled, an external DMA request is sent out every time the buffer is ready.

- Internal DMA mode (includes simple and advanced DMA accesses):
  - The internal DMA access, either by simple or advanced DMA, is over the AHB bus. For internal DMA access mode, the external DMA request will never be sent out.

    For a read operation, when there are more words in the buffer than the amount set in the RD_WML register, the internal DMA starts fetching data over the AHB bus. Except INCR4 and INCR8, the burst type is always INCR mode and the burst length depends on the shortest of following factors:

1. Burst length configured in the burst length field of the Watermark Level register
2. Watermark Level boundary
3. Block size boundary
4. Data boundary configured in the current descriptor (if the ADMA is active)
5. 1 Kbyte address boundary defined in the AHB protocol

Write operation is similar.

Sequential and contiguous access is necessary to ensure the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actually byte order is swapped inside the buffer, according to the endian mode configured by software. See Figure 26-4 and Figure 26-5. For a host write operation, byte order is swapped after data is fetched from the buffer and ready to send to the SD Bus. For a host read operation, byte order is swapped before the data is stored into the buffer.

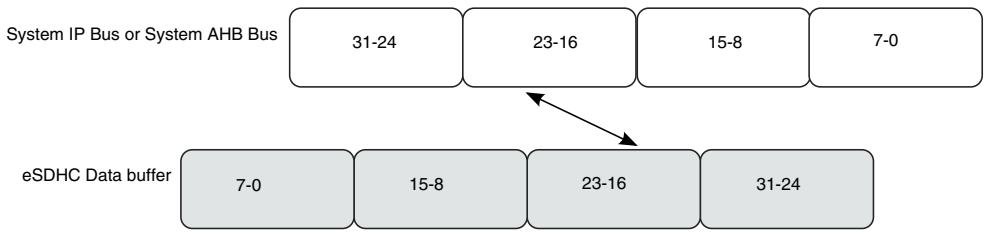

Figure 27-4. Data Swap between System Bus and ESDHC Data Buffer in Byte Little Endian Mode

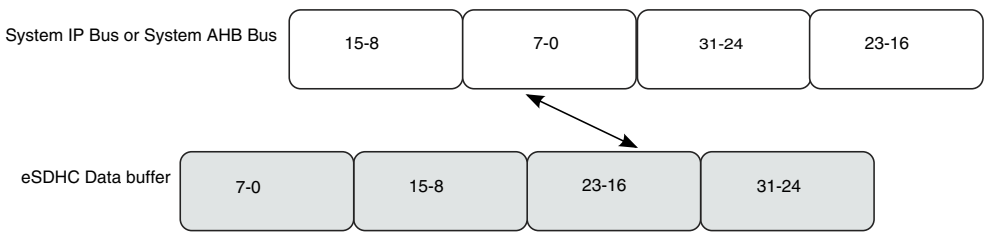

Figure 27-5. Data Swap between System Bus and ESDHC Data Buffer in Half Word Big Endian Mode

27.3.1.1 Write Operation Sequence

There are three ways to write data into the buffer when the user transfers data to the card:

1. By using external DMA through the ESDHC DMA request signal.
2. By processor core polling through the BWR bit in Interrupt Status register (interrupt or polling).
3. By using the internal DMA.

When the internal DMA is not used, (i.e. the DMAEN bit in the Transfer Type register is not set when the command is sent), the ESDHC asserts a DMA request when the amount of buffer space exceeds the value set in the WR_WML register, and is ready for receiving new data. At the same time, the ESDHC would set the BWR bit. The buffer write ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the ESDHC will not inform the system before all the required number of bytes are transferred (if no error was encountered). When an error occurs during the data transfer, the ESDHC will abort the data transfer and abandon the current block. The Host Driver should read the contents of the DMA System Address register to get the starting address of the abandoned data block. If the current data transfer is in multi block mode, the ESDHC will not automatically send CMD12, even though the

AC12EN bit in the Transfer Type register is set. The Host Driver shall send CMD12 in this scenario and re-start the write operation from that address. It is recommended that a Software Reset for Data be applied before the transfer is re-started after error recovery.

The ESDHC will not start data transmission until the number of words set in the WR_WML register can be held in the buffer. If the buffer is empty and the Host System does not write data in time, the ESDHC will stop the SD_CLK to avoid the data buffer under-run situation.

27.3.1.2 Read Operation Sequence

There are three ways to read data from the buffer when the user transfers data from the card:

1. By using the external DMA through the ESDHC DMA request signal
2. By processor core polling through the BRR bit in Interrupt Status register (interrupt or polling)
3. By using the internal DMA

When internal DMA is not used (i.e. DMAEN bit in Transfer Type register is not set when the command is sent), the ESDHC asserts a DMA request when the amount of data exceeds the value set in the RD_WML register (that is, available and ready for system fetching data). At the same time, the ESDHC would set the BRR bit. The buffer read ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the ESDHC will not inform the system before all the required number of bytes are transferred (if no error was encountered). When an error occurs during the data transfer, the ESDHC will abort the data transfer and abandon the current block. The Host Driver should read the content of the DMA System Address register to get the starting address of the abandoned data block. If the current data transfer is in multi block mode, the ESDHC will not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The Host Driver shall send CMD12 in this scenario and re-start the read operation from that address. It is recommended that a Software Reset for Data be applied before the transfer is re-started after error recovery.

For any read transfer mode, the ESDHC will not start data transmission until the number of words set in the RD_WML register are in the buffer. If the buffer is full and the Host System does not read data in time, the ESDHC will stop the SD_CLK to avoid the data buffer over-run situation.

27.3.1.3 Data Buffer and Block Size

The user needs to know the buffer size, for the buffer operation during a data transfer, to utilize it in the most optimized way. In the ESDHC, the only data buffer can hold up to 128 words (32-bit), and the watermark levels for write and read can be configured respectively. For both read and write, the watermark level can be from 1 word to the maximum of 128 words. For both read and write, the burst length, can be from 1 word to the maximum of 31 words. The Host Driver may configure the value according to the system situation and requirement.

During a multi-block data transfer, the block length may be set to any value between 1 and 4096 bytes inclusive which satisfies the requirements of the external card. The only restriction is from the external card. It might not support that large of a block or it does not support a partial block access (which is not the integer times of 512 bytes).

For block size not times of 4, that is, not word aligned, ESDHC requires stuff bytes at the end of each block, because ESDHC treats each block individually. For example, if the block size is 7 bytes and there are 12 blocks to write, the system side must write two times for each block. For each block, the ending byte will be abandoned by ESDHC because it only sends 7 bytes to the card and picks data from the following system write, making a total of 24 beats of write access.

27.3.1.4 Dividing Large Data Transfer

This SDIO command CMD53 definition, limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in block size units. If the total data length can't be divided evenly into a multiple of the block size, then there are two ways to transfer the data which depend on the function and the card design. Option 1 is for the Host Driver to split the transaction. The remainder of the block size data is then transferred by using a single block command at the end. Option 2 is to add dummy data in the last block to fill the block size. For option 2, the card must manage the removal of the dummy data.

See figure below for an example showing the dividing of large data transfers. Assuming a kind of WLAN SDIO card only supports block size up to 64 bytes. Although the ESDHC supports a block size of up to 4096 bytes, the SDIO can only accept a block size less than64 bytes, so the data must be divided (see example below).

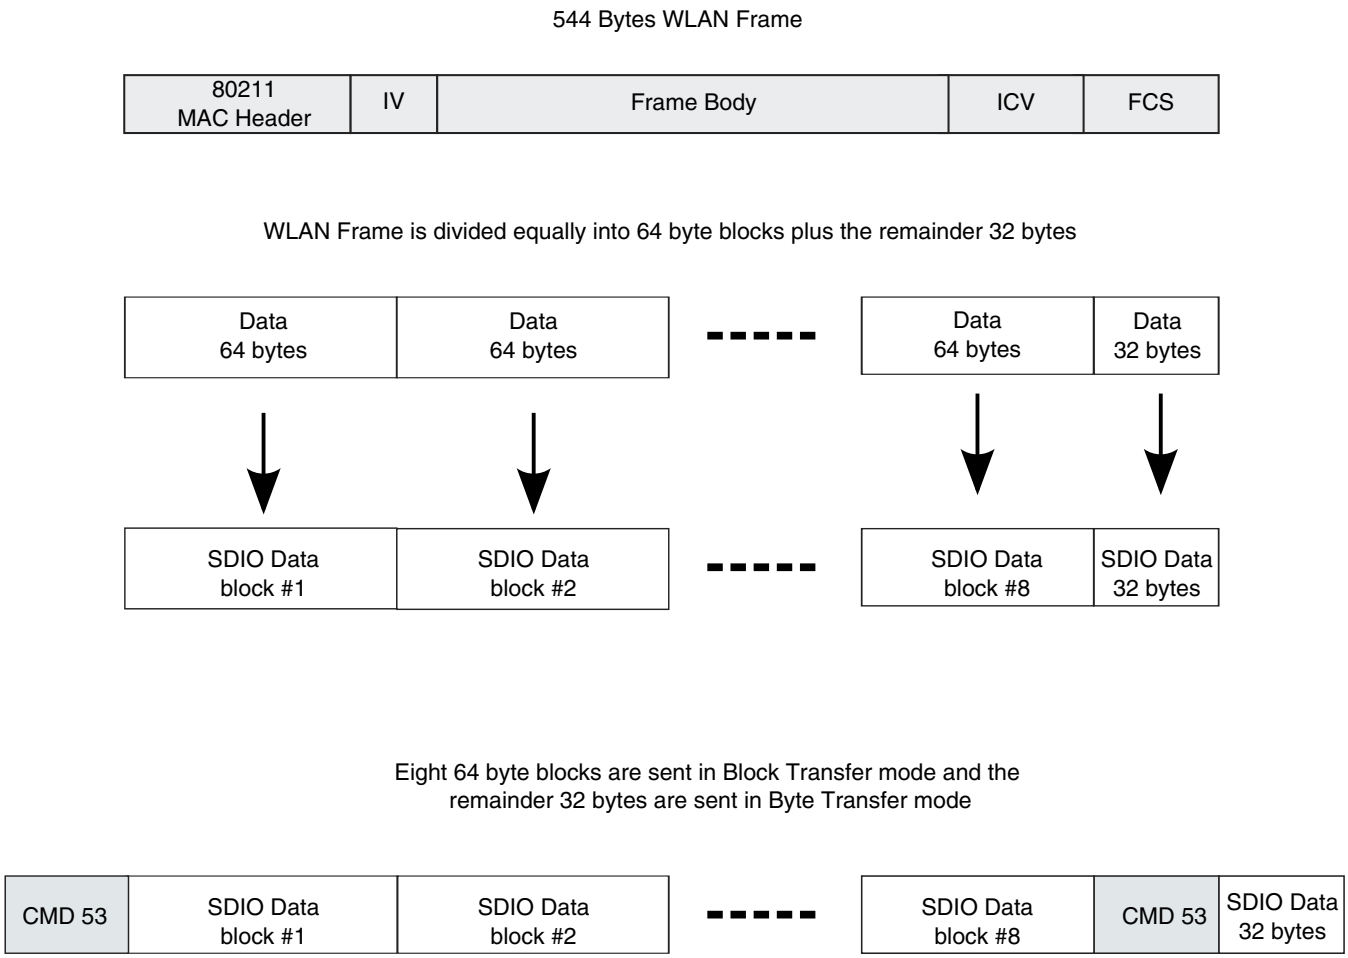

Figure 27-6. Example for Dividing Large Data Transfers

27.3.1.5 External DMA Request

When the internal DMA is not in use, and external DMA request is enabled, the Data Buffer will generate a DMA request to the system. During a write operation, when the number of WR_WML words can be held in the buffer free space, the signal esdhc_dreq_b is asserted to 0, informing the Host System of a DMA write. The BWR bit in the Interrupt Status register is also set, as long as the BWRSEN bit in the Interrupt Status Enable register is set. The DMA request is immediately de-asserted when an access to the Data Port register is made. If the buffer's free space still meets the watermark condition, the DMA request is asserted again after a cycle.

On read operation, when the number of RD_WML words are already in the buffer, the signal esdhc_dreq_b is asserted to 0, informing the Host System for a DMA read. The BRR bit in the Interrupt Status register is also set, as long as the BRRSEN bit in the

Interrupt Status Enable register is set. The DMA request is immediately de-asserted when an access to the Data Port register is made. If the buffer's data still meets the watermark condition, the DMA request is asserted again after a cycle.

Because the DMA burst length can not change during a data transfer for an external DMA transfer, the watermark level (read or write) must be a divisor of the block size. If it is not, transferring of the block may cause buffer under-run (read operation) or over-run (write operation). For example, if the block size is 512 bytes, the watermark level of read (or write) must be a power of two between 1 and 128. For processor core polling access, as the last access in the block transfer can be controlled by software, there is no such issue. The watermark level can be any value, even larger than the block size (but no greater than 128 words). This is because the actual number of bytes transferred by the software can be controlled and does not exceed the block size in each transfer.

The ESDHC also supports non-word aligned block size, as long as the card supports that block size. In this case, the watermark level should be set as the number of words. For example, if the block size is 31 bytes, the watermark level can be set to any number of word. For this case, the BLKSIZE bits of the Block Attribute register shall be set as 1fh. For the ARM platform polling access, the burst length can be 1 to 128 words, without restriction. This is because the software will transfer 8 words, and the ESDHC will also set the BWR or BRR bits when the remaining data does not violate data buffer. Refer to DMA Burst Length for more details about the dynamic watermark level of the data buffer. For the above example, even though 8 words are transferred through the Data Port register, the ESDHC will transfer only 31 bytes over the SD Bus, as required by the BLKSIZE bits. In this data transfer, with non-word aligned block size, the endian mode should be set cautiously, or invalid data will be transferred to/from the card.

27.3.2 DMA AHB Interface

The internal DMA implements a DMA engine and the AHB master. When the internal DMA is enabled, the esdhc_dreq_b will not be asserted during the transfer, but the BWR and BRR bits will be set if the BWRSEN and BRRSEN bits have been set in the Interrupt Status Enable register. See the figure below for an illustration of the DMA AHB interface block.

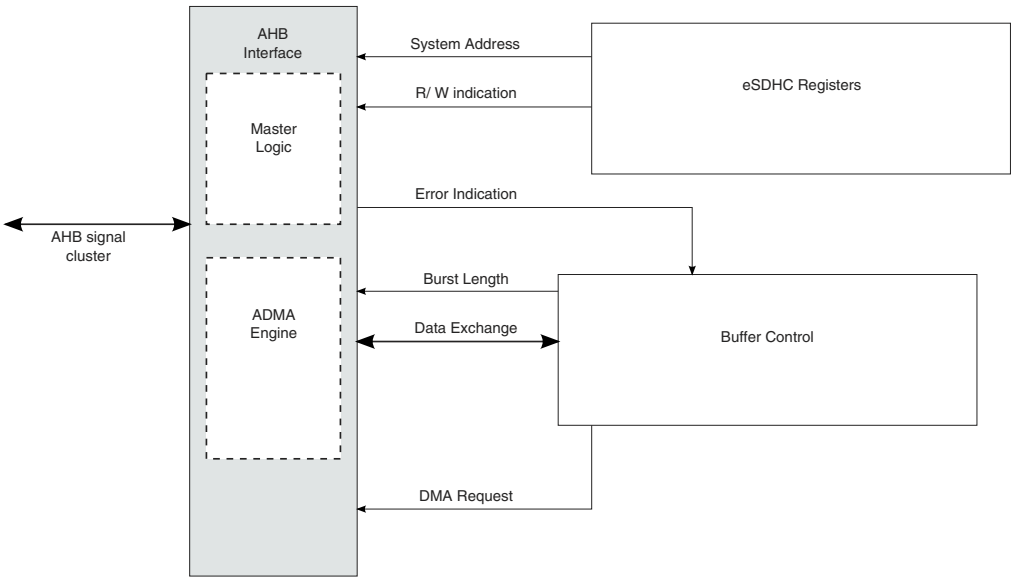

Figure 27-7. DMA AHB Interface Block

27.3.2.1 Internal DMA Request

If the watermark level requirement is met in data transfer, and the Internal DMA is enabled, the Data Buffer block will send a DMA request to AHB interface. Meanwhile, the external DMA request signal (esdhc_dreq_b) is disabled. The delay in response from the internal DMA engine depends on the system AHB bus loading and the priority assigned to the ESDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The Data Buffer de-asserts the request once an access to the buffer is made. Upon access to the buffer by internal DMA, the Data Buffer updates its internal buffer pointer, and when the watermark level is satisfied, another DMA request is sent.

The data transfer is in the block unit, and the subsequent watermark level is always set as the remaining number of words. For instance, for a multi block data read with each block size of 31 bytes, and the burst length set to 6 words. After the first burst transfer, if there are more than 2 words in the buffer (which might contain some data of the next block), another DMA request read is sent. This is because the remaining number of words to send for the current block is (31 - 6 * 4) / 4 = 2. The ESDHC will read 2 words out of the buffer, with 7 valid bytes and 1 stuff byte.

27.3.2.2 DMA Burst Length

Just like a ARM platform polling access, the DMA burst length for the internal DMA engine can be from 1 to 16 words. The actual burst length for the DMA depends on the lesser of the configured burst length or the remaining words of the current block. Take the example in Internal DMA Request again. The following burst length after 6 words are read will be 2 words, and the next burst length will be 6 words again. This is because the next block starts, which is 31 bytes, more than 6 words. The Host Driver writer may take this variable burst length into account. It is also acceptable to configure the burst length as the divisor of the block size, so that each time the burst length will be the same.

27.3.2.3 AHB Master Interface

It is possible that the internal AHB DMA engine could fail during the data transfer. When this error occurs, the DMA engine stops the transfer and goes to the idle state as well as the internal data buffer stops accepting incoming data. The DMAE bit in the Interrupt Status register is set to inform the driver.

Once the DMAE interrupt is received, the software shall send a CMD12 to abort the current transfer and read the DS_ADDR bits of the DMA System Address register to get the starting address of the corrupted block. After the DMA error is fixed, the software should apply a data reset and re-start the transfer from this address to recover the corrupted block.

27.3.2.4 ADMA Engine

In the SD Host Controller Standard, the new DMA transfer algorithm called the ADMA (Advanced DMA) is defined. For Simple DMA, once the page boundary is reached, a DMA interrupt will be generated and the new system address shall be programmed by the Host Driver. The ADMA defines the programmable descriptor table in the system memory. The Host Driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. It reduces the frequency of interrupts to the host system. Therefore, higher speed DMA transfers could be realized since the Host MCU intervention would not be needed during long DMA based data transfers.

There are two types of ADMA: ADMA1 and ADMA2 in Host Controller. ADMA1 can support data transfer of 4KB aligned data in system memory. ADMA2 removes the restriction so that data of any location and any size can be transferred in system memory. Their formats of Descriptor Table are different.

ADMA engine can recognize all kinds of descriptors define in SD Host Controller Standard, and if 'End' flag is detected in the descriptor, ADMA engine will stop after this descriptor is processed.

27.3.2.4.1 ADMA Concept and Descriptor Format

For ADMA1, including the following descriptors:

- Valid/Invalid descriptor.
- Nop descriptor.
- Set data length descriptor.
- Set data address descriptor.
- Link descriptor.
- Interrupt flag and End flag in descriptor.

For ADMA2, including the following descriptors:

- Valid/Invalid descriptor.
- Nop descriptor.
- Rsv descriptor.
- Set data length & address descriptor.
- Link descriptor.
- Interrupt flag and End flag in descriptor.

ADMA2 deals with the lower 32-bit first, and then the higher 32-bit. If the 'Valid' flag of descriptor is 0, it will ignore the high 32-bit. Address field shall be set on word aligned (lower 2-bit is always set to 0). Data length is in byte unit.

ADMA will start read/write operation after it reaches the Tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last Set type descriptor before Tran type descriptor. Every Tran type will trigger a transfer, and the transfer data length is extracted from the most recent Set type descriptor. If there is no Set type descriptor after the previous Trans descriptor, the data length will be the value for previous transfer, or 0 if no Set descriptor is ever met.

For ADMA2, Tran type descriptor contains both data length and transfer data address, so only a Tran type descriptor can start a data transfer.

Address/ Page Field		Address/ Page Field		Attribute Field

Act 2	Act1	Symbol	Comment	31- 28	27- 12
0	0	Nop	No Operation	Don't Care	
0	1	Set	Set Data Length	0000	Data Length
1	0	Tran	Transfer Data	Data Address	
1	1	Link	Link Descriptor	Descriptor Address	

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 27-8. Format of the ADMA1 Descriptor Table

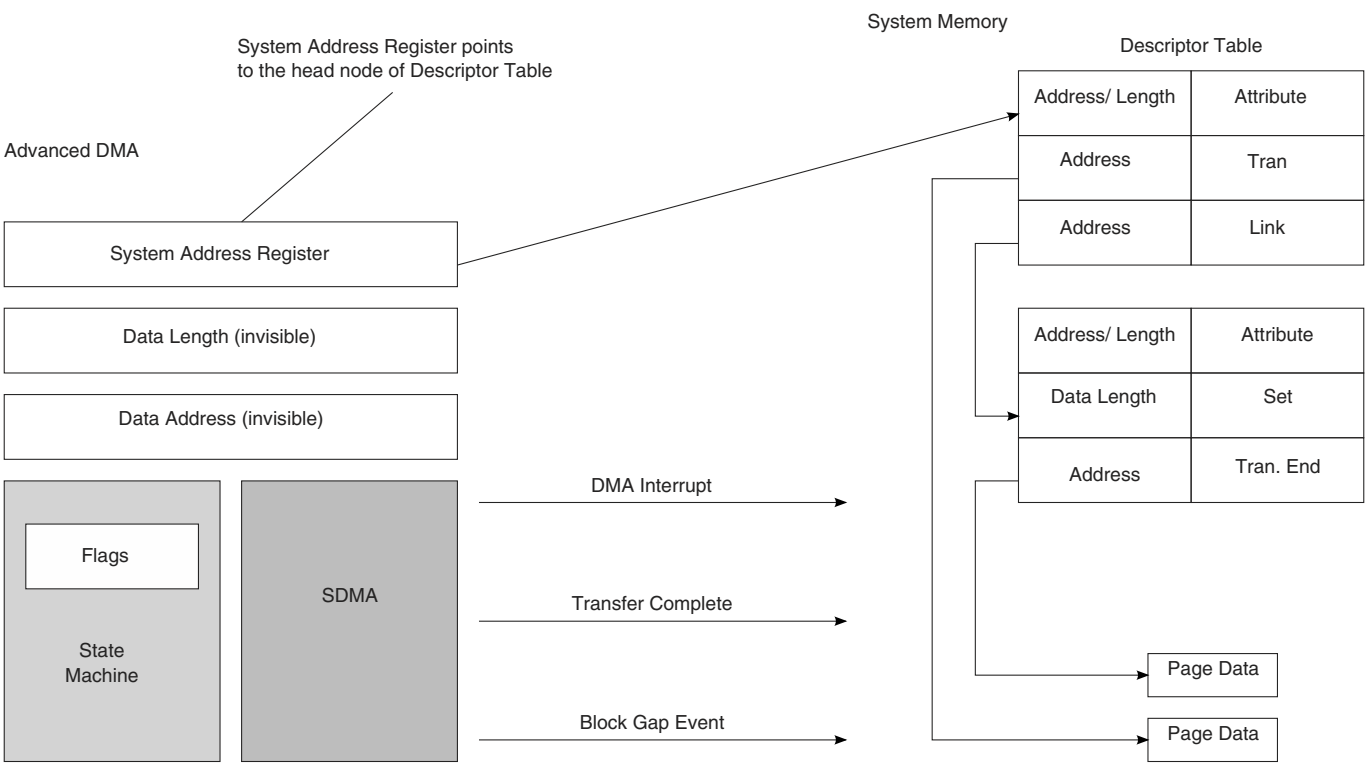

Figure 27-9. Concept and Access Method of ADMA1 Descriptor Table

Address/ Page Field		Address/ Page Field		Address/ Page Field		Attribute Field					
63	32	31	16	15	06	05	04	03	02	01	00
32-bit Address		16-bit Length		0000000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	Operation
0	0	Nop	No Operation	Don't Care
0	1	Rsv	Reserved	Same as Nop. Read this line and go to next one
1	0	Tran	Transfer Data	Transfer data with address and length set in this descriptor line
1	1	Link	Link Descriptor	Link to another descriptor

Valid	Valid = 1indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is done.

Figure 27-10. Format of the ADMA2 Descriptor Table

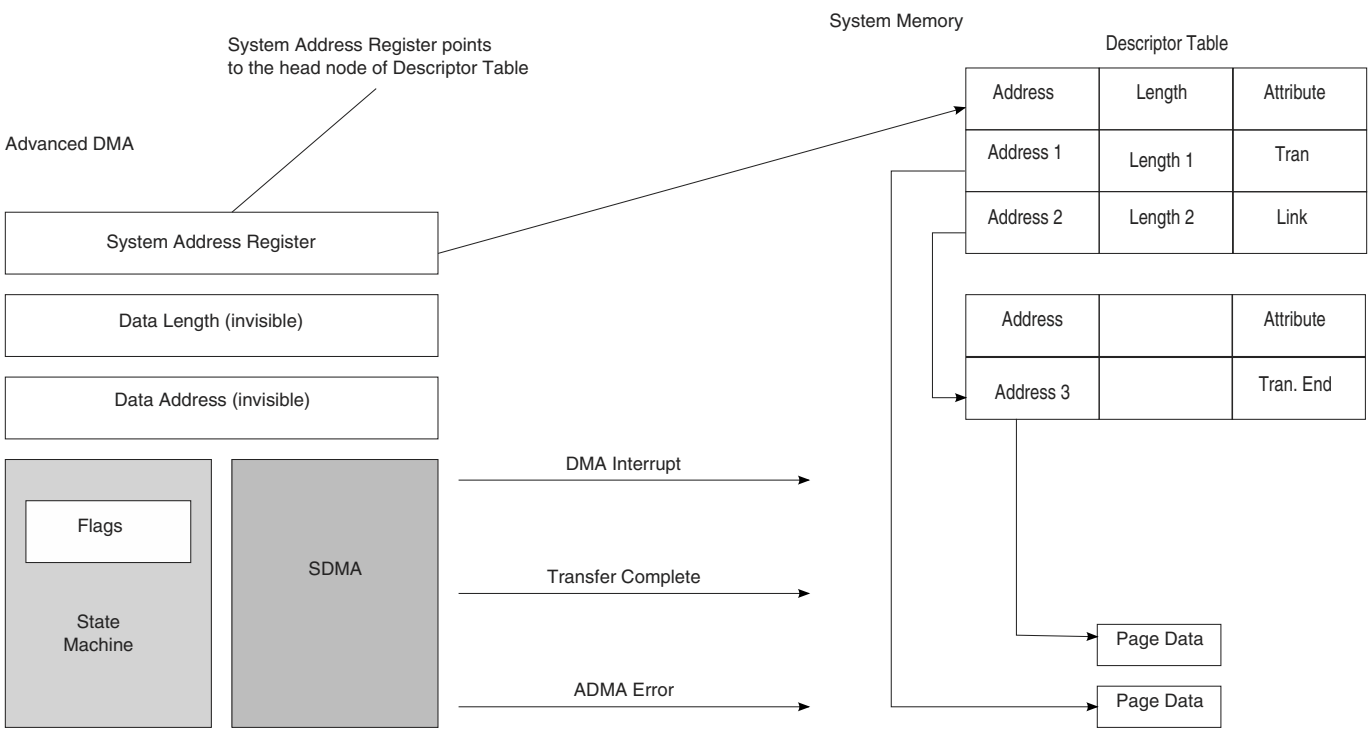

Figure 27-11. Concept and Access Method of ADMA2 Descriptor Table

27.3.2.4.2 ADMA Interrupt

If the 'Interrupt' flag of descriptor is set, ADMA will generate an interrupt according to different type descriptor:

For ADMA1:

- Set type descriptor: interrupt is generated when data length is set.
- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type descriptor: interrupt is generated when new descriptor address is set.
- Nop type descriptor: interrupt is generated just after this descriptor is fetched.

For ADMA2:

- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type descriptor: interrupt is generated when new descriptor address is set.
- Nop/Rsv type descriptor: interrupt is generated just after fetch this descriptor.

27.3.2.4.3 ADMA Error-DMA

The ADMA will stop whenever any error is encountered. These errors include:

- Fetching descriptor error
- AHB response error
- Data length mismatch error

ADMA descriptor error will be generated when it fails to detect 'Valid' flag in the descriptor. If adma descriptor error occurs, the interrupt is not generated even if the 'Interrupt' flag of this descriptor is set.

When BLKCNTEN bit is set, data length set in Block Attributes register must equal to the whole data length set in descriptor nodes, otherwise data length mismatch error will be generated.

If BLKCNTEN bit is not set, the whole data length set in descriptor should be times of block length, otherwise, when all data set in the descriptor nodes are done not at block boundary, the data mismatch error will occur.

27.3.3 Register Bank with IP Bus Interface

Register accesses via the IP Bus interface are actually on the Register Bank. See the figure below for the block diagram.

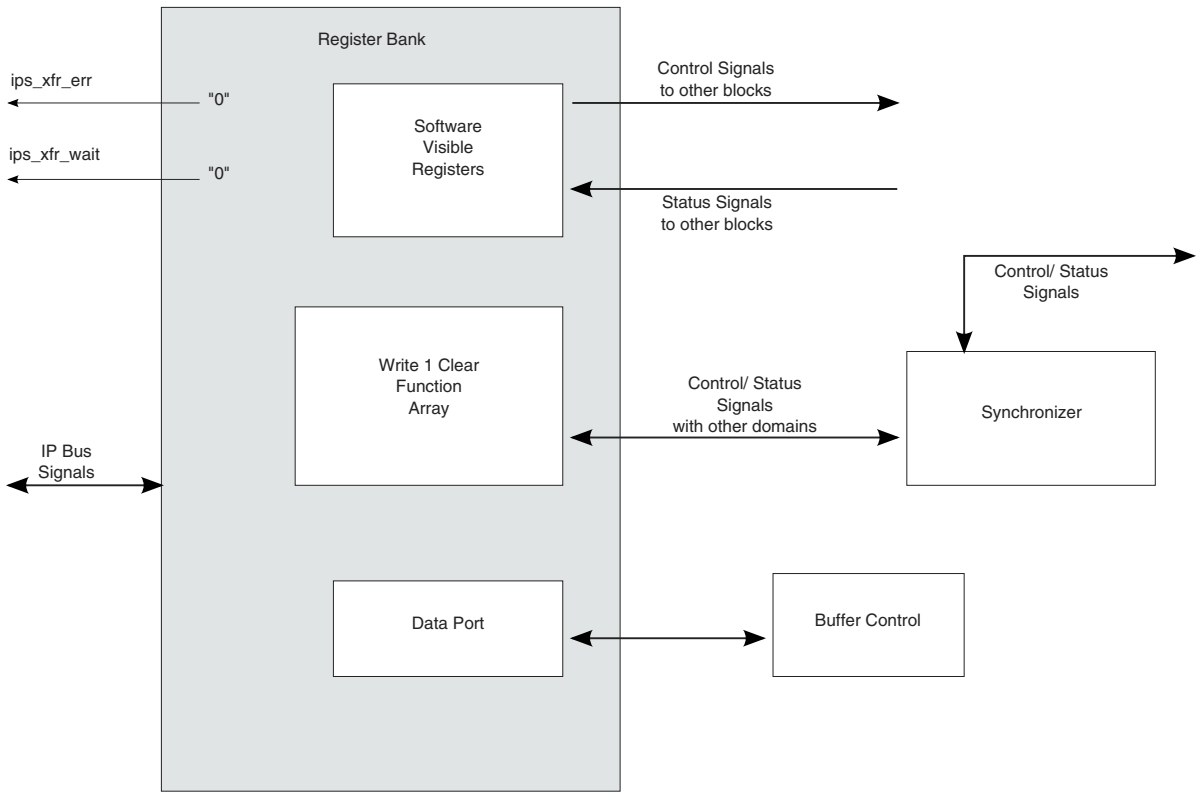

Figure 27-12. Register Bank Diagram

Only 32-bit access is allowed, and no partial read / write is supported, thus all accesses are word aligned.

27.3.4 SD Protocol Unit

The SD protocol unit deals with all SD protocol affairs.

The SD Protocol Unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into corresponding registers
- Detects the bus state on the DAT[0] line
- Monitors the interrupt from the SDIO card
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status
- Detects the write protect state

The SD Protocol Unit consists of four sub-blocks:

1. SD transceiver.

2. SD clock and monitor.
3. Command agent.
4. Data agent.

27.3.4.1 SD Transceiver

In the SD protocol unit, the transceiver is the main control sub-block. It consists of an FSM and control sub-block, from which the control signals for all other three sub-blocks are generated.

27.3.4.2 SD Clock & Monitor

This sub-block monitors the signal level on all 8 data lines, the command lines, and directly routes the level values into the Register Bank. The driver can use this for debug purposes.

The sub-block also detects the Card Detection (CD) line as well as the DAT[3] line. The transceiver reports the card insertion state according to the CD state, or the signal level on the DAT[3] line, when the D3CD bit in the Protocol Control register is set.

The sub-block detects the Write Protect (WP) line. With the information of the WP state, the Register Bank will ignore the command, accompanied by a write operation, when the WP switch is on.

If the internal data buffer is in danger, and the SD clock must be gated off to avoid buffer over/under-run, this sub-block will assert the gate of the output SD clock to shut the clock off. After the buffer danger has recovered, and when the system access of the buffer catches up, the clock gate of this sub-block will open and the SD clock will be active again.

This sub-block also drive SD_LCTL output signal when the LCTL bit is set by the driver.

27.3.4.3 Command Agent

The Command Agent deals with the transactions on the CMD line. See figure below for an illustration of the structure for the Command CRC Shift Register.

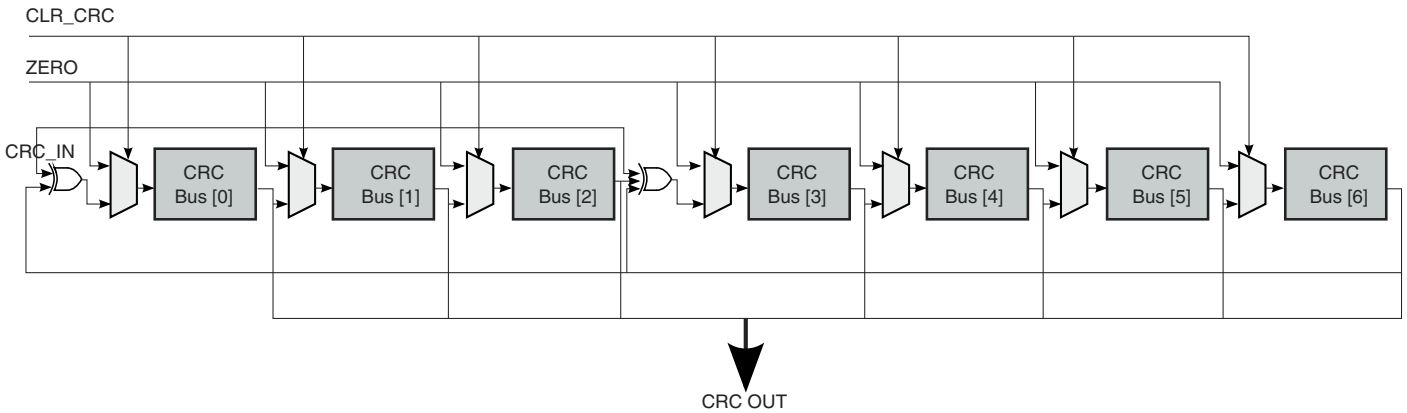

Figure 27-13. Command CRC Shift Register

The CRC polynomials for the CMD are as follows:

Generator polynomial: $G(x) = x^7 + x^3 + 1$
$M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \ldots + (\text{last bit}) * x^0$
$CRC[6:0] = \text{Remainder } [(M(x) * x^7) / G(x)]$

27.3.4.4 Data Agent

The Data Agent deals with the transactions on the eight data lines. Moreover, this sub-block also detects the busy state on the DAT[0] line, and generate the Read Wait state by the request from the Transceiver. The CRC polynomials for the DAT are as follows:

Generator polynomial: $G(x) = x^{16} + x^{12} + x^5 + 1$
$M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \ldots + (\text{last bit}) * x^0$
$CRC[15:0] = \text{Remainder } [(M(x) * x^{16}) / G(x)]$

27.3.5 Clock & Reset Manager

This sub-block controls all the reset signals within the ESDHC.

There are four kinds of reset signals within ESDHC:

1. Hardware reset.
2. Software reset for all.
3. Software reset for the data part.
4. Software reset for the command part.

All these signals are fed into this sub-block and stable signals are generated inside the module to reset all other modules. The sub-block also gates off all the inside signals.

There are three clocks inside the ESDHC:

1. ipg_clk.

2. ipg_perclk.
3. hclk.

The sub-block monitors the activities of all other sub-blocks, supplies the clocks for them, and when enabled, automatically gates off the corresponding clocks.

27.3.6 Clock Generator

The Clock Generator generates the SD_CLK by peripheral source clock in two stages. Refer to the figure below for the structure of the divider. The term "Base" represents the frequency of peripheral source clock.

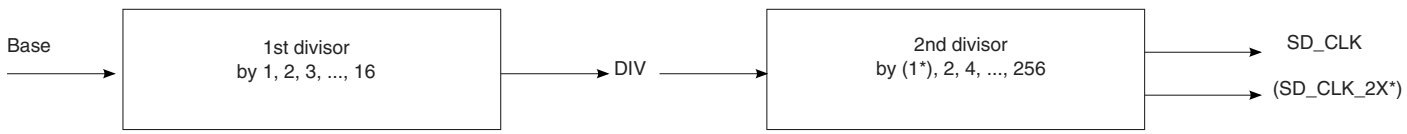

Figure 27-14. Two Stages of the Clock Divider

The first stage outputs an intermediate clock (DIV), which can be Base, Base/2, Base/3, ..., or Base/16.

The second stage is a prescaler, and outputs the actual clock (SD_CLK). Also it outputs DDR internal processing clock (SD_CLK_2X). These clocks are the driving clock for all sub-blocks of the SD Protocol Unit, and the sync FIFOs (see Figure 26-3) to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage, can be DIV/2, DIV/4,..., or DIV/256. Thus the highest frequency of the SD_CLK is Base/2, while the lowest frequency is Base/4096. If the Base clock is of equal duty ratio (usually true), the duty cycle of SD_CLK/SD_CLK_2X is also 50%, even when the compound divisor is an odd value.

27.3.7 SDIO Card Interrupt

27.3.7.1 Interrupts in 1-bit Mode

In this case the DAT[1] pin is dedicated to providing the interrupt function. An interrupt is asserted by pulling the DAT[1] low from the SDIO card, until the interrupt service is finished to clear the interrupt.

27.3.7.2 Interrupt in 4-bit Mode

Since the interrupt and data line 1 share Pin 8 in 4-bit mode, an interrupt will only be sent by the card and recognized by the host during a specific time. This is known as the Interrupt Period. The ESDHC will only sample the level on Pin 8 during the Interrupt Period. At all other times, the host will ignore the level on Pin 8, and treat it as the data signal. The definition of the Interrupt Period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the Interrupt Period becomes active two clock cycles after the completion of a data packet. This Interrupt Period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in 4-bit mode, there is only a limited period of time that the Interrupt Period can be active due to the limited period of data line availability between the multiple blocks of data. This requires a more strict definition of the Interrupt Period. For this case, the Interrupt Period is limited to two clock cycles. This begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the DAT[1] line will be held low for one clock cycle with the last clock cycle pulling DAT[1] high. On completion of the Interrupt Period, the card releases the DAT[1] line into the high Z state. The ESDHC samples the DAT[1] during the Interrupt Period when the IABG bit in the Protocol Control register is set.

Refer to SDIO Card Specification v1.10f for further information about the SDIO card interrupt.

27.3.7.3 Card Interrupt Handling

When the CINTIEN bit in the Interrupt Signal Enable Register is set to 0, the ESDHC clears the interrupt request to the Host System. The Host Driver should clear this bit before servicing the SDIO Interrupt and should set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO Status bit is cleared by resetting the SDIO interrupt. Writing to this bit would have no effects. In 1-bit mode, the ESDHC will detect the SDIO Interrupt with or without the SD clock (to support wakeup). In 4-bit mode, the interrupt signal is sampled during the Interrupt Period, so there are some sample delays between the interrupt signal from the SDIO card and the interrupt to the Host System Interrupt Controller. When the SDIO status has been set, and the Host Driver needs to service this interrupt, so the SDIO bit in the Interrupt Control Register of SDIO card will be cleared. This is required to clear the SDIO interrupt status latched in the ESDHC and to stop driving the interrupt signal to the

System Interrupt Controller. The Host Driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO Interrupt Enable bit is set to 1, and the ESDHC starts sampling the interrupt signal again.

See figure below for an illustration of the SDIO card interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

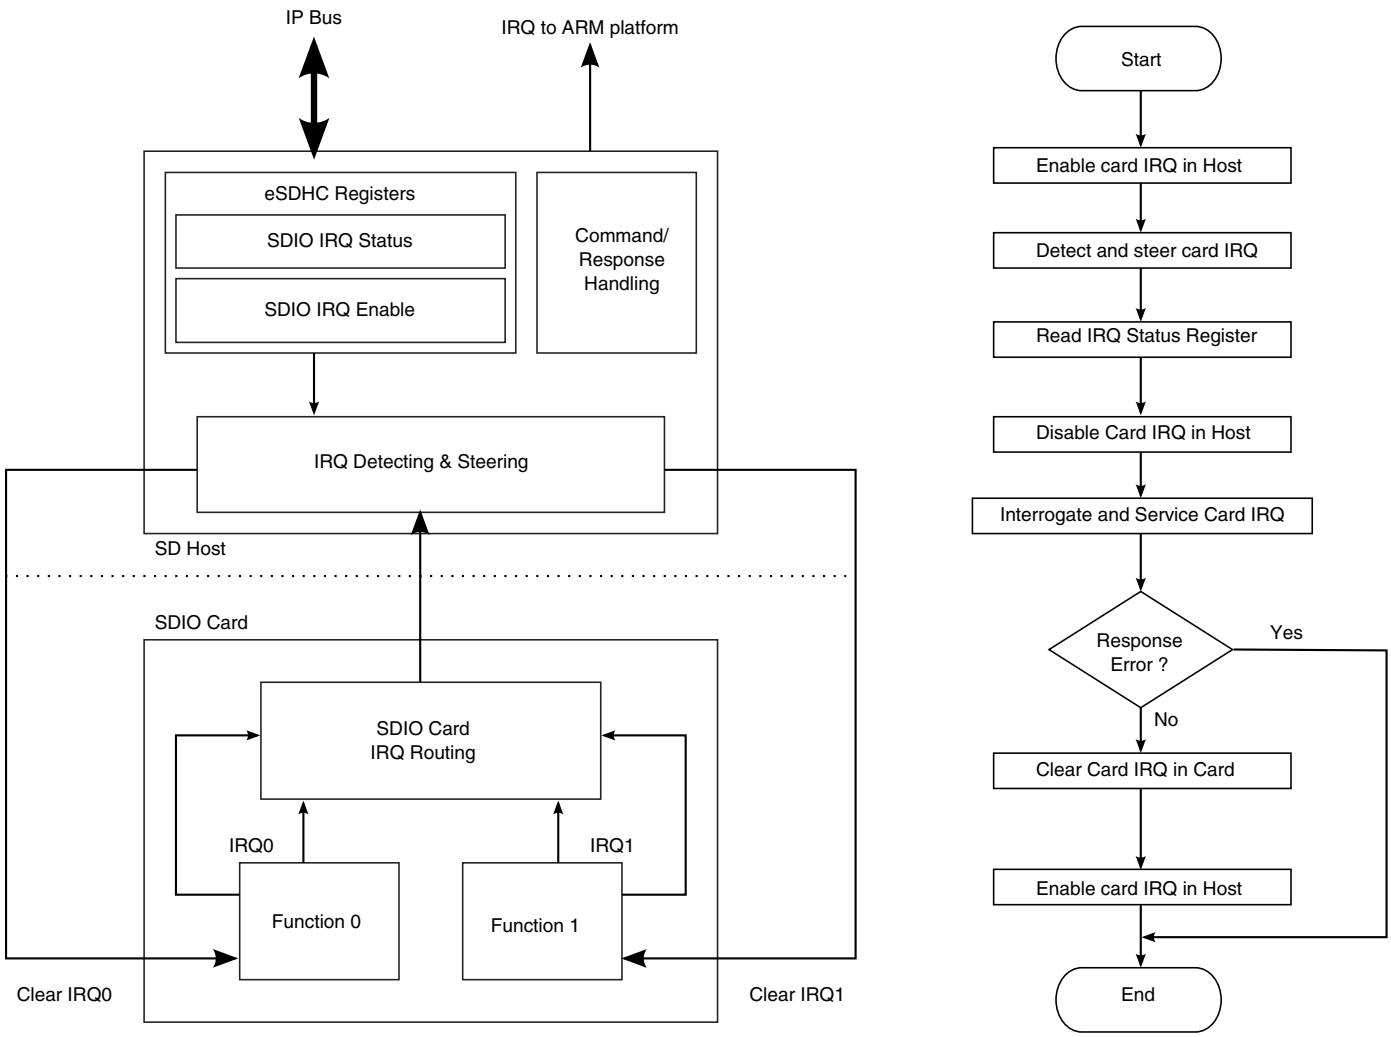

Figure 27-15. Card Interrupt Scheme and Card Interrupt Detection and Handling Procedure

27.3.8 Card Insertion and Removal Detection

The ESDHC uses either the DAT[3] pin or the CD pin to detect card insertion or removal. When there is no card on the MMC/SD bus, the DAT[3] will be pulled to a low voltage level by default. When any card is inserted to or removed from the socket, the ESDHC detects the logic value changes on the DAT[3] pin and generates an interrupt. When the DAT[3] pin is not used for card detection (for example, it is implemented in GPIO), the CD pin must be connected for card detection. Whether DAT[3] is configured for card detection or not, the CD pin is always a reference for card detection. Whether the DAT[3] pin or the CD pin is used to detect card insertion, the ESDHC will send an interrupt (if enabled) to inform the Host system that a card is inserted.

27.3.9 Power Management and Wake Up Events

When there is no operation between the ESDHC and the card through the SD bus, the user can completely disable the ipg_clk and ipg_perclk in the chip level clock control module to save power. When the user needs to use the ESDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to the ESDHC are disabled, for instance, when the system is in low power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The ESDHC can generate these interrupt even when there are no clocks enabled. The three interrupts which can be used as wake up events are:

1. Card Removal Interrupt
2. Card Insertion Interrupt
3. Interrupt from SDIO card

The ESDHC offers a power management feature. By clearing the clock enabled bits in the System Control Register (ESDHC_SYSCTL), the clocks are gated in the low position to the ESDHC. For maximum power saving, the user can disable all the clocks to the ESDHC when there is no operation in progress.

These three wake up events (or wakeup interrupts) can also be used to wake up the system from low-power modes.

NOTE

To make the interrupt a wakeup event, when all the clocks to the ESDHC are disabled or when the whole system is in low power mode, the corresponding wakeup enabled bit needs to be set. Refer to Protocol Control (ESDHCV3_PROCTL) for more information on the ESDHC Protocol Control register.

27.3.9.1 Setting Wake Up Events

For the ESDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the ARM platform enters sleep mode. Before the software disables the host clock, it should ensure that all of the following conditions have been met:

- No Read or Write Transfer is active
- Data and Command lines are not active
- No interrupts are pending
- Internal data buffer is empty

27.3.10 MMC Fast Boot

The Embedded Multimedia Card (eMMC 4.3) has a fast boot feature. In boot operation mode, the master (MultiMediaCard host) can read boot data from the slave (MMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFA (optional for slave), before issuing CMD1.

There are two supported types of fast boot mode, boot operation and alternative boot operation. Each type has with-acknowledge and without-acknowledge modes.

NOTE

For the eMMC 4.3 card setting, please see the eMMC 4.3 spec.

27.3.10.1 Boot Operation

NOTE

In this block guide, this fast boot is called normal fast boot mode.

If the CMD line is held LOW for 74 clock cycles and more after power-up before the first command is issued, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within 1 second after the CMD line goes LOW, the slave starts to send the first boot data to the master on the DAT line(s). The master must keep the CMD line LOW to read all of the boot data.

If boot acknowledge is enabled, the slave has to send acknowledge pattern '010' to the master within 50ms after the CMD line goes LOW. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate boot mode with the CMD line HIGH.

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

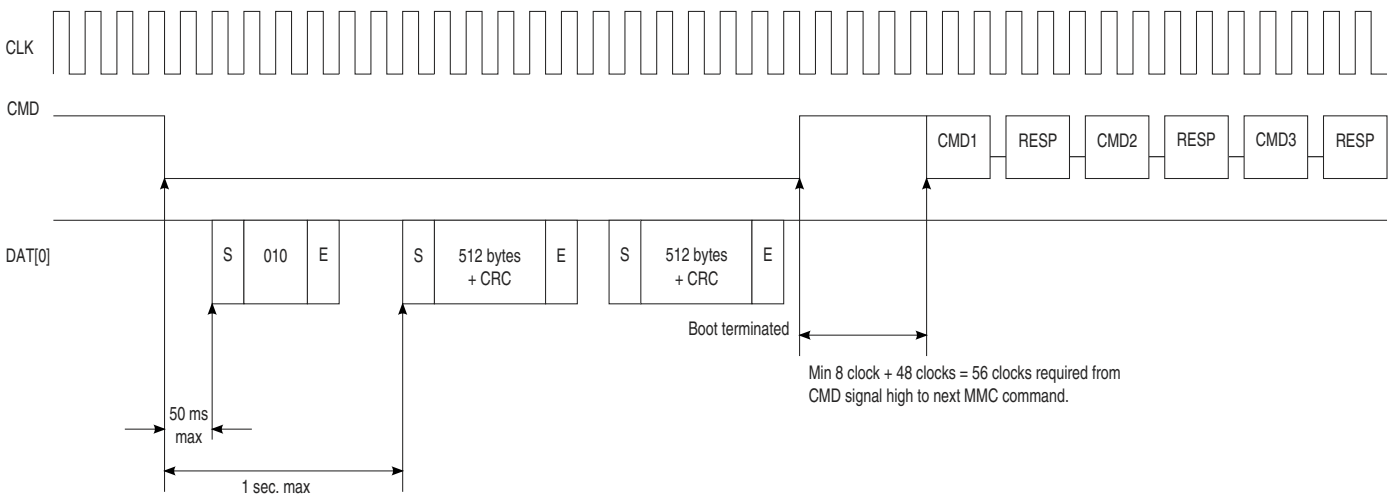

Figure 27-16. MultiMediaCard state diagram (normal boot mode)

27.3.10.2 Alternative Boot Operation

If bit 0 in the extended CSD byte[228] is set to '1', the device supports the alternative boot operation.

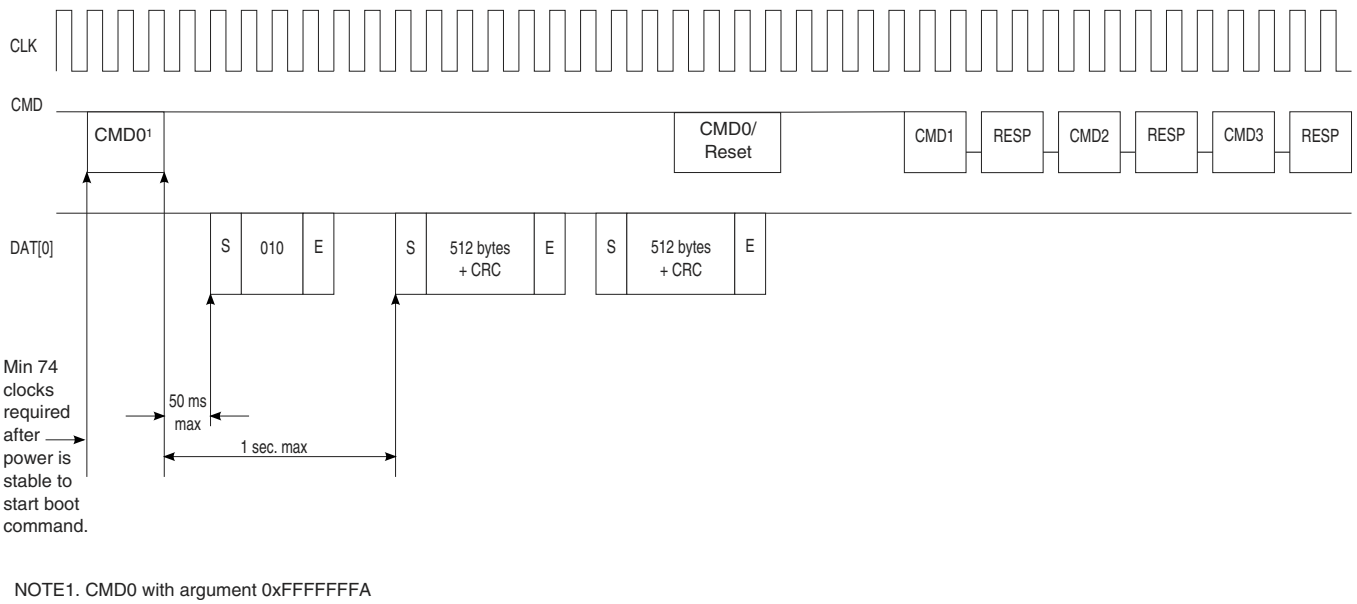
After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFA after 74 clock cycles, before CMD1is issued or the CMD line goes low, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within 1 second after CMD0 with the argument of 0xFFFFFFFA is issued, the slave starts to send the first boot data to the master on the DAT line(s).

If boot acknowledge is enabled, the slave has to send the acknowledge pattern '010' to the master within 50ms after the CMD0 with the argument of 0xFFFFFFFA is received. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate boot mode by issuing CMD0 (Reset).

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.



NOTE1. CMD0 with argument 0xFFFFFFFA

Figure 27-17. MultiMediaCard state diagram (alternative boot mode)

27.4 Initialization/Application of ESDHC

All communication between system and cards are controlled by the host. The host sends commands of two types: broadcast and addressed (point-to-point).

Broadcast commands are intended for all cards, such as "GO_IDLE_STATE", "SEND_OP_COND", "ALL_SEND_CID" and etc. In Broadcast mode, all cards are in the open-drain mode to avoid bus contention. Refer to Commands for MMC/SD/SDIO for the commands of bc and bcr categories.

After the Broadcast command CMD3 is issued, the cards enter standby mode. Addressed type commands are used from this point. In this mode, the CMD/DAT I/O pads will turn to push-pull mode, to have the driving capability for maximum frequency operation. Refer to Commands for MMC/SD/SDIO for the commands of ac and adtc categories.

27.4.1 Command Send & Response Receive Basic Operation

Assuming the data type WORD is an unsigned 32-bit integer, the below flow is a guideline for sending a command to the card(s):

```
send_command(cmd_index, cmd_arg, other requirements)
{
WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is
recommended to implement in a bit-field manner
wCmd = (<cmd_index> & 0x3f) >> 24; // set the first 8 bits as '00'+<cmd_index>
set CMDTYP, DPSEL, CICEN, CCCEN, RSTTYP, DTDSEL accorind to the command index;
if (internal DMA is used) wCmd |= 0x1;
if (multi-block transfer) {
          set MSBSEL bit;
          if (finite block number) {
                    set BCEN bit;
                    if (auto12 command is to use) set AC12EN bit;
          }
}
write_reg(CMDARG, <cmd_arg>); // configure the command argument
write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command
}
wait_for_response(cmd_index)
{
while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set
read IRQ Status register and check if any error bits about Command are set
if (any error bits are set) report error;
write 1 to clear CC bit and all Command Error bits;
}
```

For the sake of simplicity, the function wait_for_response is implemented here by means of polling. For an effective and formal way, the response is usually checked after the Command Complete Interrupt is received. By doing this, make sure the corresponding interrupt status bits are enabled.

For some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and go to the Standby State, no response to the Host when CMD2 is sent. The Host Driver shall deal with 'fake' errors like this with caution.

27.4.2 Card Identification Mode

When a card is inserted to the socket or the card was reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the Relative Card Address (RCA) or to set the RCA for the MMC cards.

27.4.2.1 Card Detect

See figure below for a flow diagram showing the detection of MMC, SD and SDIO cards using the ESDHC.

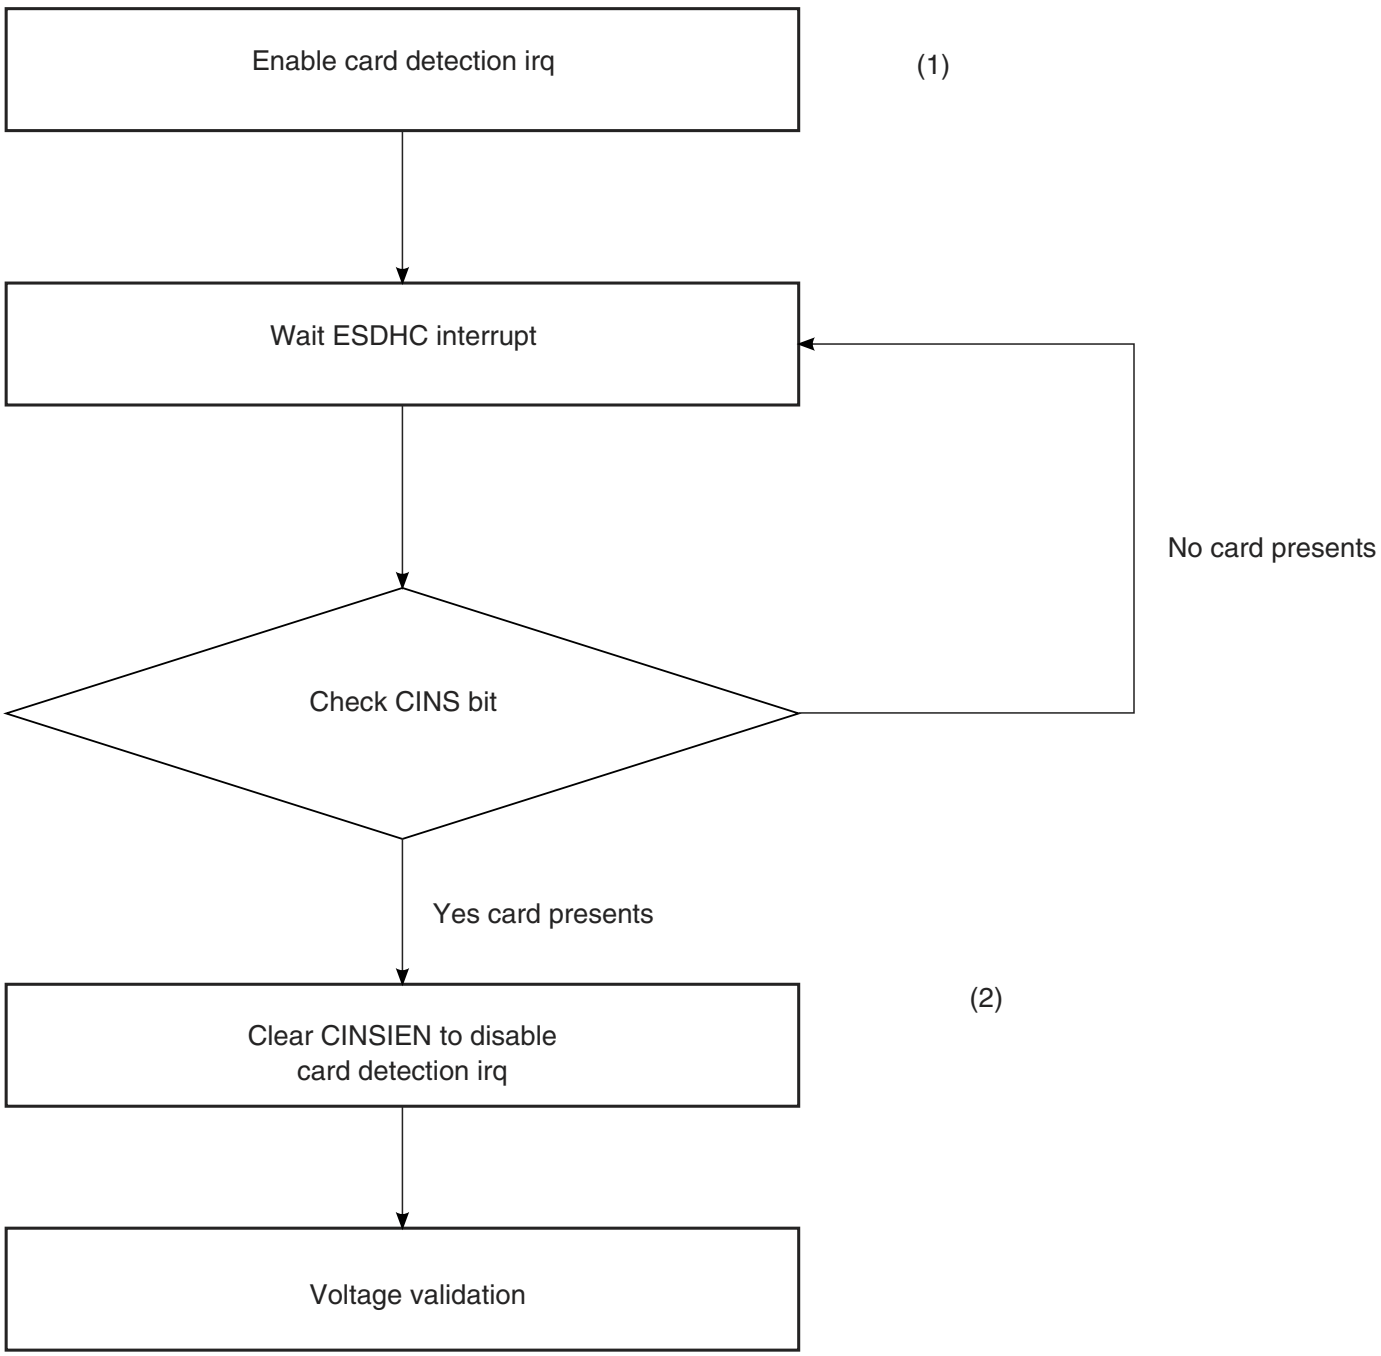


Figure 27-18. Flow Diagram for Card Detection

Here is the card detect sequence:

- Set the CINSIEN bit to enable card detection interrupt
- When an interrupt from the ESDHC is received, check the CINS bit in the Interrupt Status register to see if it was caused by card insertion
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards

27.4.2.2 Reset

The host consists of three types of resets:

- Hardware reset (Card and Host) which is driven by POR (Power On Reset)
- Software reset (Host Only) is proceed by the write operation on the RSTD, RSTC, or RSTA bits of the System Control register to reset the data part, command part, or all parts of the Host Controller, respectively
- Card reset (Card Only). The command, "Go_Idle_State" (CMD0), is the software reset command for all types of MMC cards, SD Memory cards. This command sets each card into the Idle State regardless of the current card state. For an SD I/O Card, CMD52 is used to write an I/O reset in the CCCR. The cards are initialized with a default relative card address (RCA=0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. See figure below for the software flow to reset both the ESDHC and the card.

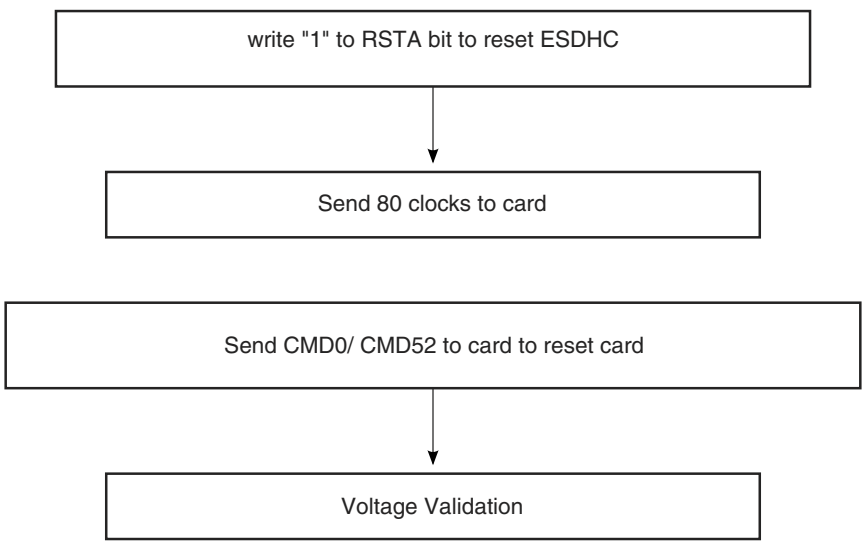

Figure 27-19. Flow Chart for Reset of the ESDHC and SD I/O Card

```
software_reset()
{
set_bit(SYSCTRL, RSTA); // software reset the Host
set DVS and SDCLKFS bit fields to get the SD_CLK of frequency around 400kHz
configure IO pad to set the power voltage of external card to around 3.0V
poll bits CIHB and CDIHB bits of PRSSTAT to wait both bits are cleared
set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
send_command(CMD_GO_IDLE_STATE, <other parameters>); // reset the card with CMD0
or send_command(CMD_IO_RW_DIRECT, <other parameters>);
}
```

27.4.2.3 Voltage Validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for Vdd are defined in the Operation Conditions Register (OCR) and may not cover the whole range. Cards that store the CID and CSD data in the preload memory are only able to communicate this information under data transfer Vdd conditions. This means if the host and card have non-common Vdd ranges, the card will not be able to complete the identification cycle, nor will it be able to send CSD data.

Therefore, a special command Send_Op_Cont (CMD1 for MMC), SD_Send_Op_Cont (ACMD41 for SD Memory) and IO_Send_Op_Cont (CMD5 for SD I/O) is used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards which do not match the Vdd range(s) desired by the host. This is accomplished by the host sending the desired Vdd voltage window as the operand of this command. Cards that can't perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive State. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before sending out-of-range cards into the Inactive State. This query should be used if the host is able to select a common voltage range or if a notification shall be sent to the system when a non-usable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```
voltage_validation(voltage_range_arguement)
{
label the card as UNKNOWN;
send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO
operation voltage, command argument is zero
if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
          if (0 < number of IO functions) {
                    label the card as SDIO;
                    IORDY = 0;
                    while (!(IORDY in IO OCR response)) { // set voltage range for each IO
function
                              send_command(IO_SEND_OP_COND, <voltage range>, <other
parameter>);
                              wait_for_response(IO_SEND_OP_COND);
                    } // end of while ...
          } // end of if (0 < ...
          if (memory part is present inside SDIO card) Label the card as SDCombo; // this is
an
SD-Combo card
} // end of if (RESP_TIMEOUT ...
if (the card is labelled as SDIO card) return; // card type is identified and voltage range
is
set, so exit the function;
send_command(APP_CMD, 0x0, <other parameters are omitted>); // CMD55, Application specific
CMD
prefix
if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55 is accepted
          send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set voltage
```

```
range
for memory part or SD card
          wait_for_response(SD_APP_OP_COND); // voltage range is set
          if (card type is UNKNOWN) label the card as SD;
          return; //
} // end of if (no error ...
else if (errors other than time-out occur) { // command/response pair is corrupted
          deal with it by program specific manner;
} // of else if (response time-out
else { // CMD55 is refuse, it must be MMC card           if (card is already labelled as
SDCombo) { // change label
                    re-label the card as SDIO;
                    ignore the error or report it;
                    return; // card is identified as SDIO card
          } // of if (card is ...
          send_command(SEND_OP_COND, <voltage range>, <...>);
          if (RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted,
either
                    label the card as UNKNOWN;
                    return;
          } // of if (RESP_TIMEOUT ...
          if (check for CE-ATA signature succeeded) { // the card is CE-ATA
                    store CE-ATA specific info from the signature;
                    label the card as CE-ATA;
          } // of if (check for CE-ATA ...
          else label the card as MMC;
} // of else
}
```

27.4.2.4 Card Registry

Card registry for the MMC and SD/SDIO/SD Combo cards are different.

For the SD Card, the Identification process starts at a clock rate lower than 400 kHz and the power voltage higher than 2.7 V (as defined by the Card spec). At this time, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host will request the card to send their valid operation conditions. The response to ACMD41 is the operation condition register of the card. The same command shall be send to all of the new cards in the system. Incompatible cards are put into the Inactive State. The host then issues the command, All_Send_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified (in the Ready State), send their CID number as the response. After the CID is sent by the card, the card goes into the Identification State.

The host then issues Send_Relative_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA will be used to address the card for future data transfer operations. Once the RCA is received, the card changes its state to the Standby State. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send_Relative_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in system.

For MMC operation, the host starts the card identification process in open-drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line allow parallel card operation during card identification. After the bus is activated the host will request the cards to send their valid operation conditions (CMD1). The response to CMD1 is the "wired OR" operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive State. The host then issues the broadcast command All_Send_CID (CMD2), asking all cards for their unique card identification (CID) number. All unidentified cards (the cards in Ready State) simultaneously start sending their CID numbers serially, while bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. Since the CID is unique for each card, only one card can be successfully send its full CID to the host. This card then goes into the Identification State. Thereafter, the host issues Set_Relative_Addr (CMD3) to assign to the card a relative card address (RCA). Once the RCA is received the card state changes to the Stand-by State, and the card does not react in further identification cycles, and its output driver switches from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

For operation as MMC cards:

```
card_registry()
{
do { // decide RCA for each card until response time-out
          if(card is labelled as SDCombo or SDIO) { // for SDIO card like device
                    send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO card to
publish its
RCA
                    retrieve RCA from response;
          } // end if (card is labelled as SDCombo ...
          else if (card is labelled as SD) { // for SD card
                    send_command(ALL_SEND_CID, <...>);
                    if (RESP_TIMEOUT == wait_for_response(ALL_SEND_CID)) break;
                    send_command(SET_RELATIVE_ADDR, <...>);
                    retrieve RCA from response;
          } // else if (card is labelled as SD ...
          else if (card is labelled as MMC or CE-ATA) { // treat CE-ATA as MMC
                    send_command(ALL_SEND_CID, <...>);
                    rca = 0x1; // arbitrarily set RCA, 1 here for example, this RCA is also
the
relative address to access the CE-ATA card
                    send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper
16
bits
          } // end of else if (card is labelled as MMC ...
} while (response is not time-out);
}
```

27.4.3 Card Access

27.4.3.1 Block Write

27.4.3.1.1 Normal Write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card shall indicate the failure on the DAT line. The transferred data will be discarded and not written, and all further transmitted blocks (in multiple block write mode) will be ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE_BLK_MISALIGN is not set), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS_ERROR error bit in the status register, and while ignoring all further data transfer, waits in the Receive-data-State for a stop command. The write operation is also aborted if the host tries to write over a write protected area.

For MMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card will report an error and not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card will begin writing and hold the DAT line low if its write buffer is full and unable to accept new data from a new WRITE_BLOCK command. The host may poll the status of the card with a SEND_STATUS command (CMD13) or other means for SDIO cards at any time, and the card will respond with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 (to select a different card) to place the card into the Standby State and release the DAT line without interrupting the write operation. When re-selecting the card, it will reactivate the busy indication by pulling DAT to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card incorporates the internal DMA and the write operation is a multi-block write with the Auto CMD12 enabled. For the other two methods (by means of external DMA or ARM platform polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is described below:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:
   a. For SD/MMC cards, use SET_BLOCKLEN (CMD16)
   b. For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the ESDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the ESDHC block attribute register, block number is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the ESDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

27.4.3.1.2 DDR Write

ESDHC supports dual data rate mode.

The software flow to write to a card in ddr mode is described as below:

1. Check the card status, wait until the card is ready for data.
2. For eMMC4.4 card, block length only can be set to 512byte.
3. Set the ESDHC number block register (NOB), nob is 5 (for instance).
4. Set eMMC4.4 card to high speed mode, use SWITCH(CMD6).
5. Set eMMC4.4 card bus with (4-bit /8-bit ddr mode), use SWITCH(CMD6).
6. Disable the buffer write ready interrupt, configure the DMA settings and enable the ESDHC DMA when sending the command with data transfer.The DDR_EN_IPG bit should be set. The AC12EN bit should also be set.
7. Wait for the Transfer Complete interrupt.
8. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

27.4.3.1.3 Write with Pause

The write operation can be paused during the transfer. Instead of stopping the SD_CLK at any time to pause all the operations, which is also inaccessible to the Host Driver, the Driver can set the SABGREQ bit in the Protocol Control register to pause the transfer

between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DAT0 line is not required to de-assert to release the busy state, no suspend command is needed.

Like in the flow described in Normal Write, the write with pause is shown with the same kind of write operation:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
   a. For SD/MMC, use SET_BLOCKLEN (CMD16)
   b. For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the ESDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the ESDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the ESDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Set the SABGREQ bit.
7. Wait for the Transfer Complete interrupt.
8. Clear the SABGREQ bit.
9. Check the status bit to see if a write CRC error occurred.
10. Set the CREQ bit to continue the write operation.
11. Wait for the Transfer Complete interrupt.
12. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of the BLKCNT field in the Block Attribute register. As the data transfer and the setting of the SABGREQ bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The Driver shall read the value of BLKCNT after the transfer is paused and the Transfer Complete interrupt is received.

It is also possible the last block has begun when the Stop At Block Gap Request is sent to the buffer. In this case, the next block gap is actually the end of the transfer. These types of requests are ignored and the Driver should treat this as a non-pause transfer and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the Host System is not stopped, and the transfer is active until the data buffer is full. Because of this (if not needed), it is recommended to avoid using the Suspend Command for the SDIO card; when such a command is sent, the ESDHC thinks the System will switch to another

function on the SDIO card, and flush the data buffer. The ESDHC takes the Resume Command as a normal command with data transfer, and it is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set as well as the AC12EN bit. However, the ESDHC will automatically send a CMD12 to mark the end of the multi-block transfer.

27.4.3.2 Block Read

27.4.3.2.1 Normal Read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer State. For multi blocks read, data blocks will be continuously transferred until a stop command is issued.

The software flow to read from a card incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other two methods (by means of external DMA or ARM platform polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is described below:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
   a. For SD/MMC, use SET_BLOCKLEN (CMD16)
   b. For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the ESDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the ESDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer read ready interrupt, configure the DMA settings and enable the ESDHC DMA when sending the command with data transfer. The AC12EN bit should also be set:
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

27.4.3.2.2 DDR Read

ESDHC supports dual data rate mode.

The software flow to write to a card in ddr mode is described below:

1. Check the card status, wait until the card is ready for data.
2. For eMMC4.4 card, block length only can be set to 512byte.
3. Set the ESDHC number block register (NOB), nob is 5 (for instance).
4. Set eMMC4.4 card to high speed mode, use SWITCH(CMD6).
5. Set eMMC4.4 card bus with (4-bit /8-bit ddr mode), use SWITCH(CMD6).
6. Disable the buffer write ready interrupt, configure the DMA settings and enable the ESDHC DMA when sending the command with data transfer.The DDR_EN_IPG bit should be set. The AC12EN bit should also be set.
7. Wait for the Transfer Complete interrupt.
8. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

27.4.3.2.3 Read with Pause

The read operation is not generally able to pause. Only the SDIO card (and SDCombo card working under I/O mode) supporting the Read Wait feature can pause during the read operation. If the SDIO card supports Read Wait (SRW bit in CCCR register is 1), the Driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks. Before setting the SABGREQ bit, make sure the RWCTL bit in the Protocol Control register is set, otherwise the ESDHC will not assert the Read Wait signal during the block gap and data corruption occurs. It is recommended that the RWCTL bit be set once the Read Wait capability of the SDIO card is recognized.

Like in the flow described in Normal Read, the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on the SDIO card to confirm the card supports Read Wait.
2. Set the RWCTL bit.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:
   a. For SD/MMC, use SET_BLOCKLEN (CMD16)
   b. For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
5. Set the ESDHC block length register to be the same as the block length set for the card in Step 2.

6. Set the ESDHC number block register (NOB), nob is 5 (for instance).
7. Disable the buffer read ready interrupt, configure the DMA setting and enable the ESDHC DMA when sending the command with data transfer. The AC12EN bit should also be set
8. Set the SABGREQ bit.
9. Wait for the Transfer Complete interrupt.
10. Clear the SABGREQ bit.
11. Check the status bit to see if read CRC error occurred.
12. Set the CREQ bit to continue the read operation.
13. Wait for the Transfer Complete interrupt.
14. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

Like the write operation, it is possible to meet the ending block of the transfer when paused. In this case, the ESDHC will ignore the Stop At Block Gap Request and treat it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause will be transferred to the Host System. No matter if the Suspend Command is sent or not, the internal data buffer is not flushed.

If the Suspend Command is sent and the transfer is later resumed by means of a Resume Command, the ESDHC takes the command as a normal one accompanied with data transfer. It is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit. However, the ESDHC will automatically send the CMD12 to mark the end of multi-block transfer.

27.4.3.2.4 DLL (Delay Line) in Read Path

The DLL (Delay Line) is added to assist in sampling read data. As in The DLL provides the ability to programmatically select a quantized delay (in fractions of the clock period) regardless of on-chip variations such as process, voltage and temperature (PVT). The reasons why the DLL is needed for ESDHC are 1.) the path of read data traveling from card to host varies. 2.) in MMC DDR mode the minimum input setup and hold time are both at 2.5 ns. The data sampling window is so small that the delay of loopback clock needs to be accurate and consistent regardless of PVT. The DLL takes the divided perclk as the reference clock and loopback clock as the input clock. It then generates a delayed version of the input clock according to the programmed target delay.

The DLL can be disabled or bypassed, and it can also be manually set for a fixed delay in override mode. The override value set is the number of delay cells. In override mode, the DLL_enable is no need to set. And another working mode of DLL is target value mode. In this mode, DLL will automatically adjust the number of delay cells according to the target value your set value and PVT changes. Be aware that target value is in the unit of 1/32 clock reference period. If the perclk is 100MHz, then the reference clock period is 10ns, setting target value of 16 means 5ns=(16/32)*10ns. Software can disable automatically update by setting dll_gate_update bit. Please refer to Figure 27-20.

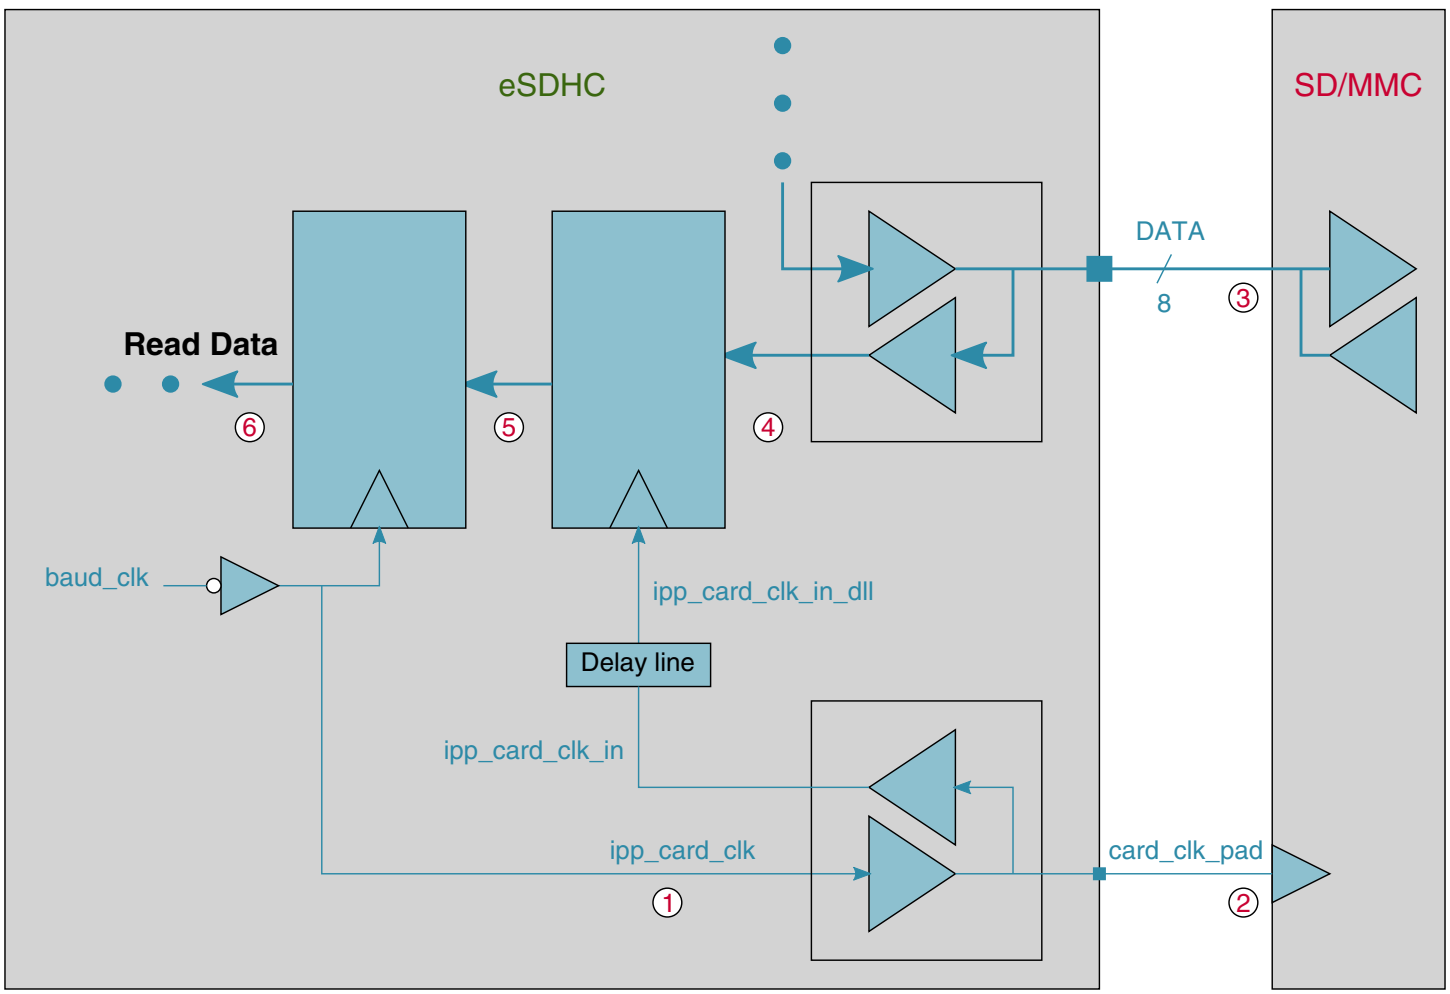

Figure 27-20. DLL (Delay Line) in Read Path

27.4.3.3 Suspend Resume

The ESDHC supports the Suspend Resume operations of SDIO cards, although slightly different than the suggested implementation of Suspend in the SDIO card specification.

Suspend

After setting the SABGREQ bit, the Host Driver may send a Suspend command to switch to another function of the SDIO card. The ESDHC does not monitor the content of the response, so it doe not know whether or not the Suspend command has succeeded. Accordingly, it does not de-assert Read Wait for read pause. To solve this problem, the Driver does not set the ESDHC_XFERTYP[CMDTYP] register to 01, that is, Suspend option. Instead, the Driver sends this command as if it were a normal command (that is, sets CMDTYP to b00). Only when the command succeeds, and the BS bit is set in the response, does the Driver send another command marked as "Suspend" to inform the ESDHC that the current transfer is suspended. This is shown in the following sequence for Suspend operation:

1. Set the SABREQ bit to pause the current data transfer at block gap.
2. After the BGE bit is set, send the Suspend command to suspend the active function. The CMDTYP bit field must be 2'b00.
3. Check the BS bit of the CCCR in the response. If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.
4. Send another normal I/O command to the suspended function. The CMDTYP of this command must be 2'b01, so the ESDHC can detect this special setting and be informed that the paused operation has successfully suspended. If the paused transfer is a read operation, the ESDHC stops driving DAT2 and goes to the idle state.
5. Save the context registers in the system memory for later use, including the DMA System Address Register (for internal DMA operation), and the Block Attribute Register.
6. Begin operation for another function on the SDIO card.

27.4.3.3.1 Resume

To resume the data transfer, a Resume command shall be issued:

1. To resume the suspended function, restore the context register with the saved value in step #5 of the Suspend operation above.
2. Send the Resume command. In the Transfer Type register, all bit fields are set to the value as if this were another ordinary data transfer, instead of a transfer resume (except the CMDTYP is set to 2'b10).
3. If the Resume command has responded, the data transfer will be resumed.

27.4.3.4 ADMA1 Usage

To use the ADMA1 in a data transfer, the Host Driver must prepare the correct descriptor chain prior to sending the read/write command. The steps to accomplish this are:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4kB address aligned).
3. If necessary, create a Link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1 ~ 3.
4. Repeat steps 1 ~ 3 until all descriptors are created.
5. In the last descriptor, set the End flag to 1 and make sure the total length of all descriptors match the product of the block size and block number configured in the Block Attribute Register.
6. Set the ADMA System Address Register to the address of the first descriptor and set the DMAS field in the Protocol Control Register to 01 to select the ADMA.
7. Issue a write or read command with the DMAEN bit set to 1 in the Transfer Type Register.

Steps 1 ~ 5 are independent of step 6, so step 6 can finish before steps 1 ~ 5. Regarding the descriptor configuration, it is recommended not to use the Link descriptor as it requires extra system memory access.

27.4.3.5 Transfer Error

27.4.3.5.1 CRC Error

It is possible at the end of a block transfer, that a write CRC status error or read CRC error occurs. For this type of error the latest block received shall be discarded. This is because the integrity of the data block is not guaranteed. It is recommended to discard the following data blocks and re-transfer the block from the corrupted one. For a multi-block transfer, the Host Driver shall issue a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the AC12EN and BCEND bits are set, the ESDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an Auto CMD12 will be sent by the ESDHC. In this case, the Driver shall re-send or re-obtain the last block with a single block transfer.

27.4.3.5.2 Internal DMA Error

During the data transfer with internal Simple DMA, if the DMA engine encounters some error on the AHB bus, the DMA operation is aborted and DMA Error interrupt is sent to the Host System. When acknowledged by such an interrupt, the Driver shall calculate the start address of data block in which the error occurs. The start address can be calculated by either:

1. Read the DMA System Address register. The error occurs during the previous burst. Taking the block size, the previous burst length and the start address of the next burst transfer into account, it is straight forward to obtain the start address of the corrupted block.
2. Read the BLKCNT field of the Block Attribute register. By the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined. When the BCEN bit is not set, the contents of the Block Attribute register does not change, so this method does not work.

When a DMA error occurs, it is recommended to abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and re-start the transfer from the corrupted block to recover from the error.

27.4.3.5.3 ADMA Error-Card Access

There are three kinds of possible ADMA errors. The AHB transfer, invalid descriptor, and data-length mismatch errors. When these errors occur, the DMA transfer stops and the corresponding error status bit is set. For acknowledging the status, the Host Driver should recover the error as shown below and re-transfer from the place of interruption.

1. AHB transfer error: Such errors may occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and re-transfer the block that was corrupted, or the next block if no block is corrupted.
2. Invalid descriptor error: For such errors, it is recommended to retrieve the transfer context, reset for the data part and re-create the descriptor chain from the invalid descriptor and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
3. Data-length mismatch error: It is similar to recover from this error. The Host Driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain, and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

27.4.3.5.4 Auto CMD12 Error

After the last block of the multi block transfer is sent or received, and the AC12EN bit is set when the data transfer is initiated by the data command, the ESDHC automatically sends a CMD12 to the card to stop the transfer. When errors with this command occur, it is recommended to the Driver to deal with the situations in the following manner:

1. Auto CMD12 response time-out. It is not certain whether the command is accepted by the card or not. The Driver should clear the Auto CMD12 error status bits and re-send the CMD12 until it is accepted by the card.
2. Auto CMD12 response CRC error. Since card responds to the CMD12, the card will abort the transfer. The Driver may ignore the error and clear the error status bit.
3. Auto CMD12 conflict error or not sent. The command is not sent, so the Driver shall send a CMD12 manually.

27.4.3.6 Card Interrupt

The external cards can inform the Host Controller by means of some special signals. For the SDIO card, it can be the low level on the DAT[1] line during some special period. The ESDHC only monitors the DAT[1] line and supports the SDIO interrupt.

When the SDIO interrupt is captured by the ESDHC, and the Host System is informed by the ESDHC asserting the ESDHC interrupt line, the interrupt service from the Host Driver is called.

As the interrupt factor is controlled by the external card, the interrupt from the SDIO card must be served before the CINT bit is cleared by written 1. Refer to Card Interrupt Handling for the card interrupt handling flow.

27.4.4 Switch Function

MMC cards transferring data at bus widths other than 1-bit is a feature in MMC spec. The high speed timing mode for all card devices, was also defined in various card specifications. To enable these features, a "switch" command shall be issued by the Host Driver.

For SDIO cards, the high speed mode is enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed. For SD cards, the high speed mode is queried and enabled by a CMD6 (with the mnemonic symbol as SWITCH_FUNC). For MMC cards, the high speed mode is queried by a CMD8 and enabled by a CMD6 (with the mnemonic symbol as SWITCH).

The 4-bit and 8-bit bus width of the MMC is also enabled by the SWITCH command, but with a different argument.

DDR mode is also selected by setting ddr mode bus width via SWITCH.

These new functions can also be disabled by a software reset. For SDIO cards it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following flowcharts do not show current capability check, which is recommended in the function switch process.

27.4.4.1 Query, Enable and Disable SDIO High Speed Mode

```
enable_sdio_high_speed_mode(void)
{
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is '0') report the SDIO card does not support high speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into ESDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is
cleared;
change clock divisor value or configure the system clock feeding into ESDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

27.4.4.2 Query, Enable and Disable SD High Speed Mode

```
enable_sd_high_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0xFFFFF1 and read 64 bytes of data accompanying the R1 response;
wait data transfer done bit is set;
check if the bit 401 of received 512 bit is set;
if (bit 401 is '0') report the SD card does not support high speed mode and return;
send CMD6, with argument 0x80FFFFF1 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into ESDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sd_high_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into ESDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

27.4.4.3 Query, Enable and Disable MMC High Speed Mode

```
enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support high speed mode and
return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
extract the value of CARD_TYPE field to check the 'high speed mode' in this MMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report MMC switching to high speed mode failed and return;
change clock divisor value or configure the system clock feeding into ESDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 0;
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into ESDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}
```

27.4.4.4 Set MMC Bus Width

```
change_mmc_bus_width(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support multiple bit width and
return;
send CMD6 with argument 0x3B70x00; (8-bit, x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}
```

27.4.5 ADMA Operation

27.4.5.1 ADMA1 Operation

```
Set_adma1_descriptor
{
if (to start data transfer) {
// Make sure the address is 4KB align.
Set 'Set' type descriptor;
{
```

```
Set Act bits to 01;
Set [31:12] bits data length (byte unit);
}
Set 'Tran' type descriptor;
{
Set Act bits to 10;
Set [31:12] bits address (4KB align);
}
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to 11;
Set [31:12] bits the next descriptor address (4KB align);
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set End bit to 1;
}
if (to generate interrupt for this descriptor) {
Set Int bit to 1;
}
Set Valid bit to 1;
}
```

27.4.5.2 ADMA2 Operation

```
Set_adma2_descriptor
{
if (to start data transfer) {
// Make sure the address is 32-bit boundary (lower 2-bit are always '00').
Set higher 32-bit of descriptor for this data transfer initial address;
Set [31:16] bits data length (byte unit);
Set Act bits to '10';
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to '11';
// Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
Set higher 32-bit of descriptor for the next descriptor address;
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set 'End' bit '1';
}
if (to generate interrupt for this descriptor) {
Set 'Int' bit '1';
}
Set the 'Valid' bit to '1';
}
```

27.4.6 Fast Boot Operation

27.4.6.1 Normal fast boot flow

1. Software need to configure init_active bit (system control register bit 27) to make sure 74 card clocks are finished.

2. Software need to configure MMC Boot Register (offset 0xc4) bit 6 to 1(enable boot), and bit 5 to 0(normal fast boot), and bit 4 to select the ack mode or not. If need to send through DMA mode, need to configure bit 7 to enable automatically stop at block gap feature. And need to configure bit 3-bit0 to select the ack timeout value according to the sd clk frequence.
3. Software then need to configure Block Attributes Register to set block size/no. If in ddr fast boot mode, block size only can be configure to 512byte.
4. Software need to configure Protocol control register to set DTW (data transfer width). If in ddr fast boot mode, DTW only can be configure to 4-bit/8-bit dataline mode.
5. Software need to configure Command Argument Register to set argument if needed (no need in normal fast boot).
6. Software need to configure Transfer Type Register to start the boot process. In normal boot mode, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1.

NOTE

DMAEN should be configured as 0 in polling mode. And if BCEN is configured as 1, better to configure blk no in Bock Attributes Register to the max value. And if in ddr fast boot mode, DDR_EN need to be set to 1.

7. When the step 6 is configured, boot process will begin. Software need to poll the data buffer ready status to read the data from buffer in time. If boot time-out happened (ack time out or the first data read time out), Interrupt will be triggered, and software need to configure MMC Boot Register to bit 6 to 0 to disable boot. Thus will make CMD high, and then after at least 56 clocks, it is ready to begin normal initialization process.
8. If no time out, software need to decide the data read is finished and then configure MMC Boot Register bit 6 to 0 to disable boot. This will make CMD line high and command completed asserted. After at least 56 clocks, it is ready to begin normal initialization process.
9. Reset the host and then can begin the normal process.

27.4.6.2 Alternative fast boot flow

1. Software need to configure init_active bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software need to configure MMC Boot Register (offset 0xc4) bit 6 to 1(enable boot), and bit 5 to 1(alternative boot), and bit 4 to select the ack mode or not. If need to send through DMA mode, need to configure bit 7 to enable automatically stop at

block gap feature. And need to configure bit 3-bit0 to select the ack timeout value according to the sd clk frequence.

3. Software then need to configure Block Attributes Register to set block size/no. If in ddr fast boot mode, block size only can be configure to 512byte.
4. Software need to configure Protocol control register to set DTW(data transfer width). If in ddr fast boot mode, DTW only can be configure to 4-bit/8-bit dataline mode.
5. Software need to configure Command Argument Register to set argument to 0xFFFFFFFA.
6. Software need to configure Transfer Type Register to start the boot process by CMD0 with 0xFFFFFFFA argument . In alternative boot, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1.

NOTE

DMAEN should be configured as 0 in polling mode. And if BCEN is configured as 1 in polling mode, better to configure blk no in Bock Attributes Register to the max value. And if in ddr fast boot mode, DDR_EN need to be set to 1.

7. When the step 6 is configured, boot process will begin. Software need to poll the data buffer ready status to read the data from buffer in time. If boot time out(ack data time out in 50ms or data time out in 1s), host will send out the interrupt and software need to send CMD0 with reset and then configure boot enable bit to 0 to stop this process. After command completed, configure MMC Boot Register bit 6 to 0 to disable boot. After at least 8 clocks from command completed, card is ready for identification step.
8. If no time out, software need to decide when to stop the boot process, and send out the CMD0 with reset and then after command completed, configure MMC Boot Register bit 6 to stop the process. After 8 clocks from command completed, slave(card) is ready for identification step.
9. Reset the host and then can begin the normal process.

27.4.6.3 Fast boot application case (in DMA mode)

In the boot application case, because the image destination and the image size are contained in the

beginning of the image, need to switch DMA parameters on the fly during MMC fast boot.

In fast boot, host can use ADMA2 (Advanced DMA2) with two destinations.

The detail flow:

1. Software need to configure init_active bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software need to configure MMC Boot Register (offset 0xc4) bit 6 to 1(enable boot); and bit 5 to 0(normal fast boot), to 1(alternative boot); and bit 4 to select the acknowledge mode or not. In DMA mode, configure bit 7 to 1 for enable automatically stop at block gap feature. Also configure bit31-bit16 to set the VALUE1 (value of block count that need to transfer first time), that host will stop at block gap when card block counter is equal to this value. And need to configure bit 3-bit0 to select the acknowledge timeout value according to the SD clock frequency.
3. Software then need to configure Block Attributes Register to set block size/no. If in DDR fast boot mode, block size only can be configure to 512byte. In DMA mode, it is better to set block number to the max value (16'hFFFF).
4. Software need to configure Protocol control register to set DTW (data transfer width). If in DDR fast boot mode, DTW can be only configured to 4-bit/8-bit data line mode.
5. Software enbables ADMA2 by configuring protocol control register bit9-bit8.
6. Software need to set at least three pairs ADMA2 descriptor in boot memory (i.e. in IRAM, at least 6 words). The first pair descriptor define the start address (i.e. IRAM) and data length (i.e. 512 bytes*VALUE1) of first part boot code. Software also need to set the second pair descriptor, the second start address (any value that is writeable), data length is suggest to set 1~2word (record as VAULE2).

NOTE

The second couple descriptor also transfer useful data even at lease 1 word. Because our ADMA2 can't support 0 data_length data transfer descriptor.

7. Software need to configure Command Argument Register to set argument to 0xFFFFFFFA in alternative fast boot, and don't need set in normal fast boot.
8. Software need to configure Transfer Type Register to start the boot process. CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, and MSBSEL is set to 1. DMAEN is configured as 1 in DMA mode. And if BCEN is configured as 1, better to configure block no in Bock Attributes Register to the max value. And if in DDR fast boot mode, DDR_EN need to be set to 1.
9. When the step 8 is configured, boot process will begin. The first VAULE1 block number data has transfer. Software need to polling TC bit (bit1 in Interrupt Status Register) to determine first transfer is end. Also software need to polling BGE bit (bit2 in Interrupt Status Register) to determine if first transfer stop at block gap.
10. When TC, BGE bit is 1, SW can analyzes the first code of VAULE1 block, initializes the new memory device, if required, and sets the third pair of descriptors to define

the start address and length of the remaining part of boot code(VAULE3 the remain boot code block). Remember set the last descriptor with END.

11. Software need to configure MMC Boot Register (offset 0xc4) again. Set bit 6 to 1(enable boot); and bit 5 to 0(normal fast boot), to 1(alternative boot); and bit 4 to select the acknowledge mode or not. In DMA mode, configure bit 7 to 1 for enable automatically stop at block gap feature. Also configure bit31-bit16 to set the (VAULE1+1+VAULE3), that host will stop at block gap when card block counter is equal to this value. And need to configure bit 3-bit0 to select the acknowledge timeout value according to the SD clock frequency.
12. Software need to clear TC and BGE bit. And software need to clear SABGREQ (bit 16 in Protocol control register), and set CREQ (bit17 Protocol control register) to 1 to resume the data transfer. Host will transfer the VALUE2 and VAULE3 data to the destination that is set by descriptor.
13. Software need to polling BGE bit to determine if the fast boot is over.

NOTE

- When ADMA boot flow is started, for ESDHC, it is like a normal ADMA read operation.
- Need a few words length memory to keep descriptor.
- For the 1~2 word data in second descriptor setting, it is the useful data, so software need to deal the data due to the application case.

27.5 Commands for MMC/SD/SDIO

See table below for the list of commands for the MMC/SD/SDIO cards.

Refer to the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the MultiMediaCard:

1. broadcast commands (bc), no response.
2. broadcast commands with response (bcr), response from all cards simultaneously.
3. addressed (point-to-point) commands (ac), no data transfer on the DAT.
4. addressed (point-to-point) data transfer commands (adtc).

The Access Bits for the EXT_CSD Access Modes are shown in table below.

Table 27-2. Commands for MMC/SD/SDIO Cards

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD0	bc	[31:0] stuff bits	-	GO_IDLE_STATE	Resets all MMC and SD memory cards to idle state.
CMD1	bcr	[31:0] OCR without busy	R3	SEND_OP_COND	Asks all MMC and SD Memory cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD2	bcr	[31:0] stuff bits	R2	ALL_SEND_CID	Asks all cards to send their CID numbers on the CMD line.
CMD3[1]	ac	[31:6] RCA [15:0] stuff bits	R1 R6 (SDIO)	SET/ SEND_RELATIVE_ADDR	Assigns relative address to the card.
CMD4	bc	[31:0] DSR [15:0] stuff bits	-	SET_DSR	Programs the DSR of all cards.
CMD5	bc	[31:0] OCR without busy	R4	IO_SEND_OP_COND	Asks all SDIO cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD6[2]	adtc	[31] Mode 0: Check function 1: Switch function [30:8] Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF) [7:4] Function group1 for command system [3:0] Function group2 for access mode	R1	SWITCH_FUNC	Checks switch ability (mode 0) and switch card function (mode 1). Refer to "SD Physical Specification V1.1" for more details.
CMD6[3]	ac	[31:26] Set to 0 [25:24] Access [23:16] Index [15:8] Value [7:3] Set to 0 [2:0] Cmd Set	R1b	SWITCH	Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to "The MultiMediaCard System Specification Version 4.0 Final draft 2" for more details.
CMD7	ac	[31:6] RCA [15:0] stuff bits	R1b	SELECT/ DESELECT_CARD	Toggles a card between the stand-by and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all.

Table continues on the next page...

Table 27-2. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD8	adtc	[31:0] stuff bits	R1	SEND_EXT_CSD	The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.
CMD9	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CSD	Addressed card sends its card-specific data (CSD) on the CMD line.
CMD10	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CID	Addressed card sends its card-identification (CID) on the CMD line.
CMD11	adtc	[31:0] data address	R1	READ_DAT_UNTIL_STOP	Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.
CMD12	ac	[31:0] stuff bits	R1b	STOP_TRANSMISSION	Forces the card to stop transmission.
CMD13	ac	[31:6] RCA [15:0] stuff bits	R1	SEND_STATUS	Addressed card sends its status register.
CMD14	Reserved				
CMD15	ac	[31:6] RCA [15:0] stuff bits	-	GO_INACTIVE_STATE	Sets the card to inactive state in order to protect the card stack against communication breakdowns.
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD.
CMD17	adtc	[31:0] data address	R1	READ_SINGLE_BLOCK	Reads a block of the size selected by the SET_BLOCKLEN command.
CMD18	adtc	[31:0] data address	R1	READ_MULTIPLE_BLOCK	Continuously transfers data blocks from card to host until interrupted by a stop command.
CMD19	Reserved				
CMD20	adtc	[31:0] data address	R1	WRITE_DAT_UNTIL_STOP	Writes data stream from the host, starting at the given address, until a STOP_TRANSMISION follows.
CMD21-23	Reserved				
CMD24	adtc	[31:0] data address	R1	WRITE_BLOCK	Writes a block of the size selected by the SET_BLOCKLEN command.
CMD25	adtc	[31:0] data address	R1	WRITE_MULTIPLE_BLOCK	Continuously writes blocks of data until a STOP_TRANSMISSION follows.

Table continues on the next page...

Table 27-2. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD26	adtc	[31:0] stuff bits	R1	PROGRAM_CID	Programming of the card identification register. This command shall be issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer.
CMD27	adtc	[31:0] stuff bits	R1	PROGRAM_CSD	Programming of the programmable bits of the CSD.
CMD28	ac	[31:0] data address	R1b	SET_WRITE_PROT	If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE).
CMD29	ac	[31:0] data address	R1b	CLR_WRITE_PROT	If the card provides write protection features, this command clears the write protection bit of the addressed group.
CMD30	adtc	[31:0] write protect data address	R1	SEND_WRITE_PROT	If the card provides write protection features, this command asks the card to send the status of the write protection bits.
CMD31	Reserved				
CMD32	ac	[31:0] data address	R1	TAG_SECTOR_START	Sets the address of the first sector of the erase group.
CMD33	ac	[31:0] data address	R1	TAG_SECTOR_END	Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.
CMD34	ac	[31:0] data address	R1	UNTAG_SECTOR	Removes one previously selected sector from the erase selection.
CMD35	ac	[31:0] data address	R1	TAG_ERASE_GROUP_START	Sets the address of the first erase group within a range to be selected for erase.
CMD36	ac	[31:0] data address	R1	TAG_ERASE_GROUP_END	Sets the address of the last erase group within a continuous range to be selected for erase.
CMD37	ac	[31:0] data address	R1	UNTAG_ERASE_GROUP	Removes one previously selected erase group from the erase selection.
CMD38	ac	[31:0] stuff bits	R1b	ERASE	Erase all previously selected sectors.

Table continues on the next page...

Table 27-2. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD39	ac	[31:0] RCA [15] register write flag [14:8] register address [7:0] register data	R4	FAST_IO	Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if the write flag is set. The R4 response contains data read from the address register. This command accesses application dependent registers which are not defined in the MMC standard.
CMD40	bcr	[31:0] stuff bits	R5	GO_IRQ_STATE	Sets the system into interrupt mode.
CMD41	Reserved				
CDM42	adtc	[31:0] stuff bits	R1b	LOCK_UNLOCK	Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.
CMD43~51	Reserved				
CMD52	ac	[31:0] stuff bits	R5	IO_RW_DIRECT	Access a single register within the total 128k of register space in any I/O function.
CMD53	ac	[31:0] stuff bits	R5	IO_RW_EXTENDED	Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.
CMD54	Reserved				
CMD55	ac	[31:16] RCA [15:0] stuff bits	R1	APP_CMD	Indicates to the card that the next command is an application specific command rather that a standard command.
CMD56	adtc	[31:1] stuff bits [0]: RD/WR	R1b	GEN_CMD	Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.
CMD57~59	Reserved				
CMD60	adtc	[31] WR [30:24] stuff bits [23:16] address [15:8] stuff bits [7:0] byte count	R1b	RW_MULTIPLE_REGISTER	These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the device. All Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 shall be used to read and write these registers.

Table continues on the next page...

Table 27-2. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD61	adtc	[31] WR [30:16] stuff bits [15:0] data unit count	R1b	RW_MULTIPLE_BLOCK	The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer.
CMD62~63	Reserved				
ACMD6[4]	ac	[31:2] stuff bits [1:0] bus width	R1	SET_BUS_WIDTH	Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.
ACMD13[4]	adtc	[31:0] stuff bits	R1	SD_STATUS	Send the SD Memory Card status.
ACMD22[4]	adtc	[31:0] stuff bits	R1	SEND_NUM_WR_SECTORS	Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.
ACMD23[4]	ac		R1	SET_WR_BLK_ERASE_COUNT	-
ACMD41[4]	bcr	[31:0] OCR	R3	SD_APP_OP_COND	Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line.
ACMD42[4]	ac		R1	SET_CLR_CARD_DETECT	-
ACMD51[4]	adtc	[31:0] stuff bits	R1	SEND_SCR	Reads the SD Configuration Register (SCR).

1. CMD3 differs for MMC and SD cards. For MMC cards, it is referred to as SET_RELATIVE_ADDR, with a response type of R1. For SD cards, it is referred to as SEND_RELATIVE_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed MMC cards and high speed SD cards. Command SWITCH_FUNC is for high speed SD cards.
3. Command SWITCH is for high speed MMC cards . The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH_ERROR status bit in the EXT_CSD register is set. The Access Bits are shown in Table 26-3.
4. ACMDs shall be preceded with the APP_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this block).

Table 27-3. EXT_CSD Access Modes

Bits	Access Name	Operation
00	Command Set	The command set is changed according to the Cmd Set field of the argument
01	Set Bits	The bits in the pointed byte are set, according to the 1 bits in the Value field.
10	Clear Bits	The bits in the pointed byte are cleared, according to the 1 bits in the Value field.
11	Write Byte	The Value field is written into the pointed byte.

27.6 Software Restrictions

27.6.1 Initialization Active

The driver cannot set INITA bit in System Control register when any of the command line or data lines is active, so the driver must ensure both CDIHB and CIHB bits are cleared. In order to auto clear the INITA bit, the SDCLKEN bit must be '1', otherwise no clocks can go out to the card and INITA will never clear.

27.6.2 Softeware Polling Procedure

For polling read or write, once the software begins a buffer read or write, it must access exactly the number of times as the values set in the Watermark Level Register; moreover, if the block size is not the times of the value in Watermark Level Register (read and write respectively), the software must access exactly the remaining number of words at the end of each block. For example, for read operation, if the RD_WML is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

27.6.3 Suspend Operation

In order to suspend the data transfer, the software must inform ESDHC that the suspend command is successfully accepted. To achieve this, after the Suspend command is accepted by the SDIO card, software must send another normal command marked as suspend command (CMDTYP bits set as '01') to inform ESDHC that the transfer is suspended.

If software needs to resume the suspended trasnfer, it should read the value in BLKCNT register to save the remaining number of blocks before sending the normal command marked as suspend, otherwise on sending a 'suspend' command, ESDHC will regard the current transfer as aborted and change BLKCNT register to its original value, rather than keeping the remaining number of blocks.

27.6.4 Data Length Setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be a multiple of 4.

27.6.5 (A)DMA Address Setting

To configure ADMA1/ADMA2/DMA address register, when TC bit is set, the register will always update itself with the internal address value to support dynamic address synchronization, so software must make sure TC bit is cleared prior to configuring ADMA1/ADMA2/DMA address register.

27.6.6 Data Port Access

Data Port does not support parallel access. For example, during an external DMA access, it is not allowed to write any data to the Data Port by ARM platform; or during a ARM read operation, it is also prohibited to write any data to the Data Port, by either ARM or external DMA. Otherwise the data would be corrupted inside the ESDHC buffer.

27.6.7 Change Clock Frequency

ESDHC does not automatically gates off the card clock when the Host Driver changes the clock frequency. To remove possible glitch on the card clock, clear SDCLKEN bit when changing clock divisor value and set SDCLKEN bit to '1' after SDSTB bit is '1' again.

27.6.8 Multi-block Read

For pre-defined multi-block read operation, that is, the number of blocks to read has been defined by previous CMD23 for MMC, or pre-defined number of blocks in CMD53 for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an abort command, either automatic or manual CMD12/CMD52, is still required by ESDHC after the pre-defined number of blocks are done, to drive the internal state machine to idle mode. In this case, the card may not respond to this extra abort command and ESDHC will get Response Timeout. It is recommended to manually send an abort command with RSPTYP[1:0] both bits cleared.

27.7 Programmable Registers

This section includes the block memory map and detailed descriptions of all registers. Each of these registers support only 32-bit accesses.

NOTE

Addresses greater than 0x44, except 0x50, 0x54, 0x58, 0x60, 0x64, 0xC0, 0xC4 and 0xFC, are reserved and read as all 0s. Write to these

ESDHCV3 memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
5002_0000	DMA System Address (ESDHCV3-3_DSADDR)	32	R/W	0000_0000h	27.7.1/ 1412

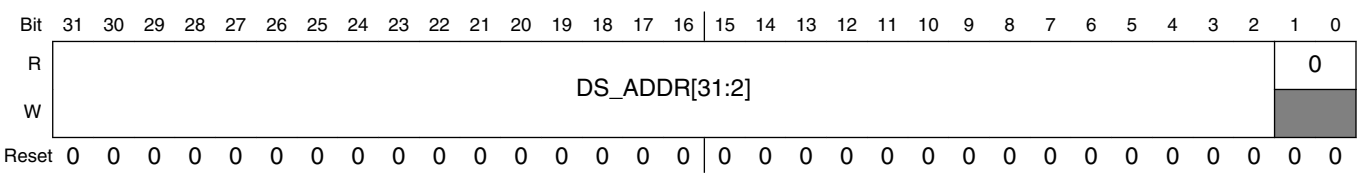
27.7.1 DMA System Address (ESDHCV3x_DSADDR)

This register contains the physical system memory address used for DMA transfers.

Addresses: ESDHCV3-3_DSADDR is 5002_0000h base + 0h offset = 5002_0000h



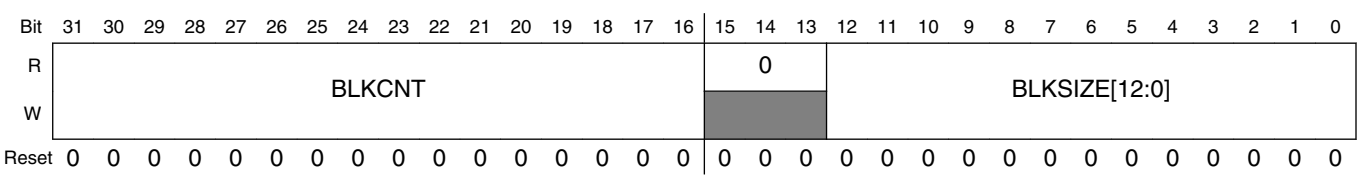
ESDHCV3x_DSADDR field descriptions

Field	Description
31–2 DS_ADDR[31:2]	DMA System Address: This register contains the 32-bit system memory address for a DMA transfer. As the address must be word (4 bytes) align, the least 2 bits are reserved, always 0. When the ESDHC stops a DMA transfer, this register points to the system address of the next contiguous data position. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operation during transfers may return an invalid value. The Host Driver shall initialize this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register. This register is protected during a data transfer. When data lines are active, write to this register is ignored. The Host driver shall wait, until ESDHCV3_PRSSTAT[DLA] bit is cleared, before writing to this register. The ESDHC internal DMA does not support a virtual memory system. It only supports continuous physical memory access. And due to AHB burst limitations, if the burst must cross the 1 KB boundary, ESDHC will automatically change SEQ burst type to NSEQ. As this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so SW cannot change this register when TC bit is set. Such restriction is also listed in Software Restrictions.
1–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

27.7.2 Block Attributes (ESDHCV3x_BLKATTR)

This register is used to configure the number of data blocks and the number of bytes in each block.

Addresses: ESDHCV3-3_BLKATTR is 5002_0000h base + 4h offset = 5002_0004h



ESDHCV3x_BLKATTR field descriptions

Field	Description
31–16 BLKCNT	Blocks Count For Current Transfer: This register is enabled when ESDHCV3_XFERTYP[BCEN] bit is set to 1 and is valid only for multiple block transfers. For single block transfer, this register will always read as 1. The Host Driver shall set this register to a value between 1 and the maximum block count. The ESDHC decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to 0 results in no data blocks being transferred. This register should be accessed only when no transaction is executing (that is, after transactions have stopped). During data transfer, read operations on this register may return an invalid value and write operations are ignored. When saving transfer content as a result of a Suspend command, the number of blocks yet to be transferred can be determined by reading this register. The reading of this register should be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend.

Table continues on the next page...

ESDHCV3x_BLKATTR field descriptions (continued)

Field	Description
	This is because when Suspend command is sent out, ESDHC will regard the current transfer is aborted and change BLKCNT register back to its original value instead of keeping the dynamical indicator of remained block count. When restoring transfer content prior to issuing a Resume command, the Host Driver shall restore the previously saved block count. 0xFFFF 65535 blocks 0x0002 2 blocks 0x0001 1 blocks 0x0000 Stop Count
15–13 Reserved	This read-only field is reserved and always has the value zero. Reserved
12–0 BLKSIZE[12:0]	Transfer Block Size: This register specifies the block size for block data transfers. Values ranging from 1 byte up to the maximum buffer size can be set. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations will be ignored. 0x1000 4096 Bytes 0x800 2048 Bytes 0x200 512 Bytes 0x1FF 511 Bytes 0x004 4 Bytes 0x003 3 Bytes 0x002 2 Bytes 0x001 1 Bytes 0x000 No data transfer

27.7.3 Command Argument (ESDHCV3x_CMDARG)

This register contains the SD/MMC Command Argument.

Addresses: ESDHCV3-3_CMDARG is 5002_0000h base + 8h offset = 5002_0008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ESDHCV3x_CMDARG field descriptions

Field	Description
31–0 CMDARG[31:0]	Command Argument: The SD/MMC Command Argument is specified as bits 39-8 of the Command Format in the SD or MMC Specification.This register is write protected when the Command Inhibit (CMD) bit in the Present State register is set.

27.7.4 Command Transfer Type (ESDHCV3x_XFERTYP)

This register is used to control the operation of data transfers. The Host Driver sets this register before issuing a command followed by a data transfer, or before issuing a Resume command. To prevent data loss, the ESDHC prevents writing to the bits, that are involved in the data transfer of this register, when data transfer is active. These bits are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN and DMAEN.

The Host Driver shall check the Command Inhibit DAT bit (CDIHB) and the Command Inhibit CMD bit (CIHB) in the Present State register before writing to this register. When the CDIHB bit in the Present State register is set, any attempt to send a command with data by writing to this register is ignored; when the CIHB bit is set, any write to this register is ignored.

On sending commands with data transfer involved, it is mandatory that the block size is non-zero. Besides, block count must also be non-zero, or indicated as single block transfer (bit 5 of this register is '0' when written), or block count is disabled (bit 1 of this register is '0' when written), otherwise ESDHC will ignore the sending of this command and do nothing. For write command, with all above restrictions, it is also mandatory that the write protect switch is not active (WPSPL bit of Present State Register is '1), otherwise ESDHC will also ignore the command.

If the commands with data transfer does not receive the response in 64 clock cycles, that is, response time-out, ESDHC will regard the external device does not accept the command and abort the data transfer. In this scenario, the driver should issue the command again to re-try the transfer. It is also possible that for some reason the card responds the command but ESDHC does not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The CMDTYP field of this register is used to initiate three special commands; these are:

- Suspend: ESDHC does not monitor the content of the Suspend command response and therefore assumes that the commnand succeeds when issued. It then operates assuming the card bus has been released and that it is permissible to issue the next command using the DAT line. It is the responsibility of S/W to check the status of the Suspend command and send another command marked as Suspend to inform the ESDHC that a Suspend command was successfully issued. Refer to Suspend Resume for more details. After the end bit of command is sent, ESDHC de-asserts Read Wait for read transactions and stops checking busy for write transactions. In 4-bit mode, the interrupt cycle starts. If the Suspend command fails, the ESDHC will maintain its

current state and the Host Driver shall restart the transfer by setting the Continue Request bit in the Protocol Control register.

- Resume: S/W re-starts the data transfer by restoring the registers saved before sending the Suspend Command and then sends the Resume Command. The ESDHC will check for a pending busy state before starting write transfers.
- Abort: If this command is set when executing a read transfer, ESDHC will stop reads to the buffer. If this command is set when executing a write transfer, ESDHC will stop driving the DAT line. After issuing the Abort command, the Host Driver should issue a software reset (Abort Transaction).

The following table shows the summary of how register settings determine the type of data transfer.

Table 27-49. Transfer Type Register Setting for Various Transfer Types

Multi/Single Block Select	Block Count Enable	Block Count	Function
0	Don't Care	Don't Care	Single Transfer
1	0	Don't Care	Infinite Transfer
1	1	Positive Number	Multiple Transfer
1	1	Zero	No Data Transfer

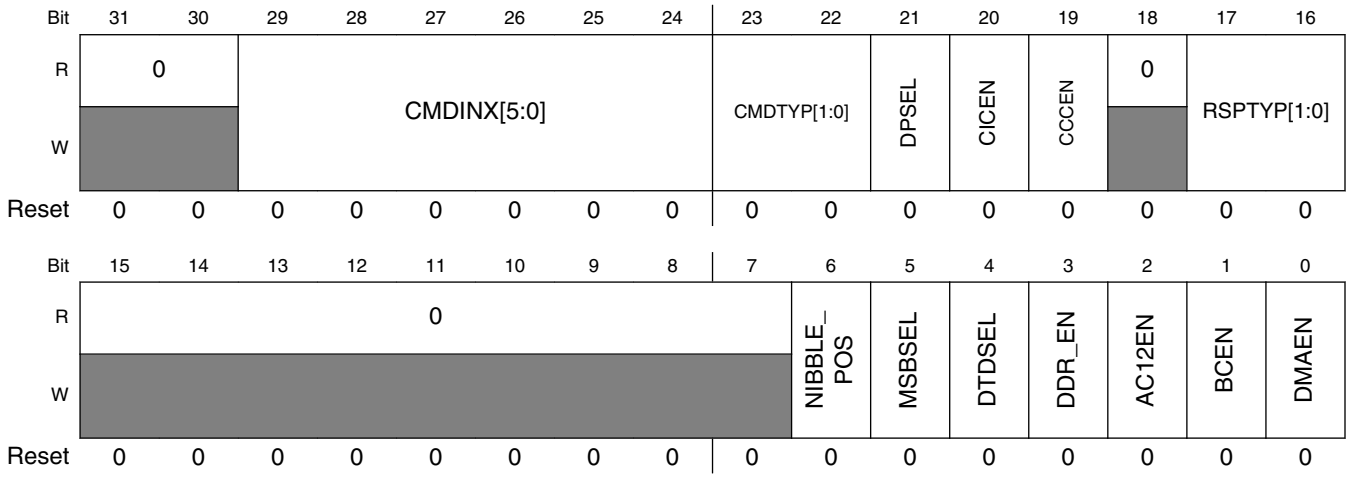
The following table shows the relationship between the Command Index Check Enable and the Command CRC Check Enable, in regards to the Response Type bits and the name of the response type.

Table 27-50. Relationship Between Parameters and the Name of the Response Type

Response Type	Index Check Enable	CRC Check Enable	Name of Response Type
00	0	0	No Response
01	0	1	R2
10	0	0	R3,R4
10	1	1	R1,R5,R6
11	1	1	R1b,R5b

- In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification. But R5b is defined in this specification to indicate that ESDHC will check the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command will be used with R5b.
- The CRC field for R3 and R4 is expected to be all 1 bits. The CRC check shall be disabled for these response types.

Addresses: ESDHCV3-3_XFERTYP is 5002_0000h base + Ch offset = 5002_000Ch



ESDHCV3x_XFERTYP field descriptions

Field	Description
31–30 Reserved	This read-only field is reserved and always has the value zero. Reserved
29–24 CMDINX[5:0]	Command Index: These bits shall be set to the command number that is specified in bits 45-40 of the Command-Format in the SD Memory Card Physical Layer Specification and SDIO Card Specification.
23–22 CMDTYP[1:0]	Command Type: 11 Abort CMD12, CMD52 for writing I/O Abort in CCCR 10 Resume CMD52 for writing Function Select in CCCR 01 Suspend CMD52 for writing Bus Suspend in CCCR 00 Normal mode. Used for all other commands
21 DPSEL	Data Present Select: This bit is set to 1 to indicate that data is present and shall be transferred using the DAT line. It is set to 0 for the following: • Commands using only the CMD line (for example, CMD52). • Commands with no data transfer, but using the busy signal on DAT[0] line (R1b or R5b such as, CMD38) **NOTE:** In resume command, this bit shall be set, and other bits in this register shall be set the same as when the transfer was initially launched. When the Write Protect switch is on, (that is, the WPSPL bit is active as '0'), any command with a write operation will be ignored. That is to say, when this bit is set, while the DTDSEL bit is 0, writes to the register Transfer Type are ignored. 1 Data Present 0 No Data Present
20 CICEN	Command Index Check Enable: If this bit is set to 1, the ESDHC will check the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this bit is set to 0, the Index field is not checked.

Table continues on the next page...

ESDHCV3x_XFERTYP field descriptions (continued)

Field	Description
	1 Enable 0 Disable
19 CCCEN	Command CRC Check Enable: If this bit is set to 1, the ESDHC shall check the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this bit is set to 0, the CRC field is not checked. The number of bits checked by the CRC field value changes according to the length of the response. (Refer to RSPTYP[1:0] and table "Relationship Between Parameters and the Name of the Response Type ".) 1 Enable 0 Disable
18 Reserved	This read-only field is reserved and always has the value zero. Reserved
17–16 RSPTYP[1:0]	Response Type Select: 00 No Response 01 Response Length 136 10 Response Length 48 11 Response Length 48, check Busy after response
15–7 Reserved	This read-only field is reserved and always has the value zero. Reserved
6 NIBBLE_POS	In DDR 4 bit mode nibble position indication. 0- the sequence is 'odd high nibble -> even high nibble -> odd low nibble -> even low nibble'; 1- the sequence is 'odd high nibble -> odd low nibble -> even high nibble -> even low nibble'.
5 MSBSEL	Multi / Single Block Select: This bit enables multiple block DAT line data transfers. For any other commands, this bit shall be set to 0. If this bit is 0, it is not necessary to set the Block Count register. (See table above.) 1 Multiple Blocks 0 Single Block
4 DTDSEL	Data Transfer Direction Select: This bit defines the direction of DAT line data transfers. The bit is set to 1 by the Host Driver to transfer data from the SD card to the ESDHC and is set to 0 for all other commands. 1 Read (Card to Host) 0 Write (Host to Card)
3 DDR_EN	Dual Data Rate mode selection
2 AC12EN	Auto CMD12 Enable: Multiple block transfers for memory require a CMD12 to stop the transaction. When this bit is set to 1, the ESDHC will issue a CMD12 automatically when the last block transfer has completed. The Host Driver shall not set this bit to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, the ESDHC will ignore this bit no matter if it is set or not. 1 Enable 0 Disable

Table continues on the next page...

ESDHCV3x_XFERTYP field descriptions (continued)

Field	Description
1 BCEN	Block Count Enable: This bit is used to enable the Block Count register, which is only relevant for multiple block transfers. When this bit is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer. 1 Enable 0 Disable
0 DMAEN	DMA Enable: This bit enables DMA functionality. If this bit is set to 1, a DMA operation shall begin when the Host Driver sets the DPSEL bit of this register. Whether the Simple DMA, or the Advanced DMA, is active depends on the DMA Select field of the Protocol Control register. 1 Enable 0 Disable

27.7.5 Command Response n (ESDHCV3x_CMDRSP*n*)

This register is used to store part n of the response bits from the card.

The table below describes the mapping of command responses from the SD Bus to Command Response registers for each response type. In the table, R[] refers to a bit range within the response data as transmitted on the SD Bus.

Table 27-52. Response Bit Definition for Each Response Type

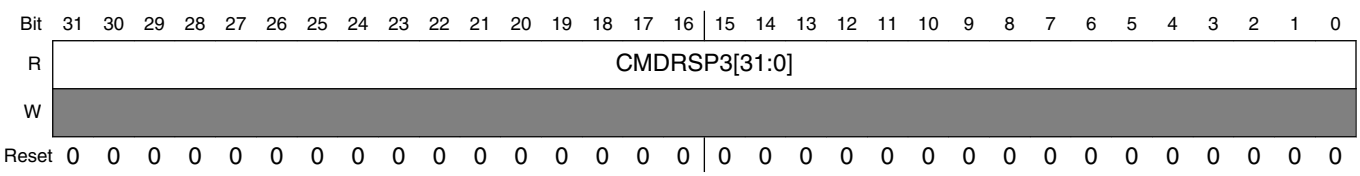
Response Type	Meaning of Response	Response Field	Response Register
R1,R1b (normal response)	Card Status	R[39:8]	ESDHCV3_CMDRSP0
R1b (Auto CMD12 response)	Card Status for Auto CMD12	R[39:8]	ESDHCV3_CMDRSP3
R2 (CID, CSD register)	CID/CSD register [127:8]	R[127:8]	{ESDHCV3_CMDRSP3[23:0] , ESDHCV3_CMDRSP2, ESDHCV3_CMDRSP1, ESDHCV3_CMDRSP0}
R3 (OCR register)	OCR register for memory	R[39:8]	ESDHCV3_CMDRSP0
R4 (OCR register)	OCR register for I/O etc.	R[39:8]	ESDHCV3_CMDRSP0
R5, R5b	SDIO response	R[39:8]	ESDHCV3_CMDRSP0
R6 (Publish RCA)	New Published RCA[31:16] and card status[15:0]	R[39:9]	ESDHCV3_CMDRSP0

This table shows that most responses with a length of 48 (R[47:0]) have 32-bits of the response data (R[39:8]) stored in the ESDHCV3_CMDRSP0 register. Responses of type R1b (Auto CMD12 responses) have response data bits (R[39:8]) stored in the ESDHCV3_CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bits of the response data (R[127:8]) stored in the ESDHCV3_CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, the ESDHC only stores part of the response data in the Command Response registers. This enables the Host Driver to efficiently read 32-bits of response data in one read cycle on a 32-bit bus system. Parts of the response, the Index field and the CRC, are checked by the ESDHC (as specified by the Command Index Check Enable and the Command CRC Check Enable bits in the Transfer Type register) and generate an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, the ESDHC will check R[47:1], and if the response length is 136 the ESDHC will check R[119:1].

As ESDHC may have a multiple block data transfer executing concurrently with a CMD_wo_DAT command, the ESDHC stores the Auto CMD12 response in the ESDHCV3_CMDRSP3 register. The CMD_wo_DAT response is stored in ESDHCV3_CMDRSP0. This allows the ESDHC to avoid overwriting the Auto CMD12 response with the CMD_wo_DAT and vice versa. When the ESDHC modifies part of the Command Response registers, as shown in the table above, it preserves the unmodified bits.

Addresses: ESDHCV3-3_CMDRSP0 is 5002_0000h base + 10h offset = 5002_0010h
ESDHCV3-3_CMDRSP1 is 5002_0000h base + 14h offset = 5002_0014h
ESDHCV3-3_CMDRSP2 is 5002_0000h base + 18h offset = 5002_0018h
ESDHCV3-3_CMDRSP3 is 5002_0000h base + 1Ch offset = 5002_001Ch



ESDHCV3x_CMDRSP*n* field descriptions

Field	Description
31–0 CMDRSP3[31:0]	Command Response n: Refer to the table "Response Bit Definition for Each Response Type" above for the mapping of command responses from the SD Bus to this register for each response type.

27.7.6 Data Buffer Access Port (ESDHCV3x_DATPORT)

This is a 32-bit data port register used to access the internal buffer.

Addresses: ESDHCV3-3_DATPORT is 5002_0000h base + 20h offset = 5002_0020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ESDHCV3x_DATPORT field descriptions

Field	Description
31–0 DATCONT[31:0]	Data Content: The Buffer Data Port register is for 32-bit data access by the ARM platform or the external DMA. When the internal DMA is enabled, any write to this register is ignored, and any read from this register will always yield 0s.

27.7.7 Present State (ESDHCV3x_PRSTAT)

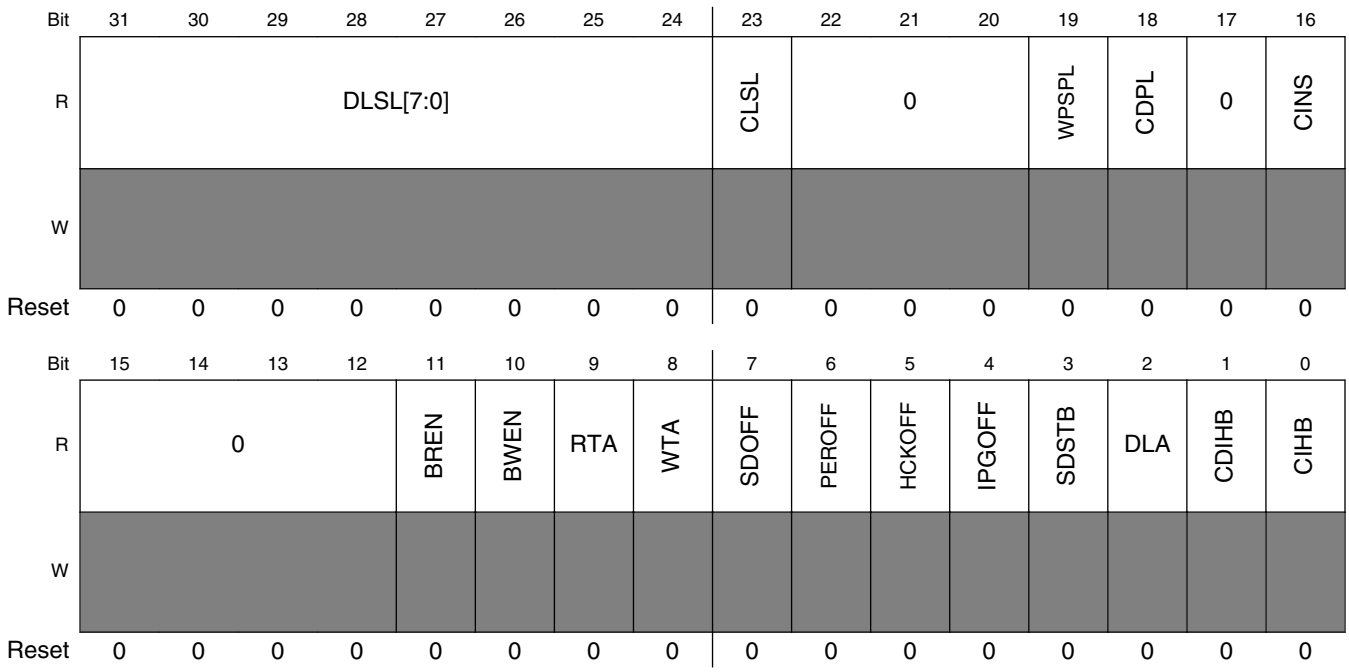
The Host Driver can get status of the ESDHC from this 32-bit read only register.

NOTE

The reset value of Present State Register depend on testbench connectivity.

- The Host Driver issues CMD0, CMD12, CMD13 (for memory) and CMD52 (for SDIO) when the DAT lines are busy during a data transfer. These commands can be issued when Command Inhibit (CMD) is set to zero. Other commands will be issued when Command Inhibit (DAT) is set to zero. Possible changes to the SD Physical Specification may add other commands to this list in the future.

Addresses: ESDHCV3-3_PRSSTAT is 5002_0000h base + 24h offset = 5002_0024h



ESDHCV3*x*_PRSSTAT field descriptions

Field	Description
31–24 DLSL[7:0]	DAT[7:0] Line Signal Level: This status is used to check the DAT line level to recover from errors, and for debugging.This is especially useful in detecting the busy signal level from DAT[0]. The reset value is effected by the external pull-up/pull-down resistors. By default, the read value of this bit field after reset is 8'b11110111, when DAT[3] is pulled down and the other lines are pulled up. DAT[7]: Data 7 line signal level DAT[6]: Data 6 line signal level DAT[5]: Data 5 line signal level DAT[4]: Data 4 line signal level DAT[3]: Data 3 line signal level DAT[2]: Data 2 line signal level DAT[1]: Data 1 line signal level DAT[0]: Data 0 line signal level
23 CLSL	CMD Line Signal Level: This status is used to check the CMD line level to recover from errors, and for debugging. The reset value is effected by the external pull-up/pull-down resistor, by default, the read value of this bit after reset is 1'b1, when the command line is pulled up.
22–20 Reserved	This read-only field is reserved and always has the value zero. Reserved
19 WPSPL	Write Protect Switch Pin Level:

Table continues on the next page...

ESDHCV3x_PRSSTAT field descriptions (continued)

Field	Description
	The Write Protect Switch is supported for memory and combo cards.This bit reflects the inverted value of the SD_WP pin of the card socket. A software reset does not affect this bit. The reset value is effected by the external write protect switch. If the SD_WP pin is not used, it should be tied low, so that the reset value of this bit is high and write is enabled. 1 Write enabled (SD_WP=0) 0 Write protected (SD_WP=1)
18 CDPL	Card Detect Pin Level: This bit reflects the inverse value of the SD_CD# pin for the card socket. Debouncing is not performed on this bit. This bit may be valid, but is not guaranteed, because of propagation delay. Use of this bit is limited to testing As it must be debounced by software. A software reset does not effect this bit. A write to the Force Event Register does not effect this bit. The reset value is effected by the external card detection pin. This bit shows the value on the SD_CD# pin (that is, when a card is inserted in the socket, it is 0 on the SD_CD# input, and consequently the CDPL reads 1.) 1 Card present (SD_CD#=0) 0 No card present (SD_CD#=1)
17 Reserved	This read-only field is reserved and always has the value zero. Reserved
16 CINS	Card Inserted: This bit indicates whether a card has been inserted. The ESDHC debounces this signal so that the Host Driver will not need to wait for it to stabilize. Changing from a 0 to 1 generates a Card Insertion interrupt in the Interrupt Status register. Changing from a 1 to 0 generates a Card Removal interrupt in the Interrupt Status register. A write to the Force Event Register does not effect this bit. The Software Reset For All in the System Control register does not effect this bit.A software reset does not effect this bit. 1 Card Inserted 0 Power on Reset or No Card
15–12 Reserved	This read-only field is reserved and always has the value zero. Reserved
11 BREN	Buffer Read Enable: This status bit is used for non-DMA read transfers. The ESDHC may implement multiple buffers to transfer data efficiently. This read only flag indicates that valid data exists in the host side buffer. If this bit is high, valid data greater than the watermark level exist in the buffer. A change of this bit from 1 to 0 occurs when any read from the buffer is made. A change of this bit from 0 to1 occurs when there is enough valid data ready in the buffer and the Buffer Read Ready interrupt has been generated and enabled. 1 Read enable 0 Read disable
10 BWEN	Buffer Write Enable: This status bit is used for non-DMA write transfers. The ESDHC can implement multiple buffers to transfer data efficiently. This read only flag indicates if space is available for write data. If this bit is 1, valid data greater than the watermark level can be written to the buffer. A change of this bit from 1 to 0 occurs when any write to the buffer is made. A change of this bit from 0 to 1 occurs when the buffer can hold valid data greater than the write watermark level and the Buffer Write Ready interrupt is generated and enabled.

Table continues on the next page...

ESDHCV3x_PRSSTAT field descriptions (continued)

Field	Description
	1 Write enable 0 Write disable
9 RTA	Read Transfer Active: This status bit is used for detecting completion of a read transfer. This bit is set for either of the following conditions: • After the end bit of the read command. • When writing a 1 to the Continue Request bit in the Protocol Control register to restart a read transfer. A Transfer Complete interrupt is generated when this bit changes to 0. This bit is cleared for either of the following conditions: • When the last data block as specified by block length is transferred to the System, that is, all data are read away from ESDHC internal buffer. • When all valid data blocks have been transferred from ESDHC internal buffer to the System and no current block transfers are being sent as a result of the Stop At Block Gap Request being set to 1. 1 Transferring data 0 No valid data
8 WTA	Write Transfer Active: This status bit indicates a write transfer is active. If this bit is 0, it means no valid write data exists in the ESDHC. This bit is set in either of the following cases: • After the end bit of the write command. • When writing 1 to the Continue Request bit in the Protocol Control register to restart a write transfer. This bit is cleared in either of the following cases: • After getting the CRC status of the last data block as specified by the transfer count (Single and Multiple). • After getting the CRC status of any block where data transmission is about to be stopped by a Stop At Block Gap Request. During a write transaction, a Block Gap Event interrupt is generated when this bit is changed to 0, as result of the Stop At Block Gap Request being set. This status is useful for the Host Driver in determining when to issue commands during Write Busy state. 1 Transferring data 0 No valid data
7 SDOFF	SD Clock Gated Off Internally: This status bit indicates that the SD Clock is internally gated off, because of buffer over/under-run or read pause without read wait assertion, or the driver has cleared SDCLKEN bit to stop the SD clock. This bit is for the Host Driver to debug data transaction on the SD bus. 1 SD Clock is gated off 0 SD Clock is active
6 PEROFF	ipg_perclk Gated Off Internally:

Table continues on the next page...

ESDHCV3x_PRSSTAT field descriptions (continued)

Field	Description
	This status bit indicates that the ipg_perclk is internally gated off. This bit is for the Host Driver to debug transaction on the SD bus. When INITA bit is set, ESDHC sending 80 clock cycles to the card, the SDCLKEN bit must be '1' to enable the output card clock, otherwise the ipg_perclk will never be gate off, so ipg_perclk and ipg_clk will be always active. 1 ipg_perclk is gated off 0 ipg_perclk is active
5 HCKOFF	hclk Gated Off Internally: This status bit indicates that the hclk is internally gated off. This bit is for the Host Driver to debug during a data transfer. 1 hclk is gated off 0 hclk is active
4 IPGOFF	ipg_clk Gated Off Internally: This status bit indicates that the ipg_clk is internally gated off. This bit is for the Host Driver to debug. 1 ipg_clk is gated off 0 ipg_clk is active
3 SDSTB	SD Clock Stable This status bit indicates that the internal card clock is stable. This bit is for the Host Driver to poll clock status when changing the clock frequency. It is recommended to clear SDCLKEN bit in System Control register to remove glitch on the card clock when the frequency is changing. 1 clock is stable 0 clock is changing frequency and not stable
2 DLA	Data Line Active This status bit indicates whether one of the DAT lines on the SD Bus is in use. In the case of read transactions: This status indicates if a read transfer is executing on the SD Bus. Changes in this value from 1 to 0, between data blocks, generates a Block Gap Event interrupt in the Interrupt Status register. This bit will be set in either of the following cases: • After the end bit of the read command. • When writing a 1 to the Continue Request bit in the Protocol Control register to restart a read transfer. This bit will be cleared in either of the following cases: (1) When the end bit of the last data block is sent from the SD Bus to the ESDHC. (2) When the Read Wait state is stopped by a Suspend command and the DAT2 line is released. The ESDHC will wait at the next block gap by driving Read Wait at the start of the interrupt cycle. If the Read Wait signal is already driven (data buffer cannot receive data), the ESDHC can wait for a current block gap by continuing to drive the Read Wait signal. It is necessary to support Read Wait in order to use the suspend / resume function. This bit will remain 1 during Read Wait. In the case of write transactions: This status indicates that a write transfer is executing on the SD Bus. Changes in this value from 1 to 0 generate a Transfer Complete interrupt in the Interrupt Status register. This bit will be set in either of the following cases:

Table continues on the next page...

ESDHCV3x_PRSSTAT field descriptions (continued)

Field	Description
	• After the end bit of the write command. • When writing to 1 to the Continue Request bit in the Protocol Control register to continue a write transfer. This bit will be cleared in either of the following cases: • When the SD card releases Write Busy of the last data block, the ESDHC will also detect if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, the ESDHC will assume the card drive "Not Busy". • When the SD card releases write busy, prior to waiting for write transfer, and as a result of a Stop At Block Gap Request. In the case of command with busy pending: This status indicates that a busy state follows the command and the data line is in use. This bit will be cleared when the DAT0 line is released. 1 DAT Line Active 0 DAT Line Inactive
1 CDIHB	Command Inhibit (DAT): This status bit is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this bit is 0, it indicates that the ESDHC can issue the next SD/MMC Command. Commands with a busy signal belong to Command Inhibit (DAT) (for example, R1b, R5b type). Except in the case when the command busy is finished, changing from 1 to 0 generates a Transfer Complete interrupt in the Interrupt Status register. **NOTE:** The SD Host Driver can save registers for a suspend transaction after this bit has changed from 1 to 0. 1 Cannot issue command which uses the DAT line 0 Can issue command which uses the DAT line
0 CIHB	Command Inhibit (CMD): If this status bit is 0, it indicates that the CMD line is not in use and the ESDHC can issue a SD/MMC Command using the CMD line. This bit is set also immediately after the Transfer Type register is written. This bit is cleared when the command response is received. Even if the Command Inhibit (DAT) is set to 1, Commands using only the CMD line can be issued if this bit is 0. Changing from 1 to 0 generates a Command Complete interrupt in the Interrupt Status register. If the ESDHC cannot issue the command because of a command conflict error (Refer to Command CRC Error) or because of a Command Not Issued By Auto CMD12 Error, this bit will remain 1 and the Command Complete is not set. The Status of issuing an Auto CMD12 does not show on this bit. 1 Cannot issue command 0 Can issue command using only CMD line

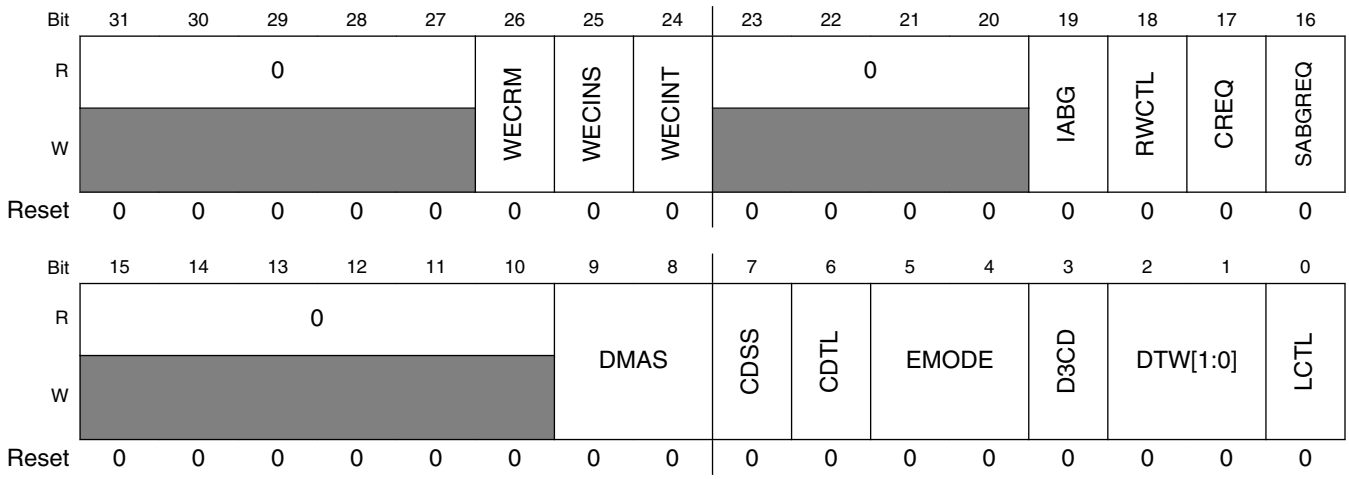
27.7.8 Protocol Control (ESDHCV3x_PROCTL)

There are three cases to restart the transfer after stop at the block gap. The appropriate case depends on whether ESDHC issues a Suspend command or the SD card accepts the Suspend command.

1. If the Host Driver does not issue a Suspend command, the Continue Request will be used to restart the transfer.
2. If the Host Driver issues a Suspend command and the SD card accepts it, a Resume command will be used to restart the transfer.
3. If the Host Driver issues a Suspend command and the SD card does not accept it, the Continue Request will be used to restart the transfer.

Any time Stop At Block Gap Request stops the data transfer, the Host Driver will wait for a Transfer Complete (in the Interrupt Status register), before attempting to restart the transfer. When restarting the data transfer by Continue Request, the Host Driver will clear the Stop At Block Gap Request before or simultaneously.

Addresses: ESDHCV3-3_PROCTL is 5002_0000h base + 28h offset = 5002_0028h



ESDHCV3x_PROCTL field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved
26 WECRM	Wakeup Event Enable On SD Card Removal: This bit enables a wakeup event, through a Card Removal, in the Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, the Card Removal Status and the ESDHC interrupt can be asserted without SD_CLK toggling. When the wakeup feature is not enabled, the SD_CLK must be active in order to assert the Card Removal Status and the ESDHC interrupt. 1 Enable 0 Disable
25 WECINS	Wakeup Event Enable On SD Card Insertion: This bit enables a wakeup event, through a Card Insertion, in the Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, the Card Insertion Status and the ESDHC interrupt can be asserted without SD_CLK toggling. When the wakeup feature is not enabled, the SD_CLK must be active in order to assert the Card Insertion Status and the ESDHC interrupt.

Table continues on the next page...

ESDHCV3x_PROCTL field descriptions (continued)

Field	Description
	1 Enable 0 Disable
24 WECINT	Wakeup Event Enable On Card Interrupt: This bit enables a wakeup event, through a Card Interrupt, in the Interrupt Status register. This bit can be set to 1 if FN_WUS (Wake Up Support) in CIS is set to 1. When this bit is set, the Card Interrupt Status and the ESDHC interrupt can be asserted without SD_CLK toggling. When the wakeup feature is not enabled, the SD_CLK must be active in order to assert the Card Interrupt Status and the ESDHC interrupt. 1 Enable 0 Disable
23–20 Reserved	This read-only field is reserved and always has the value zero. Reserved
19 IABG	Interrupt At Block Gap: This bit is valid only in 4-bit mode, of the SDIO card, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SDIO card cannot signal an interrupt during a multiple block transfer, this bit should be set to 0 to avoid an inadvertent interrupt. When the Host Driver detects an SDIO card insertion, it sets this bit according to the CCCR of the card. 1 Enabled 0 Disabled
18 RWCTL	Read Wait Control: The read wait function is optional for SDIO cards. If the card supports read wait, set this bit to enable use of the read wait protocol to stop read data using the DAT[2] line. Otherwise the ESDHC has to stop the SD Clock to hold read data, which restricts commands generation. When the Host Driver detects an SDIO card insertion, it sets this bit according to the CCCR of the card. If the card does not support read wait, this bit will never be set to 1, otherwise DAT line conflicts may occur. If this bit is set to 0, stop at block gap during read operation is also supported, but the ESDHC will stop the SD Clock to pause reading operation. 1 Enable Read Wait Control, and assert Read Wait without stopping SD Clock at block gap when SABGREQ bit is set 0 Disable Read Wait Control, and stop SD Clock at block gap when SABGREQ bit is set
17 CREQ	Continue Request: This bit is used to restart a transaction which was stopped using the Stop At Block Gap Request. When a Suspend operation is not accepted by the card, it is also by setting this bit to restart the paused transfer. To cancel stop at the block gap, set Stop At Block Gap Request to 0 and set this bit to 1 to restart the transfer. The ESDHC automatically clears this bit, therefore it is not necessary for the Host Driver to set this bit to 0. If both Stop At Block Gap Request and this bit are 1, the continue request is ignored. 1 Restart 0 No effect
16 SABGREQ	Stop At Block Gap Request: This bit is used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the Transfer Complete is set to 1, indicating a transfer completion, the Host Driver will leave this bit set to 1. Clearing both the Stop At Block Gap Request and Continue Request does not

Table continues on the next page...

ESDHCV3x_PROCTL field descriptions (continued)

Field	Description
	cause the transaction to restart. Read Wait is used to stop the read transaction at the block gap. The ESDHC will honor the Stop At Block Gap Request for write transfers, but for read transfers it requires that the SDIO card support Read Wait. Therefore, the Host Driver will not set this bit during read transfers unless the SDIO card supports Read Wait and has set the Read Wait Control to 1, otherwise the ESDHC will stop the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the Host Driver writes data to the Data Port register, the Host Driver will set this bit after all block data is written. If this bit is set to 1, the Host Driver will not write data to the Data Port register after a block is sent. Once this bit is set, the Host Driver will not clear this bit before the Transfer Complete bit in Interrupt Status Register is set, otherwise the ESDHCs behavior is undefined. This bit effects Read Transfer Active, Write Transfer Active, DAT Line Active and Command Inhibit (DAT) in the Present State register. 1 Stop 0 Transfer
15–10 Reserved	This read-only field is reserved and always has the value zero. Reserved
9–8 DMAS	DMA Select: This field is valid while DMA (SDMA or ADMA) is enabled and selects the DMA operation. 00 No DMA or Simple DMA is selected 01 ADMA1 is selected 10 ADMA2 is selected 11 reserved
7 CDSS	Card Detect Signal Selection: This bit selects the source for the card detection. 1 Card Detection Test Level is selected (for test purpose) 0 Card Detection Level is selected (for normal purpose)
6 CDTL	Card Detect Test Level: This is bit is enabled while the Card Detection Signal Selection is set to 1 and it indicates card insertion. 1 Card Detect Test Level is 1, card inserted 0 Card Detect Test Level is 0, no card inserted
5–4 EMODE	Endian Mode: The ESDHC supports all four endian modes in data transfer. Refer to Data Buffer for more details. 00 Big Endian Mode 01 Half Word Big Endian Mode 10 Little Endian Mode 11 Reserved
3 D3CD	DAT3 as Card Detection Pin: If this bit is set, DAT3 should be pulled down to act as a card detection pin. Be cautious when using this feature, because DAT3 is also a chip-select for the SPI mode. A pull-down on this pin and CMD0 may set the card into the SPI mode, which the ESDHC does not support. In case of SDIO application, if SD_CD signal is not multiplexed to ESDHC block, S/W should set D3CD bit.

Table continues on the next page...

ESDHCV3x_PROCTL field descriptions (continued)

Field	Description
	1 DAT3 as Card Detection Pin 0 DAT3 does not monitor Card Insertion
2–1 DTW[1:0]	Data Transfer Width: This bit selects the data width of the SD bus for a data transfer. The Host Driver sets it to match the data width of the card. Possible Data transfer Width is 1-bit, 4-bits or 8-bits. 10 8-bit mode 01 4-bit mode 00 1-bit mode 11 Reserved
0 LCTL	LED Control: This bit, fully controlled by the Host Driver, is used to caution the user not to remove the card while the card is being accessed. If the software is going to issue multiple SD commands, this bit can be set during all these transactions. It is not necessary to change for each transaction. When the software issues multiple SD commands, setting the bit once before the first command is sufficient; it is not necessary to reset the bit between commands. 1 LED on 0 LED off

27.7.9 System Control (ESDHCV3x_SYSCTL)

31–28 Reserved	This read-only field is reserved and always has the value zero. Reserved

Table continues on the next page...

ESDHCV3x_SYSCTL field descriptions (continued)

Field	Description
27 INITA	Initialization Active: When this bit is set, 80 SD-Clocks are sent to the card. After the 80 clocks are sent, this bit is self cleared. This bit is very useful during the card power-up period when 74 SD-Clocks are needed and the clock auto gating feature is enabled. Writing 1 to this bit when this bit is already 1 has no effect. Writing 0 to this bit at any time has no effect. When either of the CIHB and CDIHB bits in the Present State Register are set, writing 1 to this bit is ignored (that is, when command line or data lines are active, write to this bit is not allowed). On the other hand, when this bit is set, that is, during initialization active period, it is allowed to issue commands, and the command bit stream will appear on the CMD pad after all 80 clock cycles are completer. When this command ends, the driver can make sure that the 80 clock cycles are sent out, which is very useful when the driver needs to send 80 cycles to the card and does not want to wait until this bit is self cleared.
26 RSTD	Software Reset For DAT Line: Only part of the data circuit is reset. DMA circuit is also reset. The following registers and bits are cleared by this bit: • Data Port register • Buffer is cleared and initialized.Present State register • Buffer Read Enable • Buffer Write Enable • Read Transfer Active • Write Transfer Active • DAT Line Active • Command Inhibit (DAT) Protocol Control register • Continue Request • Stop At Block Gap Request Interrupt Status register • Buffer Read Ready • Buffer Write Ready • DMA Interrupt • Block Gap Event • Transfer Complete 1 Reset 0 No Reset
25 RSTC	Software Reset For CMD Line: Only part of the command circuit is reset. The following registers and bits are cleared by this bit: • Present State register Command Inhibit (CMD) • Interrupt Status register Command Complete 1 Reset 0 No Reset
24 RSTA	Software Reset For ALL: This reset effects the entire Host Controller except for the card detection circuit. Register bits of type ROC, RW, RW1C, RWAC are cleared. During its initialization, the Host Driver will set this bit to 1 to reset the ESDHC. The ESDHC will reset this bit to 0 when the capabilities registers are valid and the Host Driver can read them. Additional use of Software Reset For All does not affect the value of the Capabilities registers. After this bit is set, it is recommended that the Host Driver reset the external card and re-initialize it.

Table continues on the next page...

ESDHCV3x_SYSCTL field descriptions (continued)

Field	Description
	b Reset 0 No Reset
23 IPP_RST_N	If the card supports it, this Register value will be output directly to the CARD through the pad for hardware reset.
22–20 Reserved	This read-only field is reserved and always has the value zero. Reserved
19–16 DTOCV	Data Timeout Counter Value: This value determines the interval by which DAT line timeouts are detected. Refer to the Data Timeout Error bit in the Interrupt Status register for information on factors that dictate time-out generation. Time-out clock frequency will be generated by dividing the base clock SDCLK value by this value. The Host Driver can clear the Data Timeout Error Status Enable (in the Interrupt Status Enable register) to prevent inadvertent time-out events. 1111 Reserved 1110 SDCLK x 2^{27} 0001 SDCLK x 2^{14} 0000 SDCLK x 2^{13} 1111 Reserved (in DDR mode) 1110 SDCLK x 2^{26} (in DDR mode) 0001 SDCLK x 2^{13} (in DDR mode) 0000 SDCLK x 2^{12} (in DDR mode)
15–8 SDCLKFS	SDCLK Frequency Select: This register is used to select the frequency of the SDCLK pin. The frequency is not programmed directly, rather this register holds the prescaler (this register) and divisor (next register) of the Base Clock Frequency register. Setting 00h bypasses the frequency prescaler of the SD Clock. Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of ipg_perclk and the following Divisor bits. **NOTE:** In ESDHC this register field can not be set to 00h(that is, bypass). The smallest value is 01h, that is divided by 2. The frequency of SDCLK is set by the following formula: Clock Frequency = (Base Clock) / (prescaler x divisor) For example, if the Base Clock Frequency is 96 MHz, and the target frequency is 25 MHz, then choosing the prescaler value of 01h and divisor value of 1h will yield 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 08h and divisor value of eh yields the exact clock value of 400 kHz. The reset value of this bit field is 80h, so if the input Base Clock (ipg_perclk) is about 96 MHz, the default SD Clock after reset is 375 kHz. According to the SD Physical Specification Version 1.1 and the SDIO Card Specification Version 1.2, the maximum SD Clock frequency is 50 MHz and will never exceed this limit. Only the following settings are allowed: 0x80 Base clock divided by 256 0x40 Base clock divided by 128 0x20 Base clock divided by 64

Table continues on the next page...

ESDHCV3x_SYSCTL field descriptions (continued)

Field	Description
	0x10 Base clock divided by 32 0x08 Base clock divided by 16 0x04 Base clock divided by 8 0x02 Base clock divided by 4 0x01 Base clock divided by 2
7–4 DVS[3:0]	Divisor: This register is used to provide a more exact divisor to generate the desired SD clock frequency. **NOTE:** The divider can even support odd divisor without deterioration of duty cycle. The setting are as following: 0x0 Divisor by 1 0x1 Divisor by 2 0xe Divisor by 15 0xf Divisor by 16
3 SDCLKEN	SD Clock Enable The Host Controller will stop SDCLK when writing this bit to 0. SDCLK Frequency can be changed when this bit is 0. Then, the Host Controller will maintain the same clock frequency until SDCLK is stopped (Stop at SDCLK=0). If the Card Inserted in the Present State register is cleared, this bit should be cleared by the Host Driver to save power.
2 PEREN	Peripheral Clock Enable: If this bit is set, ipg_perclk will always be active and no automatic gating is applied. Thus the SDCLK is active except when auto gating-off during buffer danger (buffer about to over-run or under-run). When this bit is cleared, the ipg_perclk will be automatically off when there is no transaction on the SD bus. As this bit is only a feature enabling bit, clearing this bit does not stop SDCLK immediately. The ipg_perclk will be internally gated off, if none of the following factors are met: • The cmd part is reset, or • Data part is reset, or • A soft reset, or • The cmd is about to send, or • Clock divisor is just updated, or • Continue request is just set, or • This bit is set, or • Card insertion is detected, or • Card removal is detected, or • Card external interrupt is detected, or • 80 clocks for initialization phase is ongoing 1 ipg_perclk will not be automatically gated off 0 ipg_perclk will be internally gated off
1 HCKEN	HCLK Enable: If this bit is set, hclk will always be active and no automatic gating is applied. When this bit is cleared, hclk will be automatically off when no data transfer is on the SD bus. 1 hclk will not be automatically gated off 0 hclk will be internally gated off

Table continues on the next page...

ESDHCV3x_SYSCTL field descriptions (continued)

Field	Description
0 IPGEN	IPG Clock Enable: If this bit is set, ipg_clk will always be active and no automatic gating is applied. The ipg_clk will be internally gated off, if none of the following factors are met: • The cmd part is reset, or • Data part is reset, or • Soft reset, or • The cmd is about to send, or • Clock divisor is just updated, or • Continue request is just set, or • This bit is set, or • Card insertion is detected, or • Card removal is detected, or • Card external interrupt is detected, or • The ipg_perclk is not gated off **NOTE:** The ipg_clk will not be auto gated off if the ipg_perclk is not gated off. Clearing only this bit has no effect unless the PEREN bit is also cleared. 1 ipg_clk will not be automatically gated off 0 ipg_clk will be internally gated off

27.7.10 Interrupt Status (ESDHCV3x_IRQSTAT)

An interrupt is generated when the Normal Interrupt Signal Enable is enabled and at least one of the status bits is set to 1. For all bits, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. Before clearing the Card Interrupt, make sure that the card stops asserting the interrupt, that is, the Card Driver stops servicing the interrupt condition. Otherwise, the CINT bit will be asserted again.

The table below shows the relationship between the Command Timeout Error and the Command Complete.

Table 27-66. ESDHC Status for Command Timeout Error/Command Complete Bit Combinations

Command Complete	Command Timeout Error	Meaning of the Status
0	0	X
X	1	Response not received within 64 SDCLK cycles
1	0	Response received

The table below shows the relationship between the Transfer Complete and the Data Timeout Error.

Table 27-67. ESDHC Status for Data Timeout Error/Transfer Complete Bit Combinations

Transfer Complete	Data Timeout Error	Meaning of the Status
0	0	X
0	1	Timeout occurred during transfer
1	X	Data Transfer Complete

The table below shows the relationship between the Command CRC Error and Command Timeout Error.

Table 27-68. ESDHC Status for Command CRC Error/Command Timeout Error Bit Combinations

Command Complete	Command Timeout Error	Meaning of the Status
0	0	No error
0	1	Response Timeout Error
1	0	Response CRC Error
1	1	CMD line conflict

ESDHCV3*x*_IRQSTAT field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value zero. Reserved
28 DMAE	DMA Error:

Table continues on the next page...

ESDHCV3x_IRQSTAT field descriptions (continued)

Field	Description
	Occurs when an Internal DMA transfer has failed. This bit is set to 1, when some error occurs in the data transfer. This error can be caused by either Simple DMA or ADMA, depending on which DMA is in use. The value in DMA System Address register is the next fetch address where the error occurs. As any error corrupts the whole data block, the Host Driver will re-start the transfer from the corrupted block boundary. The address of the block boundary can be calculated either from the current DS_ADDR value or from the remaining number of blocks and the block size. 1 Error 0 No Error
27–25 Reserved	This read-only field is reserved and always has the value zero. Reserved
24 AC12E	Auto CMD12 Error: Occurs when detecting that one of the bits in the Auto CMD12 Error Status register has changed from 0 to 1. This bit is set to 1, not only when the errors in Auto CMD12 occur, but also when the Auto CMD12 is not executed due to the previous command error. 1 Error 0 No Error
23 Reserved	This read-only field is reserved and always has the value zero. Reserved
22 DEBE	Data End Bit Error: Occurs either when detecting 0 at the end bit position of read data, which uses the DAT line, or at the end bit position of the CRC. 1 Error 0 No Error
21 DCE	Data CRC Error: Occurs when detecting a CRC error when transferring read data, which uses the DAT line, or when detecting the Write CRC status having a value other than 010. 1 Error 0 No Error
20 DTOE	Data Timeout Error: Occurs when detecting one of following time-out conditions. • Busy time-out for R1b,R5b type • Busy time-out after Write CRC status • Read Data time-out. 1 Time out 0 No Error
19 CIE	Command Index Error: Occurs if a Command Index error occurs in the command response. 1 Error 0 No Error
18 CEBE	Command End Bit Error: Occurs when detecting that the end bit of a command response is 0.

Table continues on the next page...

ESDHCV3x_IRQSTAT field descriptions (continued)

Field	Description
	1 End Bit Error Generated 0 No Error
17 CCE	Command CRC Error: Command CRC Error is generated in two cases. • If a response is returned and the Command Timeout Error is set to 0 (indicating no time-out), this bit is set when detecting a CRC error in the command response. • The ESDHC detects a CMD line conflict by monitoring the CMD line when a command is issued. If the ESDHC drives the CMD line to 1, but detects 0 on the CMD line at the next SDCLK edge, then the ESDHC will abort the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error will also be set to 1 to distinguish CMD line conflict. 1 CRC Error Generated. 0 No Error
16 CTOE	Command Timeout Error: Occurs only if no response is returned within 64 SDCLK cycles from the end bit of the command. If the ESDHC detects a CMD line conflict, in which case a Command CRC Error will also be set (as shown in the table above), this bit will be set without waiting for 64 SDCLK cycles. Because the command will be aborted by the ESDHC. 1 Time out 0 No Error
15–9 Reserved	This read-only field is reserved and always has the value zero. Reserved
8 CINT	Card Interrupt: This status bit is set when an interrupt signal is detected from the external card. In 1-bit mode, the ESDHC will detect the Card Interrupt without the SD Clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so the interrupt from card can only be sampled during interrupt cycle, introducing some delay between the interrupt signal from the SDIO card and the interrupt to the Host System. Writing 1 to this bit will clear it, but as the interrupt factor from the SDIO card is not clear, this bit is set again. In order to clear this bit, reset the interrupt factor from the external card and then clear this bit. When this status bit is set, and the Host Driver needs to service this interrupt, the Card Interrupt Signal Enable in the Interrupt Signal Enable register should be cleared to deactivate the interrupt signal to the Host System. After completion of the card interrupt service, (it should reset the interrupt factors in the SDIO card and the interrupt signal should not be asserted), write 1 to clear this bit, enable the Card Interrupt Signal Enable and start sampling the interrupt signal again. 1 Generate Card Interrupt 0 No Card Interrupt
7 CRM	Card Removal: This status bit is set if the Card Inserted bit (PRSSTNT[CINS]) changes from 1 to 0. When the Host Driver writes this bit to 1 to clear this status, the status of CINS should be confirmed, because the card state may possibly change when the Host Driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if no card is inserted. In order to leave it cleared, clear the Card Removal Status Enable bit IRQSTATEN[CRMSEN]in Interrupt Status Enable register. 1 Card removed 0 Card state unstable or inserted

Table continues on the next page...

ESDHCV3x_IRQSTAT field descriptions (continued)

Field	Description
6 CINS	Card Insertion: This status bit is set if the Card Inserted bit in the Present State register changes from 0 to 1. When the Host Driver writes this bit to 1 to clear this status, the status of the Card Inserted in the Present State register should be confirmed. Because the card state may possibly be changed when the Host Driver clears this bit and the interrupt event may not be generated. When this bit is cleared, it will be set again if a card is inserted. In order to leave it cleared, clear the Card Inserted Status Enable bit in Interrupt Status Enable register. 1 Card inserted 0 Card state unstable or removed
5 BRR	Buffer Read Ready: This status bit is set if the Buffer Read Enable bit, in the Present State register, changes from 0 to 1. Refer to the Buffer Read Enable bit in the Present State register for additional information. 1 Ready to read buffer 0 Not ready to read buffer
4 BWR	Buffer Write Ready: This status bit is set if the Buffer Write Enable bit, in the Present State register, changes from 0 to 1. Refer to the Buffer Write Enable bit in the Present State register for additional information. 1 Ready to write buffer: 0 Not ready to write buffer
3 DINT	DMA Interrupt: Occurs only when the internal DMA finishes the data transfer successfully. When errors occur during data transfer, this bit will not be set. Instead, the DMAE bit will be set. Either Simple DMA or ADMA finishes data transferring, this bit will be set. 1 DMA Interrupt is generated 0 No DMA Interrupt
2 BGE	Block Gap Event: If the Stop At Block Gap Request bit in the Protocol Control register is set, this bit is set when a read or write transaction is stopped at a block gap. If Stop At Block Gap Request is not set to 1, this bit is not set to 1. In the case of a Read Transaction: This bit is set at the falling edge of the DAT Line Active Status (When the transaction is stopped at SD Bus timing). The Read Wait must be supported in order to use this function. In the case of Write Transaction: This bit is set at the falling edge of Write Transfer Active Status (After getting CRC status at SD Bus timing). 1 Transaction stopped at block gap 0 No block gap event
1 TC	Transfer Complete: This bit is set when a read or write transfer is completed.

Table continues on the next page...

ESDHCV3x_IRQSTAT field descriptions (continued)

Field	Description
	In the case of a Read Transaction: This bit is set at the falling edge of the Read Transfer Active Status. There are two cases in which this interrupt is generated. The first is when a data transfer is completed as specified by the data length (after the last data has been read to the Host System). The second is when data has stopped at the block gap and completed the data transfer by setting the Stop At Block Gap Request bit in the Protocol Control register (after valid data has been read to the Host System). In the case of a Write Transaction: This bit is set at the falling edge of the DAT Line Active Status. There are two cases in which this interrupt is generated. The first is when the last data is written to the SD card as specified by the data length and the busy signal is released. The second is when data transfers are stopped at the block gap, by setting the Stop At Block Gap Request bit in the Protocol Control register, and the data transfers are completed. (After valid data is written to the SD card and the busy signal released.) 1 Transfer complete 0 Transfer not complete
0 CC	Command Complete: This bit is set when you receive the end bit of the command response (except Auto CMD12). Refer to the Command Inhibit (CMD) in the Present State register. 1 Command complete 0 Command not complete

27.7.11 Interrupt Status Enable (ESDHCV3x_IRQSTATEN)

Setting the bits in this register to 1 enables the corresponding Interrupt Status to be set by the specified event. If any bit is cleared, the corresponding Interrupt Status bit is also cleared (that is, when the bit in this register is cleared, the corresponding bit in Interrupt Status Register is always 0).

- Depending on IABG bit setting, ESDHC may be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There will be some delays on the Card Interrupt, asserted from the card, to the time the Host System is informed.
- To detect a CMD line conflict, the Host Driver must set both Command Timeout Error Status Enable and Command CRC Error Status Enable to 1.

Addresses: ESDHCV3-3_IRQSTATEN is 5002_0000h base + 34h offset = 5002_0034h

27.7.12 Interrupt Signal Enable (ESDHCV3x_IRQSIGEN)

This register is used to select which interrupt status is indicated to the Host System as the interrupt. These status bits all share the same interrupt line. Setting any of these bits to 1 enables interrupt generation. The corresponding Status register bit will generate an interrupt when the corresponding interrupt signal enable bit is set.

Addresses: ESDHCV3-3_IRQSIGEN is 5002_0000h base + 38h offset = 5002_0038h

27.7.13 Auto CMD12 Status (ESDHCV3x_AUTOC12ERR)

When the Auto CMD12 Error Status bit in the Status register is set, the Host Driver will check this register to identify what kind of error the Auto CMD12 indicated. This register is valid only when the Auto CMD12 Error status bit is set.

The table below shows the relationship between the Auto CMGD12 CRC Error and the Auto CMD12 Command Timeout Error.

Table 27-72. Relationship Between Command CRC Error and Command Timeout Error for Auto CMD12

Auto CMD12 CRC Error	Auto CMD12 Timeout Error	Type of Error
0	0	No Error
0	1	Response Timeout Error
1	0	Response CRC Error
1	1	CMD line conflict

Changes in Auto CMD12 Error Status register can be classified in three scenarios:

1. When the ESDHC is going to issue an Auto CMD12.
   - Set bit 0 to 1 if the Auto CMD12 cannot be issued due to an error in the previous command
   - Set bit 0 to 0 if the Auto CMD12 is issued
2. At the end bit of an Auto CMD12 response.
   - Check errors correspond to bits 1-4.
   - Set bits 1-4 corresponding to detected errors.
   - Clear bits 1-4 corresponding to detected errors
3. Before reading the Auto CMD12 Error Status bit 7.
   - Set bit 7 to 1 if there is a command that cannot be issued
   - Clear bit 7 if there is no command to issue

The timing for generating the Auto CMD12 Error and writing to the Command register are asynchronous. After that, bit 7 will be sampled when the driver is not writing to the Command register. It is suggested to read this register only when the AC12E bit in Interrupt Status register is set. An Auto CMD12 Error Interrupt is generated when one of the error bits (0-4) is set to 1. The Command Not Issued By Auto CMD12 Error does not generate an interrupt.

Addresses: ESDHCV3-3_AUTOC12ERR is 5002_0000h base + 3Ch offset = 5002_003Ch

23 SRS	Suspend / Resume Support:

Table continues on the next page...

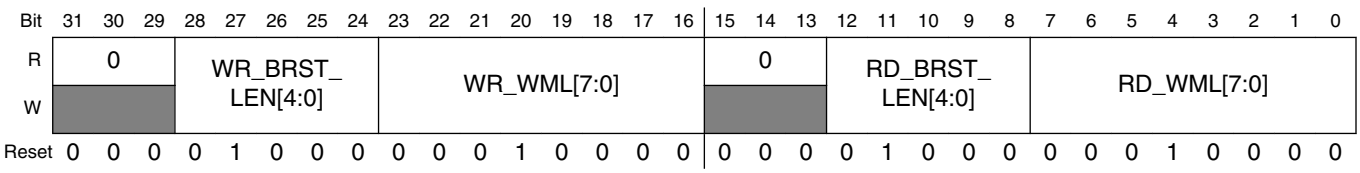
ESDHCV3x_HOSTCAPBLT field descriptions (continued)

Field	Description
	This bit indicates whether the ESDHC supports Suspend / Resume functionality. If this bit is 0, the Suspend and Resume mechanism, as well as the Read Wait, are not supported, and the Host Driver will not issue either Suspend or Resume commands. 1 Supported 0 Not supported
22 DMAS	DMA Support: This bit indicates whether the ESDHC is capable of using the internal DMA to transfer data between system memory and the data buffer directly. 1 DMA Supported 0 DMA not supported
21 HSS	High Speed Support: This bit indicates whether the ESDHC supports High Speed mode and the Host System can supply a SD Clock frequency from 25 MHz to 50 MHz. 1 High Speed Supported 0 High Speed Not Supported
20 ADMAS	ADMA Support: This bit indicates whether the ESDHC supports the ADMA feature. 1 Advanced DMA Supported 0 Advanced DMA Not supported
19 -	Reserved
18–16 MBL[2:0]	Max Block Length: This value indicates the maximum block size that the Host Driver can read and write to the buffer in the ESDHC. The buffer will transfer block size without wait cycles. 000 512 bytes 001 1024 bytes 010 2048 bytes 011 4096 bytes
15–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

27.7.15 Watermark Level (ESDHCV3x_WML)

Both write and read watermark levels (FIFO threshold) are configurable. There value can range from 1 to 128 words. Both write and read burst lengths are also configurable. There value can range from 1 to 31 words.

Addresses: ESDHCV3-3_WML is 5002_0000h base + 44h offset = 5002_0044h



ESDHCV3x_WML field descriptions

Field	Description
31–29 Reserved	This read-only field is reserved and always has the value zero. Reserved
28–24 WR_BRST_ LEN[4:0]	Write Burst Length: The number of words the ESDHC writes in a single burst. The write burst length must be less than or equal to the write watermark level, and all bursts within a watermark level transfer will be in back-to-back mode. On reset, this field will be 8. Writing 0 to this field will result in '01000' (that is, it is not able to clear this field). **NOTE:** Due to a system restriction, the actual burst length may not exceed 16.
23–16 WR_WML[7:0]	Write Watermark Level: The number of words used as the watermark level (FIFO threshold) in a DMA write operation. Also the number of words as a sequence of write bursts in back-to-back mode. The maximum legal value for the write watermark level is 128.
15–13 Reserved	This read-only field is reserved and always has the value zero. Reserved
12–8 RD_BRST_ LEN[4:0]	Read Burst Length: The number of words the ESDHC reads in a single burst. The read burst length must be less than or equal to the read watermark level, and all bursts within a watermark level transfer will be in back-to-back mode. On reset, this field will be 8. Writing 0 to this field will result in '01000' (that is, it is not able to clear this field. **NOTE:** Due to a system restriction, the actual burst length may not exceed 16.
7–0 RD_WML[7:0]	Read Watermark Level: The number of words used as the watermark level (FIFO threshold) in a DMA read operation. Also the number of words as a sequence of read bursts in back-to-back mode. The maximum legal value for the read water mark level is 128.

27.7.16 Force Event (ESDHCV3x_FEVT)

The Force Event Register is not a physically implemented register. Rather, it is an address at which the Interrupt Status Register can be written if the corresponding bit of the Interrupt Status Enable Register is set. This register is a write only register and writing 0 to it has no effect. Writing 1 to this register sets the corresponding bit of Interrupt Status Register. A read from this register always results in 0's. In order to change the corresponding status bits in the Interrupt Status Register, set IPGEN bit in System Control Register so that ipg_clk is always active.

Forcing a card interrupt will generate a short pulse on the DAT[1] line, and the driver will treat this interrupt as a normal interrupt. The interrupt service routine will skip polling the card interrupt factor as the interrupt is self cleared.

Addresses: ESDHCV3-3_FEVT is 5002_0000h base + 50h offset = 5002_0050h

27.7.17 ADMA Error Status Register (ESDHCV3x_ADMAES)

When an ADMA Error Interrupt occurrs, the ADMA Error States field (ADMAES) in this register holds the ADMA state and the ADMA System Address register (ADSADDR) holds the address of the error descriptor.

To recover from this error, the Host Driver requires the ADMA state to identify the error descriptor address as follows:

- ST_STOP: Previous location set in the ADMA System Address register is the error descriptor address
- ST_FDS: Current location set in the ADMA System Address register is the error descriptor address
- ST_CADR: This state is never set because it only increments the descriptor pointer and doesn't generate an ADMA error
- ST_TFR: Previous location set in the ADMA System Address register is the error descriptor address

In case of a write operation, the Host Driver should use ACMD22 command (see below table) to get the number of the written block, because unwritten data may exist in the Host Controller.

The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) in the ST_FDS state. The Host Driver can distinguish this error by reading the Valid bit of the error descriptor.

Table 27-77. ADMA Error State Coding

D01-D00	ADMA Error State (when error has occurred)	Contents of ADMA System Address Register
00	ST_STOP (Stop DMA)	Holds the address of the next executable Descriptor command
01	ST_FDS (Fetch Descriptor)	Holds the valid Descriptor address

Table continues on the next page...

Table 27-77. ADMA Error State Coding (continued)

D01-D00	ADMA Error State (when error has occurred)	Contents of ADMA System Address Register
10	ST_CADR (Change Address)	No ADMA Error is generated
11	ST_TFR (Transfer Data)	Holds the address of the next executable Descriptor command

Addresses: ESDHCV3-3_ADMAES is 5002_0000h base + 54h offset = 5002_0054h

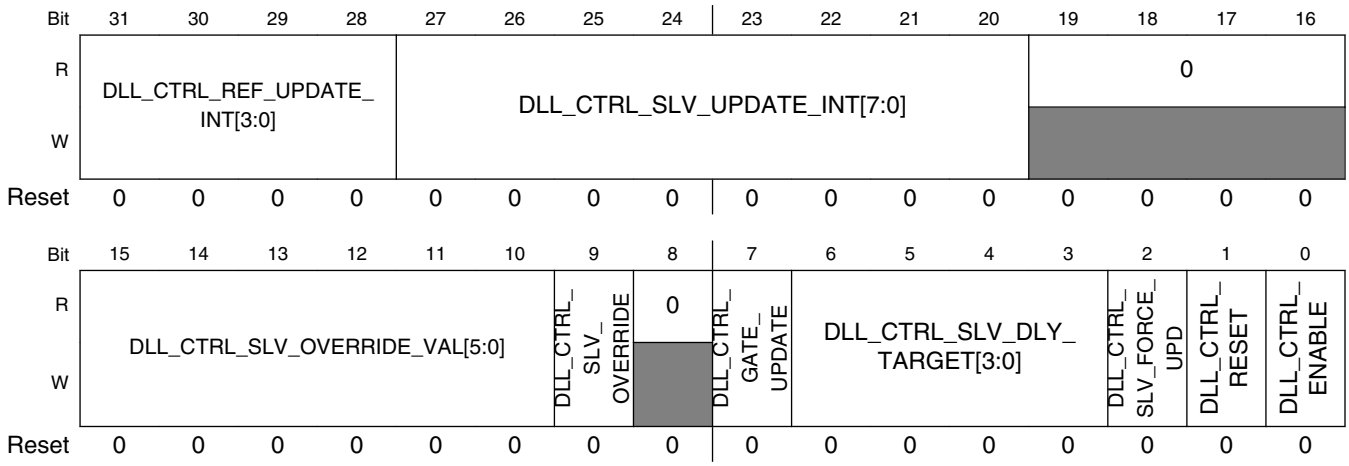
ESDHCV3x_ADSADDR field descriptions

Field	Description
31–2 ADS_ ADDR[31:0]	ADMA System Address: This register holds the word address of the executing command in the Descriptor table. At the start of ADMA, the Host Driver will set the start address of the Descriptor table. The ADMA engine increments this register address whenever fetching a Descriptor command. When the ADMA is stopped at the Block Gap, this register indicates the address of the next executable Descriptor command. When the ADMA Error Interrupt is generated, this register will hold the valid Descriptor address depending on the ADMA state. The lower 2 bits of this register is tied to '0' so the ADMA address is always word aligned. As this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so this register value cannot be changed when the TC bit is set. Such restriction is also listed in on page 30-142.
1–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

27.7.19 DLL (Delay Line) Control (ESDHCV3x_DLLCTRL)

This register contains control bits for DLL.

Addresses: ESDHCV3-3_DLLCTRL is 5002_0000h base + 60h offset = 5002_0060h



ESDHCV3x_DLLCTRL field descriptions

Field	Description
31–28 DLL_CTRL_REF_UPDATE_INT[3:0]	DLL control loop update interval. The interval cycle is (2 + REF_UPDATE_INT) * ref_clock. By default, the DLL control loop will update every two ref_clock cycles. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that may effect the delay (such as voltage and temperature)
27–20 DLL_CTRL_SLV_UPDATE_INT[7:0]	Slave delay line update interval. If default 0 is used, it means 256 cycles of ref_clock. A value of 0x0f results in 15 cycles and so on. **NOTE:** The software can always cause an update of the slave-delay line using the SLV_FORCE_UPDATE register. **NOTE:** The slave delay line will also update automatically when the reference DLL transitions to a locked state (from an un-locked state).
19–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15–10 DLL_CTRL_SLV_OVERRIDE_VAL[5:0]	When SLV_OVERRIDE=1 This field is used to select 1 of 64 physical taps manually. A value of 0 selects tap 1, and a value of 0x3f selects tap 64.
9 DLL_CTRL_SLV_OVERRIDE	Set this bit to 1 to Enable manual override for slave delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to tbe enabled using the ENABLE bit. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE=0
8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7 DLL_CTRL_GATE_UPDATE	Set this bit to 1 to force DLL to not update from now on. Beacue, when clock_in exists, glitches might appear during update. This bit is used by software if we met such kind of condition. Set it to 0 to allow DLL to update automatically

Table continues on the next page...

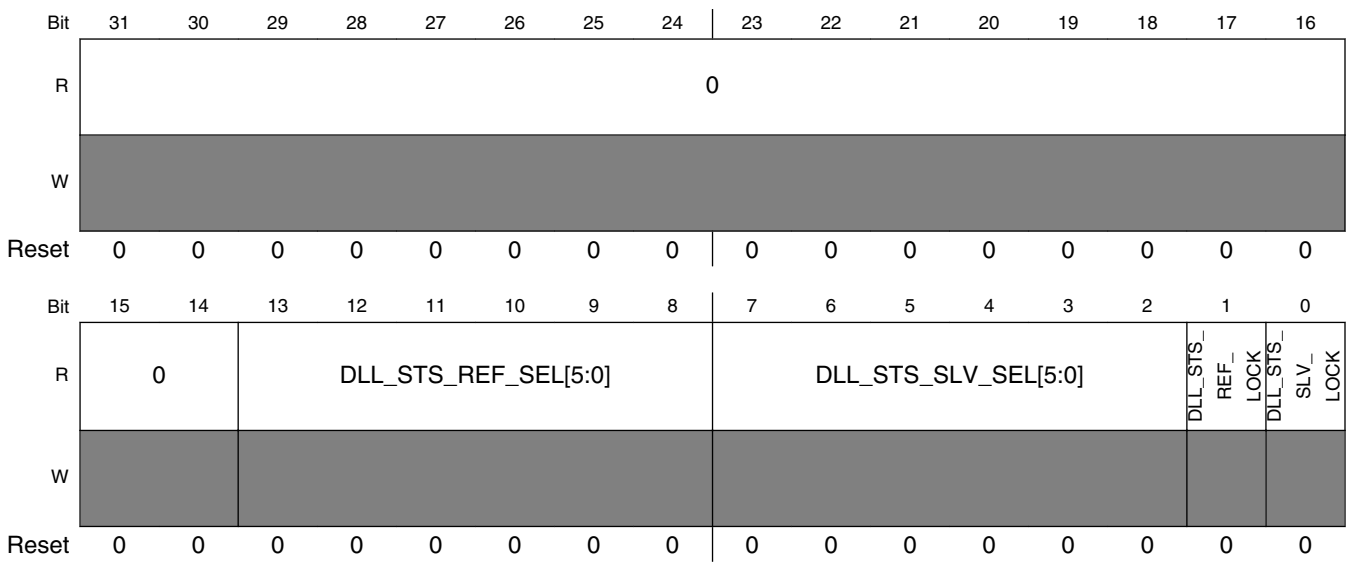
ESDHCV3x_DLLCTRL field descriptions (continued)

Field	Description
6–3 DLL_CTRL_ SLV_DLY_ TARGET[3:0]	The delay target for the ESDHC loopback read clock can be programmed in 1/16th increments of an ref_clock half-period. So the input read-clock can be delayed relative input data from (ref_clock/2)/16 to ref_clock/2
2 DLL_CTRL_ SLV_FORCE_ UPD	Setting this bit to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line will update automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when ESDHC is idle. This function may not work when ESDHC is working on data/cmd/response.
1 DLL_CTRL_ RESET	Setting this bit to 1 force a reset on DLL. This will cause the DLL to lose lock and re-calibrate to detect an ref_clock half period phase shift. This signal is used by the DLL as edge-sensitive, so in order to create a subsequent reset, RESET must be taken low and then asserted again
0 DLL_CTRL_ ENABLE	Set this bit to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. **NOTE:** Using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE VAL, the DLL does not need to be enabled

27.7.20 DLL Status (ESDHCV3x_DLLSTS)

This register contains the DLL status information. All bits are read only and will read the same as the power-reset value.

Addresses: ESDHCV3-3_DLLSTS is 5002_0000h base + 64h offset = 5002_0064h



ESDHCV3x_DLLSTS field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value zero. Reserved

Table continues on the next page...

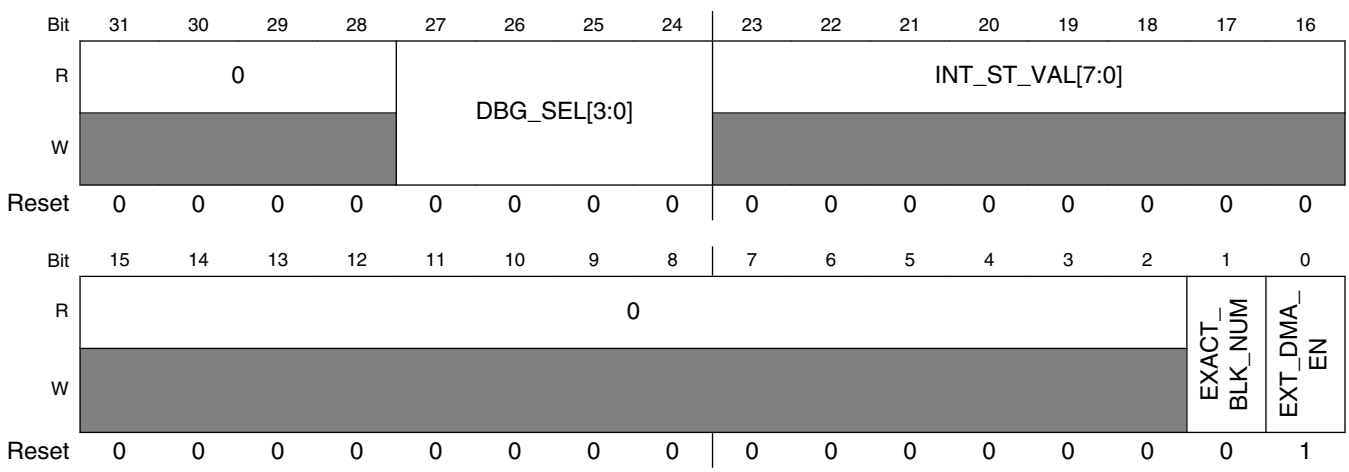
ESDHCV3x_DLLSTS field descriptions (continued)

Field	Description
13–8 DLL_STS_REF_SEL[5:0]	Reference delay line select taps. **NOTE:** this is encoded by 6 bits for 64 taps.
7–2 DLL_STS_SLV_SEL[5:0]	Slave delay line select status. This is the instant value generated from the reference chain. Because only when ref_lock is detected can the reference chain get updated, this value should be the right value to be updated next to the slave line when reference is locked.
1 DLL_STS_REF_LOCK	Reference DLL lock status. This signifies that the DLL has detected and locked to a half-phase ref_clock shift, allowing the slave delay-line to perform programmed clock delays
0 DLL_STS_SLV_LOCK	Slave delay-line lock status. This signifies that a valid calibration has been set to the slave-delay line and that the slave-delay line is implementing the programmed delay value

27.7.21 Vendor Specific Register (ESDHCV3x_VENDOR)

This register contains the vendor specific control/status register.

Addresses: ESDHCV3-3_VENDOR is 5002_0000h base + C0h offset = 5002_00C0h



ESDHCV3x_VENDOR field descriptions

Field	Description
31–28 Reserved	This read-only field is reserved and always has the value zero. Reserved
27–24 DBG_SEL[3:0]	Debug Select Select the internal sub-block to show its internal state value.
23–16 INT_ST_VAL[7:0]	Internal State Value Internal state value, reflecting the corresponding state value selected by Debug Select field. This field is read-only and write to this field does not have effect.

Table continues on the next page...

ESDHCV3x_VENDOR field descriptions (continued)

Field	Description
15–2 Reserved	This read-only field is reserved and always has the value zero. Reserved
1 EXACT_BLK_NUM	Exact block number block read enable for SDIO CMD53 This bit should be set before S/W issues CMD53 multi-block read with exact block number. This bit should not be set if the CMD53 multi-block read is not exact block number. 0 none exact block read 1 exact block read for SDIO CMD53
0 EXT_DMA_EN	External DMA Request Enable Enable the request to external DMA. When the internal DMA (either Simple DMA or Advanced DMA) is not in use, and this bit is set, ESDHC will send out DMA request when the internal buffer is ready. This bit is particularly useful when transferring data by ARM platform polling mode, and it is not allowed to send out the external DMA request. By default, this bit is set. 0 In any scenario, ESDHC does not send out external DMA request 1 When internal DMA is not active, the external DMA request will be sent out

27.7.22 MMC Boot Register (ESDHCV3x_MMCBOOT)

This register contains the MMC Fast Boot control register.

Addresses: ESDHCV3-3_MMCBOOT is 5002_0000h base + C4h offset = 5002_00C4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	BOOT_BLK_CNT[15:0]

7–0 SVN[7:0]	Specification Version Number: These status bits indicate the Host Controller Specification Version. Settings not shown are reserved. — 0x01 SD Host Specification Version 2.0, supports Test Event Register and ADMA.

Chapter 28
Fast Ethernet Controller (FEC)

28.1 Overview

This chapter provides a feature-set overview, a functional block diagram, and transceiver connection information for the 10- and 100-Mbps reduced media independent interfaces (RMII) and the 7-wire serial interface. Detailed functional descriptions and application/ initialization information are included.

The Fast Ethernet controller (FEC) is designed to support both 10- and 100-Mbps Ethernet/IEEE 802.3 networks. An external transceiver interface and transceiver function are required to complete the interface to the media. The FEC supports two different standard physical interfaces (MAC-PHY) for connection to an external Ethernet transceiver.

NOTE

Only RMII signals are available. The additional signals required for MII interface to the transceiver are not available.

The FEC is implemented with a combination of hardware and microcode. The following figure is a block diagram of the FEC.

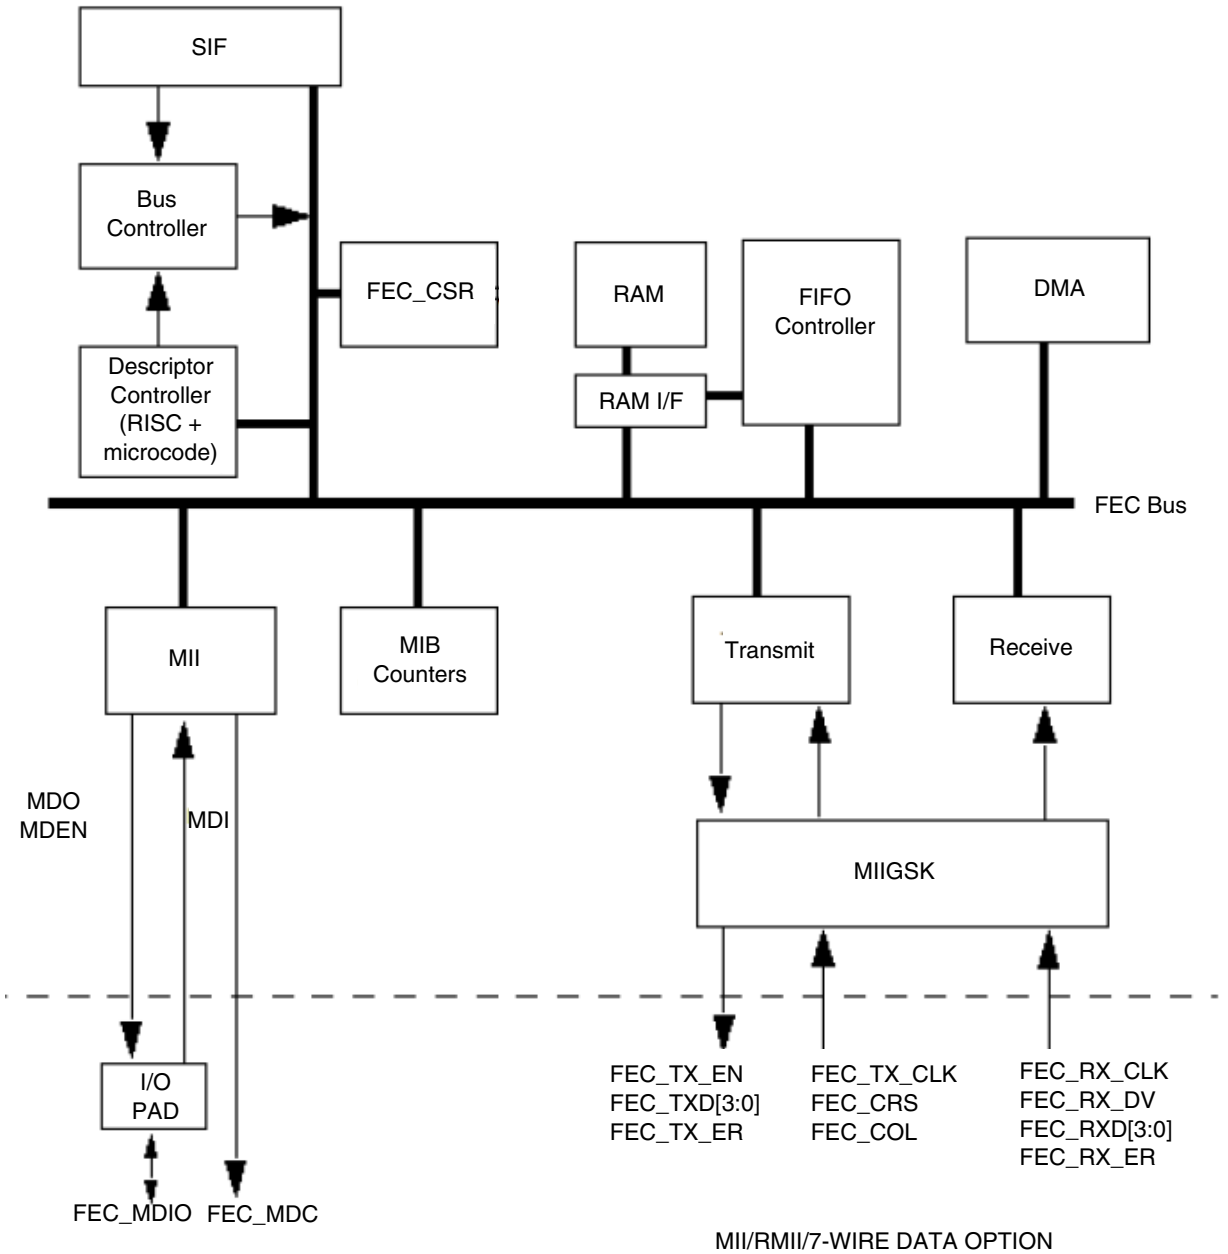

Figure 28-1. FEC Block Diagram

The following section provides information regarding the FEC submodules.

- The descriptor controller is a RISC-based controller that provides the following functions in the FEC:
  - Initialization (those internal registers not initialized by the user or hardware)
  - High-level control of the DMA channels (initiating DMA transfers)
  - Interpreting buffer descriptors
  - Address recognition for receive frames
  - Random number generation for transmit collision backoff timer

NOTE

This DMA engine is for the transfer of FEC data only and is not related to the system DMA controller.

- The RAM is the focal point of all data flow in the FEC and is divided into transmit and receive FIFOs. The FIFO boundaries are programmable using the FEC_FRSR register. User data flows to and from the DMA block, from and to the receive/transmit FIFOs. Transmit data flows from the transmit FIFO to the transmit block, and receive data flows from the receive block to the receive FIFO.
- The user controls the FEC by writing, through the slave interface (SIF) submodule, to control registers located in each block. The control and status register (FEC_CSR) provides global control (for example, Ethernet reset and enable) and interrupt handling registers.
- The MII provides a serial channel for control/status communication with the external physical layer device (transceiver). This serial channel consists of the management data clock and management data input/output lines of the MII interface (FEC_MDC and FEC_MDIO, respectively).
- The DMA provides multiple channels allowing transmit data, transmit descriptor, receive data and receive descriptor accesses to run independently.
- The transmit and receive blocks provide the Ethernet MAC functionality (with some assistance from microcode).
- The message information block (MIB) maintains counters for a variety of network events and statistics. It is not necessary for operation of the FEC but provides valuable counters for network management. The counters supported are the RMON (RFC 1757) Ethernet statistics group and some of the IEEE 802.3 counters. See Message Information Block (MIB) Counters Memory Map, for more information.
- The MII gasket block (MIIGSK) provides an interface between the MII (Media Independent Interface specified by IEEE 802.3 standard) I/F and RMII (low pin count Reduced Media Independent Interface as specified by the RMII Consortium™ standard) I/F.

28.1.1 Features

The FEC incorporates the following features:

- Support for two different Ethernet physical interfaces:
  - 10-Mbps and 100-Mbps RMII
  - 10-Mbps 7-wire interface (industry standard)
- IEEE 802.3 full-duplex flow control
- Programmable max frame length supports IEEE 802.1 VLAN tags and priority

- Support for full-duplex operation (200Mbps throughput) with a minimum system clock rate of 50 MHz
- Support for half-duplex operation (100Mbps throughput) with a minimum system clock rate of 25 MHz
- Retransmission from transmit FIFO following a collision (no processor bus utilization)
- Automatic internal flushing of the receive FIFO for runts (collision fragments) and address recognition rejects (no processor bus utilization)
- Address recognition
  - Frames with broadcast address can be always accepted or always rejected
  - Exact match for single 48-bit individual (unicast) address
  - Hash (64-bit hash) check of individual (unicast) addresses
  - Hash (64-bit hash) check of group (multicast) addresses
  - Promiscuous mode

28.2 Modes of Operation

The primary operational modes are described in this section.

28.2.1 Full- and Half-Duplex Operation

Full-duplex mode is intended for use on point to point links between switches or end node to switch. Half-duplex mode is used in connections between an end node and a repeater or between repeaters. Selection of the duplex mode is controlled by the FEC_TCR[FDEN] bit. When configured for full-duplex mode, flow control can be enabled, which is effected by the FEC_TCR[RFC_PAUSE], FEC_TCR[TFC_PAUSE], and FEC_RCR[FCE] bits. See Full-Duplex Flow Control, for more details.

28.2.2 Interface Options

The following interface options are supported. A detailed discussion of the interface configurations is provided in Network Interface Options.

28.2.2.1 10-Mbps and 100-Mbps Media Independent Interface (MII)

The MII is defined by the IEEE 802.3 standard for 10/100-Mbps operation. The MAC-PHY interface can be configured to operate in MII mode by asserting FEC_RCR[MII_MODE].

The speed of operation is determined by the FEC_TX_CLK and FEC_RX_CLK signals which are driven by the external transceiver. The transceiver either autonegotiates the speed or control by software via the serial management interface (FEC_MDC/FEC_MDIO) signals to the transceiver. See the descriptions in MII management frame register (FEC_MMFR) and MII speed control register (FEC_MSCR) respectively, as well as MII documentation for a description of how to read and write registers in the transceiver through this interface.

28.2.2.2 10 Mbps and 100 Mbps RMII Interface

RMII is a reduced MII interface specified by the RMII Consortium^{TM} standard. The purpose of this interface is to provide a low cost alternative to the MII, with 8 pin interface instead of 16 (Not including MDC, MDIO pins).

The FEC uses a gasket (MIIGSK) to support RMII. It will operate in RMII mode by setting FEC_MIIGSK_CFGR[I/F_MODE] = 01, while setting FEC_MIIGSK_CFGR[I/F_MODE] = 00 will disable RMII mode. The speed selection in RMII Mode is supported by configuring the FEC_MIIGSK_CFGR[FRCONT]. The serial management interface is still available in RMII mode.

28.2.2.3 10-Mbps 7-Wire Interface Operation

The FEC supports a 7-wire interface as used by many 10 Mbps ethernet transceivers. The FEC_RCR[MII_MODE] bit controls this functionality. If this bit is cleared, the MII mode is disabled and the 10 Mbps, 7-wire mode is enabled.

28.2.3 Address Recognition Options

The address options supported are promiscuous, broadcast reject, individual address (hash or exact match), and multicast hash match. Address recognition options are discussed in detail in Ethernet Address Recognition.

28.2.4 Internal Loopback

Two levels of internal loopback modes are supported. The first level, which will loop data back before they enter MIIGSK, is selected by FEC_RCR[LOOP]. The second level, which will loop data back inside MIIGSK RMII domain, is selected by setting FEC_MIIGSK_CFGR[LBMODE] and FEC_MIIGSK_CFGR[I/F_MODE] = 01. Loopback mode is discussed in detail in Internal and External Loopback.

28.3 Functional Description

This section provides a detailed description of the functions of the FEC including:

- Network interface options
- Frame transmission and reception
- Full-duplex flow control
- Internal and external loopback

28.3.1 Network Interface Options

The FEC supports an RMII interface for 10/100 Mbps Ethernet and a 7-wire serial interface for 10 Mbps Ethernet.

The interface mode is selected by FEC_MIIGSK_CFGR[I/F_MODE] together with the FEC_RCR[MII_MODE] bit as shown in the table below.

Table 28-1. Interface Mode Selection

FEC_MIIGSK_CFGR[I/F_MODE]	FEC_RCR[MII_MODE]	Interface Mode Selected
00	0	7-Wire
01	1	RMII

In RMII mode, a reduced set of 10 signals (a subset of the 18 signals defined by the IEEE 802.3 standard) are used. These signals are shown in Table 28-2.

Table 28-2. RMII Mode Signal Configuration

Signal Description	FEC Signal Name	Direction
Synchronous clock reference (REF_CLK)	FEC_TX_CLK	In
Transmit Enable	FEC_TX_EN	Out
Transmit Data	FEC_TXD[1:0]	Out
Carrier Sense/Receive Data Valid (CRS_DV)	FEC_RX_DV	In

Table continues on the next page...

Table 28-2. RMII Mode Signal Configuration (continued)

Signal Description	FEC Signal Name	Direction
Receive Data	FEC_RXD[1:0]	In
Receive Error	FEC_RX_ER	In
Management Data Clock	FEC_MDC	Out
Management Data Input/Output	FEC_MDIO	I/O

The 7-wire serial interface operates in what is generally referred to as AMD mode. 7-wire mode connections to the external transceiver are shown in Table 28-3.

Table 28-3. 7-Wire Mode Signal Configuration

Signal Description	FEC Signal Name	Direction
Transmit clock	FEC_TX_CLK	In
Transmit enable	FEC_TX_EN	Out
Transmit data	FEC_TXD[0]	Out
Collision	FEC_COL	In
Receive clock	FEC_RX_CLK	In
Receive data valid	FEC_RX_DV	In
Receive data	FEC_RXD[0]	In

28.3.2 FEC Frame Transmission

The Ethernet transmitter is designed to work with almost no intervention from software. After FEC_ECR[ETHER_EN] is set to 1 and data appears in the transmit FIFO, the FEC is able to transmit on to the network.

When the transmit FIFO fills to the watermark (defined by the FEC_TFWR register), the FEC transmit logic asserts FEC_TX_EN and starts transmitting the preamble (PA) sequence, the start frame delimiter (SFD), and then the frame information from the FIFO. However, the controller postpones transmission if the network is busy (that is, the carrier sense signal FEC_CRS is asserted). Before transmitting, the controller waits for carrier sense to become inactive, then determines if carrier sense remains inactive for 60 bit periods. If so, the transmission begins after waiting an additional 36 bit periods (96 bit periods after carrier sense originally became inactive). See Transmission Error Handling for more details.

If a collision occurs during transmission of a frame in half-duplex mode, the Ethernet controller follows the specified backoff procedures (see Collision Handling) and attempts to retransmit the frame until the retry limit is reached. The transmit FIFO stores at least

the first 64 bytes of the transmit frame, so that they do not have to be retrieved from system memory in case of a collision. This improves bus utilization and latency in case immediate retransmission is necessary.

When all the frame data has been transmitted, if the TC bit is set in the transmit frame control word then a 32-bit cyclic redundancy check (CRC) known as the frame check sequence (FCS) is appended. If the ABC bit is set in the transmit frame control word, a bad CRC is appended to the frame data regardless of the TC bit value. Following the transmission of the CRC, the Ethernet controller writes the frame status information to the MIB block. Short frames are automatically padded by the transmit logic (if the TC bit in the transmit buffer descriptor for the end of frame buffer is set to 1).

Both buffer (TXB) and frame (TXF) interrupts can be generated as determined by the settings in the FEC_EIMR.

The transmit error interrupts are HBERR, BABT, LATE_COL, COL_RETRY_LIM, and XFIFO_UN. If the transmit frame length exceeds MAX_FL bytes the BABT interrupt is asserted: however, the entire frame is transmitted (no truncation).

Transmission is paused by setting the graceful transmit stop (GTS) bit in the FEC_TCR register. When the FEC_TCR[GTS] is set to 1, the FEC transmitter stops immediately if transmission is not in progress; otherwise, it continues transmission until the current frame either finishes or terminates with a collision. After the transmitter has stopped the GRA (graceful stop complete) interrupt is asserted. If FEC_TCR[GTS] is cleared, the FEC resumes transmission with the next frame.

The Ethernet controller transmits bytes LSB first.

28.3.2.1 Transmit Inter-Packet Gap (IPG) Time

The minimum inter-packet gap (IPG) time for back-to-back transmission is 96 bit periods. After completing a transmission or after the backoff algorithm completes, the transmitter waits for carrier sense to be negated before starting its 96-bit-period IPG counter. Frame transmission begins 96 bit periods after carrier sense is negated if it stays negated for at least 60 bit periods. If carrier sense is asserted during the last 36 bit periods, it is ignored and a collision occurs.

28.3.2.2 Collision Handling

If a collision occurs during frame transmission, the Ethernet controller continues the transmission for at least 32 bit periods, transmitting a jam pattern consisting of 32 ones. If the collision occurs during the preamble sequence, the jam pattern is sent after the end of the preamble sequence.

If a collision occurs within 512 bit periods, the retry process is initiated. The transmitter waits a random number of slot periods, where one slot period is 512 bit periods. If a collision occurs after 512 bit periods, then no retransmission is performed and the end of frame buffer is closed with a late collision (LC) error indication.

28.3.2.3 Transmission Error Handling

The Ethernet controller reports frame transmission error conditions using the FEC RxBDs, the FEC_EIR register, and the MIB block counters.

There are four types of transmission errors:

- Transmitter underrun
- Retransmission attempts limit expired
- Late collision
- Heartbeat

The FEC's procedures for handling these errors are described in the following subsections.

28.3.2.3.1 Transmitter Underrun

If this error occurs, the FEC sends 32 bits that ensure a CRC error, then stops transmitting. All remaining buffers for that frame are then flushed and closed. The UN bit is set in the FEC_EIR and the UN interrupt is asserted (if enabled in the FEC_EIMR register). The FEC then continues to the next transmit buffer descriptor and begin transmitting the next frame.

28.3.2.3.2 Retransmission Attempts Limit Expired

When this error occurs, the FEC terminates transmission. All remaining buffers for that frame are flushed and closed, and the RL bit is set in the FEC_EIR. The FEC then continues to the next transmit buffer descriptor and begin transmitting the next frame.

The "RL" interrupt is asserted if enabled in the FEC_EIMR register.

28.3.2.3.3 Late Collision

When a collision occurs after the slot time (512 bits starting at the preamble), the FEC terminates transmission. All remaining buffers for that frame are flushed and closed, and the LC bit is set in the FEC_EIR register. The FEC then continues to the next transmit buffer descriptor and begin transmitting the next frame.

The LC interrupt is asserted if enabled in the FEC_EIMR register.

28.3.2.3.4 Heartbeat

Some transceivers have a self-test feature called "heartbeat" or "signal quality error." To signify a good self-test, the transceiver indicates a collision to the FEC within 4 microseconds after completion of a frame transmitted by the Ethernet controller. This indication of a collision does not imply a real collision error on the network, but is rather an indication that the transceiver still seems to be functioning properly. This is called the heartbeat condition.

If the HBC bit is set in the FEC_TCR register and the heartbeat condition is not detected by the **FEC** after a frame transmission, then a heartbeat error occurs. When this error occurs, the FEC closes the buffer, sets the HB bit in the FEC_EIR register, and generates the HBERR interrupt if it is enabled.

28.3.3 FEC Frame Reception

The FEC receiver is designed to work with almost no intervention from the host and can perform address recognition, CRC checking, short frame checking, and maximum frame length checking.

When the driver enables the FEC receiver by setting FEC_ECR[ETHER_EN] to 1, it immediately starts processing receive frames. When FEC_RX_DV asserts, the receiver first checks for a valid PA/SFD header. If the PA/SFD is valid, it is stripped and the frame is processed by the receiver. If a valid PA/SFD is not found, the frame is ignored.

In serial mode, the first 16 bit periods of RX_D0 following assertion of FEC_RX_DV are ignored. Following the first 16 bit periods the data sequence is checked for alternating 1/0s. If a 0b11 or 0b00 data sequence is detected during bit periods 17 to 21, the remainder of the frame is ignored. After bit period 21, the data sequence is monitored for a valid SFD (11). If a 0b00 is detected, the frame is rejected. When a 0b11 is detected, the PA/SFD sequence is complete.

In MII mode, the receiver checks for at least one byte matching the SFD. Zero or more PA bytes can occur, but if a 0b00 bit sequence is detected prior to the SFD byte, the frame is ignored.

After the first 6 bytes of the frame have been received, the FEC performs address recognition on the frame.

After a collision window (64 bytes) of data has been received, and if address recognition has not rejected the frame, the receive FIFO is signaled that the frame is accepted and can be passed on to the DMA. If the frame is a runt (due to collision) or is rejected by address recognition, the receive FIFO is notified to reject the frame. Thus no collision fragments are presented to the user except late collisions, which indicate serious LAN problems.

During reception, the Ethernet controller checks for various error conditions and after the entire frame is written into the FIFO, a 32-bit frame status word is written into the FIFO. This status word contains the M, BC, MC, LG, NO, CR, OV and TR status bits, and the frame length. See Reception Error Handling for more details.

Receive Buffer (RXB) and Frame Interrupts (RXF) can be generated if enabled by the FEC_EIMR register. The only receive error interrupt is babbling receiver error (BABR). Receive frames are not truncated if they exceed the max frame length (MAX_FL); however, the BABR interrupt occurs and the LG bit in the receive buffer descriptor (RxBD) is set. See Ethernet Receive Buffer Descriptor (RxBD) for more details.

When the receive frame is complete, the FEC sets the L bit in the RxBD, writes the other frame status bits into the RxBD, and clears the E bit. The Ethernet controller next generates a maskable interrupt (RXF bit in FEC_EIR, maskable by RXF bit in FEC_EIMR), indicating that a frame has been received and is in memory. The Ethernet controller then waits for a new frame.

The Ethernet controller receives serial data LSB first.

28.3.3.1 Receive Inter-Packet Gap (IPG) Time

The receiver receives back-to-back frames with a minimum spacing of 28-bit periods. If an inter-packet gap between receive frames is less than 28 bit periods, the second frame may be discarded by the receiver.

28.3.3.2 Ethernet Address Recognition

Address recognition is accomplished through the use of the receive block and microcode running on the microcontroller. The flowchart shown in Figure 28-2 illustrates the address recognition decisions made by the receive block, while Figure 28-3 illustrates the decisions made by the microcontroller.

The FEC filters the received frames based on destination address (DA) type - individual (unicast), group (multicast), or broadcast (all-ones group address). The difference between an individual address and a group address is determined by the I/G bit in the DA field.

If the DA is a broadcast address, and broadcast reject (FEC_RCR[BC_REJ]) is cleared, then the frame is accepted unconditionally, as shown in Figure 28-2. Otherwise, if the DA is not a broadcast address, then the microcontroller runs the address recognition subroutine, as shown in Figure 28-3.

If the DA is a group (multicast) address and flow control is disabled, then the microcontroller performs a group hash table lookup using the 64-entry hash table programmed in FEC_GAUR and FEC_GALR. If a hash match occurs, the receiver accepts the frame. The hash algorithm is described in Hash Algorithm.

If flow control is enabled, the microcontroller does an exact address match check between the DA and the designated PAUSE DA (01:80:C2:00:00:01). If the receive block determines that the received frame is a valid pause frame, then the frame is rejected.

NOTE

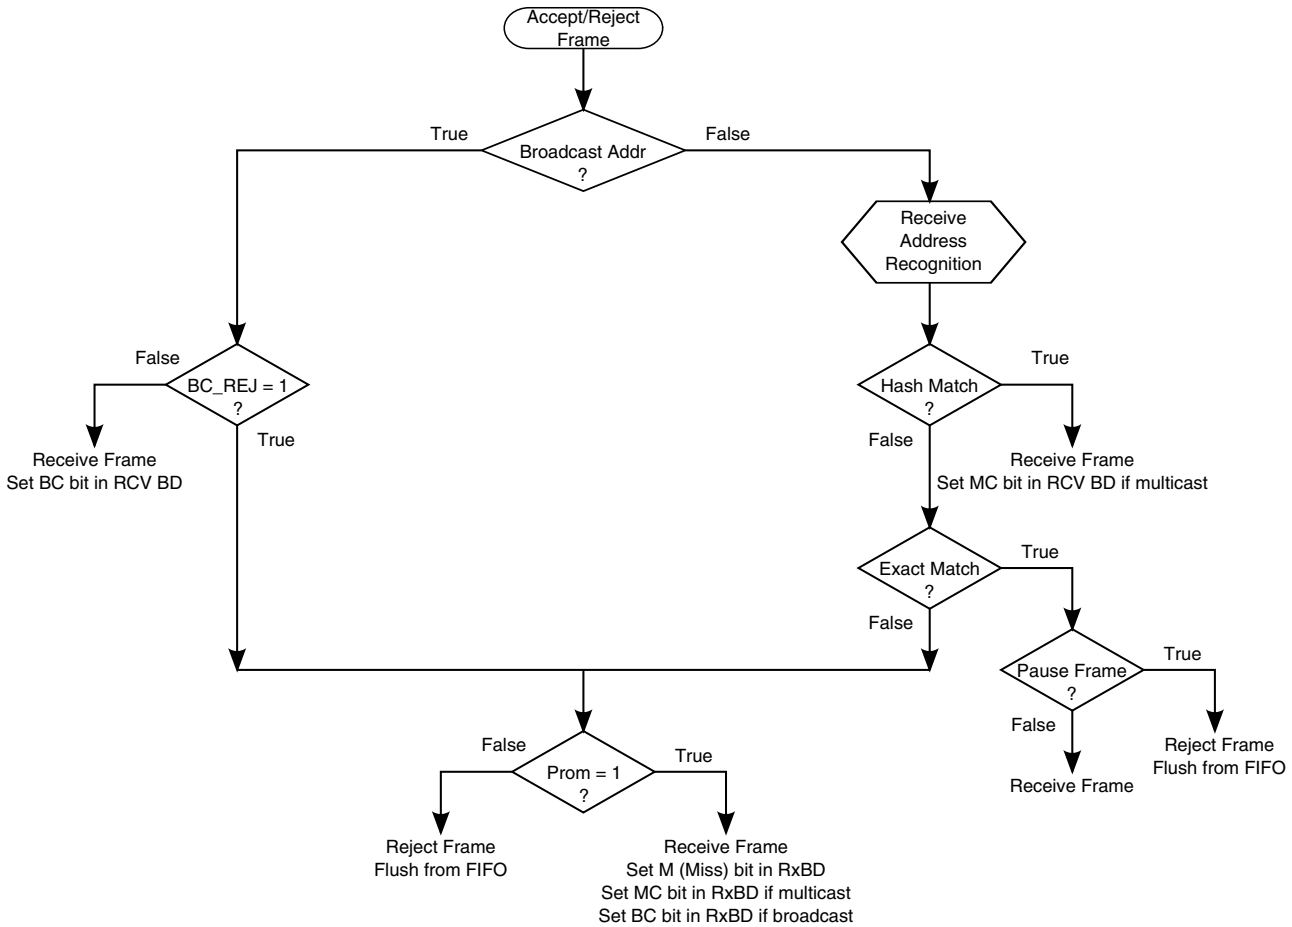
The receiver detects a pause frame with the DA field set to either the designated PAUSE DA or the unicast physical address.

If the DA is the individual (unicast) address, the microcontroller performs an individual exact match comparison between the DA and 48-bit physical address that the user programs in the FEC_PALR and FEC_PAUR registers. If an exact match occurs, the frame is accepted; otherwise, the microcontroller does an individual hash table lookup using the 64-entry hash table programmed in registers, FEC_IAUR and FEC_IALR (the hash algorithm is described in Hash Algorithm). In the case of an individual hash match, the frame is accepted. Again, the receiver accepts or rejects the frame based on pause frame detection, shown in Figure 28-2.

If neither a hash match (group or individual), nor an exact match occur, then if promiscuous mode is enabled (FEC_RCR[PROM] = 1), the frame is accepted and the MISS bit in the receive buffer descriptor is set. Otherwise, the frame is rejected.

Similarly, if the DA is a broadcast address, broadcast reject (FEC_RCR[BC_REJ]) is asserted, and promiscuous mode is enabled, then the frame is accepted and the MISS bit in the receive buffer descriptor is set. Otherwise, the frame is rejected.

In general, when a frame is rejected, it is flushed from the FIFO.



NOTES:
BC_REJ - Field in RCR register (BroadCast REJect)
PROM-Field in RCR register (PROMiscuous mode)
Pause Frame - Valid PAUSE frame received

Figure 28-3. Ethernet Address Recognition-Microcode Decisions

28.3.3.2.1 Hash Algorithm

The hash table algorithm used in the group and individual hash filtering operates as follows. The 48-bit destination address is mapped into one of 64 bits, which are represented by 64 bits stored in FEC_GAUR, FEC_GALR (group address hash match) or FEC_IAUR, FEC_IALR (individual address hash match). This mapping is performed by passing the 48-bit address through the on-chip 32-bit CRC generator and selecting the six most significant bits of the CRC-encoded result to generate a number between 0 and 63. The MSB of the CRC result selects FEC_GAUR (MSB = 1) or FEC_GALR (MSB = 0). The least significant five bits of the hash result select the bit within the selected register. If the CRC generator selects a bit that is set in the hash table, the frame is accepted; otherwise, it is rejected. For example, if eight group addresses are stored in the hash table

and random group addresses are received, the hash table prevents roughly 56/64 (87.5%) of the group address frames from reaching memory. Those that do reach memory must be further filtered by the processor to determine if they truly contain one of the eight desired addresses.

The effectiveness of the hash table declines as the number of addresses increases.

The hash table registers must be initialized by the user. The CRC32 polynomial to use in computing the hash is shown in the following equation:

$$X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^{8} + X^{7} + X^{5} + X^{4} + X^{2} + X + 1$$

Table 28-4 shows example destination addresses and corresponding hash values is included below for reference.

28.3.3.3 Reception Error Handling

The Ethernet controller reports frame reception error conditions using the FEC RxBDs, the FEC_EIR register, and the MIB counters.

There are five types of reception errors:

- Overrun
- Non-octet (dribbling bits)
- CRC
- Frame-length violation
- Truncation

These are described in the following subsections.

28.3.3.3.1 Overrun

If the receive block has data to put into the receive FIFO and the receive FIFO is full, the FEC sets the OV bit in the RxBD. All subsequent data in the frame is discarded, and subsequent frames can also be discarded until the receive FIFO is serviced by the DMA and space is made available. At this point the receive frame/status word is written into the FIFO with the OV bit set. This frame must be discarded by the driver.

28.3.3.3.2 Non-Octet (Dribbling Bits)

The Ethernet controller handles up to seven dribbling bits when the receive frame terminates past an non-octet aligned boundary. Dribbling bits are not used in the CRC calculation. If there is a CRC error, then the frame non-octet aligned (NO) error is reported in the RxBD. If there is no CRC error, then no error is reported.

28.3.3.3.3 CRC

When a CRC error occurs with no dribble bits, the FEC closes the buffer and sets the CR bit in the RxBD. CRC checking cannot be disabled, but the CRC error can be ignored if checking is not required.

28.3.3.3.4 Frame Length Violation

When the receive frame length exceeds MAX_FL bytes the BABR interrupt is generated, and the LG bit in the end of frame RxBD is set. The frame is not truncated unless the frame length exceeds 2047 bytes).

28.3.3.3.5 Truncation

When the receive frame length exceeds 2047 bytes, the frame is truncated and the TR bit is set in the RxBD.

28.3.4 Full-Duplex Flow Control

Full-duplex flow control allows the user to transmit pause frames and to detect received pause frames. Upon detection of a pause frame, FEC data frame transmission stops for a given pause duration.

To enable pause frame detection, the FEC must operate in full-duplex mode (FEC_TCR[FDEN] asserted) and flow control enable (FEC_RCR[FCE]) must be asserted. The FEC detects a pause frame when the fields of the incoming frame match the pause frame specifications, as shown in Table 28-5. In addition, the receive status associated with the frame indicates that the frame is valid.

Table 28-5. Pause Frame Field Specification

48-bit destination address	0x0180_C200_0001 or physical address
48-bit source address	Any
16-bit type	0x8808
16-bit opcode	0x0001

Table continues on the next page...

Table 28-5. Pause Frame Field Specification (continued)

48-bit destination address	0x0180_C200_0001 or physical address
16-bit pause duration	0x0000-0xFFFF

Pause frame detection is performed by the receiver and microcontroller modules. The microcontroller runs an address recognition subroutine to detect the specified pause frame destination address, while the receiver detects the type and opcode pause frame fields. On detection of a pause frame, FEC_TCR[GTS] is asserted by the FEC internally. When transmission has paused, the FEC_EIR[GRA] interrupt is asserted and the pause timer begins to increment.

NOTE

The pause timer makes use of the transmit backoff timer hardware, which is used for tracking the appropriate collision backoff time in half-duplex mode. The pause timer increments after every slot time, until FEC_OPD[PAUSE_DUR] slot times have expired.

On FEC_OPD[PAUSE_DUR] expiration, FEC_TCR[GTS] is cleared allowing FEC data frame transmission to resume.

NOTE

The receive flow control pause (FEC_TCR[RFC_PAUSE]) status bit is asserted while the transmitter is paused due to reception of a pause frame.

To transmit a pause frame, the FEC must operate in full-duplex mode and the user must assert flow control pause (FEC_TCR[TFC_PAUSE]). On assertion of transmit flow control pause (FEC_TCR[TFC_PAUSE]), the transmitter asserts FEC_TCR[GTS] internally. When the transmission of data frames stops, the FEC_EIR[GRA] (graceful stop complete) interrupt asserts. Following FEC_EIR[GRA] assertion, the pause frame is transmitted. On completion of pause frame transmission, flow control pause (FEC_TCR[TFC_PAUSE]) and FEC_TCR[GTS] are cleared internally.

The user must specify the desired pause duration in the FEC_OPD register.

NOTE

When the transmitter is paused due to receiver/microcontroller pause frame detection, transmit flow control pause (FEC_TCR[TFC_PAUSE]) still can be asserted and causes the transmission of a single pause frame. In this case, the FEC_EIR[GRA] interrupt is not asserted.

28.3.5 Internal and External Loopback

Both internal and external loopback are supported by the Ethernet controller. In loopback mode, both of the FIFOs are used and the FEC actually operates in a full-duplex fashion. Both internal and external loopback are configured using combinations of the LOOP and DRT bits in the FEC_RCR register, the FDEN bit in the FEC_TCR register and the LBMODE bit in FEC_MIIGSK_CFGR register. Furthermore internal loopback has two levels which loops data back in MII domain and RMII domain respectively.

For both internal and external loopback set FDEN = 1 and FEC_RCR[DRT] = 0.

For the MII domain internal loopback set FEC_RCR[LOOP] = 1 and FEC_MIIGSK_CFGR[LBMODE] = 0. FEC_TX_EN and FEC_TX_ER will not assert during internal loopback. During the MII domain internal loopback, the transmit/receive data rate is higher than in normal operation because the internal system clock is used by the transmit and receive blocks instead of the clocks from the external transceiver. This will cause an increase in the required system bus bandwidth for transmit and receive data being DMA'd to/from external memory. It may be necessary to pace the frames on the transmit side and/or limit the size of the frames to prevent transmit FIFO underrun and receive FIFO overflow.

For the RMII domain internal loopback, set FEC_RCR[LOOP] = 0 and FEC_MIIGSK_CFGR[LBMODE] = 1. The data is sent from the MII domain into MIIGSK, converted to RMII format by a RMII transmitter inside the MIIGSK, then looped back through a RMII receiver of the MIIGSK, finally gets back to the MII domain.

For external loopback set FEC_RCR[LOOP] = 0, FEC_MIIGSK_CFGR[LBMODE] = 0, and configure the external transceiver for loopback.

28.4 Initialization/Application Information

28.4.1 Initialization Sequence

This section describes which registers are reset due to hardware reset, which are reset by the FEC RISC, and what locations the user must initialize prior to enabling the FEC.

28.4.1.1 Hardware Controlled Initialization

In the FEC, registers and control logic that generate interrupts are reset by hardware. A hardware reset negates output signals and resets general configuration bits.

Other registers are reset when the FEC_ECR[ETHER_EN] bit is cleared, as indicated in Table 28-6. FEC_ECR[ETHER_EN] is cleared by a hard reset or can be cleared by software to halt operation. By clearing FEC_ECR[ETHER_EN], the configuration control registers such as the FEC_TCR and FEC_RCR do not reset, but the entire data path resets.

Table 28-6. Effect on FEC of Clearing FEC_ECR[ETHER_EN]

Register/Machine	Reset Value
XMIT block	Transmission is aborted (bad CRC appended)
RECV block	Receive activity is aborted
DMA block	All DMA activity is terminated
FEC_RDAR	Cleared
FEC_TDAR	Cleared
Descriptor Controller block	Halt operation
MIIGSK	Interface to transceiver is disabled

28.4.1.2 User Initialization (Prior to Asserting FEC_ECR[ETHER_EN])

The user must initialize portions of the FEC prior to setting the FEC_ECR[ETHER_EN] bit. The exact values depend on the particular application. The order of initializations is not important except those that are explicitly mentioned.

The FEC and FEC FIFO/DMA registers which require initialization are defined in Table 28-7.

Table 28-7. Registers Requiring Initialization before Setting FEC_ECR[ETHER_EN]

Register	Location (FEC or FIFO/DMA)	Comments
FEC_EIMR	FEC	Requires initialization
FEC_EIR	FEC	Must be cleared by writing 0xFFFF_FFFF
FEC_TFWR	FEC	Optional
FEC_IALR / FEC_IAUR	FEC	-
FEC_GAUR / FEC_GALR	FEC	-

Table continues on the next page...

Table 28-7. Registers Requiring Initialization before Setting FEC_ECR[ETHER_EN] (continued)

Register	Location (FEC or FIFO/ DMA)	Comments
FEC_PALR / FEC_PAUR	FEC	-
FEC_OPD	FEC	Only needed for full-duplex flow control
FEC_RCR	FEC	-
FEC_TCR	FEC	-
FEC_MSCR	FEC	Optional
FEC_MIIGSK_CFGR	FEC	Must be configured before setting FEC_MIIGSK_ENR[EN]
FEC_MIIGSK_ENR	FEC	EN bit must be set
MIB counters	FEC	Must be cleared
FEC_FRSR	FIFO/DMA	Initialization is optional
FEC_EMRBR	FIFO/DMA	-
FEC_ERDSR	FIFO/DMA	-
FEC_ETDSR	FIFO/DMA	-
Transmit Descriptor ring	FIFO/DMA	Must be emptied
Receive Descriptor ring	FIFO/DMA	Must be emptied

28.4.1.3 Microcontroller Initialization

In the FEC, the descriptor control RISC initializes some registers after FEC_ECR[ETHER_EN] is asserted. After the microcontroller initialization sequence is complete, the hardware is ready for operation.

The microcontroller initialization sequence follows:

1. Initialize BackOff Random Number Seed
2. Activate Receiver
3. Activate Transmitter
4. Clear Transmit FIFO
5. Clear Receive FIFO
6. Initialize Transmit Ring Pointer
7. Initialize Receive Ring Pointer
8. Initialize FIFO Count Register

28.4.1.4 User Initialization (after asserting FEC_ECR[ETHER_EN])

After asserting FEC_ECR[ETHER_EN], the user can set up the buffer/frame descriptors and write to the FEC_TDAR and FEC_RDAR. See Buffer Descriptors for more details.

28.4.2 Buffer Descriptors

This section provides a description of the operation of the driver/DMA through the buffer descriptors (BD). It is followed by a detailed description of the receive and transmit descriptor fields.

28.4.2.1 Driver/DMA Operation with Buffer Descriptors

The data for the FEC frames must reside in memory external to the FEC. The data for a frame is placed in one or more buffers. Associated with each buffer is a buffer descriptor (BD) which contains a starting address (pointer), data length, and status/control information (which contains the current state for the buffer). To permit maximum user flexibility, the BDs are also located in external memory and are read in by the FEC DMA engine.

Software "produces" buffers by allocating/initializing memory and initializing buffer descriptors. Setting the RxBD[E] or TxBD[R] bit "produces" the buffer. Software writing to either the FEC_TDAR or FEC_RDAR tells the FEC that a buffer has been placed in external memory for the transmit or receive data traffic, respectively. The hardware reads the BDs and "consumes" the buffers after they have been produced. After the data DMA is complete and the buffer descriptor status bits have been written by the DMA engine, the RxBD[E] or TxBD[R] bit is cleared by hardware to signal the buffer has been "consumed." Software can poll the BDs to detect when the buffers have been consumed or can rely on the buffer/frame interrupts. These buffers can then be processed by the driver and returned to the free list.

The FEC_ECR[ETHER_EN] signal operates as a reset to the BD/DMA logic. When FEC_ECR[ETHER_EN] is cleared the DMA engine BD pointers are reset to point to the starting transmit and receive BDs. The buffer descriptors are not initialized by hardware during reset. At least one transmit and receive buffer descriptor must be initialized by software before the FEC_ECR[ETHER_EN] bit is set.

The buffer descriptors operate as two separate rings. FEC_ERDSR defines the starting address for receive BDs and FEC_ETDSR defines the starting address for transmit BDs. The last buffer descriptor in each ring is defined by the Wrap (W) bit. When set, W indicates that the next descriptor in the ring is at the location pointed to by FEC_ERDSR and FEC_ETDSR for the receive and transmit rings, respectively.

NOTE

Buffer descriptor rings must start on a 128-bit boundary.

28.4.2.2 Ethernet Transmit Buffer Descriptor (TxBD)

Table 28-8 shows the transmit buffer descriptor format. Table 28-9 describes the TxBD fields.

Status bits for the buffer/frame are not included in the transmit buffer descriptors. Transmit frame status is indicated by individual interrupt bits (error conditions) and in statistic counters in the MIB block. See Message Information Block (MIB) Counters Memory Map, for more details.

Table 28-8. Transmit Buffer Descriptor (TxBD)

Offset	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

0x0004	Tx Data Buffer Pointer A[31:16]															
	Tx Data Buffer Pointer A[15:0]															

Table 28-9. Transmit Buffer Descriptor Field Definitions

Offset	Field	Description
0x0000	31 R	Ready. Written by the FEC and the user. 0 The data buffer associated with this BD is not ready for transmission. The user is free to manipulate this BD or its associated data buffer. The FEC clears this bit after the buffer has been transmitted or after an error condition is encountered. 1 The data buffer, which has been prepared for transmission by the user, has not been transmitted or is currently being transmitted. No fields of this BD can be written by the user after this bit is set.
0x0000	30 TO1	Transmit software ownership. This field is reserved for software use. This read/write bit is not modified by hardware, nor does its value affect hardware.
0x0000	29 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location 1 The next buffer descriptor is found at the location defined in FEC_ETDSR.
0x0000	28 TO2	Transmit software ownership. This field is reserved for use by software. This read/write bit is not modified by hardware, nor does its value affect hardware.
0x0000	27 L	Last in frame. Written by user. 0 The buffer is not the last in the transmit frame. 1 The buffer is the last in the transmit frame.

Table continues on the next page...

Table 28-9. Transmit Buffer Descriptor Field Definitions (continued)

Offset	Field	Description
0x0000	26 TC	Tx CRC. Written by user (only valid if L = 1). 0 End transmission immediately after the last data byte. 1 Transmit the CRC sequence after the last data byte.
0x0000	25 ABC	Append bad CRC. Written by user (only valid if L = 1). 0 No effect 1 Transmit the CRC sequence inverted after the last data byte (regardless of TC value).
0x0000	24 PTP	PTP. Written by user (only valid if L = 1). 0 No effect 1 The frame is an IEEE1588 PTP frame. FEC will inform IPTP Assist modue to capture the timestamp for this frame in case of successful transmission. If unmasked, an interrupt will be issued by the IPTP Assist block after the timestamp is available.
0x0000	23-16	Reserved.
0x0000	15-0 Data Length	Data Length, written by user. Data length is the number of octets the FEC transmits from this BD's data buffer. It is never modified by the FEC. Bits [10:0] are used by the DMA engine, bits[15:11] are ignored.
0x0004	31-0 A	Tx data buffer pointer[1]

1. The transmit buffer pointer, which contains the address of the associated data buffer, must always be divisible by 16. The buffer must reside in memory external to the FEC. This value is never modified by the Ethernet controller.

28.4.2.2.1 Driver/DMA Operation with Transmit Buffer Descriptors

Data is presented to the FEC for transmission by arranging it in buffers referenced by the channel's TxBDs. After the software driver has set up the buffers for a frame, it sets up the corresponding BDs. In the TxBD the user initializes the R, W, L, and TC bits and the length (in bytes) in the first longword, and the buffer pointer in the second longword.The last step in setting up the BDs for a transmit frame is to set the R bit in the first BD for the frame. The driver follows that with a write to FEC_TDAR which triggers the FEC to poll the next BD in the ring.

The Ethernet controller confirms transmission by clearing the ready bit (R bit) when DMA of the buffer is complete.

28.4.2.2.1.1 Transmit Frame in Multiple Buffers

Typically a transmit frame is divided between multiple buffers. For example, it is possible to have an application payload in one buffer, TCP header in a 2nd buffer, IP header in a 3rd buffer, and Ethernet/IEEE 802.3 header in a 4th buffer. The FEC does not prepend the Ethernet header (Destination Address, Source Address, Length/Type

field(s)), so this must be provided by the driver in one of the transmit buffers. The FEC or the driver can append the Ethernet CRC to the frame. The driver must set the TC bit in the transmit BD to determine whether the CRC is appended by the FEC or by the driver.

The driver (TxBD software producer) sets up Tx BDs in such a way that a complete transmit frame is given to the hardware at once. If a transmit frame consists of three buffers, first the BD's are initialized with pointer, length and control (W, L, TC, ABC) and then the TxBD[R] bits are set to 1 in *reverse order* (3rd, 2nd, 1st BD) to insure that the complete frame is ready in memory before the DMA begins. If the TxBDs are set up in order, the DMA controller could DMA the first BD before the 2nd was made available, potentially causing a transmit FIFO underrun.

In the FEC, the DMA is notified by the driver that new transmit frame(s) are available by writing to the FEC_TDAR register. When this register is written to (data value is not significant) the FEC RISC tells the DMA to read the next transmit BD in the ring. After started, the RISC + DMA continues to read and interpret transmit BDs in order and DMA the associated buffers, until a transmit BD is encountered with the R bit = 0. At this point the FEC polls this BD one more time. If the R bit = 0 the second time, then the RISC stops the transmit descriptor read process until software sets up another transmit frame and writes to FEC_TDAR.

When the DMA of each transmit buffer is complete, the DMA writes back to the BD to clear the R bit, indicating that the hardware consumer is finished with the buffer.

28.4.2.3 Ethernet Receive Buffer Descriptor (RxBD)

Table 28-10. Receive Buffer Descriptor (RxBD)

Offset	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Table 28-11. Receive Buffer Descriptor Field Definitions (continued)

Offset	Field	Description
0x0000	30 RO1	Receive software ownership. This field is reserved for use by software. This read/write bit is not modified by hardware, nor does its value affect hardware.
0x0000	29 W	Wrap. Written by user. 0 The next buffer descriptor is found in the consecutive location 1 The next buffer descriptor is found at the location defined in FEC_ERDSR.
0x0000	28 RO2	Receive software ownership. This field is reserved for use by software. This read/write bit is not modified by hardware, nor does its value affect hardware.
0x0000	27 L	Last in frame. Written by the FEC. 0 The buffer is not the last in a frame. 1 The buffer is the last in a frame.
0x0000	26 PTP	PTP frame received. Written by the FEC. This bit is valid only if the L-bit is set. 0 Received frame is not an IEEE1588 PTP frame. 1 Received frame is an IEEE1588 PTP frame. FEC has informed IPTP Assist block to capture the timestamp for this frame. If unmasked, an interrupt will be issued by the IPTP Assist block after the timestamp is available.
0x0000	25	Reserved.
0x0000	24 M	Miss. Written by the FEC. This bit is set by the FEC for frames that were accepted in promiscuous mode, but were flagged as a "miss" by the internal address recognition. Thus, while in promiscuous mode, the user can use the M-bit to quickly determine whether the frame was destined to this station. This bit is valid only if the L-bit is set and the PROM bit is set. 0 The frame was received because of an address recognition hit. 1 The frame was received because of promiscuous mode.
0x0000	23 BC	Set if the DA is broadcast (FF:FF:FF:FF:FF:FF).
0x0000	22 MC	Set if the DA is multicast and not BC.
0x0000	21 LG	Rx frame length violation. Written by the FEC. A frame length greater than FEC_RCR[MAX_FL] was recognized. This bit is valid only if the L-bit is set. The receive data is not altered in any way unless the length exceeds 2047 bytes.
0x0000	20 NO	Receive non-octet aligned frame. Written by the FEC. A frame that contained a number of bits not divisible by 8 was received, and the CRC check that occurred at the preceding byte boundary generated an error. This bit is valid only if the L-bit is set. If this bit is set the CR bit is not set.
0x0000	19	Reserved
0x0000	18 CR	Receive CRC error. Written by the FEC. This frame contains a CRC error and is an integral number of octets in length. This bit is valid only if the L-bit is set.

Table continues on the next page...

Table 28-11. Receive Buffer Descriptor Field Definitions (continued)

Offset	Field	Description
0x0000	17 OV	Overrun. Written by the FEC. A receive FIFO overrun occurred during frame reception. If this bit is set, the other status bits, M, LG, NO, CR, and CL lose their normal meaning and is zero. This bit is valid only if the L-bit is set.
0x0000	16 TR	Set if the receive frame is truncated (frame length > 2047 bytes). If the TR bit is set the frame is discarded and the other error bits ignored as they can be incorrect.
0x0000	15-0 Data Length	Data length. Written by the FEC. Data length is the number of octets written by the FEC into this BD's data buffer if L = 0 (the value is equal to FEC_EMRBR), or the length of the frame including CRC if L = 1. It is written by the FEC once as the BD is closed.
0x0004	31-0	RX data buffer pointer[1]

1. The receive buffer pointer, which contains the address of the associated data buffer, must always be divisible by 16. The buffer must reside in memory external to the FEC. This value is never modified by the Ethernet controller.

28.4.2.3.1 Driver/DMA Operation with Receive Buffer Descriptors

Unlike the transmit case, the length of the receive frame is unknown by the driver ahead of time. Therefore the driver must set a variable to define the length of all receive buffers. In the FEC, this variable is written to the FEC_EMRBR register.

The driver (RxBD software producer) sets up some number of "empty" buffers for the Ethernet by initializing the address field and the E and W bits of the associated receive BDs. The hardware (receive DMA) consumes these buffers by filling them with data as frames are received, and clearing the E bit and writing to the L bit (1 indicates last buffer in frame), the frame status bits (if L = 1) and the length field.

If a receive frame spans multiple receive buffers, the L bit is only set for the last buffer in the frame. For non-last buffers, the length field in the receive BD is written by the DMA (at the same time the E bit is cleared) with the default receive buffer length value. For end of frame buffers, the L=1 bit is set in the receive BD, and information written to the status bits (M, BC, MC, LG, NO, CR, OV, TR). Some of the status bits are error indicators which, if set, indicate the receive frame is discarded and not given to higher layers. The frame status/length information is written into the receive FIFO following the end of the frame (as a single 32-bit word) by the receive logic. The length field for the end of frame buffer is written with the length of the entire frame, not just the length of the last buffer.

For simplicity the driver can assign the default receive buffer length to be large enough to contain an entire frame, keeping in mind that a malfunction on the network or out-of-specification implementation could result in giant frames. Frames of 2 Kbytes (2048 bytes) or larger are truncated by the FEC at 2047 bytes, so software never sees a receive frame larger than 2047 bytes.

As in the transmit case, the FEC polls the receive descriptor ring after the driver sets up receive BDs and writes to the FEC_RDAR register. As frames are received the FEC fills receive buffers and update the associated BDs, then reads the next BD in the receive descriptor ring. If the FEC reads a receive BD and finds the E bit is cleared, it polls this BD once more. If E is still cleared, then the FEC stops reading receive BDs until the driver writes to FEC_RDAR.

NOTE

Whenever the software driver sets an E bit in one or more receive descriptors, the driver follows that with a write to FEC_RDAR.

28.5 Programmable Registers

28.5.1 Top Level Block Memory Map

The FEC implementation requires a 1 Kbyte memory space. This space is divided into 2 sections of 512 bytes each. The first is used for control/status registers, and the second contains event/statistics counters held in the MIB block.

Table 28-12 defines the top level memory map. For the base address of a particular block instantiation, see the system memory map.

Table 28-12. Block Memory Map

Base Address Offset	Function
0x0000-01FF	Control/Status Registers
0x0200-02FF	MIB Block Counters
0x0300-03FF	Extension Registers (MIIGSK)

28.5.2 Message Information Block (MIB) Counters Memory Map

Table 28-13 shows the MIB counters memory map, which defines the locations in the MIB RAM space where hardware maintained counters reside. It is the responsibility of software to poll the counters often enough to ensure that rollover is detected. For example, on a 100 Mbps channel an octets counter could roll over every 5.7 minutes.

These counters fall in the 0x0200-0x03FF address offset range, and are divided into RMON counters and IEEE counters, as follows:

- RMON counters are included which cover the Ethernet statistics counters defined in RFC 1757. In addition to the counters defined in the Ethernet statistics group, a counter is included to count truncated frames as the FEC only supports frame lengths up to 2047 bytes. The RMON counters are implemented independently for transmit and receive to insure accurate network statistics when operating in full-duplex mode.
- IEEE counters are included which support the mandatory and recommended counter packages defined in section 5 of ANSI/IEEE Std. 802.3 (1998 edition). The IEEE basic package objects are supported by the FEC but do not require counters in the MIB block. In addition, some of the recommended package objects which are supported do not require MIB counters. Counters for transmit and receive full-duplex flow control frames are included as well.

Table 28-13. MIB Counters Memory Map

Base Address Offset	Mnemonic	Description
0x0200	RMON_T_DROP	Count of frames not counted correctly
0x0204	RMON_T_PACKETS	RMON Tx packet count
0x0208	RMON_T_BC_PKT	RMON Tx broadcast packets
0x020C	RMON_T_MC_PKT	RMON Tx multicast packets
0x0210	RMON_T_CRC_ALIGN	RMON Tx packets w CRC/Align error
0x0214	RMON_T_UNDERSIZE	RMON Tx packets < 64 bytes, good crc
0x0218	RMON_T_OVERSIZE	RMON Tx packets > MAX_FL bytes, good crc
0x021C	RMON_T_FRAG	RMON Tx packets < 64 bytes, bad crc
0x0220	RMON_T_JAB	RMON Tx packets > MAX_FL bytes, bad crc
0x0224	RMON_T_COL	RMON Tx collision count
0x0228	RMON_T_P64	RMON Tx 64 byte packets
0x022C	RMON_T_P65TO127	RMON Tx 65 to 127 byte packets
0x0230	RMON_T_P128TO255	RMON Tx 128 to 255 byte packets
0x0234	RMON_T_P256TO511	RMON Tx 256 to 511 byte packets
0x0238	RMON_T_P512TO1023	RMON Tx 512 to 1023 byte packets
0x023C	RMON_T_P1024TO2047	RMON Tx 1024 to 2047 byte packets
0x0240	RMON_T_P_GTE2048	RMON Tx packets w > 2048 bytes
0x0244	RMON_T_OCTETS	RMON Tx octets
0x0248	IEEE_T_DROP	Count of frames not counted correctly
0x024C	IEEE_T_FRAME_OK	Frames transmitted OK
0x0250	IEEE_T_1COL	Frames transmitted with single collision
0x0254	IEEE_T_MCOL	Frames transmitted with multiple collisions
0x0258	IEEE_T_DEF	Frames transmitted after deferral delay
0x025C	IEEE_T_LCOL	Frames transmitted with late collision

Table continues on the next page...

Table 28-13. MIB Counters Memory Map (continued)

Base Address Offset	Mnemonic	Description
0x0260	IEEE_T_EXCOL	Frames transmitted with excessive collisions
0x0264	IEEE_T_MACERR	Frames transmitted with Tx FIFO underrun
0x0268	IEEE_T_CSERR	Frames transmitted with carrier sense error
0x026C	IEEE_T_SQE	Frames transmitted with SQE error
0x0270	IEEE_T_FDXFC	Flow control pause frames transmitted
0x0274	IEEE_T_OCTETS_OK	Octet count for frames transmitted w/o error
0x0284	RMON_R_PACKETS	RMON Rx packet count
0x0288	RMON_R_BC_PKT	RMON Rx broadcast packets
0x028C	RMON_R_MC_PKT	RMON Rx multicast packets
0x0290	RMON_R_CRC_ALIGN	RMON Rx packets w CRC/Align error
0x0294	RMON_R_UNDERSIZE	RMON Rx packets < 64 bytes, good crc
0x0298	RMON_R_OVERSIZE	RMON Rx packets > MAX_FL bytes, good crc
0x029C	RMON_R_FRAG	RMON Rx packets < 64 bytes, bad crc
0x02A0	RMON_R_JAB	RMON Rx packets > MAX_FL bytes, bad crc
0x02A4	RMON_R_RESVD_0	-
0x02A8	RMON_R_P64	RMON Rx 64 byte packets
0x02AC	RMON_R_P65TO127	RMON Rx 65 to 127 byte packets
0x02B0	RMON_R_P128TO255	RMON Rx 128 to 255 byte packets
0x02B4	RMON_R_P256TO511	RMON Rx 256 to 511 byte packets
0x02B8	RMON_R_P512TO1023	RMON Rx 512 to 1023 byte packets
0x02BC	RMON_R_P1024TO2047	RMON Rx 1024 to 2047 byte packets
0x02C0	RMON_R_P_GTE2048	RMON Rx packets w > 2048 bytes
0x02C4	RMON_R_OCTETS	RMON Rx octets
0x02C8	IEEE_R_DROP	Count of frames not counted correctly
0x02CC	IEEE_R_FRAME_OK	Frames received OK
0x02D0	IEEE_R_CRC	Frames received with CRC error
0x02D4	IEEE_R_ALIGN	Frames received with alignment error
0x02D8	IEEE_R_MACERR	Receive FIFO overflow count
0x02DC	IEEE_R_FDXFC	Flow control pause frames received
0x02E0	IEEE_R_OCTETS_OK	Octet count for frames received w/o error

28.5.3 MIIGSK Registers Memory Map

Table 28-14. MIIGSK Registers Memory Map

Offset	Mnemonic	Description
0x0300	FEC_MIIGSK_CFGR	MIIGSK Configuration Register
0x0308	FEC_MIIGSK_ENR	MIIGSK Enable Register

This section includes the FEC memory map and detailed descriptions of all the registers, followed by a description of the buffers.

The FEC is programmed by a combination of control and status registers (FEC_CSRs) and buffer descriptors. The FEC_CSRs are used for mode control and to extract global status information. The descriptors are used to pass data buffers and related buffer information between the hardware and software.

The FEC implementation requires a 1 Kbyte memory space. This space is divided into 2 sections of 512 bytes each. The first is used for control/status registers, and the second contains event/statistics counters held in the MIB block.

Table defines the top level memory map. For the base address of a particular block instantiation, see the system memory map.

Table 28-16. Block Memory Map

Base Address Offset	Function
0x0000-01FF	Control/Status Registers
0x0200-02FF	MIB Block Counters
0x0300-03FF	Extension Registers (MIIGSK)

The following table shows the FEC register memory map. For the base address of a particular block instantiation, see the system memory map.

FEC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
63FE_C004	Ethernet interrupt event register (FEC_EIR)	32	R/W	0000_0000h	28.5.4/ 1494
63FE_C008	Ethernet interrupt mask register (FEC_EIMR)	32	R/W	0000_0000h	28.5.5/ 1496

Table continues on the next page...

FEC memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
63FE_C010	Receive descriptor active register (FEC_RDAR)	32	R/W	0000_0000h	28.5.6/ 1498
63FE_C014	Transmit descriptor active register (FEC_TDAR)	32	R/W	0000_0000h	28.5.7/ 1499
63FE_C024	Ethernet control register (FEC_ECR)	32	R/W	F000_0000h	28.5.8/ 1500
63FE_C040	MII management frame register (FEC_MMFR)	32	R/W	Unaffected	28.5.9/ 1501
63FE_C044	MII speed control register (FEC_MSCR)	32	R/W	0000_0000h	28.5.10/ 1503
63FE_C064	MIB control register (FEC_MIBC)	32	R/W	C000_0000h	28.5.11/ 1505
63FE_C084	Receive control register (FEC_RCR)	32	R/W	05EE_0001h	28.5.12/ 1506
63FE_C0C4	Transmit control register (FEC_TCR)	32	R/W	0000_0000h	28.5.13/ 1507
63FE_C0E4	Physical address low register (FEC_PALR)	32	R/W	0000_0000h	28.5.14/ 1508
63FE_C0E8	Physical address upper register (FEC_PAUR)	32	R/W	0000_8808h	28.5.15/ 1509
63FE_C0EC	Opcode and pause duration register (FEC_OPDR)	32	R/W	0001_0000h	28.5.16/ 1510
63FE_C118	Descriptor individual address upper register (FEC_IAUR)	32	R/W	0000_0000h	28.5.17/ 1510
63FE_C11C	Descriptor individual address lower register (FEC_IALR)	32	R/W	0000_0000h	28.5.18/ 1511
63FE_C120	Descriptor group address upper register (FEC_GAUR)	32	R/W	0000_0000h	28.5.19/ 1511
63FE_C124	Descriptor group address lower register (FEC_GALR)	32	R/W	0000_0000h	28.5.20/ 1512
63FE_C144	Transmit FIFO watermark register (FEC_TFWR)	32	R/W	0000_0000h	28.5.21/ 1512
63FE_C14C	FIFO receive bound register (FEC_FRBR)	32	R	0000_0600h	28.5.22/ 1513
63FE_C150	FIFO receive FIFO start registers (FEC_FRSR)	32	R/W	0000_0500h	28.5.23/ 1513
63FE_C180	Receive buffer descriptor ring start register (FEC_ERDSR)	32	R/W	Unaffected	28.5.24/ 1514
63FE_C184	Transmit buffer descriptor ring start register (FEC_ETDSR)	32	R/W	0000_0000h	28.5.25/ 1515

Table continues on the next page...

FEC memory map (continued)

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
63FE_C188	Maximum receive buffer size register (FEC_EMRBR)	32	R/W	0000_0000h	28.5.26/ 1515

28.5.4 Ethernet interrupt event register (FEC_EIR)

The FEC_EIR bit assignments are shown below. When an event occurs that sets a bit in the FEC_EIR, an interrupt is generated if the corresponding bit in the interrupt mask register (FEC_EIMR) is also set. The bit in the FEC_EIR is cleared if a one is written to that bit position; writing zero has no effect. This register is cleared upon hardware reset.

Interrupts can be divided into three classes as follows:

- Interrupts that occur in normal operation: these include GRA, TXF, TXB, RXF, RXB, and MII.
- Interrupts that result from errors or problems detected in the network or transceiver: these include HBERR, BABR, BABT, LC, and RL.
- Interrupts that result from internal errors are EBERR and UN.

Some of the error interrupts are independently counted in the MIB block counters. The correspondence between interrupts and counters is shown in the following table. Software can choose to mask off the interrupts because these errors are visible to network management through the MIB counters.

Table 28-18. Error Interrupts and Block Counters

Interrupt	Counter(s)
HBERR	IEEE_T_SQE
BABR	RMON_R_OVERSIZE (good CRC), RMON_R_JAB (bad CRC)
BABT	RMON_T_OVERSIZE (good CRC), RMON_T_JAB (bad CRC)
LATE_COL	IEEE_T_LCOL
COL_RETRY_LIM	IEEE_T_EXCOL
XFIFO_UN	IEEE_T_MACERR

Address: FEC_EIR is 63FE_C000h base + 4h offset = 63FE_C004h

FEC_EIR field descriptions

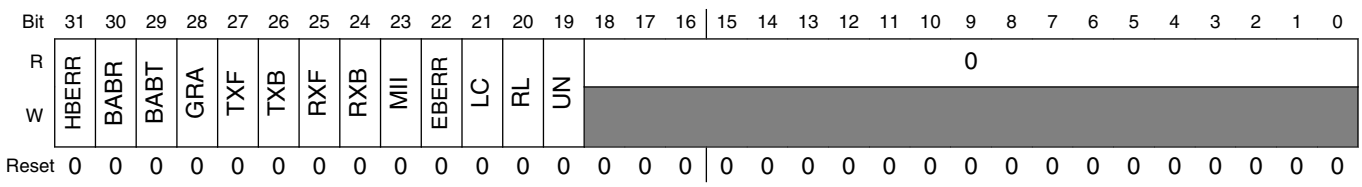
Field	Description
31 HBERR	Heartbeat error. This interrupt indicates that HBC is set in the FEC_TCR register and that the COL input was not asserted within the Heartbeat window following a transmission.
30 BABR	Babbling receive error. This bit indicates a frame was received with length in excess of FEC_RCR[MAX_FL] bytes.
29 BABT	Babbling transmit error. This bit indicates that the transmitted frame length has exceeded FEC_RCR[MAX_FL] bytes. This condition is usually caused by a frame that is too long being placed into the transmit data buffer(s). Truncation does not occur.
28 GRA	Graceful stop complete. This interrupt is asserted for one of three reasons. Graceful stop means that the transmitter is put into a pause state after completion of the frame currently being transmitted. 1) A graceful stop, which was initiated by the setting of the FEC_TCR[GTS] bit is now complete. 2) A graceful stop, which was initiated by the setting of the FEC_TCR[TFC_PAUSE] bit is now complete. 3) A graceful stop, which was initiated by the reception of a valid full-duplex flow control "pause" frame is now complete. See the "Full-Duplex Flow Control" section of the Functional Description chapter.
27 TXF	Transmit frame interrupt. This bit indicates that a frame has been transmitted and that the last corresponding buffer descriptor has been updated.
26 TXB	Transmit buffer interrupt. This bit indicates that a transmit buffer descriptor has been updated.
25 RXF	Receive frame interrupt. This bit indicates that a frame has been received and that the last corresponding buffer descriptor has been updated.
24 RXB	Receive buffer interrupt. This bit indicates that a receive buffer descriptor has been updated that was not the last in the frame.
23 MII	MII interrupt. This bit indicates that the MII has completed the data transfer requested.
22 EBERR	Ethernet bus error. This bit indicates that a system bus error occurred when a DMA transaction was underway. When the EBERR bit is set, FEC_ECR[ETHER_EN] is cleared, halting frame processing by the FEC_ When this occurs software needs to insure that the FIFO controller and DMA are also soft reset.
21 LC	Late collision. This bit indicates that a collision occurred beyond the collision window (slot time) in half-duplex mode. The frame is truncated with a bad CRC and the remainder of the frame is discarded.
20 RL	Collision retry limit. This bit indicates that a collision occurred on each of 16 successive attempts to transmit the frame. The frame is discarded without being transmitted and transmission of the next frame commences. Can only occur in half-duplex mode.
19 UN	Transmit FIFO underrun. This bit indicates that the transmit FIFO became empty before the complete frame was transmitted. A bad CRC is appended to the frame fragment and the remainder of the frame is discarded.
18–0 -	Reserved, read as 0

28.5.5 Ethernet interrupt mask register (FEC_EIMR)

The FEC_EIMR controls which of the interrupt events flagged in the FEC_EIR are allowed to generate actual interrupts. If the corresponding bits in both the FEC_EIR and FEC_EIMR are set, the interrupt is signaled to the ARM platform. The interrupt signal remains asserted until a 1 is written to the FEC_EIR bit (write 1 to clear) or a 0 is written to the FEC_EIMR bit. This register is cleared upon a hardware reset.

The FEC_EIMR bit assignments are the same as for the FEC_EIR.

Address: FEC_EIMR is 63FE_C000h base + 8h offset = 63FE_C008h



FEC_EIMR field descriptions

Field	Description
31 HBERR	Interrupt mask. Each bit corresponds to an interrupt source defined by the FEC_EIR register. The corresponding FEC_EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the FEC_EIR samples the signal generated by the interrupting source. The corresponding FEC_EIR bit reflects the state of the interrupt signal even if the corresponding FEC_EIMR bit is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
30 BABR	Interrupt mask. Each bit corresponds to an interrupt source defined by the FEC_EIR register. The corresponding FEC_EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the FEC_EIR samples the signal generated by the interrupting source. The corresponding FEC_EIR bit reflects the state of the interrupt signal even if the corresponding FEC_EIMR bit is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
29 BABT	Interrupt mask. Each bit corresponds to an interrupt source defined by the FEC_EIR register. The corresponding FEC_EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the FEC_EIR samples the signal generated by the interrupting source. The corresponding FEC_EIR bit reflects the state of the interrupt signal even if the corresponding FEC_EIMR bit is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
28 GRA	Interrupt mask. Each bit corresponds to an interrupt source defined by the FEC_EIR register. The corresponding FEC_EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the FEC_EIR samples the signal generated by the interrupting source. The corresponding FEC_EIR bit reflects the state of the interrupt signal even if the corresponding FEC_EIMR bit is cleared.

Table continues on the next page...

FEC_EIMR field descriptions (continued)

Field	Description
	0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
27 TXF	Interrupt mask. Each bit corresponds to an interrupt source defined by the FEC_EIR register. The corresponding FEC_EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the FEC_EIR samples the signal generated by the interrupting source. The corresponding FEC_EIR bit reflects the state of the interrupt signal even if the corresponding FEC_EIMR bit is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
26 TXB	Interrupt mask. Each bit corresponds to an interrupt source defined by the FEC_EIR register. The corresponding FEC_EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the FEC_EIR samples the signal generated by the interrupting source. The corresponding FEC_EIR bit reflects the state of the interrupt signal even if the corresponding FEC_EIMR bit is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
25 RXF	Interrupt mask. Each bit corresponds to an interrupt source defined by the FEC_EIR register. The corresponding FEC_EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the FEC_EIR samples the signal generated by the interrupting source. The corresponding FEC_EIR bit reflects the state of the interrupt signal even if the corresponding FEC_EIMR bit is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
24 RXB	Interrupt mask. Each bit corresponds to an interrupt source defined by the FEC_EIR register. The corresponding FEC_EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the FEC_EIR samples the signal generated by the interrupting source. The corresponding FEC_EIR bit reflects the state of the interrupt signal even if the corresponding FEC_EIMR bit is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
23 MII	Interrupt mask. Each bit corresponds to an interrupt source defined by the FEC_EIR register. The corresponding FEC_EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the FEC_EIR samples the signal generated by the interrupting source. The corresponding FEC_EIR bit reflects the state of the interrupt signal even if the corresponding FEC_EIMR bit is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
22 EBERR	Interrupt mask. Each bit corresponds to an interrupt source defined by the FEC_EIR register. The corresponding FEC_EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the FEC_EIR samples the signal generated by the interrupting source. The corresponding FEC_EIR bit reflects the state of the interrupt signal even if the corresponding FEC_EIMR bit is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.

Table continues on the next page...

FEC_EIMR field descriptions (continued)

Field	Description
21 LC	Interrupt mask. Each bit corresponds to an interrupt source defined by the FEC_EIR register. The corresponding FEC_EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the FEC_EIR samples the signal generated by the interrupting source. The corresponding FEC_EIR bit reflects the state of the interrupt signal even if the corresponding FEC_EIMR bit is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
20 RL	Interrupt mask. Each bit corresponds to an interrupt source defined by the FEC_EIR register. The corresponding FEC_EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the FEC_EIR samples the signal generated by the interrupting source. The corresponding FEC_EIR bit reflects the state of the interrupt signal even if the corresponding FEC_EIMR bit is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
19 UN	Interrupt mask. Each bit corresponds to an interrupt source defined by the FEC_EIR register. The corresponding FEC_EIMR bit determines whether an interrupt condition can generate an interrupt. At every system clock, the FEC_EIR samples the signal generated by the interrupting source. The corresponding FEC_EIR bit reflects the state of the interrupt signal even if the corresponding FEC_EIMR bit is cleared. 0 The corresponding interrupt source is masked. 1 The corresponding interrupt source is not masked.
18–0 Reserved	This read-only field is reserved and always has the value zero. Reserved, read as 0

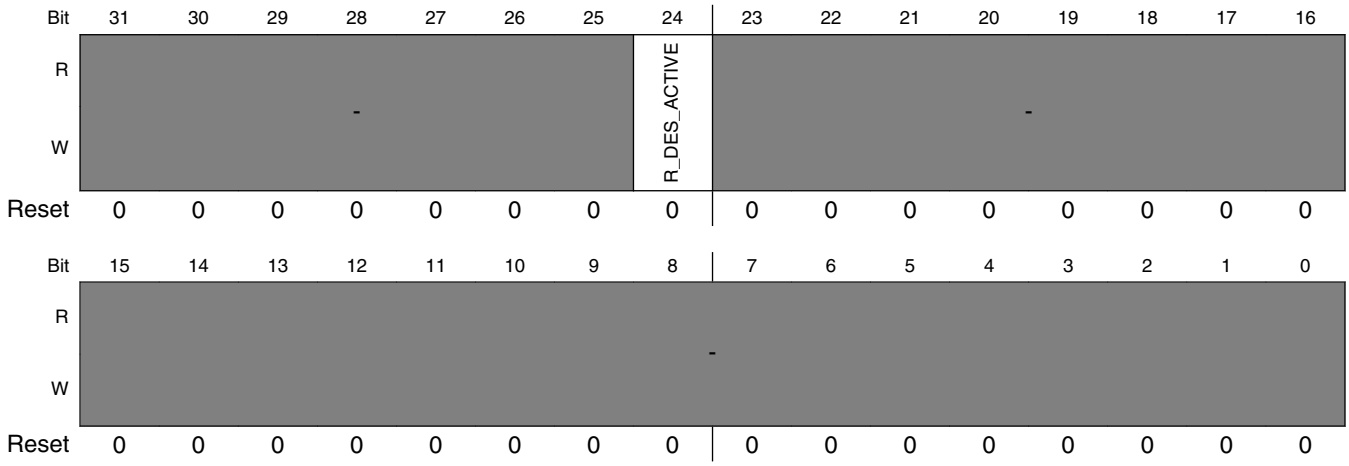
28.5.6 Receive descriptor active register (FEC_RDAR)

FEC_RDAR is a user-writeable command register which indicates that the receive descriptor ring has been updated, and that empty receive buffers have been produced by the driver with the empty bit set.

The FEC_RDAR[R_DES_ACTIVE] bit is set whenever the register is written, independent of the data actually written by the user. When set, the FEC polls the receive descriptor ring and processes receive frames (provided FEC_ECR[ETHER_EN] is also set to 1). After the FEC polls a receive descriptor whose empty bit is not set, then the FEC clears the FEC_RDAR[R_DES_ACTIVE] bit and ceases receive descriptor ring polling until the user sets the bit again, signifying that additional descriptors have been placed into the receive descriptor ring.

The FEC_RDAR is cleared at reset, and when FEC_ECR[ETHER_EN] is cleared.

Address: FEC_RDAR is 63FE_C000h base + 10h offset = 63FE_C010h



FEC_RDAR field descriptions

Field	Description
31–25 -	Reserved, read as 0
24 R_DES_ACTIVE	Set to one when this register is written, regardless of the value written. Cleared by the FEC device when the FEC polls a receive descriptor whose empty bit is not set. Also cleared when FEC_ECR[ETHER_EN] is cleared.
23–0 -	Reserved, read as 0

28.5.7 Transmit descriptor active register (FEC_TDAR)

The FEC_TDAR is a command register, written to by the user, to indicate that the transmit descriptor ring has been updated (transmit buffers have been produced by the driver with the ready bit set in the buffer descriptor).

Whenever the register is written the FEC_TDAR[X_DES_ACTIVE] bit is set to 1, independent of the data actually written by the user. When set, the FEC polls the transmit descriptor ring and process transmit frames (provided FEC_ECR[ETHER_EN] is also set to 1). After the FEC polls a transmit descriptor whose ready bit is not set, then the FEC clears the FEC_TDAR[X_DES_ACTIVE] bit and ceases transmit descriptor ring polling until the user sets the bit again, signifying additional descriptors have been placed into the transmit descriptor ring.

The FEC_TDAR is cleared at reset, when FEC_ECR[ETHER_EN] is cleared, or when FEC_ECR[RESET] is set to 1.

Address: FEC_TDAR is 63FE_C000h base + 14h offset = 63FE_C014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	-														ETHER_EN	RESET
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FEC_ECR field descriptions

Field	Description
31–2 -	Reserved.
1 ETHER_EN	When this bit is set, the FEC is enabled, and reception and transmission are possible. When this bit is cleared, reception is immediately stopped and transmission is stopped after a bad CRC is appended to any currently transmitted frame. The buffer descriptor(s) for an aborted transmit frame are not updated after clearing this bit. When ETHER_EN is cleared, the DMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers. The ETHER_EN bit is altered by hardware under the following conditions: FEC_ECR[RESET] is set by software, in which case ETHER_EN is cleared an error condition causes the FEC_EIR[EBERR] bit to set, in which case ETHER_EN is cleared
0 RESET	When this bit is set, the equivalent of a hardware reset is performed but it is local to the FEC_ ETHER_EN is cleared and all other FEC registers take their reset values. Also, any transmission/ reception currently in progress is abruptly aborted. This bit is automatically cleared by hardware during the reset sequence. The reset sequence takes approximately 8 system clock cycles after RESET is written with a 1.

28.5.9 MII management frame register (FEC_MMFR)

The FEC_MMFR is used to communicate with the attached MII compatible PHY device(s), providing read/write access to their MII registers. Performing a write to FEC_MMFR causes a management frame to be generated unless the MII-SPEED field of the FEC_MSCR has been set to 0, in which case FEC_MSCR is set to a non-zero value and an MII frame is generated with the data previously written to FEC_MMFR. This allows FEC_MMFR and FEC_MSCR to be programmed in either order if the MII-SPEED field of FEC_MSCR is zero (for further details see MII speed control register (FEC_MSCR)).

The FEC_MMFR does not reset to a definite value.

To perform a read or write operation on the MII Management Interface, the FEC_MMFR must be written to by the user. To generate a valid read or write management frame, the ST field must be written with a 01 pattern, and the TA field must be written with a 10. If other patterns are written to these fields, a frame is generated but does not comply with the IEEE 802.3 MII definition.

To generate an IEEE 802.3-compliant MII management interface write frame (write to a PHY register), the user must write {01 01 PHYAD REGAD 10 DATA} to the bit fields of the FEC_MMFR, as shown in MII management frame register (FEC_MMFR). Writing this pattern causes the control logic to shift out the data in the FEC_MMFR following a preamble generated by the control state machine. During this time the contents of the FEC_MMFR is altered as the contents are serially shifted and is unpredictable if read by

the user. After the write management frame operation has completed, the MII interrupt is generated. At this time the contents of the FEC_MMFR matches the original value written.

To generate an MII management interface read frame (read a PHY register) the user must write {01 10 PHYAD REGAD 10 XXXX} to the bit fields of the FEC_MMFR shown in MII management frame register (FEC_MMFR) (the contents of the 4-bit DATA field are arbitrary). Writing this pattern causes the control logic to shift out the data in the FEC_MMFR following a preamble generated by the control state machine. During this time the contents of the FEC_MMFR is altered as the contents are serially shifted, and is unpredictable if read by the user. After the read management frame operation has completed, the MII interrupt is generated. At this time the contents of the FEC_MMFR matches the original value written except for the DATA field whose contents have been replaced by the value read from the PHY register.

If the FEC_MMFR is written to while frame generation is in progress, the frame contents is altered. Software uses the MII interrupt to avoid writing to the FEC_MMFR while frame generation is in progress.

Address: FEC_MMFR is 63FE_C000h base + 40h offset = 63FE_C040h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

* Notes:
- u = Unaffected by reset.

FEC_MMFR field descriptions

Field	Description
31–30 ST	Start of frame delimiter. These bits must be programmed to 01 for a valid MII management frame.
29–28 OP	Operation code. This field must be programmed to 10 (read) or 01 (write) to generate a valid MII management frame. A value of 11 produces "read" frame operation while a value of 00 produces "write" frame operation, but these frames is not MII compliant.
27–23 PA	PHY address. This field specifies one of up to 32 attached PHY devices.
22–18 RA	Register address. This field specifies one of up to 32 registers within the specified PHY device.
17–16 TA	Turn around. This field must be programmed to 10 to generate a valid MII management frame.
15–0 DATA	Management frame data. This is the field for data to be written to or read from the PHY register.

28.5.10 MII speed control register (FEC_MSCR)

The FEC_MSCR provides control of the frequency of the MII clock (FEC_MDC signal), and allows a preamble drop on the MII management frame.

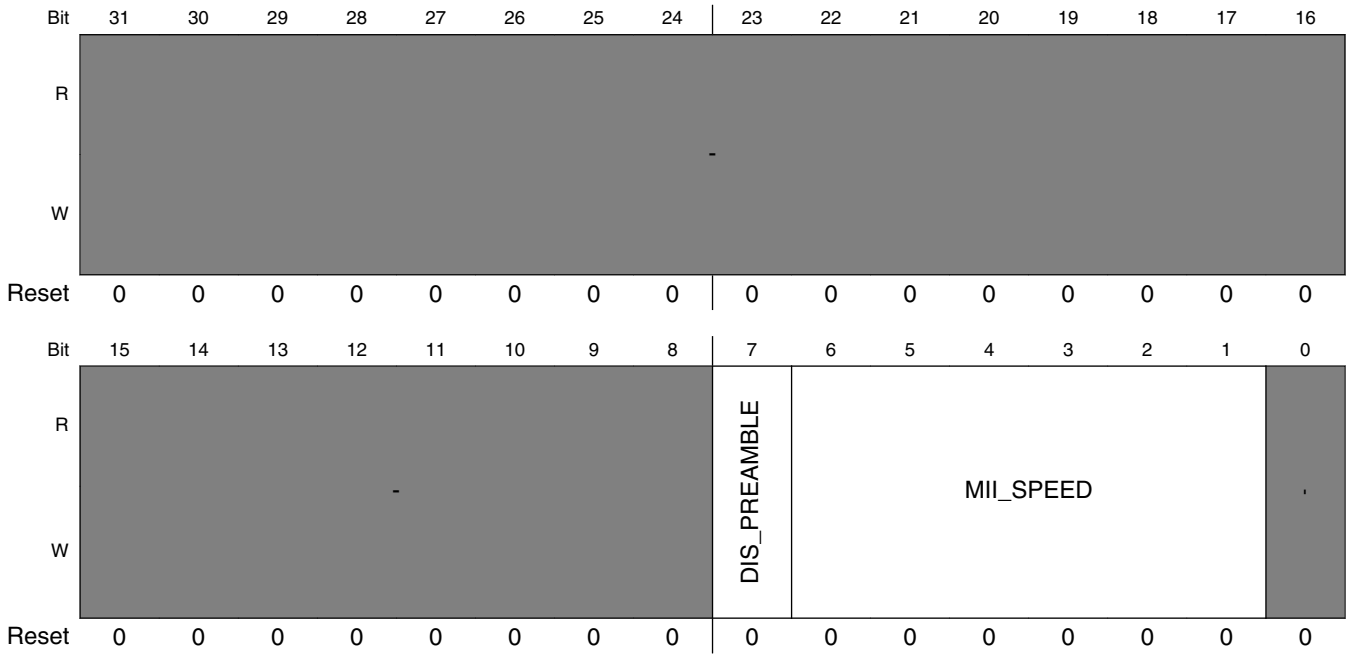
The MII_SPEED field must be programmed with a value to provide an FEC_MDC frequency of less than or equal to 2.5 MHz to be compliant with the IEEE 802.3 MII specification. The MII_SPEED must be set to a non-zero value in order to generate a read or write management frame. After the management frame is complete the FEC_MSCR can optionally be set to zero to turn off the FEC_MDC. The FEC_MDC generated has a 50% duty cycle except when MII_SPEED is changed during operation (change takes effect following either a rising or falling edge of FEC_MDC).

The FEC_MDC frequency depends on both the system clock frequency and the MII_SPEED register. If the system clock is 25 MHz, programming the MII_SPEED register to 0x0000_0005 results in an FEC_MDC frequency of 25 MHz * 1/10 = 2.5 MHz. A table showing optimum values for MII_SPEED for different system clock frequencies is provided below.

Table 28-25. Programming Examples for FEC_MSCR

System Clock Frequency	MII_SPEED (field in reg)	FEC_MDC frequency
25 MHz	0x5	2.5 MHz
33 MHz	0x7	2.36 MHz
40 MHz	0x8	2.5 MHz
50 MHz	0xA	2.5 MHz
66 MHz	0xD	2.54 MHz

Address: FEC_MSCR is 63FE_C000h base + 44h offset = 63FE_C044h



FEC_MSCR field descriptions

Field	Description
31–8 -	Reserved, read as 0
7 DIS_PREAMBLE	Asserting this bit causes preamble (0xFFFF_FFFF) not to be prepended to the MII management frame. The MII standard allows the preamble to be dropped if the attached PHY device(s) does not require it.
6–1 MII_SPEED	MII_SPEED controls the frequency of the MII management interface clock (FEC_MDC) relative to the system clock. A value of 0 in this field "turns off" the FEC_MDC and leave it in low voltage state. Any non-zero value results in the FEC_MDC frequency of 1/(MII_SPEED*2) of the system clock frequency.
0 -	Reserved, read as 0

28.5.11 MIB control register (FEC_MIBC)

The MIB control register is a read/write register used to provide control of and to observe the state of the Message Information Block (MIB). This register is accessed by user software if there is a need to disable the MIB operation. For example, in order to clear all MIB counters in RAM the user disables the MIB, then clears all the MIB RAM locations, then enables the MIB. The MIB_DISABLE bit is reset to 1. See MIB Counters Memory Map for the locations of the MIB counters.

Address: FEC_MIBC is 63FE_C000h base + 64h offset = 63FE_C064h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	MIB_DISABLE	MB_IDLE	-													
W																
Reset	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	-															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

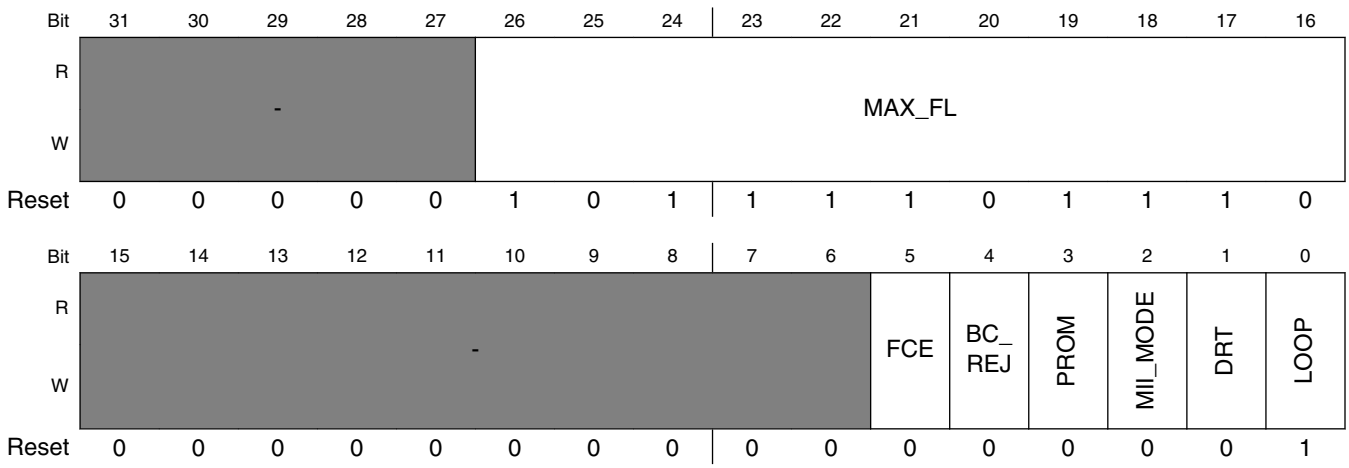
FEC_MIBC field descriptions

Field	Description
31 MIB_DISABLE	A read/write control bit. If set, the MIB logic halts and not update any MIB counters.
30 MB_IDLE	A read-only status bit. If set the MIB block is not currently updating any MIB counters.
29–0 -	Reserved.

28.5.12 Receive control register (FEC_RCR)

The FEC_RCR is programmed by the user, and controls the operational mode of the receive block. It can only be written to when FEC_ECR[ETHER_EN] = 0 (that is, during initialization).

Address: FEC_RCR is 63FE_C000h base + 84h offset = 63FE_C084h



FEC_RCR field descriptions

Field	Description
31–27 -	Reserved, read as 0
26–16 MAX_FL	Maximum frame length. Resets to decimal 1518. Length is measured starting at DA and includes the CRC at the end of the frame. Transmit frames longer than MAX_FL causes the BABT interrupt to occur. Receive Frames longer than MAX_FL causes the BABR interrupt to occur and sets the LG bit in the end of frame receive buffer descriptor. The recommended default value to be programmed by the user is 1518 or 1522 (if VLAN Tags are supported).
15–6 -	Reserved, read as 0
5 FCE	Flow control enable. When FCE is set to 1, the receiver detects pause frames. Upon pause frame detection, the transmitter stops transmitting data frames for a given duration.
4 BC_REJ	Broadcast frame reject. When BC_REJ is set to 1, frames with DA (destination address) = 0xFF_FF_FF_FF_FF_FF are rejected unless the PROM bit is set to 1. If both BC_REJ and PROM are set to 1, then frames with broadcast DA is accepted and the M (MISS) bit is set in the receive buffer descriptor.
3 PROM	Promiscuous mode. All frames are accepted regardless of address matching.
2 MII_MODE	Media independent interface mode. Selects external interface mode. Setting this bit to one selects MII mode, setting this bit equal to zero selects 7-wire mode (used only for serial 10 Mbps). This bit controls the interface mode for both transmit and receive blocks.
1 DRT	Disable receive on transmit.

Table continues on the next page...

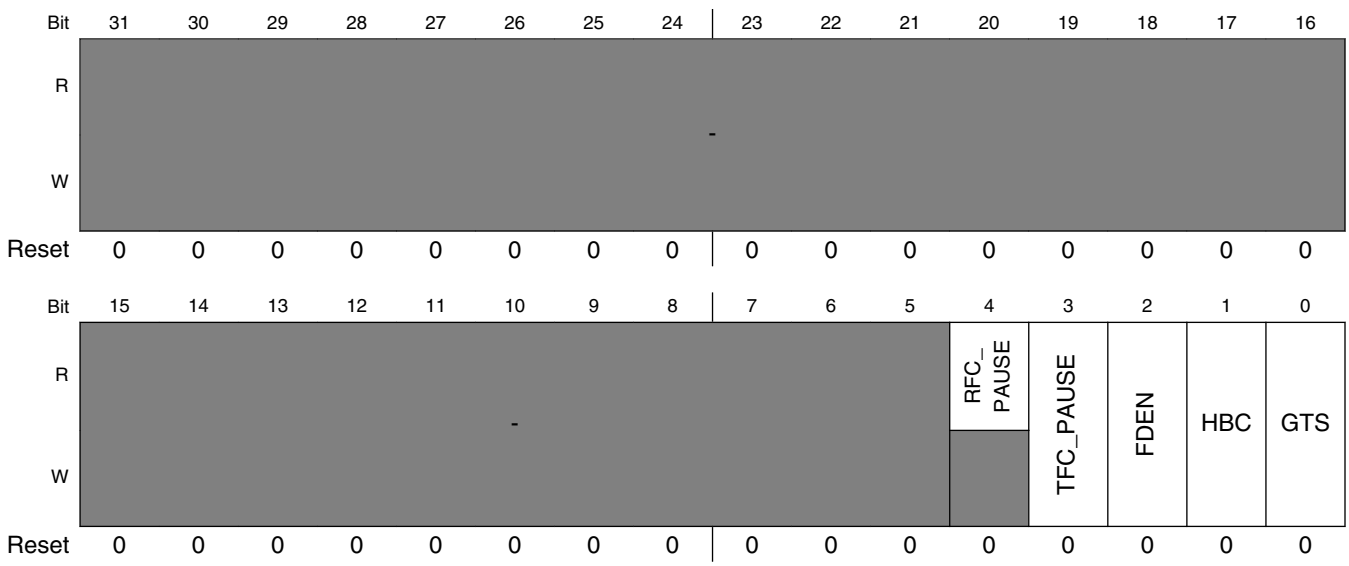
FEC_RCR field descriptions (continued)

Field	Description
	0 Receive path operates independently of transmit (use for full-duplex or to monitor transmit activity in half-duplex mode). 1 Disable reception of frames while transmitting (normally used for half-duplex mode).
0 LOOP	Internal loopback.When LOOP is set to 1, transmitted frames are looped back internal to the device and the transmit output signals are not asserted. The system clock is substituted for the FEC_TX_CLK when LOOP is set to 1. DRT must be set to zero when setting LOOP to 1.

28.5.13 Transmit control register (FEC_TCR)

This register is read/write, and is written by the user to configure the transmit block. Bits [2:1] must only be modified when FEC_ECR[ETHER_EN] = 0 (that is, during initialization). This register is cleared at system reset.

Address: FEC_TCR is 63FE_C000h base + C4h offset = 63FE_C0C4h



FEC_TCR field descriptions

Field	Description
31–5 -	Reserved read as 0
4 RFC_PAUSE	Receive frame control pause. This read-only status bit is set to 1 when a full-duplex flow control pause frame has been received and the transmitter is paused for the duration defined in this pause frame. This bit automatically clears when the pause duration is complete. 0 Transmitter is not paused 1 Transmitter is paused after reception of full-duplex flow control pause frame
3 TFC_PAUSE	Transmit frame control pause. When this bit is set to 1, a pause frame is transmitted according to the following steps:

Table continues on the next page...

FEC_TCR field descriptions (continued)

Field	Description
	1. FEC stops transmission of data frames after the current transmission is complete. 2. The GRA interrupt in the FEC_EIR register is asserted. 3. With transmission of data frames stopped, the FEC transmits a MAC control pause frame. 4. The FEC clears the TFC_PAUSE bit and resume transmitting data frames. The FEC can still transmit a MAC control pause frame when the transmitter is paused due to user assertion of GTS or reception of a pause frame. 0 No pause frame is transmitted 1 Pause frame is transmitted
2 FDEN	Full duplex enable. When FDEN is set to 1, frames are transmitted independent of carrier sense and collision inputs. This bit must only be modified when ETHER_EN is cleared. 0 Full duplex is not enabled 1 Full duplex is enabled
1 HBC	Heartbeat control. When HBC is set to 1, the heartbeat check is performed after end of transmission and the HB bit in the status register is set if the collision input does not assert within the heartbeat window. This bit must only be modified when ETHER_EN is cleared. 0 Heartbeat check is not performed after end of transmission 1 Heartbeat check is performed after end of transmission
0 GTS	Graceful transmit stop. When GTS is set to 1, the FEC stops transmission after any frame that is currently being transmitted is complete and the GRA interrupt in the FEC_EIR register is asserted. If frame transmission is not currently underway, the GRA interrupt is asserted immediately. After transmission has completed, a "restart" can be accomplished by clearing the GTS bit. The next frame in the transmit FIFO is then transmitted. If an early collision occurs during transmission when GTS = 1, transmission stops after the collision. The frame is transmitted again after GTS is cleared. There can be old frames in the transmit FIFO that is transmitted when GTS is reasserted. To avoid this, clear FEC_ECR[ETHER_EN] following the GRA interrupt. 0 Graceful transmit stop is not enabled 1 Graceful transmit stop is enabled.

28.5.14 Physical address low register (FEC_PALR)

The FEC_PALR is written by the user, and contains the lower 32 bits (bytes 0,1,2,3) of the 48-bit address used in the address recognition process to check for possible match between the DA field of receive frames and an individual DA. This register is also used for bytes 0 through 3 of the 6-byte source address field when transmitting pause frames. This register is unaffected by reset and must be initialized by the user.

Address: FEC_PALR is 63FE_C000h base + E4h offset = 63FE_C0E4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

FEC_PALR field descriptions

Field	Description
31–0 PADDR1	Bytes 0 (bits 31:24), 1 (bits 23:16), 2 (bits 15:8) and 3 (bits 7:0) of the 6-byte individual address to be used for exact match, and the source address field in pause frames.

28.5.15 Physical address upper register (FEC_PAUR)

The FEC_PAUR is written by the user, and contains the upper 16 bits (bytes 4 and 5) of the 48-bit address used in the address recognition process to check for possible match between the DA field of receive frames and an individual DA. In addition, this register is used in bytes 4 and 5 of the 6-byte source address field when transmitting pause frames. Bits 15:0 of FEC_PAUR contain a constant type field (0x8808) used for transmission of pause frames. This register is unaffected by reset, and bits 31:16 must be initialized by the user.

Address: FEC_PAUR is 63FE_C000h base + E8h offset = 63FE_C0E8h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

FEC_PAUR field descriptions

Field	Description
31–16 PADDR2	Bytes 4 (bits 31:24) and 5 (bits 23:16) of the 6-byte individual address to be used for exact match, and the source address field in pause frames.
15–0 TYPE	Type field in pause frames. This field has a constant value of 0x8808.

28.5.16 Opcode and pause duration register (FEC_OPDR)

FEC_OPDR contains the 16-bit Opcode, and 16-bit pause duration fields used in transmission of a pause frame. The Opcode field is a constant value, 0x0001. When another node detects a pause frame, that node pauses transmission for the duration specified in the pause duration field. This register is not reset and must be initialized by the user.

Address: FEC_OPDR is 63FE_C000h base + ECh offset = 63FE_C0ECh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

FEC_GALR field descriptions

Field	Description
31–0 GADDR2	The GADDR2 register contains the lower 32 bits of the 64-bit hash table used in the address recognition process for receive frames with a multicast address. Bit 31 of GADDR2 contains hash index bit 31. Bit 0 of GADDR2 contains hash index bit 0.

28.5.21 Transmit FIFO watermark register (FEC_TFWR)

The FEC_TFWR is programmed by the user to control the amount of data required in the transmit FIFO before transmission of a frame can begin. This allows the user to minimize transmit latency (FEC_TFWR[1:0] = 0n) or allow for larger bus access latency (FEC_TFWR[1:0] = 11) due to contention for the system bus. Setting the watermark to a high value minimizes the risk of transmit FIFO underrun due to contention for the system bus. In some use cases the byte counts associated with the FEC_TFWR field need to be modified to match system requirements, such as the worst-case bus access latency by the transmit data DMA channel.

Address: FEC_TFWR is 63FE_C000h base + 144h offset = 63FE_C144h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

FEC_TFWR field descriptions

Field	Description
31–2 -	Reserved, read as 0

Table continues on the next page...

FEC_TFWR field descriptions (continued)

Field	Description
1–0 X_WMRK	Number of bytes written to transmit FIFO before transmission of a frame begins 0x 64 bytes written 10 128 bytes written 11 192 bytes written

28.5.22 FIFO receive bound register (FEC_FRBR)

The FEC_FRBR register can be read to determine the upper address bound of the FIFO RAM. Drivers can use this value, along with the FEC_FRSR to appropriately divide the available FIFO RAM between the transmit and receive data paths.

Address: FEC_FRBR is 63FE_C000h base + 14Ch offset = 63FE_C14Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	0	0	0	0

FEC_FRBR field descriptions

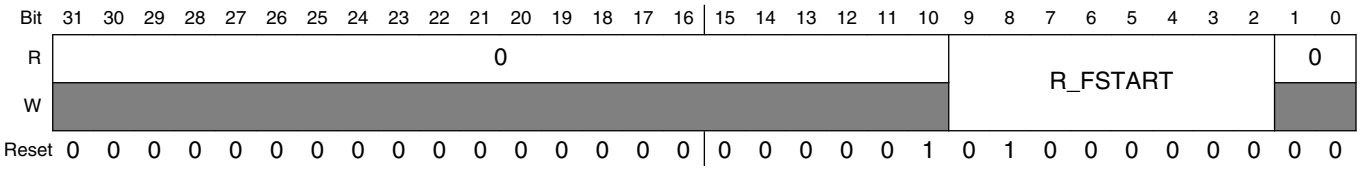
Field	Description
31–10 Reserved	This read-only field is reserved and always has the value zero. Reserved, read as 0 (except bit 10, which is read as 1).
9–2 R_BOUND	Read-only. Highest valid FIFO RAM address.
1–0 Reserved	This read-only field is reserved and always has the value zero. Reserved, read as 0.

28.5.23 FIFO receive FIFO start registers (FEC_FRSR)

FEC_FRSR is an 8-bit register programmed by the user to indicate the starting address of the receive FIFO. FEC_FRSR marks the boundary between the transmit and receive FIFOs. The transmit FIFO uses addresses from the start of the FIFO to the location four bytes before the address programmed into the FEC_FRSR. The receive FIFO uses the addresses from FEC_FRSR to FEC_FRBR inclusive.

The default value of the receive FIFO starting address is 0x40. This is the value assigned by hardware at reset.

Address: FEC_FRSR is 63FE_C000h base + 150h offset = 63FE_C150h



FEC_FRSR field descriptions

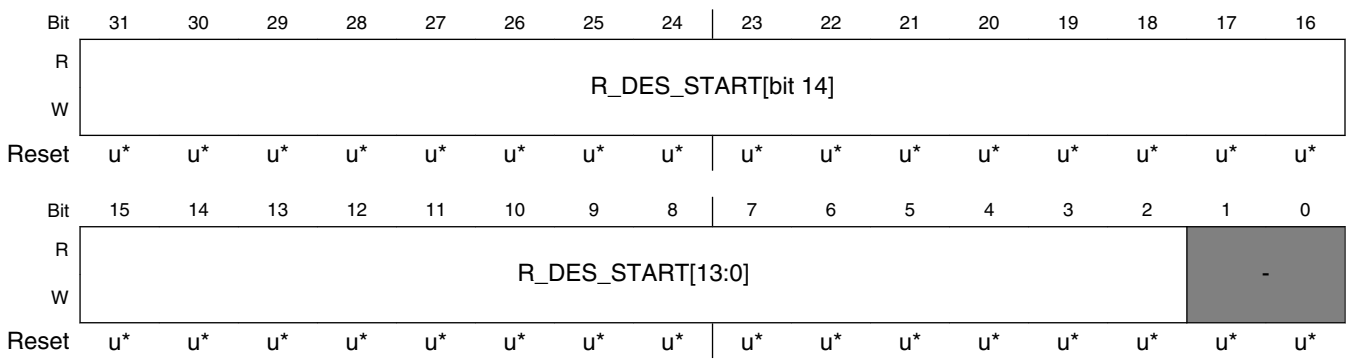
Field	Description
31–10 Reserved	This read-only field is reserved and always has the value zero. Reserved, read as 0 (except bit 10, which is read as 1).
9–2 R_FSTART	Address of first receive FIFO location. Acts as delimiter between receive and transmit FIFOs.
1–0 Reserved	This read-only field is reserved and always has the value zero. Reserved, read as 0.

28.5.24 Receive buffer descriptor ring start register (FEC_ERDSR)

The register is written by the user, and provides a pointer to the start of the circular receive buffer descriptor queue in external memory. This pointer must be 128-bit aligned (that is, evenly divisible by 16).

This register is unaffected by reset and must be initialized by the user prior to operation.

Address: FEC_ERDSR is 63FE_C000h base + 180h offset = 63FE_C180h



* Notes:

- u = Unaffected by reset.

FEC_ERDSR field descriptions

Field	Description
31–2 R_DES_START	Pointer to start of receive buffer descriptor queue.
1–0 -	Reserved, read as 0

28.5.25 Transmit buffer descriptor ring start register (FEC_ETDSR)

The register is written by the user, and provides a pointer to the start of the circular transmit buffer descriptor queue in external memory. This pointer must be 128-bit aligned (that is, evenly divisible by 16).

This register is unaffected by reset and must be initialized by the user prior to operation.

Address: FEC_ETDSR is 63FE_C000h base + 184h offset = 63FE_C184h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	X_DES_START[bit 14]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	X_DES_START[13:0]														-	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

FEC_ETDSR field descriptions

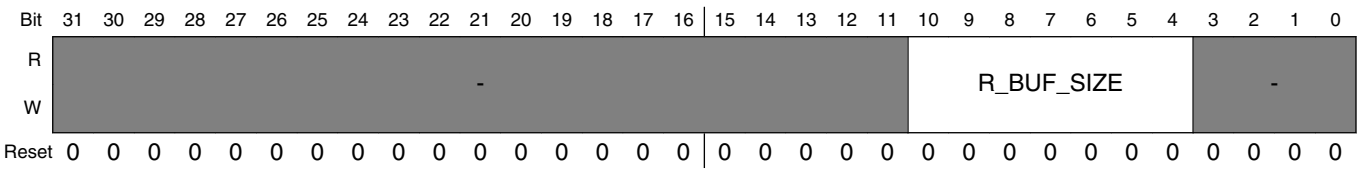
Field	Description
31–2 X_DES_START	Pointer to start of transmit buffer descriptor queue.
1–0 -	Reserved, read as 0

28.5.26 Maximum receive buffer size register (FEC_EMRBR)

The FEC_EMRBR is a user-programmable register which dictates the maximum size of all receive buffers. Note that because receive frames is truncated at 2k-1(2047) bytes, bits 31-11 are not used. The programmed value accounts for the fact that the receive CRC is always written into the last receive buffer. To allow one maximum size frame per buffer, FEC_EMRBR must be set to FEC_RCR[MAX_FL] or larger. The FEC_EMRBR must be evenly divisible by 16. To ensure this, bits 3-0 are forced low, and hence only bits 10-4 are actually used. To minimize bus utilization (descriptor fetches) it is recommended that FEC_EMRBR be greater than or equal to 256 bytes.

The FEC_EMRBR is unaffected by reset, and must be initialized by the user.

Address: FEC_EMRBR is 63FE_C000h base + 188h offset = 63FE_C188h



FEC_EMRBR field descriptions

Field	Description
31–11 -	Reserved, is written to 0 by the host processor.
10–4 R_BUF_SIZE	Receive buffer size.
3–0 -	Reserved, is written to 0 by the host processor.

Chapter 29
General Power Controller (GPC)

29.1 Introduction

GPC is a General Power Control module.

29.1.1 Overview

GPC block includes the following sub-blocks of Advanced Power Saving techniques:

- Two DVFS sub-blocks (ARM platform and peripherals clock/power domains)
- SRPG sub-block for SRPG-ed module: ARM platform

Each of the sub-blocks has its own IP registers. The GPC also includes an arbitration block of DVFS voltage/frequency updates.

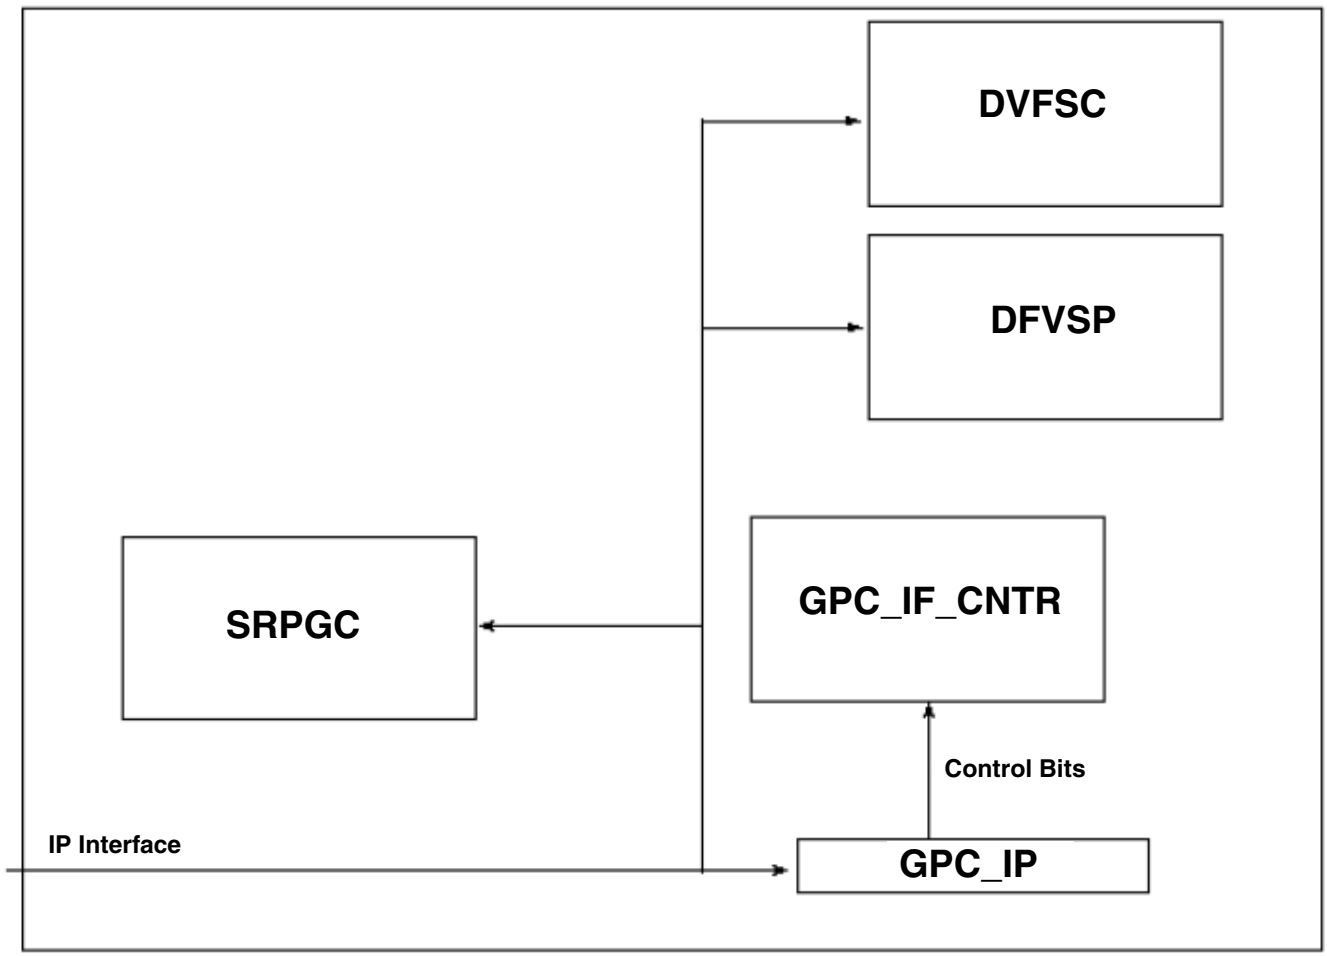


Figure 29-1. GPC Block Diagram

29.1.2 Features

- Simultaneous usage of DVFS of each domain.

- Internal counter for bypass of voltage_ready signal

- Possibility of switching between Configurable SPI (CSPI) usage and I2C Interface (I2C) .

29.2 Functional Description

GPC block includes the following sub-blocks of Advanced Power Saving techniques:

- 2 DVFS sub-blocks (ARM platform and peripherals clock/power domains)
- SRPG sub-block for SRPG-ed module: ARM platform

Each of sub-blocks has its own IP registers. As well, GPC includes an arbitration block of DVFS voltage/frequency updates.

In the following sections the global operation of the sub-blocks is described. For further details of DVFS and SRPG refer appropriate sub-block Block Guide document.

29.2.1 DVFS - Dynamic Voltage & Frequency Scaling

Dynamic Voltage & Frequency Scaling is a well-known technique to reduce power consumption in mobile devices.

In order to improve power saving efficiency, DVFS is applied both on ARM platform domain (DVFSC) and peripherals domain (DVFSP). DVFSC uses mainly ARM's IDLE signal for load monitoring, but also uses s/w writable info as secondary inputs. DVFSP uses hardware accelerators activity signals, bus activity signals and memory activity indicators for load monitoring. Both DVFS load tracking controllers are h/w implemented, providing: high resolution of load tracking (for higher efficiency), no MIPS requirements from ARM platform for continuous operation (more power saving, no additional ARM platform load).

Voltage update requests (to PMIC, via CSPI) may be served in one of the following ways:

- Hardware triggering of CSPI, by GPC
- ARM interrupts serving CSPI

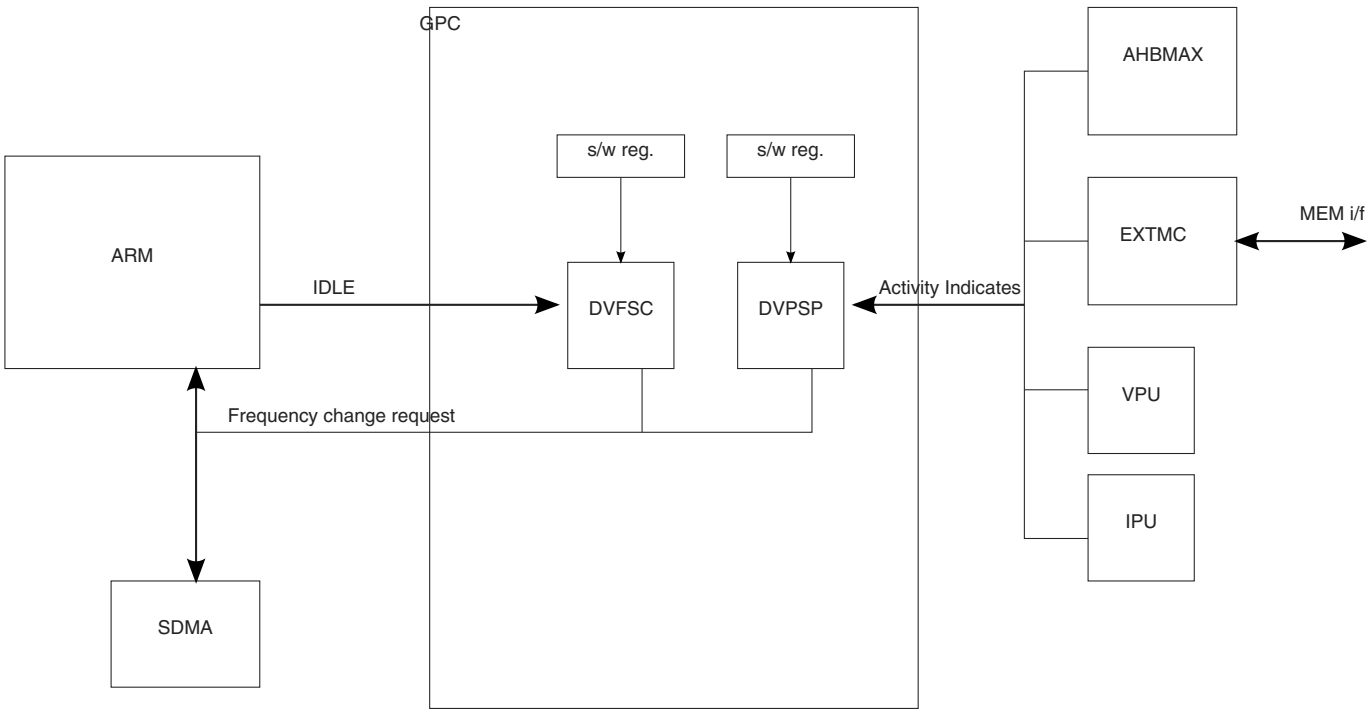

Figure 29-2. DVFS System High Level Diagram

29.2.2 DVFS Change Request Sequence Diagrams

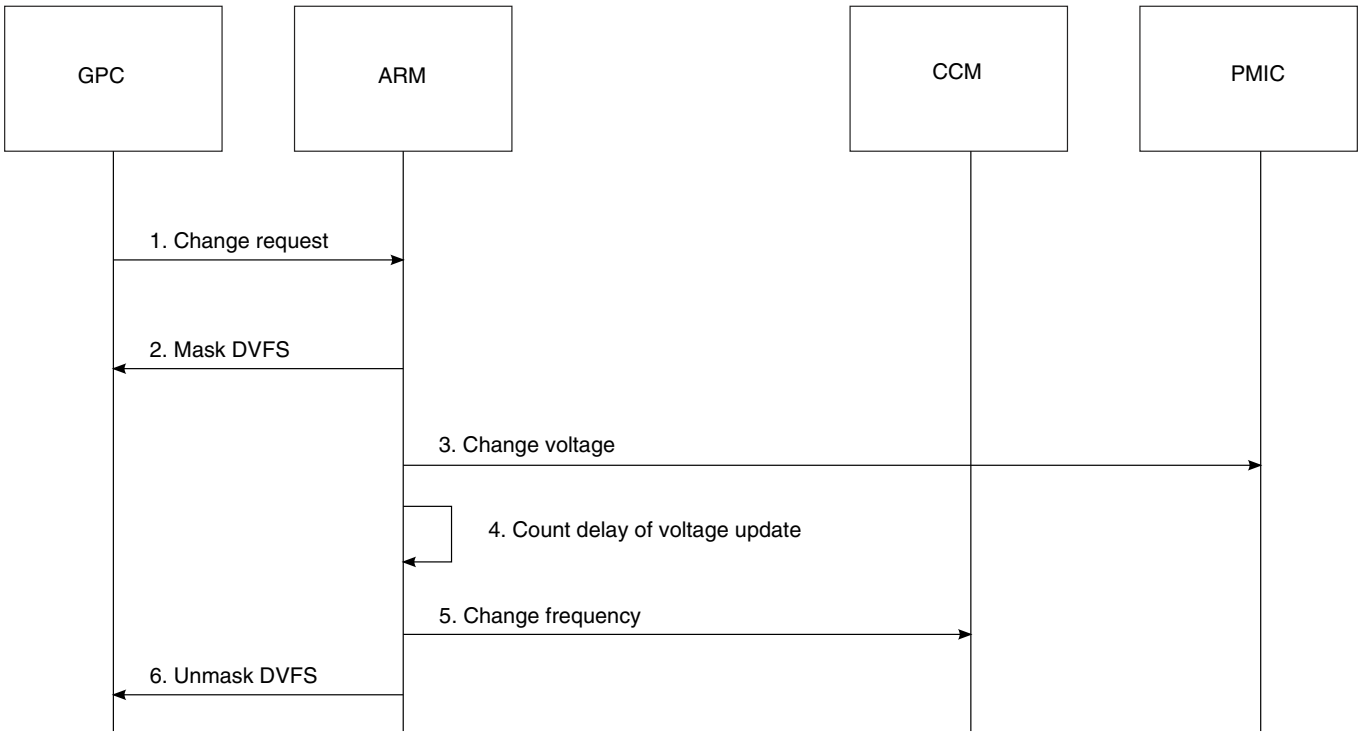

Figure 29-3. DVFS - frequency increase

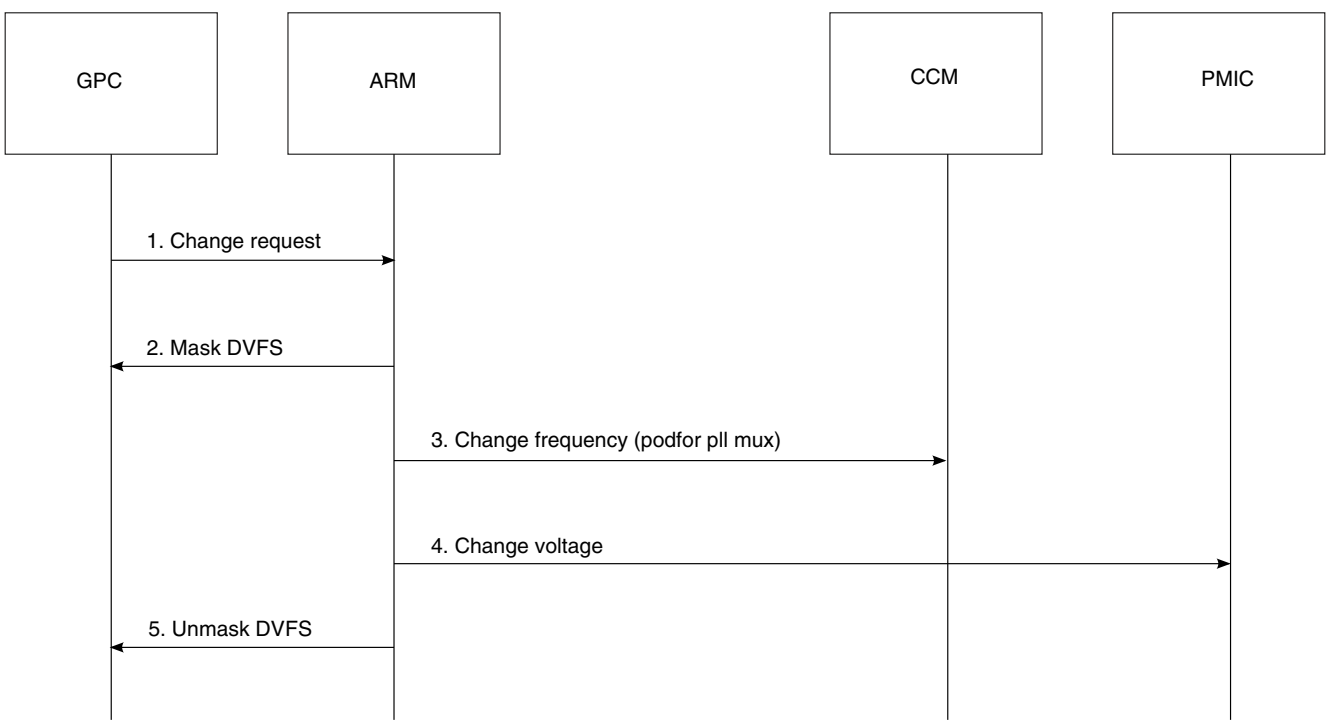

Figure 29-4. DVFS - frequency decrease

DVFSC and DVFSP will have one common interrupt line to ARM and DMA request to SDMA. SDMA (or ARM) will choose only one domain to serve.

DVFSP frequency change will be performed with post-dividers values update only.

DVFSC frequency change can be performed in 2 ways:

- PLL and post-dividers values update
- post-dividers values only update

When PLL update is required, Controller will switch ARM platform clock to another PLL, will wait until the previous PLL is locked on the required frequency, and then will switch the ARM platform clock back to the first PLL.

29.2.3 Frequency / Voltage Change Controller Description

Controller is responsible of correct frequency and voltage update flow.

29.2.3.1 GPC Controller Description

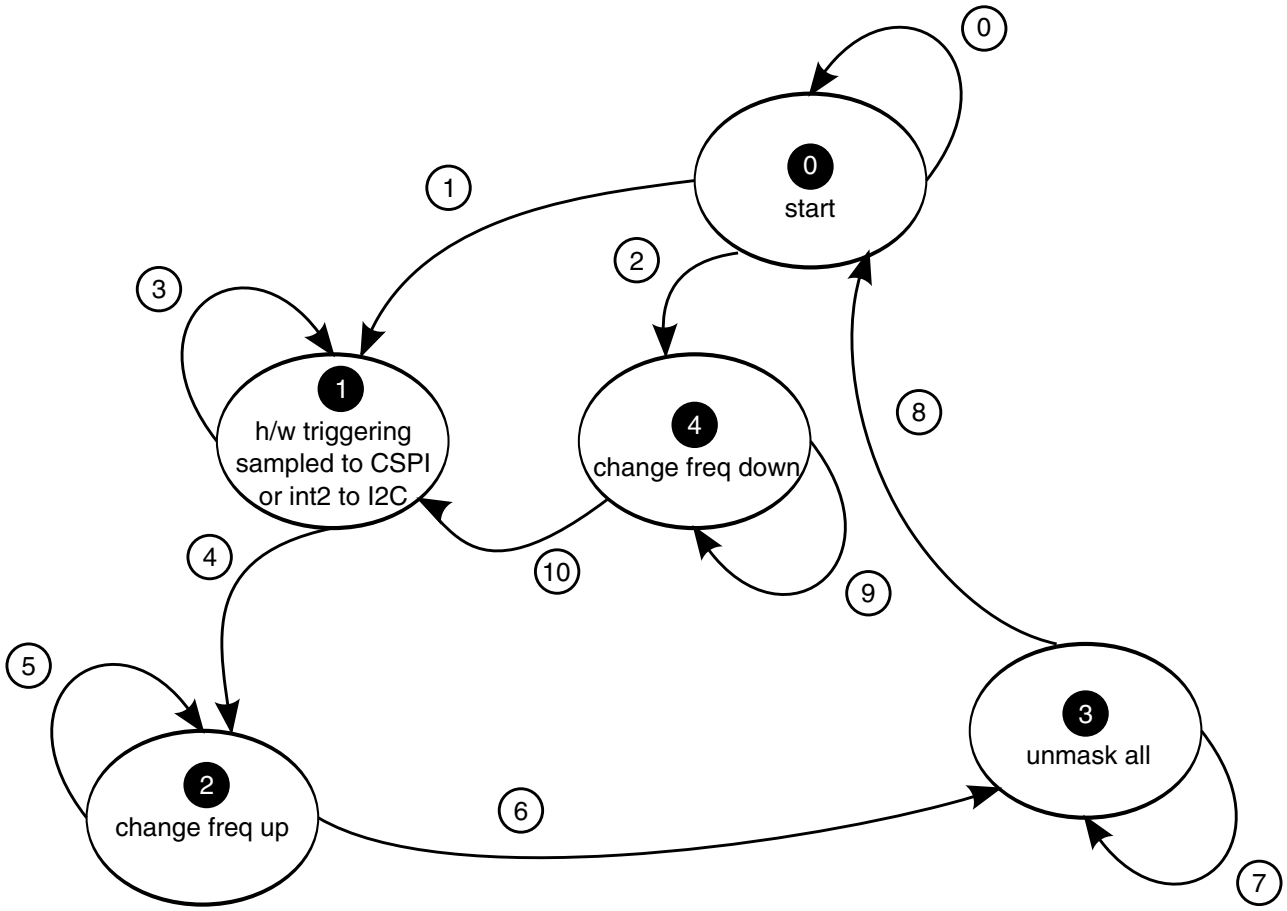

Figure 29-5. GPC DVFS State machine

Table 29-1. GPC Controller Description

Transition	Transition condition	Output
0	not (1)	-

10	(dvfs update dw& clk change ack) | !(dvfs update dw) | !freq_update	-

29.2.3.2 Clock Control Module Frequency Update Controller Description

Additional State Machine is required in CCM to take care about frequency update sequence, as defined below:

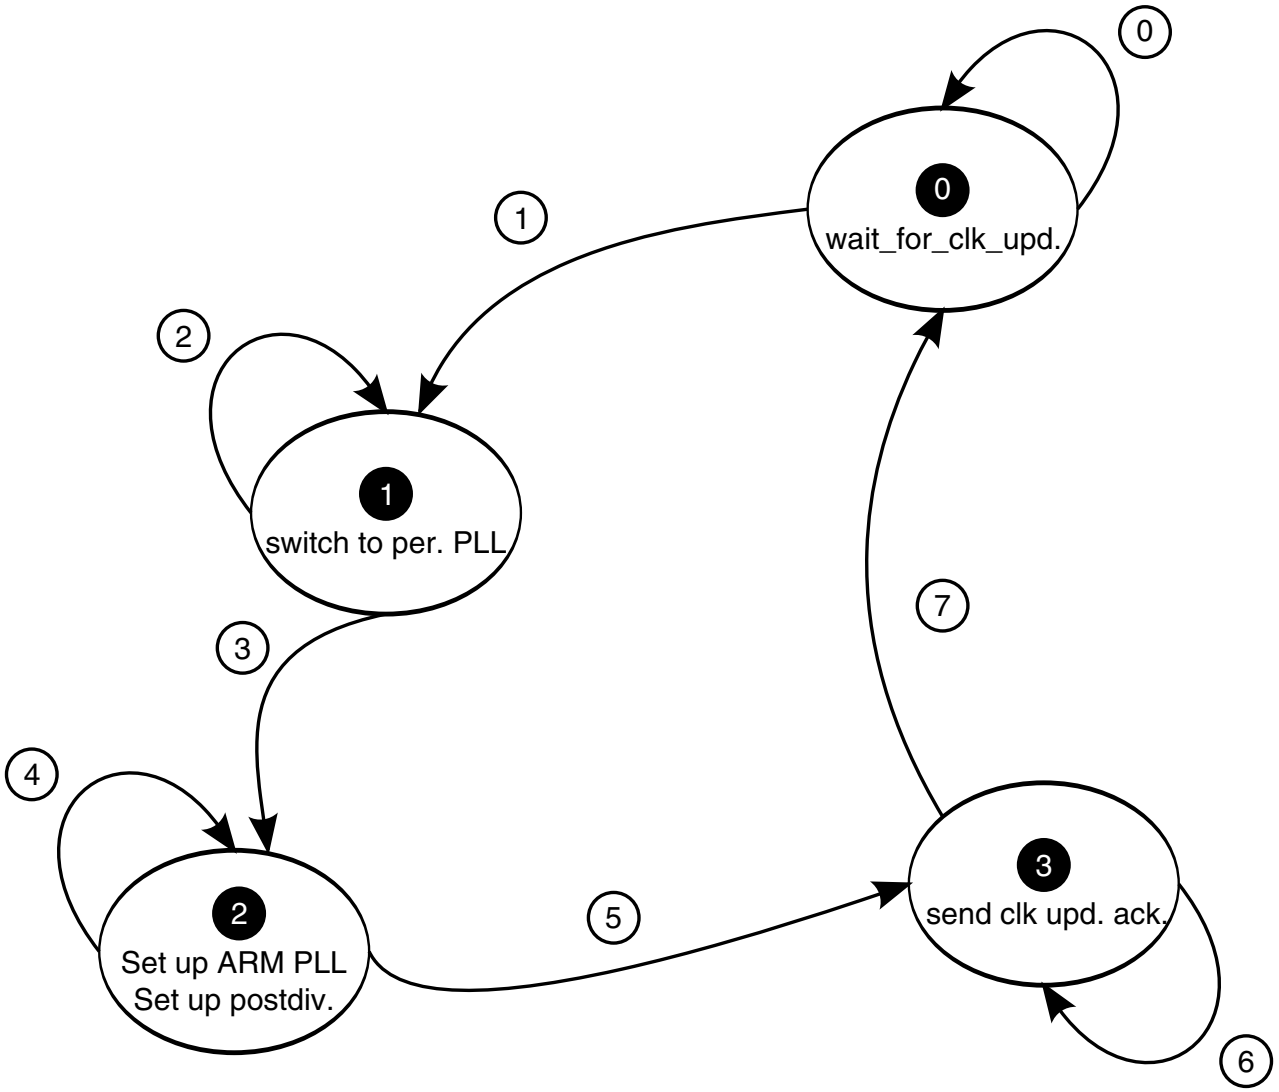

Figure 29-6. CCM Frequency Update Controller

Table 29-2. CCM Frequency Update Controller Description

Transition	Transition condition	Output
0	not (1)	clk upd ack negated
1	clk update request	-
2	not (3)	switch ARM clk to per. PLL
3	clk switched to per. PLL	-
4	not (5)	apply new PLL settings, if needed apply new postdiv settings if needed
5	ARM PLL & postdiv upd ack.	-
6	1 clk	clk update ack to GPC asserted.

Table continues on the next page...

Table 29-2. CCM Frequency Update Controller Description (continued)

Transition	Transition condition	Output
7	not (6)	-

29.2.4 State Retention Power Gating (SRPG)

State Retention Power Gating (SRPG) is an advanced power saving technique - the values of FFs are saved, while the supply for the combinational logic is gated. Such special power gating allows significant power saving during low-power (stand-by) states, when no logical operation is needed. Relatively the simple Power Gating techniques, SRPG allows to restore the state very quickly and continue the processing from the state, sampled before stand-by period.

SRPG Controller manages all the related signals for entering and exiting SRPG state of relevant modules. Not all the modules have SRPG design.

SRPG power down sequence:

CCM sends power down request when the chip enters stop or wait mode. The user should define which modules will be powered down (PGCR registers of corresponding SRPG, bit 0).

SRPG power up sequence:

The modules receive power up request in following order:

NEON and CTA8.

29.2.5 PMIC Interface Requirements for APM Support

PMIC APM interface is done through SPI protocol by enhanced CSPI module with HW triggering. Below is the description of modules requirements for APM support.

- CSPI
  - Will have 16 HW trigger registers.
  - Each register will be 32 bits:
    - 1 bits read/write (always write)
    - 6 bits address
    - 1 bit not used
    - 24 bits data
  - Each register will have an associated signal that starts the transaction to Atlas

- GPC
  - will have a 4-bit select register to select one of 16 HW trigger signals, if CSPI is used.
  - will trigger the signals during DVFS state machine according to select register value.
- PMIC
  - Only one 24-bit register should be updated for voltage change. One CSPI HW trigger will be able to make the change, or I2C will get int2.

Ability to use SDMA for h/w controllers inputs analysis and/or CSPI programming will provide high level of s/w flexibility and will be kept for backup.

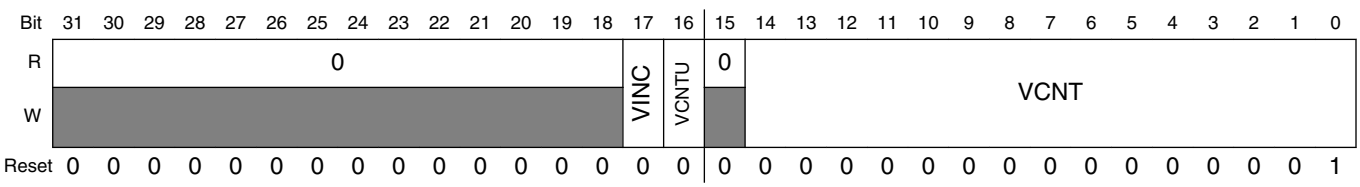
29.3.2 Voltage Counter Register (GPC_VCR)

VCR Register - Voltage Counter Register

Address: GPC_VCR is 53FD_8000h base + 8h offset = 53FD_8008h



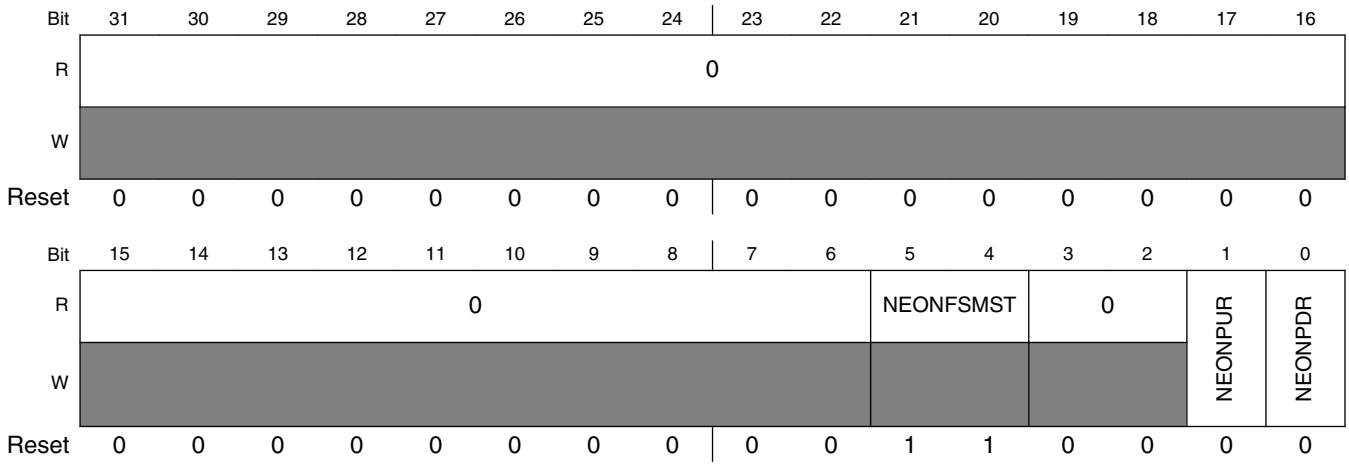
GPC_VCR field descriptions

Field	Description
31–18 Reserved	This read-only field is reserved and always has the value zero. Reserved
17 VINC	Voltage increase 1 Voltage will be increased 0 Voltage will be decreased
16 VCNTU	Voltage Count Used 1 VCNT is used 0 VCNT is not used, "voltage ready" signal of PMIC will be used.
15 Reserved	This read-only field is reserved and always has the value zero. Reserved
14–0 VCNT	Voltage update Count Counting delay of the voltage update, if PMIC's "voltage ready" signal is not used Counter is using SYS_CLK (CKIH) clock

29.3.3 NEON register (GPC_NEON)

NEON Register - Register Control Power for NEON

Address: GPC_NEON is 53FD_8000h base + 10h offset = 53FD_8010h



GPC_NEON field descriptions

Field	Description
31–6 Reserved	This read-only field is reserved and always has the value zero. Reserved
5–4 NEONFSMST	Neon FSM status bits - state of Neon State Machine: 11 Power up acknowledge / Normal state 01 Power down request 00 Power down acknowledge 10 Power up request
3–2 Reserved	This read-only field is reserved and always has the value zero. Reserved
1 NEONPUR	NEON Power Up Request. Assertion causes Neon PowerDown state machine to change state from PowerDown to PowerUp request. Will clear itself after a single clock.
0 NEONPDR	NEON Power Down Request. Assertion starts Neon PowerDown state machine. Will clear itself after a single clock.

Chapter 30
General Purpose Input/Output (GPIO)

30.1 Overview

The general purpose input/output (GPIO) module generates up to 32 signals for general-purpose. A block diagram of the GPIO is shown in Figure 30-1.

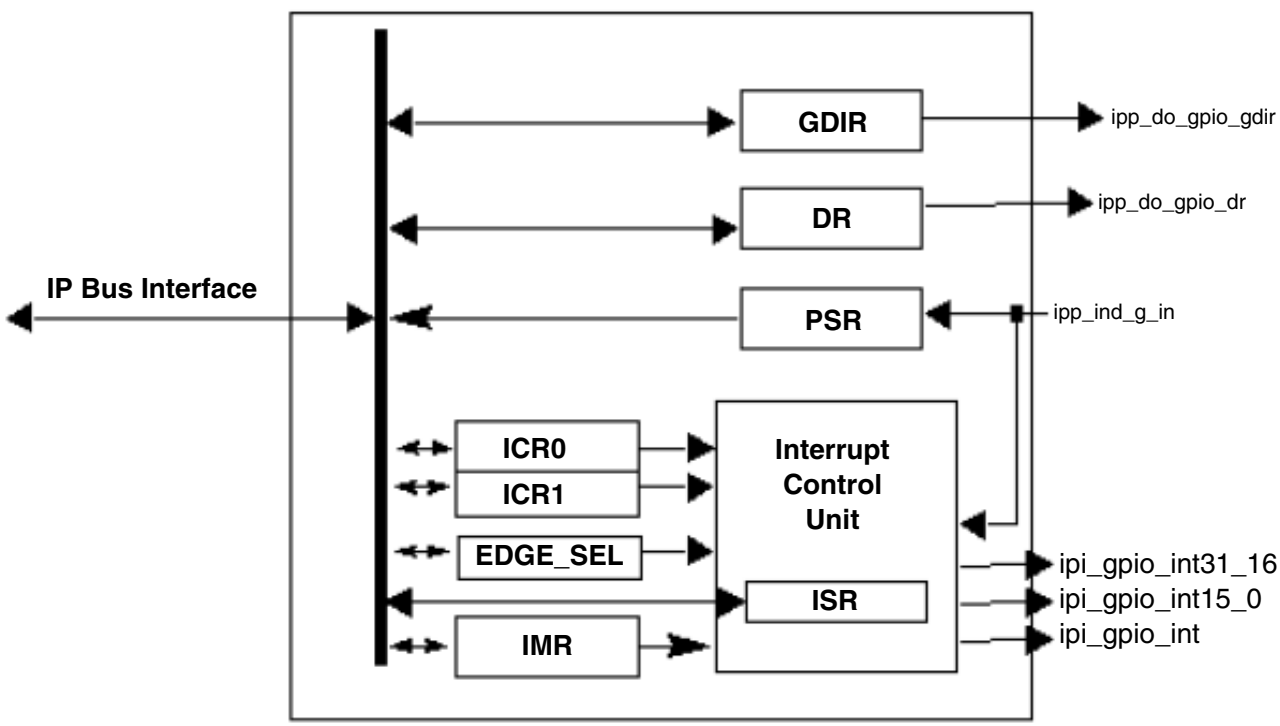


Figure 30-1. GPIO Block Diagram

The GPIO general-purpose input/output peripheral provides dedicated general-purpose pins that can be configured as either inputs or outputs. When configured as an output, you can write to an internal register to control the state driven on the output pin. When configured as an input, you can detect the state of the input by reading the state of an internal register.

In addition, the GPIO peripheral can produce CORE interrupts.

The GPIO module is one of the modules controlling the IOMUX of the SoC (System on a Chip). Figure 30-2. shows the SoC muxing scheme.

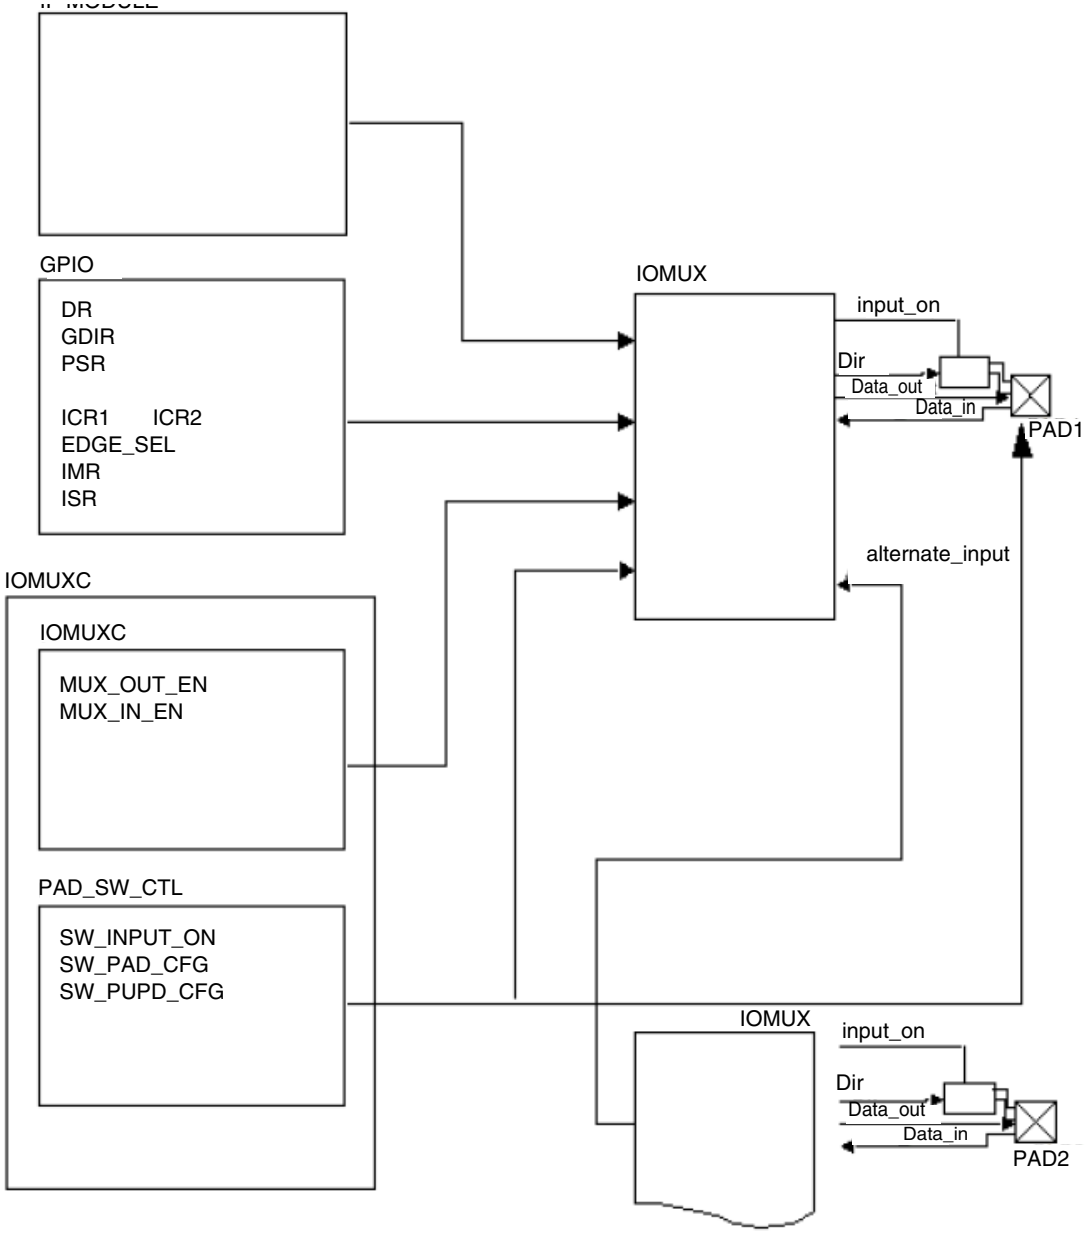

Figure 30-2. SoC IOMUX Scheme

The GPIO functionality is provided through eight registers, an edge-detect circuit, and interrupt generation logic.

The eight registers are:

- Data register (DR)
- GPIO direction register (GDIR)

- Pad sample register (PSR)
- Interrupt control registers (ICR1, ICR2)
- Edge select register (EDGE_SEL)
- Interrupt mask register (IMR)
- Interrupt status register (ISR)

These registers are described in detail in the Programmable Registers section.

Each GPIO input has a dedicated edge-detect circuit which can be configured through software to detect rising edges, falling edges, logic low-levels or logic high-levels on the input signals. The outputs of the edge detect circuits are optionally masked by setting the corresponding bit in the interrupt mask register (IMR). These qualified outputs are OR'ed together to generate three one-bit interrupt lines:

- ini_gpio_int31_16: One-bit interrupt OR of 16 high interrupts.
- ipi_gpio_int15_0: One-bit interrupt OR of 16 low interrupts.
- ipi_gpio_int: One-bit interrupt OR of 32 interrupts.

In addition, the 32-bit signal ipi_gpio_int32 gives the user access to all 32 individual interrupts.

The GPIO edge detection is described further in Interrupt Control Unit.

The GPIO's overall functionality is described further in GPIO Functional Description.

30.1.1 Features

The GPIO includes the following features:

- General purpose input/output logic capabilities:
  - Drives specific data to output using the data register (DR)
  - Controls the direction of the signal using the GPIO direction register (GDR)
  - Enables the core to sample the status of the corresponding inputs by reading the pad sample register (PSR).
- GPIO interrupt capabilities:
  - Supports up to 32 interrupts
  - Identifies interrupt edges
  - Generates three active-high interrupts to the SoC interrupt controller

30.2 GPIO Functional Description

30.2.1 GPIO Function

A GPIO signal can operate as a general-purpose input/output when the IOMUX is set to GPIO mode. Each GPIO signal my be independently configured as either an input or an output using the GPIO direction register (GDIR). When configured as an output (GDIR bit = 1), the value in the data bit in the GPIO data register (DR) is driven on the corresponding GPIO line. When a signal is configured as an input (GDIR bit = 0), the state of the input can be read from the corresponding PSR bit.

30.2.2 GPIO Programming

30.2.2.1 GPIO Read Mode

The programming sequence for reading input signals should be as follows:

1. Configure IOMUX to select GPIO mode (Via IOMUXC).
2. Configure GPIO direction register (GDR) to input.
3. Read value from data register/pad status register.

A pseudocode description to read [input3:input0] values is as follows:

```
write sw_mux_ctl_<input0>_<input1>_<input2>_<input3> , 32'h00000000      // SET INPUTS TO
GPIO MODE.
write GDIR[31:4,input3_bit, input2_bit, input1_bit, input0_bit,] 32'hxxxxxxx0 // SET GDIR TO
INPUT.
read DR                                                          // READ INPUT VALUE FROM DR.
read PSR                                                        // READ INPUT VALUE FROM PSR.
```

NOTE

While the GPIO direction is set to input (GDIR = 0), a read access to DR does not return DR data. Instead, it returns the PSR data, which is the corresponding input signal value.

30.2.2.2 GPIO Write Mode

The programming sequence for driving output signals should be as follows:

1. Configure IOMUX to select GPIO mode (Via IOMUXC).
2. Configure GPIO direction register (GDR) to output.
3. Write value to data register (DR).

A pseudocode description to drive 4'b0101 on [output3:output0] is as follows:

```
write sw_mux_ctl_<output0>_<output1>_<output2>_<output3> , 32'h00000000   // SET OUTPUTS TO
GPIO MODE.
```

```
write GDIR[31:4,output3_bit,output2_bit, output1_bit, output0_bit,] 32'hxxxxxxxF // SET GDIR
TO OUTPUT.
write DR, 32'hxxxxxxx5                                                  // WRITE OUTPUT VALUE
TO DR.
read_cmp PSR, 32'hxxxxxxx5                                              // READ OUTPUT VALUE
FROM PSR ONLY.
```

NOTE

While GPIO direction is set to output, the real internal value can only be verified through the PSR, and not through the DR.

30.2.3 Interrupt Control Unit

In addition to the general-purpose input/output function, the edge-detect logic in the GPIO peripheral reflects whether a transition has occurred on a given GPIO signal that is configured as an input (GDIR bit = 0). The interrupt control registers (ICR1 and ICR2) may be used to independently configure the interrupt condition of each input signal (low-to-high transition, high-to-low transition, low, or high). For information about ICR1 and ICR2 settings, refer to GPIO interrupt configuration register1 (GPIO_GPIO_ICR1) and GPIO interrupt configuration register2 (GPIO_GPIO_ICR2).

The interrupt control unit is built of 32 interrupt control subunits, where each subunit handles a single interrupt line.

30.3 Programmable Registers

There are eight 32-bit GPIO registers. All registers are accessible from the IP interface. Only 32-bit access is supported.

GPIO memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
53F8_4000	GPIO data register (GPIO-1_GPIO_DR)	32	R/W	0000_0000h	30.3.1/ 1542

30.3.1 GPIO data register (GPIOx_GPIO_DR)

The 32-bit GPIO DR register stores data that is ready to be driven to the output lines. If the IOMUX is in GPIO mode and a given GPIO direction bit is set, then the corresponding DR bit is driven to the output. If a given GPIO direction bit is cleared, then a read of DR reflects the value of the corresponding signal.Two wait states are required in read access for synchronization.

The results of a read of a DR bit depends on the IOMUX input mode settings and the corresponding GDIR bit as follows:

- If GDIR[*n*] is set and IOMUX input mode is GPIO, then reading DR[*n*] returns the contents of DR[*n*].
- If GDIR[*n*] is cleared and IOMUX input mode is GPIO, then reading DR[*n*] returns the corresponding input signal's value.
- If GDIR[*n*] is set and IOMUX input mode is not GPIO, then reading DR[*n*] returns the contents of DR[*n*].
- If GDIR[*n*] is cleared and IOMUX input mode is not GPIO, then reading DR[*n*] always returns zero.

Addresses: GPIO-1_GPIO_DR is 53F8_4000h base + 0h offset = 53F8_4000h
GPIO-2_GPIO_DR is 53F8_8000h base + 0h offset = 53F8_8000h

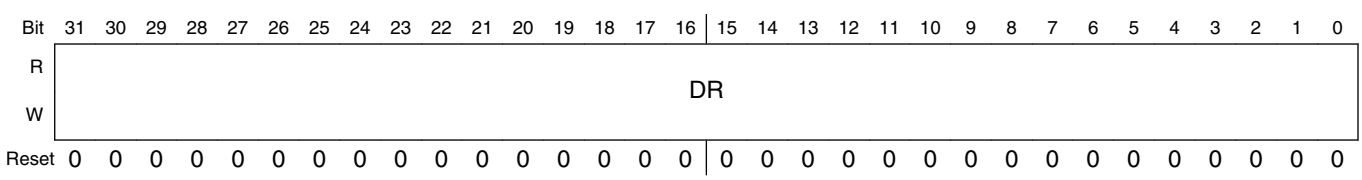
GPIO-5_GPIO_DR is 53FD_C000h base + 0h offset = 53FD_C000h
GPIO-6_GPIO_DR is 53FE_0000h base + 0h offset = 53FE_0000h



GPIOx_GPIO_DR field descriptions

Field	Description
31–0 DR	Data bits. This register defines the value of the GPIO output when the signal is configured as an output (GDIR[n]=1). Writes to this register are stored in a register. Reading DR returns the value stored in the register if the signal is configured as an output (GDIR[n]=1), or the input signal's value if configured as an input (GDIR[n]=0). **NOTE:** The I/O multiplexer must be configured to GPIO mode for the DR value to connect with the signal. Reading the data register with the input path disabled always returns a zero value.

30.3.2 GPIO direction register (GPIOx_GPIO_GDIR)

GDIR functions as direction control when the IOMUX is in GPIO mode. Each bit specifies the direction of a one-bit signal. The mapping of each DIR bit to a corresponding SoC signal is determined by the SoC's pin assignment and the IOMUX table-for more details consult the IOMUX chapter.

Addresses: GPIO-1_GPIO_GDIR is 53F8_4000h base + 4h offset = 53F8_4004h
GPIO-2_GPIO_GDIR is 53F8_8000h base + 4h offset = 53F8_8004h
GPIO-3_GPIO_GDIR is 53F8_C000h base + 4h offset = 53F8_C004h
GPIO-4_GPIO_GDIR is 53F9_0000h base + 4h offset = 53F9_0004h
GPIO-5_GPIO_GDIR is 53FD_C000h base + 4h offset = 53FD_C004h
GPIO-6_GPIO_GDIR is 53FE_0000h base + 4h offset = 53FE_0004h

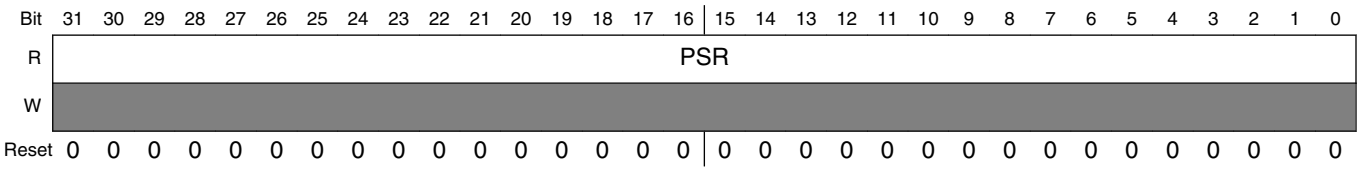
GPIOx_GPIO_GDIR field descriptions

Field	Description
31–0 GDIR	GPIO direction bits. Bit n of this register defines the direction of the GPIO[n] signal. **NOTE:** GDIR affects only the direction of the I/O signal when the corresponding bit in the I/O MUX is configured for GPIO. 0 GPIO is configured as input. 1 GPIO is configured as output.

30.3.3 GPIO pad status register (GPIOx_GPIO_PSR)

PSR is a read-only register. Each bit stores the value of the corresponding input signal (as configured in the IOMUX). This register is clocked with the ipg_clk_s clock, meaning that the input signal is sampled only when accessing this location. Two wait states are required any time this register is accessed for synchronization.

Addresses: GPIO-1_GPIO_PSR is 53F8_4000h base + 8h offset = 53F8_4008h
GPIO-2_GPIO_PSR is 53F8_8000h base + 8h offset = 53F8_8008h
GPIO-3_GPIO_PSR is 53F8_C000h base + 8h offset = 53F8_C008h
GPIO-4_GPIO_PSR is 53F9_0000h base + 8h offset = 53F9_0008h
GPIO-5_GPIO_PSR is 53FD_C000h base + 8h offset = 53FD_C008h
GPIO-6_GPIO_PSR is 53FE_0000h base + 8h offset = 53FE_0008h



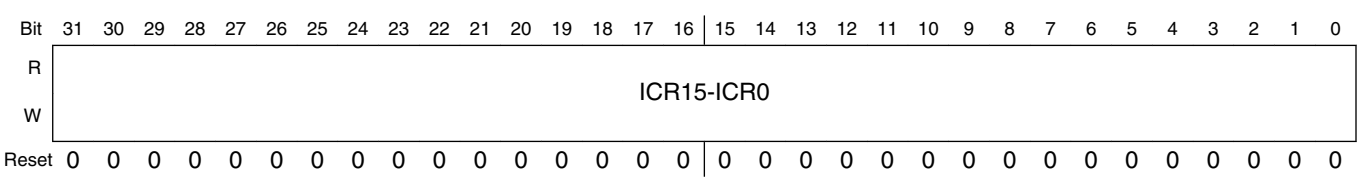
GPIOx_GPIO_PSR field descriptions

Field	Description
31–0 PSR	GPIO pad status bits (status bits). Reading PSR returns the state of the corresponding input signal. Settings: **NOTE:** The I/O multiplexer must be configured to GPIO mode for PSR to reflect the state of the corresponding signal.

30.3.4 GPIO interrupt configuration register1 (GPIOx_GPIO_ICR1)

ICR1 contains 16 two-bit fields, where each field specifies the interrupt configuration for a different input signal.

Addresses: GPIO-1_GPIO_ICR1 is 53F8_4000h base + Ch offset = 53F8_400Ch
GPIO-2_GPIO_ICR1 is 53F8_8000h base + Ch offset = 53F8_800Ch
GPIO-3_GPIO_ICR1 is 53F8_C000h base + Ch offset = 53F8_C00Ch
GPIO-4_GPIO_ICR1 is 53F9_0000h base + Ch offset = 53F9_000Ch
GPIO-5_GPIO_ICR1 is 53FD_C000h base + Ch offset = 53FD_C00Ch
GPIO-6_GPIO_ICR1 is 53FE_0000h base + Ch offset = 53FE_000Ch



GPIOx_GPIO_ICR1 field descriptions

Field	Description
31–0 ICR15-ICR0	Interrupt configuration 1 fields. This register controls the active condition of the interrupt function for lines 15 to 0. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 Interrupt n is low-level sensitive. 01 Interrupt n is high-level sensitive. 10 Interrupt n is rising-edge sensitive. 11 Interrupt n is falling-edge sensitive.

30.3.5 GPIO interrupt configuration register2 (GPIOx_GPIO_ICR2)

ICR2 contains 16 two-bit fields, where each field specifies the interrupt configuration for a different input signal.

Addresses: GPIO-1_GPIO_ICR2 is 53F8_4000h base + 10h offset = 53F8_4010h
GPIO-2_GPIO_ICR2 is 53F8_8000h base + 10h offset = 53F8_8010h
GPIO-3_GPIO_ICR2 is 53F8_C000h base + 10h offset = 53F8_C010h
GPIO-4_GPIO_ICR2 is 53F9_0000h base + 10h offset = 53F9_0010h
GPIO-5_GPIO_ICR2 is 53FD_C000h base + 10h offset = 53FD_C010h
GPIO-6_GPIO_ICR2 is 53FE_0000h base + 10h offset = 53FE_0010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

GPIOx_GPIO_ICR2 field descriptions

Field	Description
31–0 ICR31-ICR16	Interrupt configuration 2 fields. These fields control the active condition of the interrupt function for lines 31 to 16. Settings: Bits ICRn[1:0] determine the interrupt condition for signal n as follows: 00 Interrupt n is low-level sensitive. 01 Interrupt n is high-level sensitive. 10 Interrupt n is rising-edge sensitive. 11 Interrupt n is falling-edge sensitive.

30.3.6 GPIO interrupt mask register (GPIOx_GPIO_IMR)

IMR contains masking bits for each interrupt line.

Addresses: GPIO-1_GPIO_IMR is 53F8_4000h base + 14h offset = 53F8_4014h
GPIO-2_GPIO_IMR is 53F8_8000h base + 14h offset = 53F8_8014h
GPIO-3_GPIO_IMR is 53F8_C000h base + 14h offset = 53F8_C014h
GPIO-4_GPIO_IMR is 53F9_0000h base + 14h offset = 53F9_0014h
GPIO-5_GPIO_IMR is 53FD_C000h base + 14h offset = 53FD_C014h
GPIO-6_GPIO_IMR is 53FE_0000h base + 14h offset = 53FE_0014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

GPIOx_GPIO_IMR field descriptions

Field	Description
31–0 IMR	Interrupt Mask bits. This register is used to enable or disable the interrupt function on each of the 32 GPIO signals. Settings: Bit IMR[n] (n=0...31) controls interrupt n as follows: 0 Interrupt n is disabled. 1 Interrupt n is enabled.

30.3.7 GPIO interrupt status register (GPIOx_GPIO_ISR)

The ISR functions as an interrupt status indicator. Each bit indicates whether an interrupt condition has been met for the corresponding input signal. When an interrupt condition is met (as determined by the corresponding interrupt condition register field), the corresponding bit in this register is set. Two wait states are required in read access for synchronization. One wait state is required for reset.

Addresses: GPIO-1_GPIO_ISR is 53F8_4000h base + 18h offset = 53F8_4018h
GPIO-2_GPIO_ISR is 53F8_8000h base + 18h offset = 53F8_8018h
GPIO-3_GPIO_ISR is 53F8_C000h base + 18h offset = 53F8_C018h
GPIO-4_GPIO_ISR is 53F9_0000h base + 18h offset = 53F9_0018h
GPIO-5_GPIO_ISR is 53FD_C000h base + 18h offset = 53FD_C018h
GPIO-6_GPIO_ISR is 53FE_0000h base + 18h offset = 53FE_0018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPIOx_GPIO_ISR field descriptions

Field	Description
31–0 ISR	Interrupt status bits - Bit n of this register is asserted (active high) when the active condition (as determined by the corresponding ICR bit) is detected on the GPIO input and is waiting for service. The value of this register is independent of the value in IMR. When the active condition has been detected, the corresponding bit remains set until cleared by software. Status flags are cleared by writing a 1 to the corresponding bit position.

30.3.8 GPIO edge select register (GPIO*x*_GPIO_EDGE_SEL)

EDGE_SEL may be used to override the ICR registers' configuration. If the EDGE_SEL bit is set, then a rising edge or falling edge in the corresponding signal generates an interrupt. This register provides backward compatibility. On reset all bits are cleared (ICR is not overridden).

Addresses: GPIO-1_GPIO_EDGE_SEL is 53F8_4000h base + 1Ch offset = 53F8_401Ch
GPIO-2_GPIO_EDGE_SEL is 53F8_8000h base + 1Ch offset = 53F8_801Ch
GPIO-3_GPIO_EDGE_SEL is 53F8_C000h base + 1Ch offset = 53F8_C01Ch
GPIO-4_GPIO_EDGE_SEL is 53F9_0000h base + 1Ch offset = 53F9_001Ch
GPIO-5_GPIO_EDGE_SEL is 53FD_C000h base + 1Ch offset = 53FD_C01Ch
GPIO-6_GPIO_EDGE_SEL is 53FE_0000h base + 1Ch offset = 53FE_001Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPIO*x*_GPIO_EDGE_SEL field descriptions

Field	Description
31–0 EDGE_SEL	Edge select. When EDGE_SEL[*n*] is set, the GPIO disregards the ICR[*n*] setting, and detects any edge on the corresponding input signal.

Chapter 31
General-Purpose Media Interface (GPMI)

31.1 Introduction

This chapter describes the general-purpose media interface (GPMI) on the i.MX50.

31.2 Overview

The GPMI controller is a flexible interface to up to eight NAND flash.

- ONFI 2.2, samsung Toggle NAND protocol compatible
- The NAND mode has configurable address and command behavior, providing support for future devices not yet specified.

The GPMI resides on the APBH. The GPMI also provides an interface to the BCH module to allow direct parity processing.

Registers are clocked on the HCLK domain. The I/O and pin timing are clocked on a dedicated GPMICLK domain. GPMICLK can be set to maximize I/O performance.

Figure 31-1 shows a block diagram of the GPMI controller.

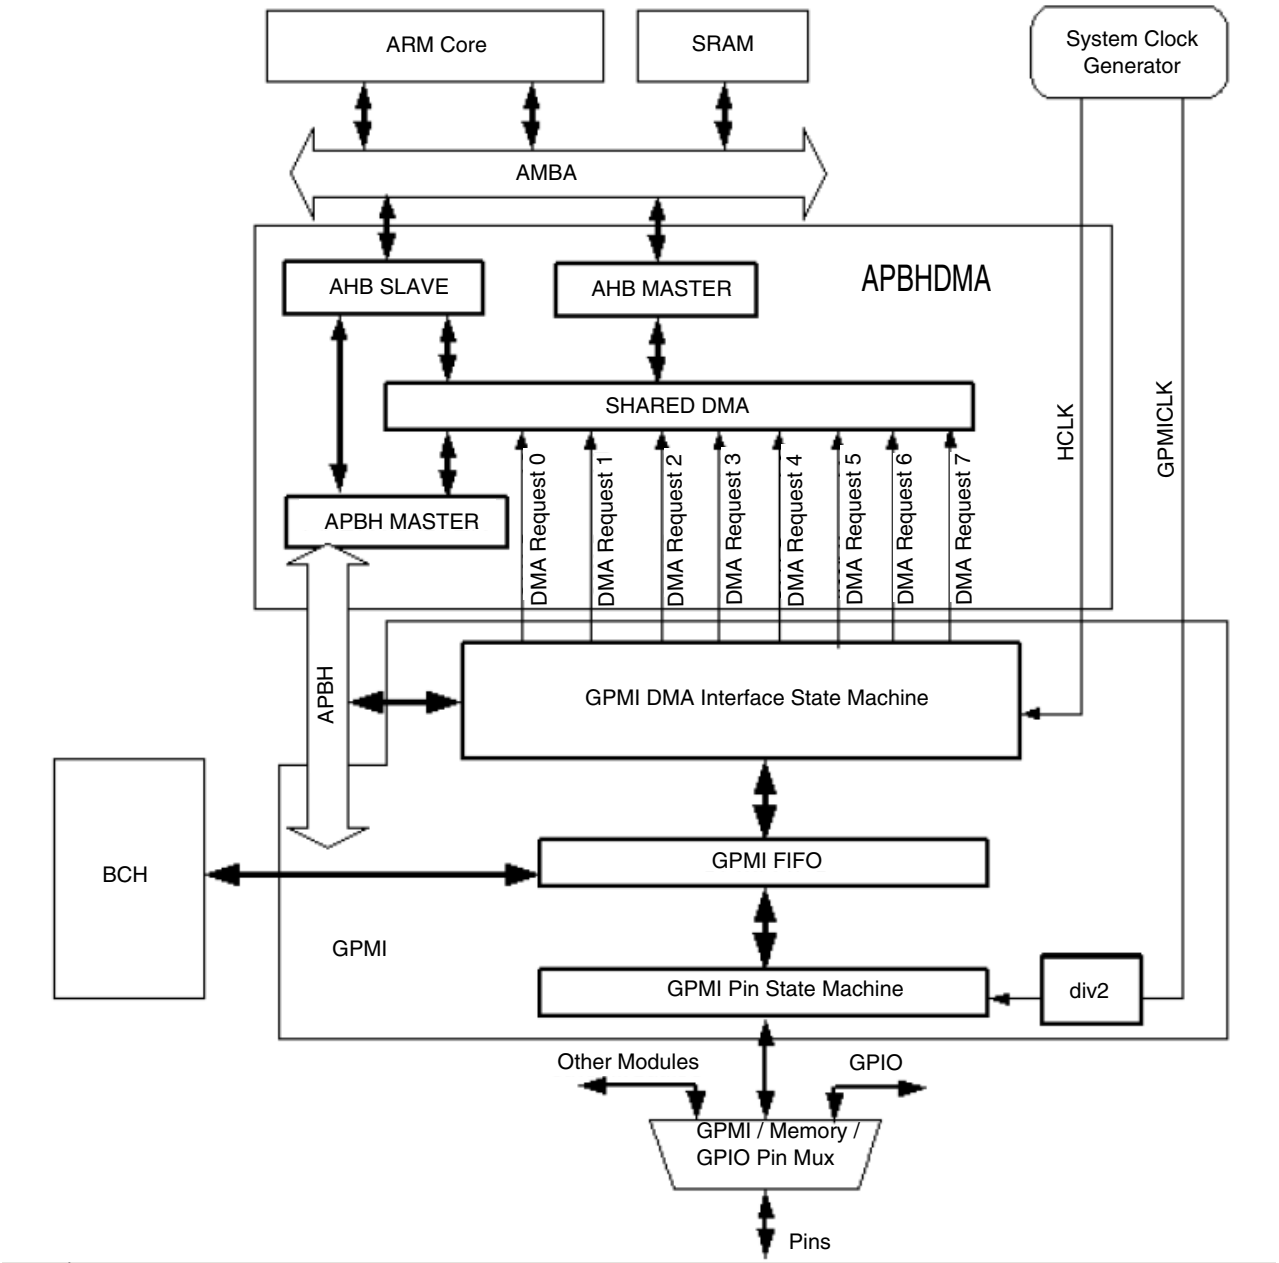

Figure 31-1. General-Purpose Media Interface Controller Block Diagram

31.3 GPMI NAND Mode

The general-purpose media interface has several features to efficiently support NAND:

- Individual chip select and ready/busy pins for up to eight NANDs.
- Individual state machine and DMA channel for each chip select.

- Special command modes work with DMA controller to perform all normal NAND functions without ARM platform intervention.
- Configurable timing based on a dedicated clock allows optimal balance of high NAND performance and low system power.

GPMI and DMA have been designed to handle complex multi-page operations without ARM platform intervention. The DMA uses a linked descriptor function with branching capability to automatically handle all of the operations needed to read/write multiple pages:

- Data/Register Read/Write-The GPMI can be programmed to read or write multiple cycles to the NAND address, command or data registers.
- Wait for NAND Ready-The GPMI's Wait-for-Ready mode can monitor the ready/busy signal of a single NAND flash and signal the DMA when the device has become ready. It also has a time-out counter and can indicate to the DMA that a time-out error has occurred. The DMAs can conditionally branch to a different descriptor in the case of an error.
- Check Status-The Read-and-Compare mode allows the GPMI to check NAND status against a reference. If an error is found, the GPMI can instruct the DMA to branch to an alternate descriptor, which attempts to fix the problem or asserts a ARM platform IRQ.

31.3.1 Multiple NAND Support

The GPMI supports up to eight NAND chip selects, each with independent ready/busy signals. Since they share a data bus and control lines, the GPMI can only actively communicate with a single NAND at a time. However, all NANDs can concurrently perform internal read, write, or erase operations. With fast NAND flash and software support for concurrent NAND operations, this architecture allows the total throughput to approach the data bus speed, which can be as high as 50 MB/s (8-bit bus running at 50 MHz single clock edge) in asynchronous mode and 200MB/s (8-bit bus running at 100MHz both edges clock) in Source Synchronous mode.

There are two options for controlling the eight NAND chip selects via the DMA interface. The first option is the one to one mapping, where the each DMA channel is tied to it own NAND. For example DMA channel 'n' accesses only NAND attached to chip select 'n'. The second option is the decoupled mode where a DMA channel can access any or all NANDs connected to the GPMI. A DMA channel will signify the NAND it wants to access by writing its chip select value in the GPMI_CTRL0_CS field and setting the GPMI_CTRL1_DECOUPLE_CS to 1. This option is useful if software chooses to use only one DMA channel to access all the attached NAND devices.

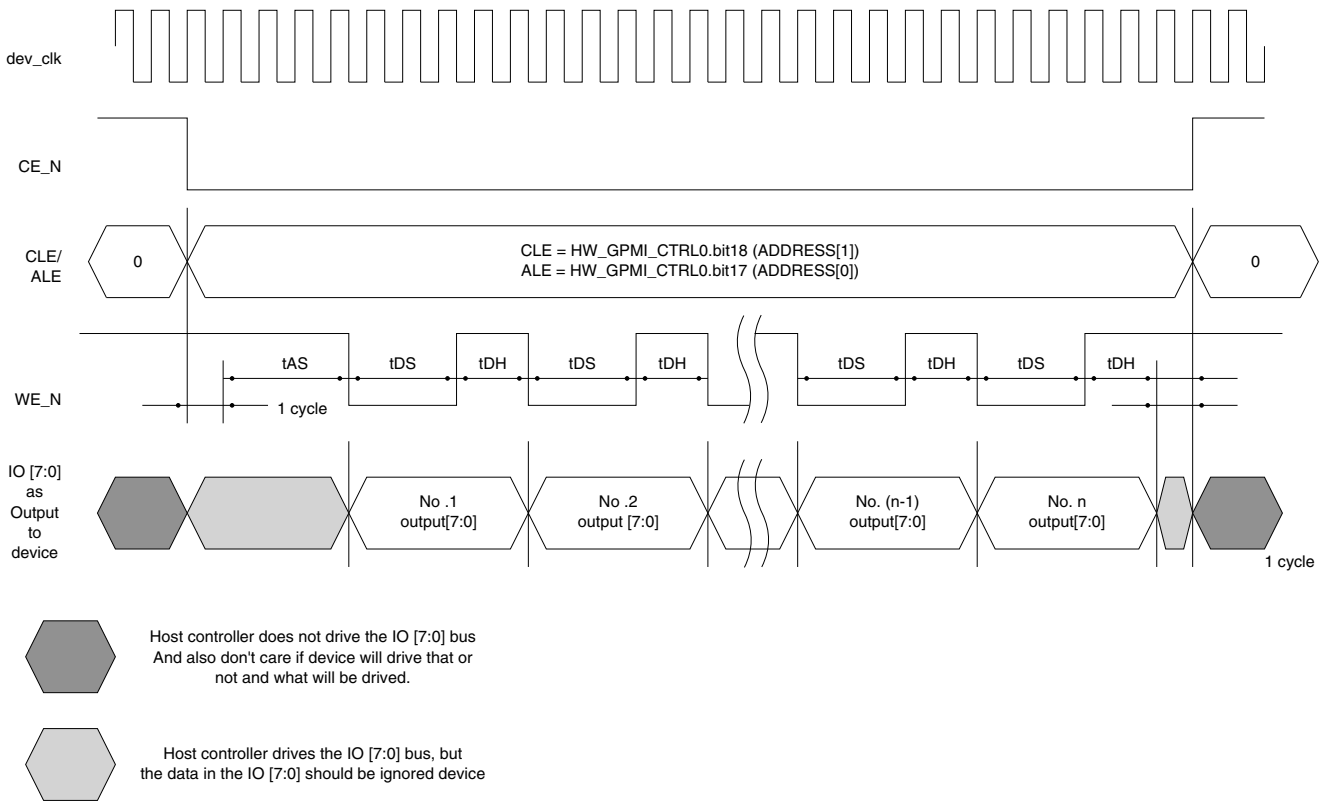
31.3.2 GPMI NAND Timing and Clocking

The dedicated clock, GPMICLK, is used as a timing reference for NAND flash I/O. Since various NANDs have different timing requirements, GPMICLK may need to be adjusted for each application. While the actual pin timings are limited by the NAND chips used, the GPMI can support data bus speeds of up to 200 MHz x 8 bits. The actual read/write strobe timing parameters are adjusted as indicated in the register descriptions in the Programmable Registers section.

31.3.3 Basic NAND Timing

31.3.3.1 NAND Asynchronous Timing

Figure 31-4 and illustrates the operation of the output (from host to device) timing parameters in NAND ONFI asynchronous mode.



- tAS is configurable by programming HW_GPMI_TIMING0 Address_Setup: In this example, Address_Setup - 4, tAS is equal to 4 dev_clk cycles.
- tDS is configurable by programming HW_GPMI_TIMING0 Data_Setup; In this example, Data_Setup - 3, tDS is equal to 3 dev_clk cycles
- tDH is configuarble by programming HW_GPMI_TIMING0 Data_Hold: In this example, Data_Hold = 2, tDH is equal to 2 dev_clk cycles
- tAS/tDS/tDH will extend, if the output data us not ready in device fifo.

Figure 31-2. Asynchronous mode basic write timing diagram

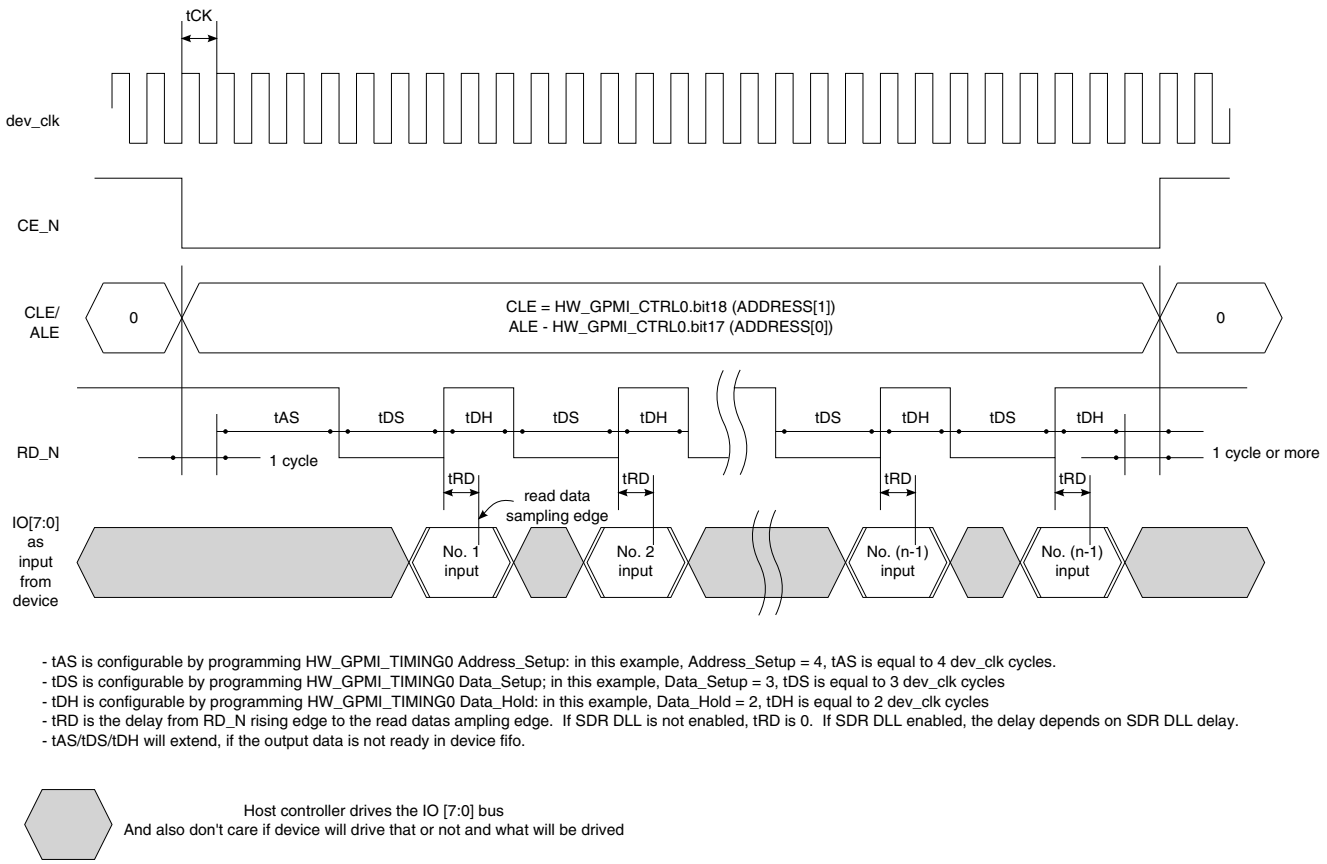


Figure 31-3. ONFI asynchronous mode basic read timing diagram

31.3.3.2 NAND Asynchronous EDO Mode Timing

In high-speed NANDS, the read data may not be valid until after the read strobe (RDN) deasserts. This is the case when the minimum tDS is programmed to achieve higher bandwidth. The GPMI implements a feedback read strobe to sample the read data. The feedback read strobe can be delayed to support fast nand EDO (Extended Data Out) timing where the read strobe may deassert before the read data is valid, and read data is valid for some time after read strobe. Nand EDO timings is applied typically for read cycle frequency above 33 MHz. See Figure 31-4.

The GPMI provides control over the amount of delay applied to the feedback read strobe. This delay depends on the maximum read access time (tREA) of the nand and the read pulse width (tRP) used to access the nand. tRP is specified by GPMI_TIMING0_DATA_SETUP register. When (tREA + 4ns) is less than tRP, no

delay is required to sample to nand read data. (The 4ns provides adequate data setup time for the GPMI.) In this case set GPMI_CTRL1_HALF_PERIOD = 0; GPMI_CTRL1_RDN_DELAY = 0; GPMI_CTRL1_DLL_ENABLE = 0.

When (tREA + 4ns) is greater than or equal to tRP, a delay of the feedback read strobe is required to sample to nand read data. This delay is equal to the difference between these two timings:

DELAY = tREA + 4ns - tRP.

Since the GPMI delay chain is limited to 16ns maximum, if DELAY > 16ns then increase tRP by increasing the value of GPMI_TIMING0_DATA_SETUP until DELAY is less than or equal to 16ns.

The GPMI programming for this DELAY depends on the GPMICLK period. The GPMI DLL will not function properly if the GPMICLK period is greater than 32ns: disable the DLL if this is the case. If the GPMICLK period is greater than 16ns (and not greater than 32ns), set the GPMI_CTRL1_HALF_PERIOD=1; This will cause the DLL reference period (RP) to be one-half of the GPMICLK period. If the GPMICLK period is 16ns or less then set the GPMI_CTRL1_HALF_PERIOD=0; This will cause the DLL reference period (RP) to be equal to the GPMICLK period. DELAY is a multiple (0 to 1.875) of RP.

The GPMI_CTRL1_RDN_DELAY is encoded as a 1-bit integer and 3-bit fraction delay factor. See table below. DELAY is a multiple of the delay factor and the reference period:

HW_GPMI_CTRL1_RDN_DELAY	0	1	2	3	4	5	6	7
Delay Factor	0.000	0.125	0.250	0.375	0.500	0.625	0.750	0.875
HW_GPMI_CTRL1_RDN_DELAY	8	9	10	11	12	13	14	15
Delay Factor	1.000	1.125	1.250	1.375	1.500	1.625	1.750	1.875

DELAY = DelayFactor x RP or DELAY = GPMI_CTRL1_RDN_DELAY x 0.125 x RP.

Use this equation to calculate the value for GPMI_CTRL1_RDN_DELAY. Then set GPMI_CTRL1_DLL_ENABLE=1.

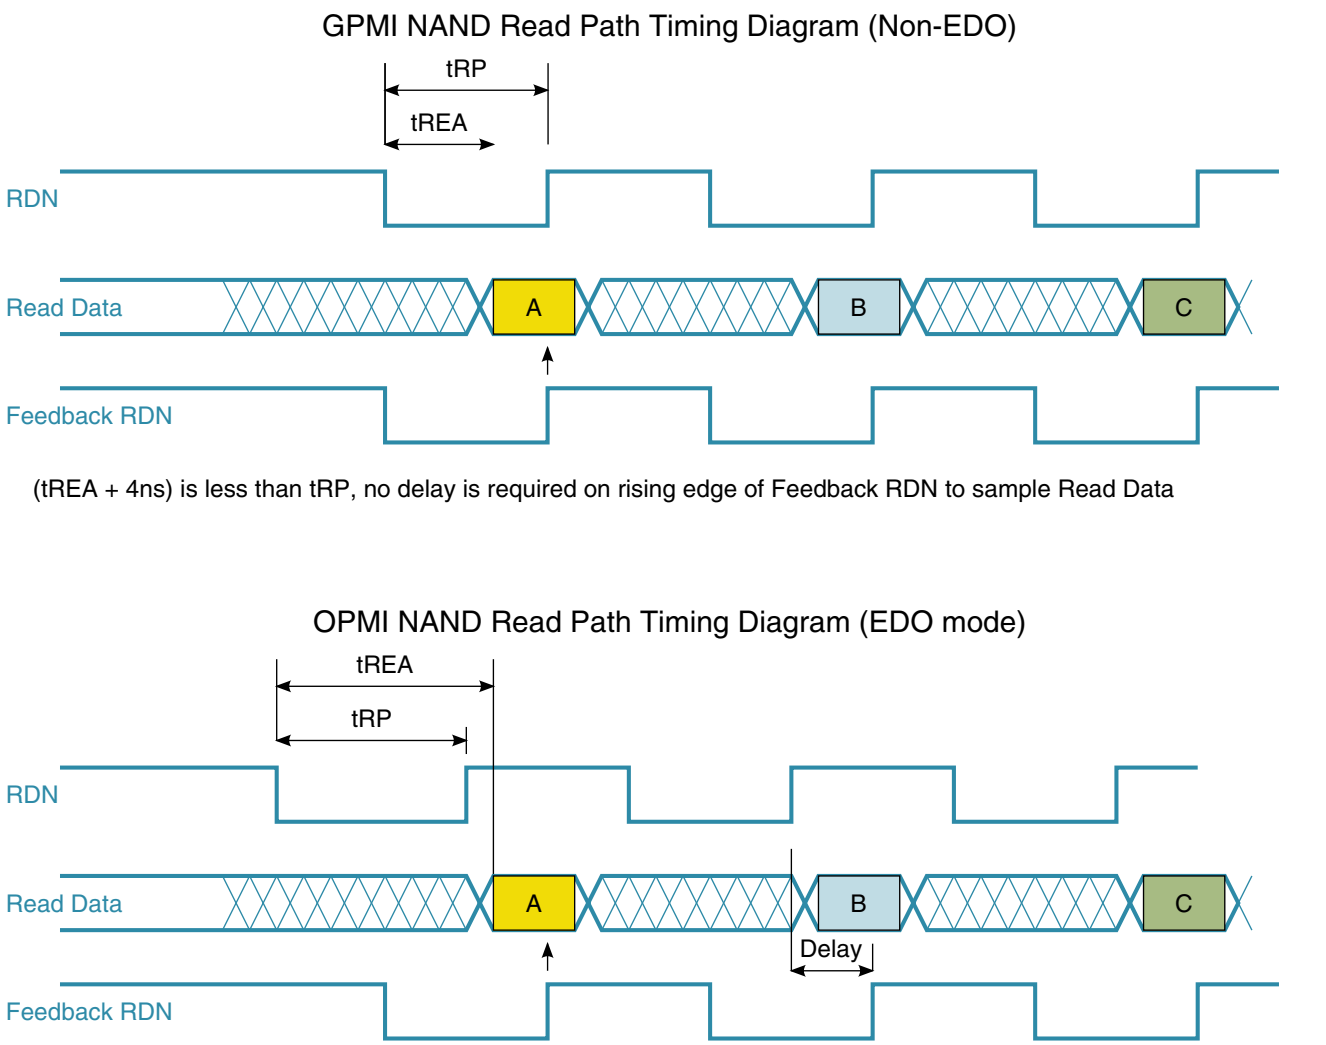

Figure 31-4. NAND Read Path Timing

For example, a nand with tREAmax = 20 ns, tRPmin = 12 ns, and tRCmin = 25 ns (read cycle time) may be programmed as follows:

- GPMICLK clock frequency: Consider 480/6 = 80 MHz which is 12.5 ns clock period. This is too close to the minimum nand spec if we program the data setup and hold to 1 GPMICLK cycle. Consider 480/7=68.57 MHz which is 14.58 ns clock period. With data setup and hold set to 1, we have a tRP of 14.58ns and a tRC of 29.16 ns (good margins).
- Since (tREA +4ns) is greater than tRP, required DELAY = tREA + 4ns - tRP = 20 + 4 - 14.58ns = 9.42 ns.

- HALF_PERIOD =0, since GPMICLK period is less than 16ns. So RP=GPMICLK period = 14.58ns.
- DELAY = GPMI_CTRL1_RDN_DELAY x 0.125 x RP. 9.42 ns = GPMI_CTRL1_RDN_DELAY x 0.125 x 14.58ns. GPMI_CTRL1_RDN_DELAY = 5 (round off 5.169)

NOTE

It is recommended that the drive strength of GPMI_RDn and GPMI_WRn output pins be set to 8 mA. This will reduce the transition time under heavy loads. Low transition times will be important when NAND interface read and write cycle times are below 30 ns. The other GPMI pins may remain at 4 mA, since their frequency is only up to half that of GPMI_RDn and GPMI_WRn.

31.3.3.3 NAND ONFI Source Synchronous Mode Timing

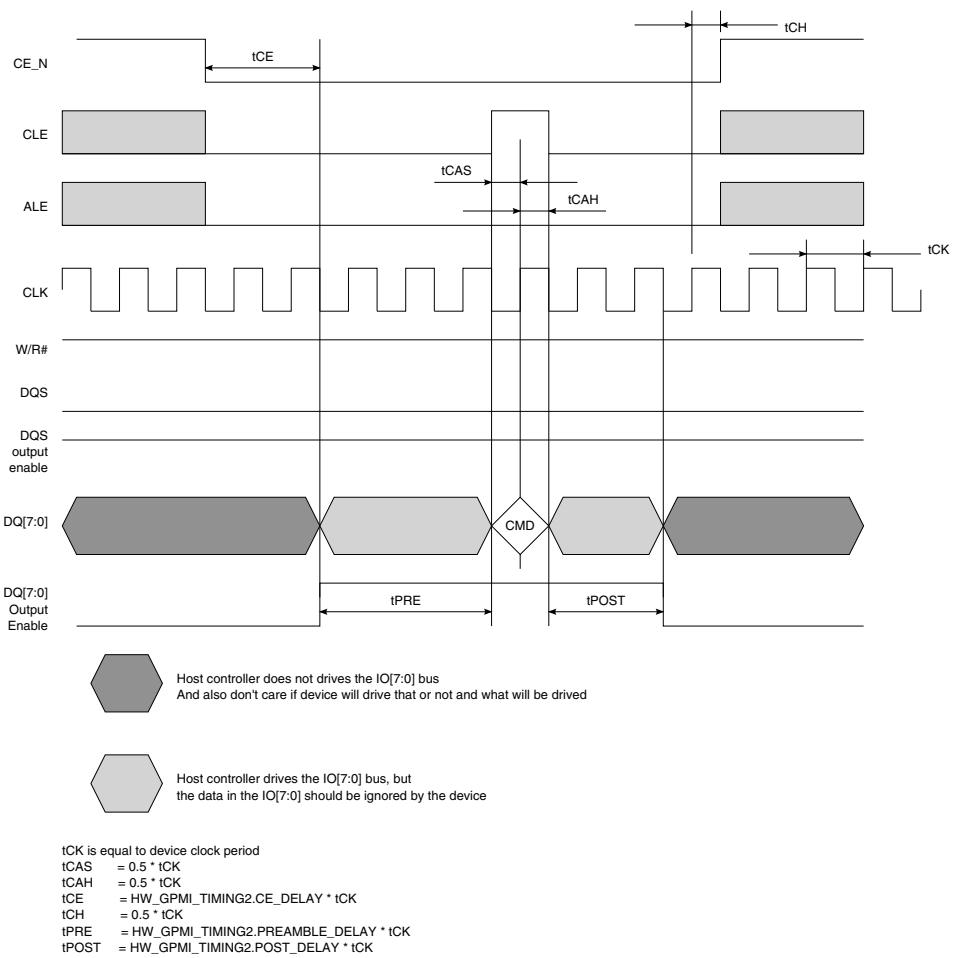

Figure 31-5. ONFI source synchronous mode basic command write timing diagram

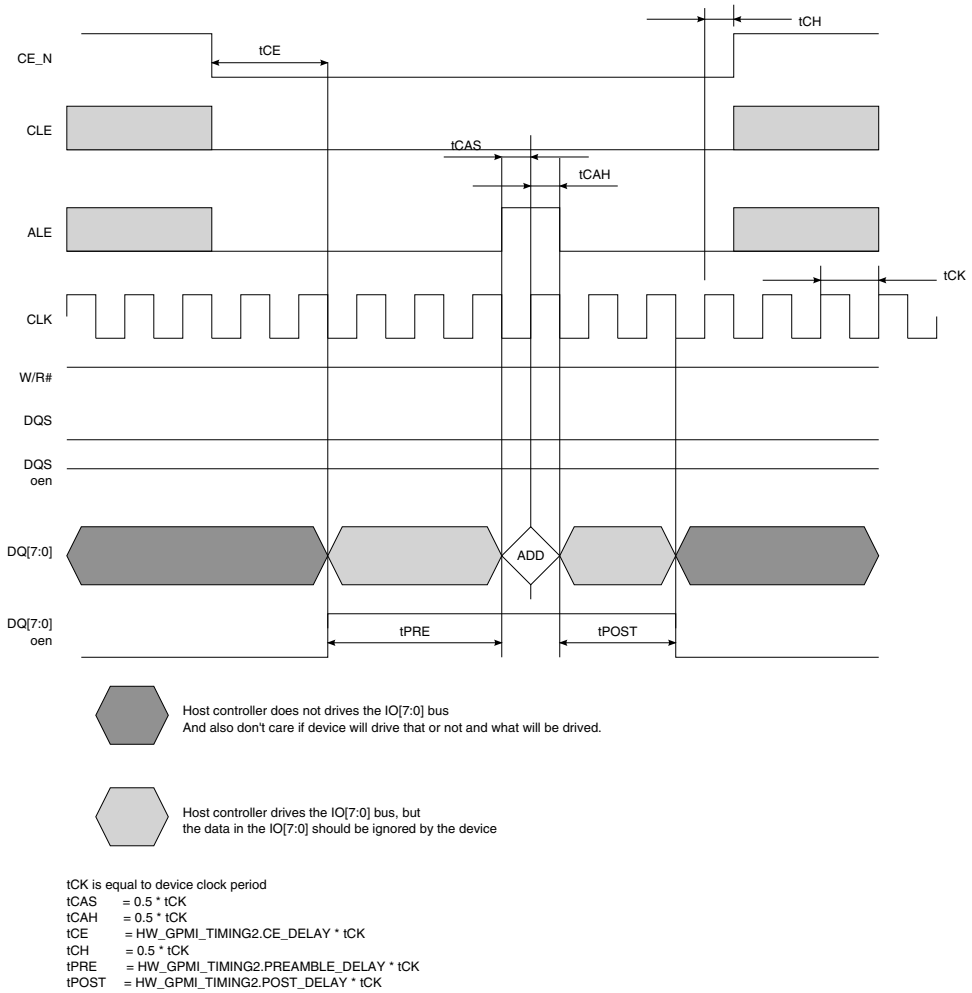

Figure 31-6. ONFI source synchronous mode basic address write timing diagram

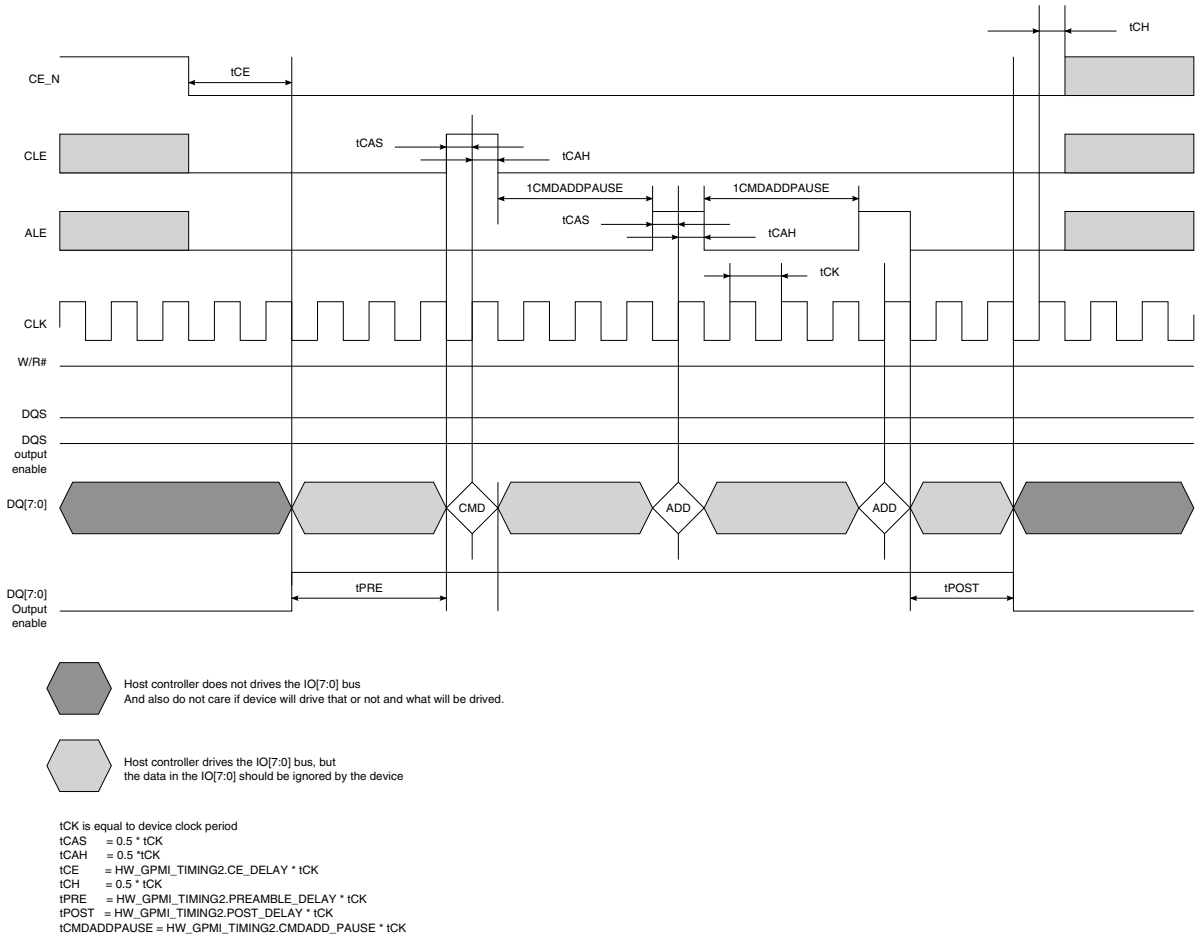

Figure 31-7. ONFI source synchronous mode comand + address write timing diagram

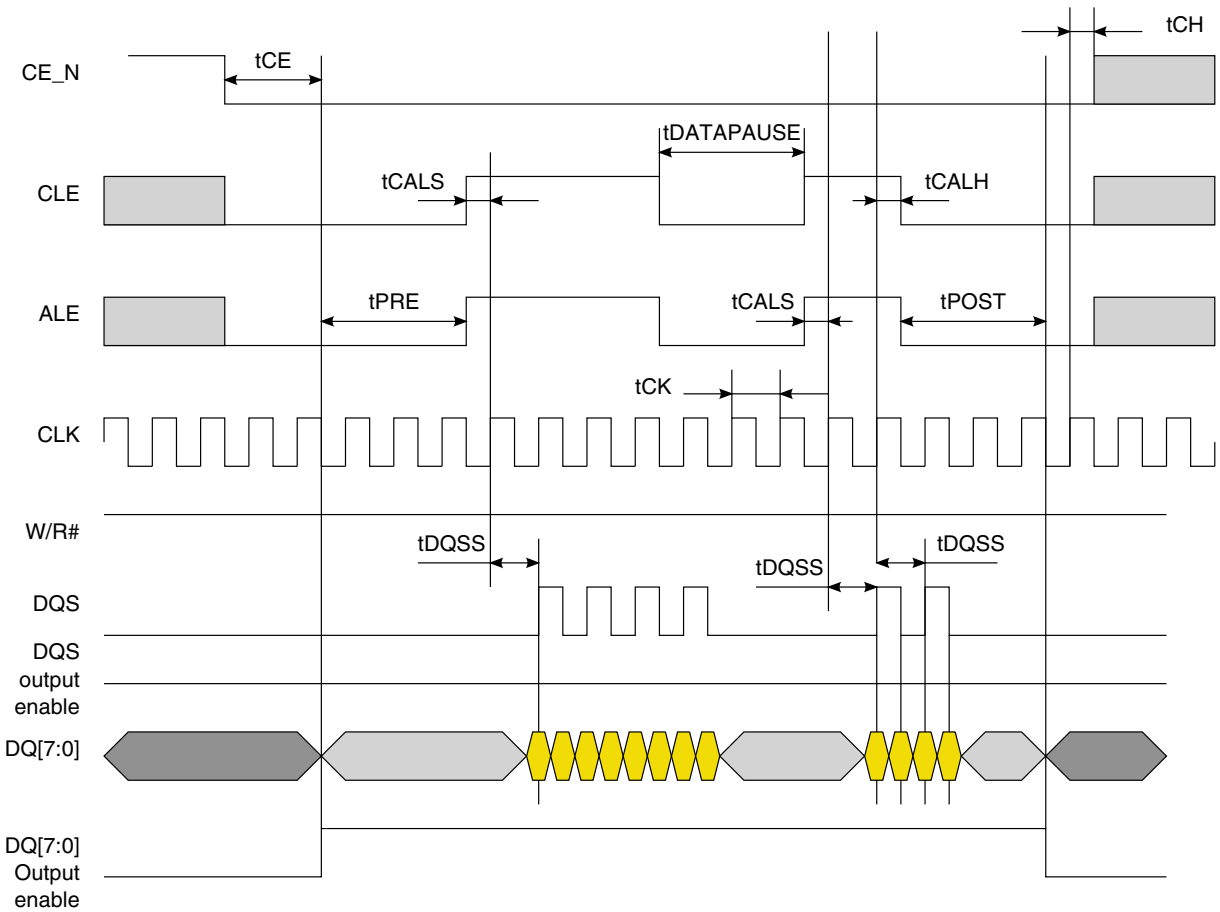
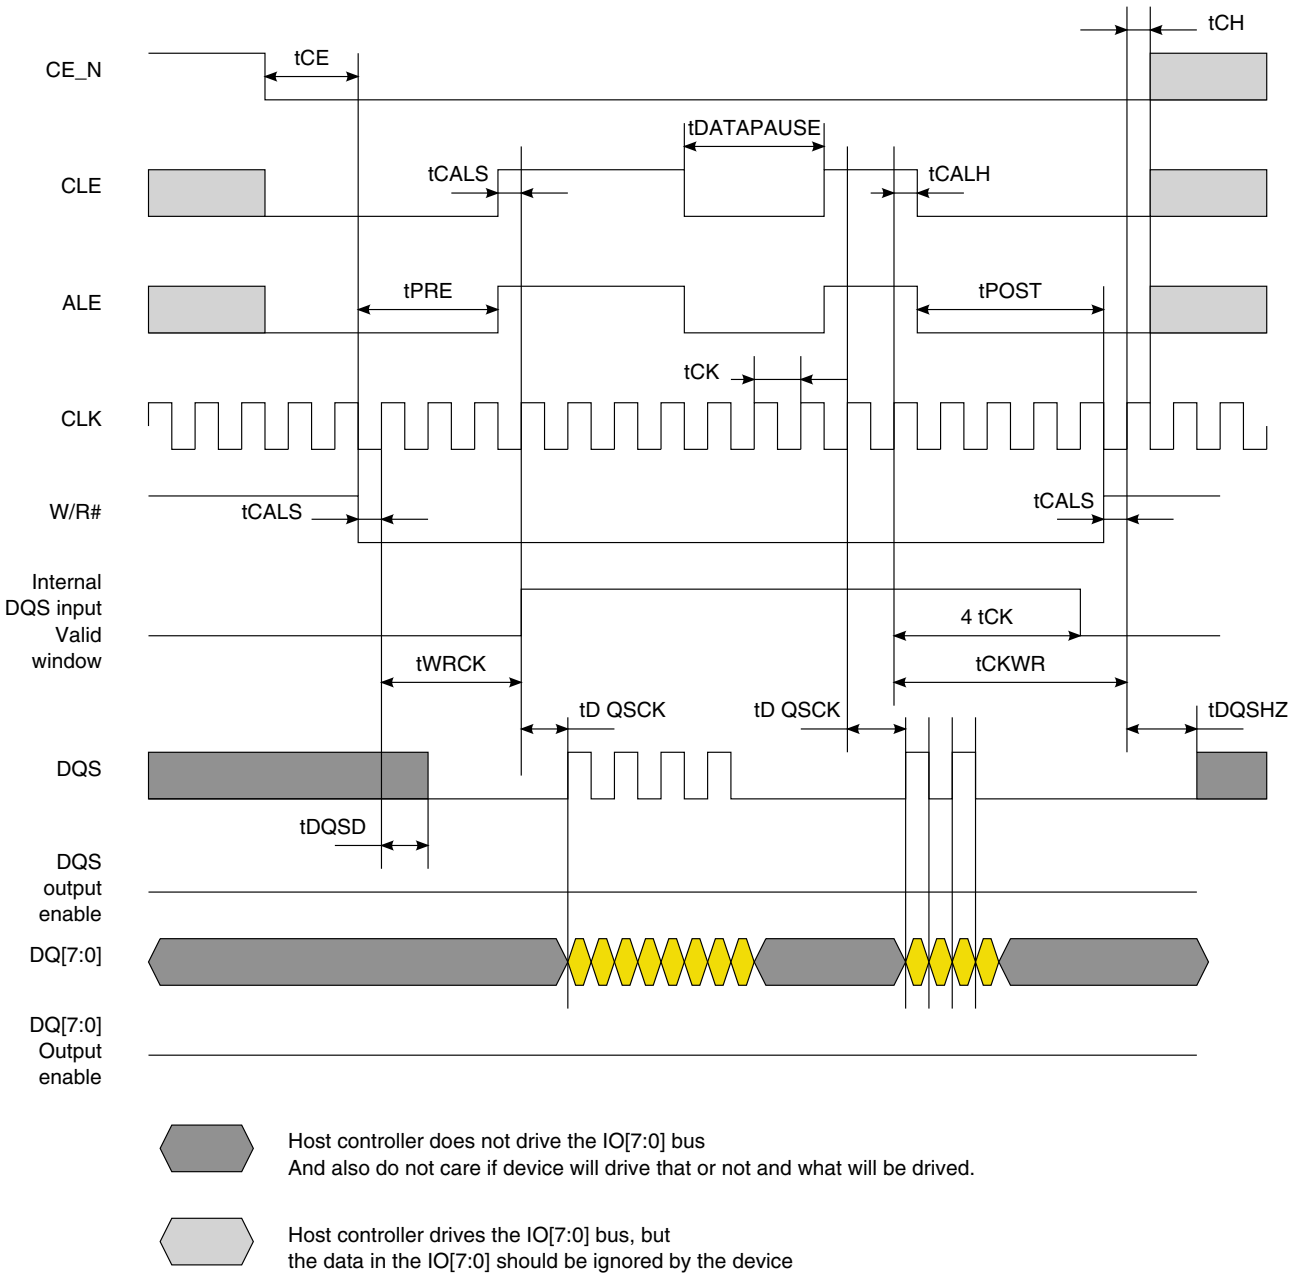


tCK is equal to device clock period
tCE = HW_GPI_TIMING2.CE_DELAY * tCK
tCH = 0.5 * tCK
tCALS = 0.5 * tCK
tCALH = 0.5 * tCK
tPRE = HW_GPMI_TIMING2.PREAMBLE_DELAY *tCK
tPOST = HW_GPMI_TIMING2.POST_DELAY * tCK
tDATAPAUSE = HW_GPMI_TIMING2.DATA_PAUSE * tCK
tDQSS = tCK

Figure 31-8. ONFI source synchornous mode data write timing diagram



tCK is equal to device clock period
tCE = HW_GPI_TIMING2.CE_DELAY * tCK
tCH = 0.5 * tCK
tCALS = 0.5 * tCK
tCALH = 0.5 * tCK
tPRE = HW_GPMI_TIMING2.PREAMBLE_DELAY *tCK
tPOST = HW_GPMI_TIMING2.POST_DELAY * tCK
tDATAPAUSE = HW_GPMI_TIMING2.DATA_PAUSE * tCK
tWRCK/tCKWR/tDQSD/tDASCK/tDASHZ are device parameters

Figure 31-9. ONFI source synchronous mode data read timing diagram

31.3.3.4 NAND Toggle Mode Timing

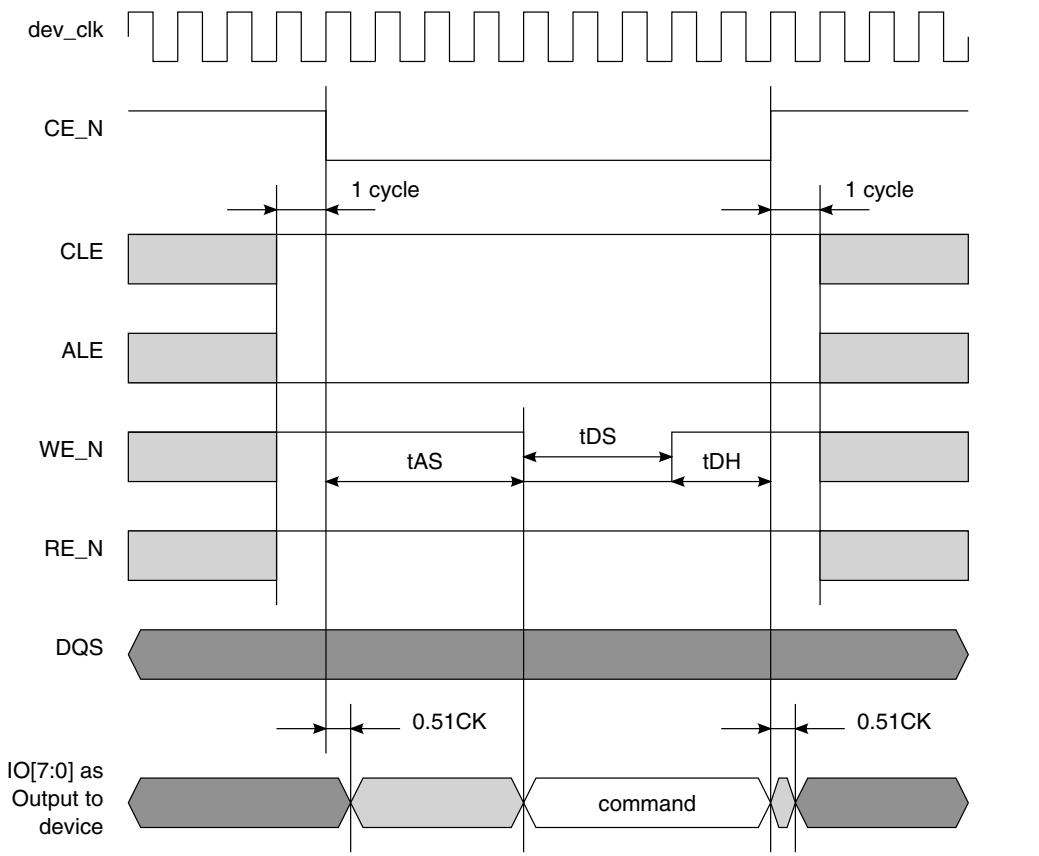


Figure 31-10. SAMSUNG toggle mode basic command write timing diagram

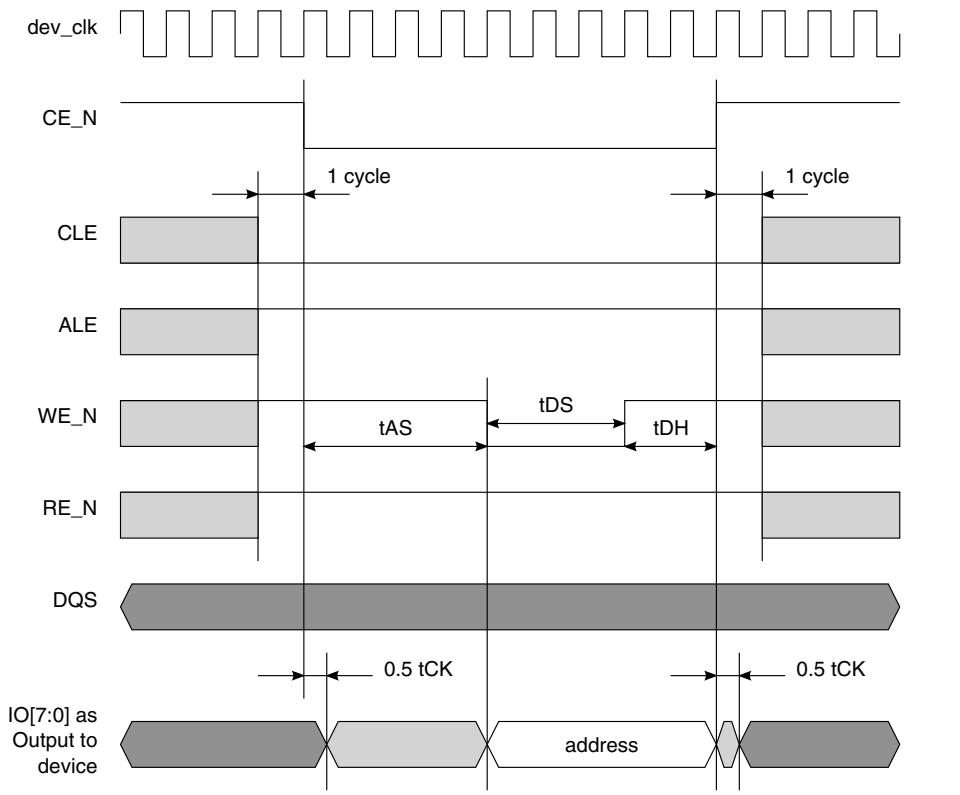

Host controller does not drive the IO[7:0] bus
And also does not care if device will drive that or not and what will be drived.

Host controller drives the IO[7:0] bus, but
the data in the IO[7:0] should be ignored by the device

- tAS is configurable by programming HW_GPMI_TIMING0 Address_Setup;
- tDS is configurable by programming HW_GPMI_TIMING0 Data_Setup;
- tDH is configurable br programming HW_GPMI_TIMING Data_Hold;
- tAS/tDS/tDH will extend, if the output data is not ready in device fifo.

Figure 31-11. SAMSUNG toggle mode basic address write timing diagram

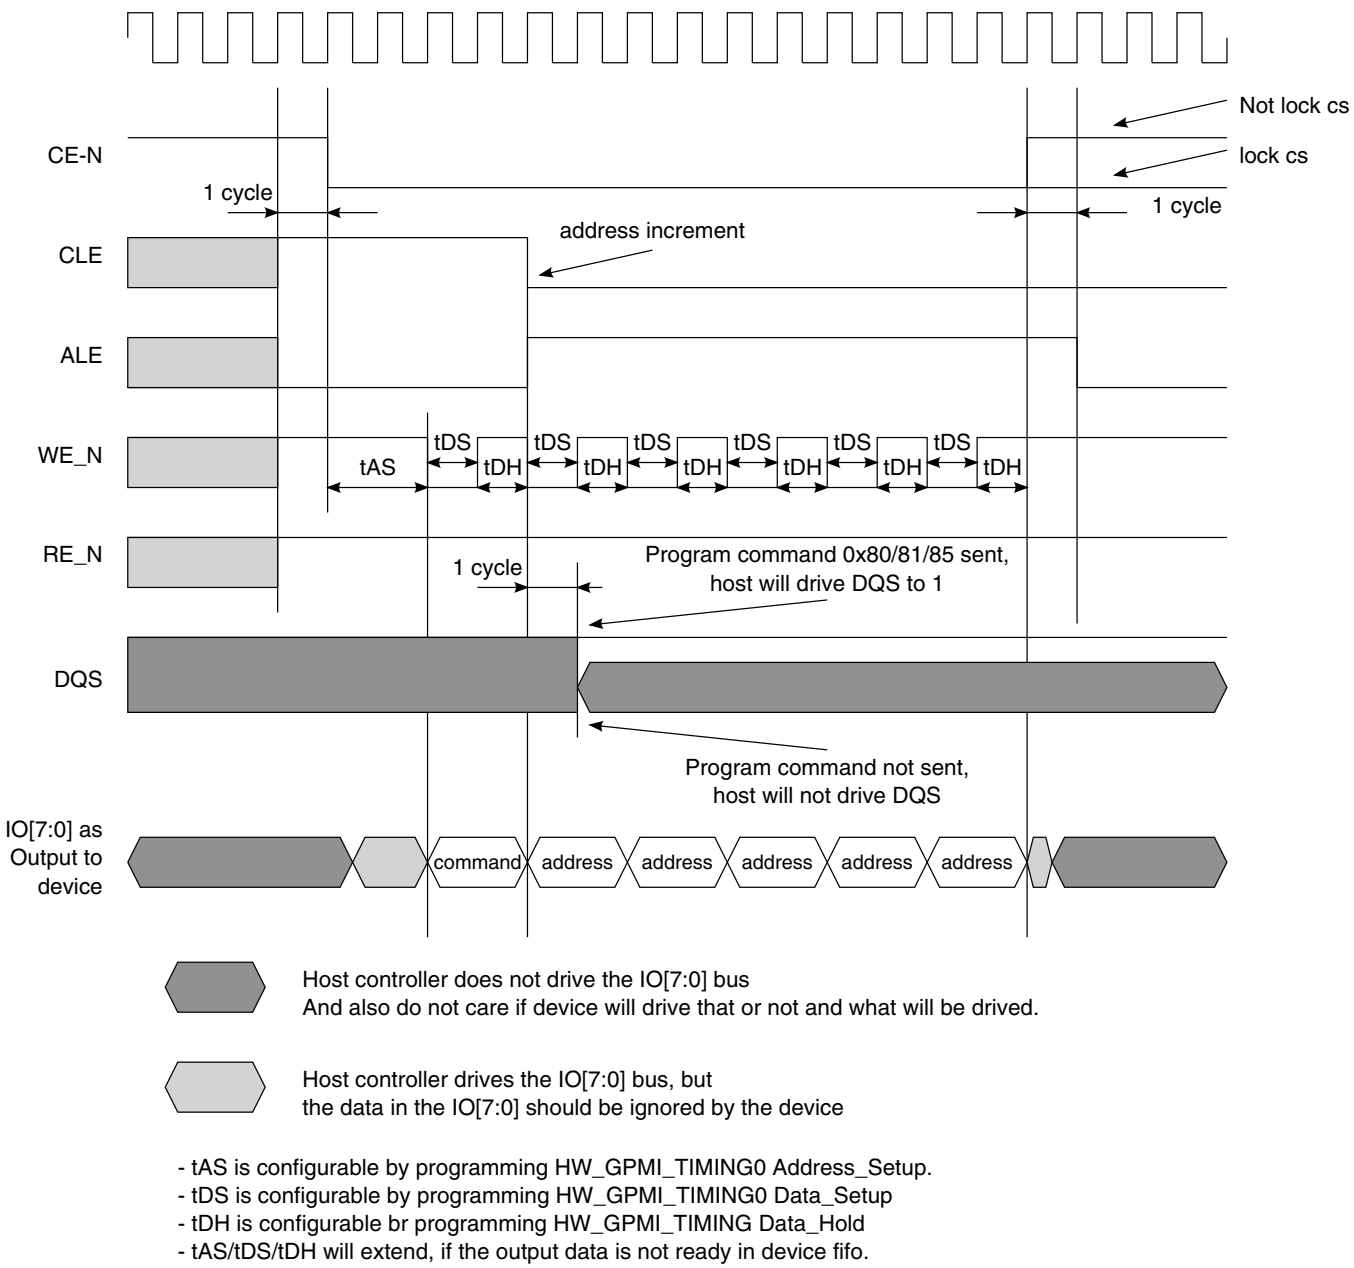

Figure 31-12. SAMSUNG toggle mode basic command + address timing diagram

31.3.4 Hardware BCH Interface

The GPMI provides an interface to the BCH module. This reduces the SOC bus traffic and the software involvement. When in BCH mode, parity information is inserted on-the-fly during writes to 8-bit NAND devices. The BCH will supply payload and parity to the

GPMI to write to the NAND. During NAND reads, parity is checked and ECC processing is performed after each read block. In this case the GPMI reads the NAND device and redirects the data and parity to the BCH module for ECC processing.

To program the BCH for NAND writes, remove the soft reset and clock gates from HW_BCH_CTRL_SFTRST and HW_BCH_CTRL_CLKGATE. The bulk of BCH programming is actually applied to the GPMI via PIO operations embedded in its DMA command structures. This has a subtle implication when writing to the GPMI ECC registers: access to the these registers must be written in progressive register order. Thus, to write to the HW_GPMI_ECCCOUNT register, write first (in order) to registers HW_GPMI_CTRL0, HW_GPMI_COMPARE, and HW_GPMI_ECCCTRL before writing to HW_GPMI_ECCCOUNT. These additional register writes need to be accounted for in the CMDWORDS field of the respective DMA channel command register.

Note that the HW_GPMI_PAYLOAD and HW_GPMI_AUXILIARY pointers need to be word-aligned for proper ECC operation. If those pointers are non-word-aligned, then the BCH engine will not operate properly and could possibly corrupt system memory in the adjoining memory regions.

31.4 Behavior During Reset

A soft reset (SFTRST) can take multiple clock periods to complete, so do NOT set CLKGATE when setting SFTRST. The reset process gates the clocks automatically.

31.5 Programmable Registers

GPMI Hardware Register Format Summary

GPMI memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

31.5.1 GPMI Control Register 0 (GPMI_CTRL0*n*)

The GPMI control register 0 specifies the GPMI transaction to perform for the current command chain item.

Addresses: GPMI_CTRL0 is 4100_6000h base + 0h offset = 4100_6000h

GPMI_CTRL0_SET is 4100_6000h base + 4h offset = 4100_6004h

GPMI_CTRL0_CLR is 4100_6000h base + 8h offset = 4100_6008h

GPMI_CTRL0_TOG is 4100_6000h base + Ch offset = 4100_600Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R/W	SFTRST	CLKGATE	RUN	DEV_IRQ_EN	LOCK_CS	UDMA	COMMAND_MODE		WORD_LENGTH	CS			ADDRESS			ADDRESS_INCREMENT
Reset	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R/W	XFER_COUNT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPMI_CTRL0*n* field descriptions

Field	Description
31 SFTRST	Set to zero for normal operation. When this bit is set to one (default), then the entire block is held in its reset state. This will not work if the CLKGATE bit is already set to '1'. CLKGATE must be cleared to '0' before issuing a soft reset. Also the GPMICLK must be running for this to work properly.

Table continues on the next page...

GPMI_CTRL0*n* field descriptions (continued)

Field	Description
	0x0 **RUN** — Allow GPMI to operate normally. 0x1 **RESET** — Hold GPMI in reset.
30 CLKGATE	Set this bit zero for normal operation. Setting this bit to one (default), gates all of the block level clocks off for miniminizing AC energy consumption. 0x0 **RUN** — Allow GPMI to operate normally. 0x1 **NO_CLKS** — Do not clock GPMI gates in order to minimize power consumption.
29 RUN	The GPMI is busy running a command whenever this bit is set to '1'. The GPMI is idle whenever this bit set to zero. This can be set to one by a ARM platform write. In addition, the DMA sets this bit each time a DMA command has finished its PIO transfer phase. 0x0 **IDLE** — The GPMI is idle. 0x1 **BUSY** — The GPMI is busy running a command.
28 DEV_IRQ_EN	When set to '1' and ATA_IRQ pin is asserted, the GPMI_IRQ output will assert.
27 LOCK_CS	For ATA/NAND mode: 0= Deassert chip select (CS) after RUN is complete. 1= Continue to assert chip select (CS) after RUN is complete. For Camera Mode: 0= Dont wait for VSYNC rising edge before capturing data. 1= Wait for VSYNC rising edge before capturing data (Camera mode only). 0x0 **DISABLED** — Deassert chip select (CS) after RUN is complete. 0x1 **ENABLED** — Continue to assert chip select (CS) after RUN is complete.
26 UDMA	0= Use ATA-PIO mode on the external bus. 1= Use ATA-Ultra DMA mode on the external bus. 0x0 **DISABLED** — Use ATA-PIO mode on the external bus. 0x1 **ENABLED** — Use ATA-Ultra DMA mode on the external bus.
25–24 COMMAND_ MODE	00= Write mode. 01= Read Mode. 10= Read and Compare Mode (setting sense flop). 11= Wait for Ready. 0x0 **WRITE** — Write mode. 0x1 **READ** — Read mode. 0x2 **READ_AND_COMPARE** — Read and Compare mode (setting sense flop). 0x3 **WAIT_FOR_READY** — Wait for Ready mode. For ATA WAIT_FOR_READY command set CS=01.
23 WORD_ LENGTH	0= 16-bit Data Bus Mode. 1= 8-bit Data Bus mode. This bit should only be changed when RUN==0. When GPMI works at DDR interface, that is in Source Synchronous Mode or Samsung Toggle Mode, this bit should be set to 0x0, which is 16-bit Data Bus Mode. 0x0 **16_BIT** — 16-bit Data Bus Mode. 0x1 **8_BIT** — 8-bit Data Bus mode.

Table continues on the next page...

GPMI_CTRL0*n* field descriptions (continued)

Field	Description
22–20 CS	Selects which chip select is active for this command. For ATA WAIT_FOR_READY command, this must be set to b01.
19–17 ADDRESS	Specifies the three address lines for ATA mode. In NAND mode, use A0 for CLE and A1 for ALE. 0x0 **NAND_DATA** — In NAND mode, this address is used to read and write data bytes. 0x1 **NAND_CLE** — In NAND mode, this address is used to write command bytes. 0x2 **NAND_ALE** — In NAND mode, this address is used to write address bytes.
16 ADDRESS_ INCREMENT	0= Address does not increment. 1= Increment address. In ATA mode, the address will increment with each cycle. In NAND mode, the address will increment once, after the first cycle (going from CLE to ALE). 0x0 **DISABLED** — Address does not increment. 0x1 **ENABLED** — Increment address.
15–0 XFER_COUNT	Number of words (8 or 16 bit wide) to transfer for this command. A value of zero will transfer 64K words. When GPMI woks at DDR interface, that is Source Synchronous Mode or Samsung Toggle Mode, XFER_COUNT should be calculated according to the WORD_LENGTH being set to 16 bits.

31.5.2 GPMI Compare Register (GPMI_COMPARE)

The GPMI compare register specifies the expect data and the xor mask for comparing to the status values read from the device. This register is used by the Read and Compare command.

Address: GPMI_COMPARE is 4100_6000h base + 10h offset = 4100_6010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	MASK																REFERENCE															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

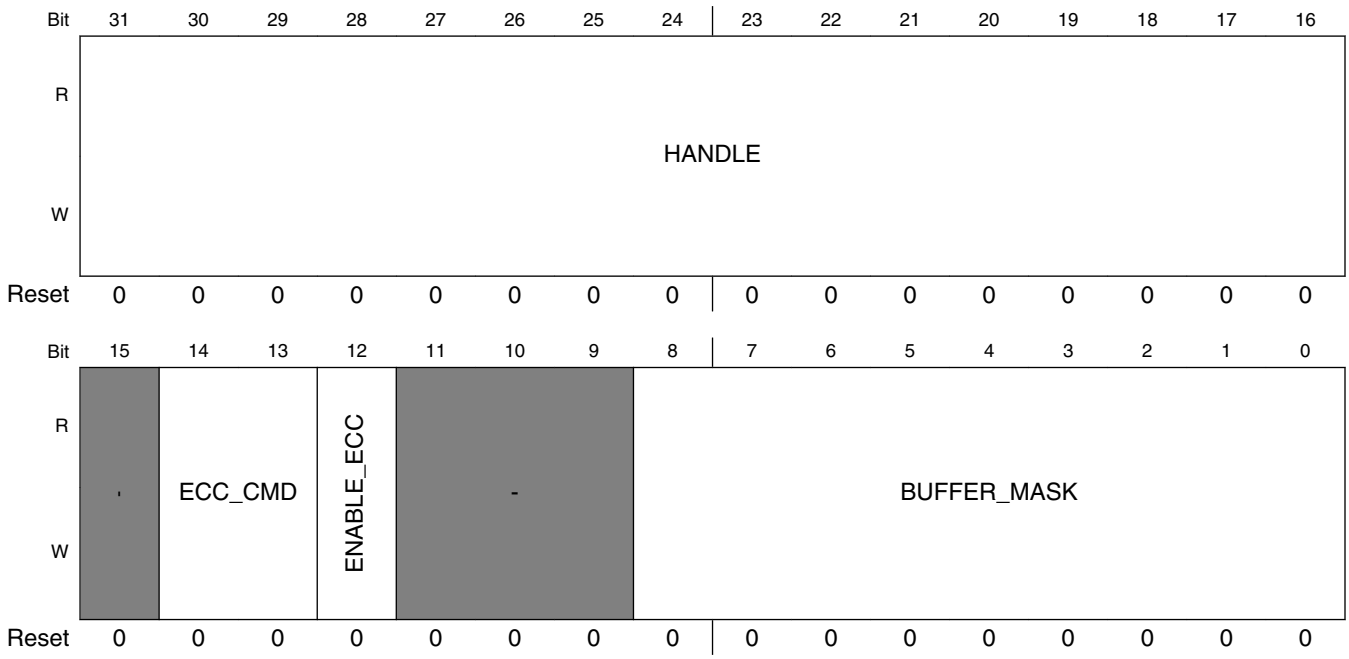
GPMI_COMPARE field descriptions

Field	Description
31–16 MASK	16-bit mask which is applied after the read data is XORed with the REFERENCE bit field.
15–0 REFERENCE	16-bit value which is XORed with data read from the NAND device.

31.5.3 GPMI Integrated ECC Control Register (GPMI_ECCCTRL*n*)

The GPMI ECC control register handles configuration of the integrated ECC accelerator.

Addresses: GPMI_ECCCTRL is 4100_6000h base + 20h offset = 4100_6020h
GPMI_ECCCTRL_SET is 4100_6000h base + 24h offset = 4100_6024h
GPMI_ECCCTRL_CLR is 4100_6000h base + 28h offset = 4100_6028h
GPMI_ECCCTRL_TOG is 4100_6000h base + 2Ch offset = 4100_602Ch



GPMI_ECCCTRL*n* field descriptions

Field	Description
31–16 HANDLE	This is a register available to software to attach an identifier to a transaction in progress. This handle will be available from the ECC register space when the completion interrupt occurs.
15 -	Always write zeroes to this bit field.
14–13 ECC_CMD	ECC Command information. 0x0 **DECODE** — Decode. 0x1 **ENCODE** — Encode. 0x2 **RESERVE2** — Reserved. 0x3 **RESERVE3** — Reserved.
12 ENABLE_ECC	Enable ECC processing of GPMI transfers. 0x1 **ENABLE** — Use integrated ECC for read and write transfers. 0x0 **DISABLE** — Integrated ECC remains in idle.
11–9 -	Always write zeroes to this bit field.

Table continues on the next page...

GPMI_ECCCTRL*n* field descriptions (continued)

Field	Description
8–0 BUFFER_MASK	ECC buffer information. The BCH error correction only allows two configurations of the buffer mask - software may either read just the first block on the flash page or the entire flash page. Write operations must be for the entire flash page. Invalid buffer mask values will cause the DMA descriptor command to be terminated. 0x100 **BCH_AUXONLY** — Set to request transfer from only the auxiliary buffer (block 0 on flash). 0x1FF **BCH_PAGE** — Set to request transfer to/from the entire page.

31.5.4 GPMI Integrated ECC Transfer Count Register (GPMI_ECCCOUNT)

The GPMI ECC Transfer Count Register contains the count of bytes that flow through the ECC subsystem.

Address: GPMI_ECCCOUNT is 4100_6000h base + 30h offset = 4100_6030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	-																COUNT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPMI_ECCCOUNT field descriptions

Field	Description
31–16 -	Always write zeroes to this bit field.
15–0 COUNT	Number of bytes to pass through ECC. This is the GPMI transfer count plus the syndrome count that will be inserted into the stream by the ECC. In DMA2ECC_MODE this count must match the GPMI_CTRL0_XFER_COUNT. A value of zero will transfer 64K words. When GPMI works at DDR interface, that is Source Synchronous Mode or Samsung Toggle Mode, XFER_COUNT should be calculated according to the WORD_LENGTH being set to 16 bits.

31.5.5 GPMI Payload Address Register (GPMI_PAYLOAD)

The GPMI payload address register specifies the location of the data buffers in system memory. This value must be word aligned.

Address: GPMI_PAYLOAD is 4100_6000h base + 40h offset = 4100_6040h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	ADDRESS [31:2]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDRESS [31:2]														-	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPMI_PAYLOAD field descriptions

Field	Description
31–2 ADDRESS [31:2]	Pointer to an array of one or more 512 byte payload buffers.
1–0 -	Always write zeroes to this bit field.

31.5.6 GPMI Auxiliary Address Register (GPMI_AUXILIARY)

The GPMI auxiliary address register specifies the location of the auxiliary buffers in system memory. This value must be word aligned.

Address: GPMI_AUXILIARY is 4100_6000h base + 50h offset = 4100_6050h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	ADDRESS[31:2]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDRESS[31:2]														-	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPMI_AUXILIARY field descriptions

Field	Description
31–2 ADDRESS[31:2]	Pointer to ECC control structure and meta-data storage.
1–0 -	Always write zeroes to this bit field.

31.5.7 GPMI Control Register 1 (GPMI_CTRL1*n*)

The GPMI control register 1 specifies additional control fields that are not used on a per-transaction basis.

Addresses: GPMI_CTRL1 is 4100_6000h base + 60h offset = 4100_6060h

GPMI_CTRL1_SET is 4100_6000h base + 64h offset = 4100_6064h

GPMI_CTRL1_CLR is 4100_6000h base + 68h offset = 4100_6068h

GPMI_CTRL1_TOG is 4100_6000h base + 6Ch offset = 4100_606Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	DEV_CLK_STOP	SSYNC_CLK_STOP	WRITE_CLK_STOP	TOGGLE_MODE	CLK_DIV2_EN	UPDATE_CS	SSYNCMODE	DECOUPLE_CS	WRN_DLY_SEL		-	TIMEOUT_IRQ_EN	GANGED_RDYBUSY	BCH_MODE	DLL_ENABLE	HALF_PERIOD
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

GPMI_CTRL1*n* field descriptions

Field	Description
31 DEV_CLK_ STOP	set this bit to 1 will stop gpmi io working clk.
30 SSYNC_CLK_ STOP	set this bit to 1 will stop the source synchronous mode clk.

Table continues on the next page...

GPMI_CTRL1*n* field descriptions (continued)

Field	Description
29 WRITE_CLK_STOP	In onfi source synchronous mode, host may save power during the data write cycles by holding the CLK signal high (i.e. stopping the CLK). The host may only stop the CLK during data write, by setting this bit to 1, if the device supports this feature as indicated in the parameter page.
28 TOGGLE_MODE	enable samsung toggle mode.
27 CLK_DIV2_EN	enable the gpmi clk divider. This bit should be reset to 0 in asynchronous mode. The frequence ratio of (device clock : ccm gpmi clock) will be (1 : 1). This bit should be set to 1, in source synchronous mode or toggle mode. The frequence raito of (device clock : ccm gpmi clock) will be (1 : 2). 0x0 **DISABLED** — internal factor-2 clock divider is disabled 0x1 **ENABLED** — internal factor-2 clock divider is enabled
26 UPDATE_CS	force the CS value is be updated to external chip select pin, even GPMI is idle.
25 SSYNCMODE	source synchronouse mode 1 or asynchrous mode 0. 0x0 **ASYNC** — Asynchronous mode. 0x1 **SSYNC** — Source Synchronous mode.
24 DECOUPLE_CS	Decouple Chip Select from DMA Channel. Setting this bit to 1 will allow a DMA channel to specify any value in the CTRL0_CS register field. Software can use one DMA channel to access all 8 Nand devices.
23–22 WRN_DLY_SEL	Since the GPMI write strobe (WRN) is a fast clock pin, the delay on this signal can be programmed to match the load on this pin. 0 = no delay; 1 = 4ns to 8ns; 2 = 6ns to 10ns; 3 = 7ns to 12ns.
21 -	Always write zeroes to this bit field.
20 TIMEOUT_IRQ_EN	Setting this bit to '1' will enable timeout IRQ for transfers in ATA mode only, and for WAIT_FOR_READY commands in both ATA and Nand mode. The Device_Busy_Timeout value is used for this timeout.
19 GANGED_RDYBUSY	Set this bit to 1 will force all Nand RDY_BUSY inputs to be sourced from (tied to) RDY_BUSY0. This will free up all, except one, RDY_BUSY input pins.
18 BCH_MODE	This bit selects which error correction unit will access GPMI. This bit must always be set to '1', since only the BCH unit is available in this design.
17 DLL_ENABLE	Set this bit to 1 to enable the GPMI DLL. This is required for fast NAND reads (above 30MHz read strobe). After setting this bit, wait 64 GPMI clock cycles for the DLL to lock before performing a NAND read.
16 HALF_PERIOD	Set this bit to 1 if the GPMI clock period is greater than 16ns for proper DLL operation. DLL_ENABLE must be zero while changing this field.
15–12 RDN_DELAY	This variable is a factor in the calculated delay to apply to the internal read strobe for correct read data sampling. The applied delay (AD) is between 0 and 1.875 times the reference period (RP). RP is one half of the GPMI clock period if HALF_PERIOD=1

Table continues on the next page...

GPMI_CTRL1*n* field descriptions (continued)

Field	Description
	otherwise it is the full GPMI clock period. The equation is: AD = RDN_DELAY x 0.125 x RP. This value must not exceed 16ns. This variable is used to achieve faster NAND access. For example if the Read Strobe is asserted from time 0 to 13ns but the read access time is 20ns, then choose AD=12ns will cause the data to be sampled at time 25ns (13+12) giving a 5ns data setup time. If RP=13ns then RDN_DELAY = 12/(0.125 x 13ns) = 7.38 (0111b). DLL_ENABLE must be zero while changing this field.
11 DMA2ECC_ MODE	This is mainly for testing HWECC without involving the Nand device. Setting this bit will cause DMA write data to redirected to HWECC module (instead of Nand Device) for encoding or decoding.
10 DEV_IRQ	This bit is set when an Interrupt is received from the ATA device. Write 0 to clear.
9 TIMEOUT_IRQ	This bit is set when a timeout occurs using the Device_Busy_Timeout value. Write 0 to clear.
8 BURST_EN	When set to 1 each DMA request will generate a 4-transfer burst on the APB bus.
7 ABORT_WAIT_ REQUEST	Request to abort "wait for ready" command on channel indicated by ABORT_WAIT_FOR_READY_CHANNEL. Hardware will clear this bit when abort is done.
6–4 ABORT_WAIT_ FOR_READY_ CHANNEL	Abort a wait for ready command on selected channel. Set the ABORT_WAIT_REQUEST to kick of operation.
3 DEV_RESET	0= Device Reset pin is held low (asserted). 1= Device Reset pin is held high (de-asserted). 0x0 **ENABLED** — Device Reset pin is held low (asserted). 0x1 **DISABLED** — Device Reset pin is held high (de-asserted).
2 ATA_IRQRDY_ POLARITY	For ATA MODE: 0= External ATA IORDY and IRQ are active low. 1= External ATA IORDY and IRQ are active high. For NAND MODE: 0= External RDY_BUSY[1] and RDY_BUSY[0] pins are ready when low and busy when high. 1= External RDY_BUSY[1] and RDY_BUSY[0] pins are ready when high and busy when low. Note NAND_RDY_BUSY[3:2] are not affected by this bit. 0x0 **ACTIVELOW** — ATA IORDY and IRQ are active low, or NAND_RDY_BUSY[1:0] are active low ready. 0x1 **ACTIVEHIGH** — ATA IORDY and IRQ are active high, or NAND_RDY_BUSY[1:0] are active high ready.
1 CAMERA_ MODE	When set to 1 and ATA UDMA is enabled the UDMA interface becomes a camera interface.

Table continues on the next page...

GPMI_CTRL1*n* field descriptions (continued)

Field	Description
0 MODE	0= NAND mode. 1= ATA mode. ATA mode is only supported on channel zero. If ATA mode is selected, then only channel three is available for NAND use. 0x0 **NAND** — NAND mode. 0x1 **ATA** — ATA mode.

31.5.8 GPMI Timing Register 0 (GPMI_TIMING0)

The GPMI timing register 0 specifies the timing parameters that are used by the cycle state machine to guarantee the various setup, hold and cycle times for the external media type.

Address: GPMI_TIMING0 is 4100_6000h base + 70h offset = 4100_6070h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	-								ADDRESS_SETUP								DATA_HOLD								DATA_SETUP							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	1	0	0	0	0	0	0	0	1	1

GPMI_TIMING0 field descriptions

Field	Description
31–24 -	Always write zeroes to this bit field.
23–16 ADDRESS_ SETUP	Number of GPMICLK cycles that the CE/ADDR signals are active before a strobe is asserted. A value of zero is interpreted as 0. For ATA PIO modes this is known in the ATA7 specification as "Address valid to DIOR-/DIOW- setup"
15–8 DATA_HOLD	Data bus hold time in GPMICLK cycles. Also the time that the data strobe is de-asserted in a cycle. A value of zero is interpreted as 256. For ATA PIO modes this is known in the ATA7 specification as "DIOR-/DIOW- recovery time"
7–0 DATA_SETUP	Data bus setup time in GPMICLK cycles. Also the time that the data strobe is asserted in a cycle. This value must be greater than 2 for ATA devices that use IORDY to extend transfer cycles. A value of zero is interpreted as 256. For ATA PIO modes this is known in the ATA7 specification as ""DIOR-/DIOW-"

31.5.9 GPMI Timing Register 1 (GPMI_TIMING1)

The GPMI timing register 1 specifies the timeouts used when monitoring the NAND READY pin or the ATA IRQ and IOWAIT signals.

Address: GPMI_TIMING1 is 4100_6000h base + 80h offset = 4100_6080h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DEVICE_BUSY_TIMEOUT																-															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPMI_TIMING1 field descriptions

Field	Description
31–16 DEVICE_BUSY_TIMEOUT	Timeout waiting for NAND Ready/Busy or ATA IRQ. Used in WAIT_FOR_READY mode. This value is the number of GPMI_CLK cycles multiplied by 4096.
15–0 -	Always write zeroes to this bit field.

31.5.10 GPMI Timing Register 2 (GPMI_TIMING2)

The GPMI timing register 2 specifies the double data rate timing parameters that are used by the cycle state machine to guarantee the various cs delay, pre-amble delay, post-amble delay, command/address delay, data delay and read latency cycle times for the external media type.

Address: GPMI_TIMING2 is 4100_6000h base + 90h offset = 4100_6090h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	-					READ_ LATENCY			-			CE_DELAY					PREAMBLE_ DELAY				POSTAMBLE_ DELAY				CMDADD_ PAUSE				DATA_ PAUSE

GPMI_TIMING2 field descriptions

Field	Description
31–27 -	Always write zeroes to this bit field.
26–24 READ_ LATENCY	This field is for double data rate read latency configuration. 3'b000 : READ LATENCY is 0 3'b001 : READ LATENCY is 1 3'b010 : READ LATENCY is 2

Table continues on the next page...

GPMI_TIMING2 field descriptions (continued)

Field	Description
	3'b011 : READ LATENCY is 3 3'b100 : READ LATENCY is 4 3'b101 : READ LATENCY is 5 others : READ LATENCY is 3
23–21 -	Always write zeroes to this bit field.
20–16 CE_DELAY	GPMI dealy from CEn assert to W/Rn changing edge. value of zero is interpreted as 32.
15–12 PREAMBLE_ DELAY	GPMI pre-amble delay in GPMICLK cycles. A value of zero is interpreted as 16.
11–8 POSTAMBLE_ DELAY	GPMI post-amble delay in GPMICLK cycles. A value of zero is interpreted as 16.
7–4 CMDADD_ PAUSE	GPMI delay time from command or addres pause to command or address resume in GPMICLK cycles. A value of zero is interpreted as 16.
3–0 DATA_PAUSE	GPMI delay time from data pause to data resume in GPMICLK cycles. A value of zero is interpreted as 16.

31.5.11 GPMI DMA Data Transfer Register (GPMI_DATA)

The GPMI DMA data transfer register is used by the DMA to read or write data to or from the ATA/NAND control state machine.

Address: GPMI_DATA is 4100_6000h base + A0h offset = 4100_60A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DATA																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

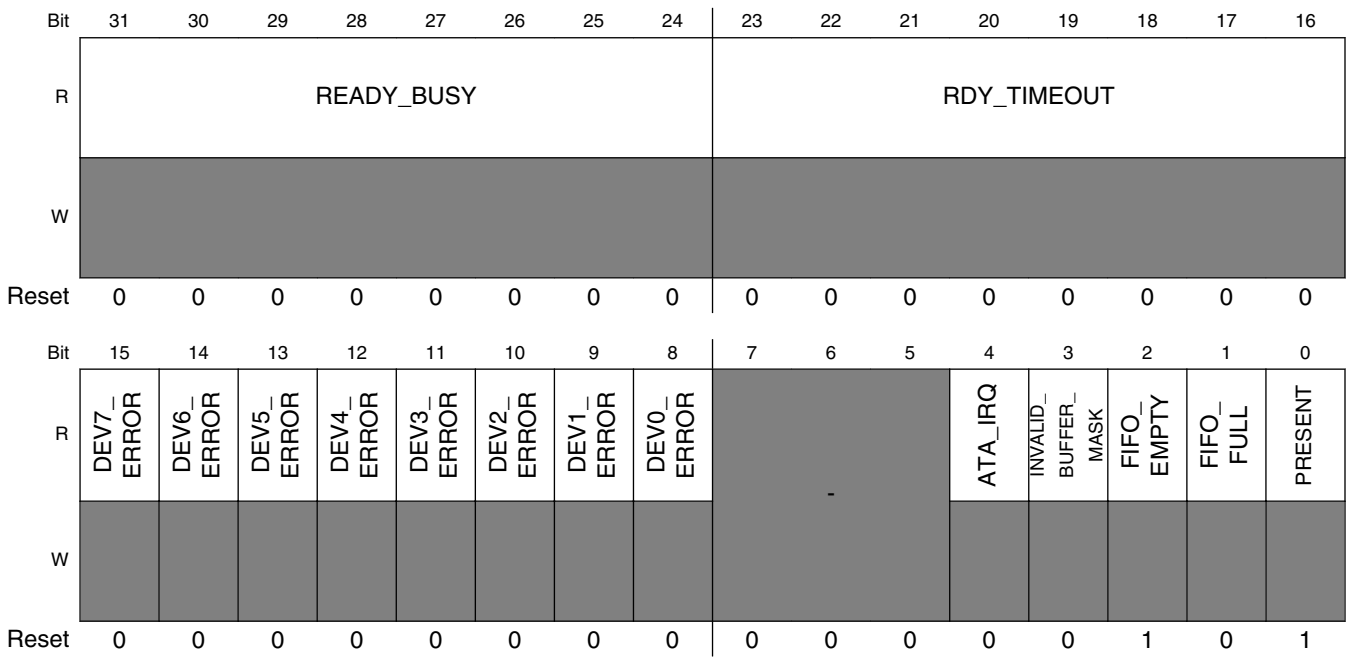
GPMI_DATA field descriptions

Field	Description
31–0 DATA	In 16-bit mode, this register can be accessed in two 16-bit operations, one bus cycle per operation. In 8-bit mode, one, two, three or four bytes can can be accessed to send the same number of bus cycles.

31.5.12 GPMI Status Register (GPMI_STAT)

The GPMI control and status register provides a read back path for various operational states of the GPMI controller.

Address: GPMI_STAT is 4100_6000h base + B0h offset = 4100_60B0h



GPMI_STAT field descriptions

Field	Description
31–24 READY_BUSY	Read-only view of NAND Ready_Busy Input pins.
23–16 RDY_TIMEOUT	State of the RDY/BUSY Timeout Flags. When any bit is set to '1' in this field, it indicates that a time out has occurred while waiting for the ready state of the requested NAND device. Multiple bits may be set simultaneously. When GPMI_CTRL1_DECOUPLE_CS = 0, RDY_TIMEOUT[n] is associated with the NAND device on chip_select[n]. When GPMI_CTRL1_DECOUPLE_CS = 1, these flags become associated to a DMA channel instead of a NAND device. For example if DMA channel 6 sends a WAIT_FOR_READY command for NAND Device 2, and a timeout occured on READY_BUSY2, then READY_TIMEOUT[6] will be set instead of READY_TIMEOUT[2].
15 DEV7_ERROR	0= No error condition present on ATA/NAND Device accessed by DMA channel 7. 1= An Error has occurred on ATA/NAND Device accessed by DMA channel 7 (Timeout or compare failure, depending on COMMAND_MODE).
14 DEV6_ERROR	0= No error condition present on ATA/NAND Device accessed by DMA channel 6.

Table continues on the next page...

GPMI_STAT field descriptions (continued)

Field	Description
	1= An Error has occurred on ATA/NAND Device accessed by DMA channel 6 (Timeout or compare failure, depending on COMMAND_MODE).
13 DEV5_ERROR	0= No error condition present on ATA/NAND Device accessed by DMA channel 5. 1= An Error has occurred on ATA/NAND Device accessed by DMA channel 5 (Timeout or compare failure, depending on COMMAND_MODE).
12 DEV4_ERROR	0= No error condition present on ATA/NAND Device accessed by DMA channel 4. 1= An Error has occurred on ATA/NAND Device accessed by DMA channel 4 (Timeout or compare failure, depending on COMMAND_MODE).
11 DEV3_ERROR	0= No error condition present on ATA/NAND Device accessed by DMA channel 3. 1= An Error has occurred on ATA/NAND Device accessed by DMA channel 3 (Timeout or compare failure, depending on COMMAND_MODE).
10 DEV2_ERROR	0= No error condition present on ATA/NAND Device accessed by DMA channel 2. 1= An Error has occurred on ATA/NAND Device accessed by DMA channel 2 (Timeout or compare failure, depending on COMMAND_MODE).
9 DEV1_ERROR	0= No error condition present on ATA/NAND Device accessed by DMA channel 1. 1= An Error has occurred on ATA/NAND Device accessed by DMA channel 1 (Timeout or compare failure, depending on COMMAND_MODE).
8 DEV0_ERROR	0= No error condition present on ATA/NAND Device accessed by DMA channel 0. 1= An Error has occurred on ATA/NAND Device accessed by DMA channel 0 (Timeout or compare failure, depending on COMMAND_MODE).
7–5 -	Always write zeroes to this bit field.
4 ATA_IRQ	Status of the ATA_IRQ input pin.
3 INVALID_ BUFFER_MASK	0= ECC Buffer Mask is not invalid. 1= ECC Buffer Mask is invalid.
2 FIFO_EMPTY	0= FIFO is not empty. 1= FIFO is empty. 0x0 **NOT_EMPTY** — FIFO is not empty. 0x1 **EMPTY** — FIFO is empty.
1 FIFO_FULL	0= FIFO is not full. 1= FIFO is full. 0x0 **NOT_FULL** — FIFO is not full. 0x1 **FULL** — FIFO is full.
0 PRESENT	0= GPMI is not present in this product. 1= GPMI is present is in this product. 0x0 **UNAVAILABLE** — GPMI is not present in this product. 0x1 **AVAILABLE** — GPMI is present in this product.

31.5.13 GPMI Debug Information Register (GPMI_DEBUG)

The GPMI debug information register provides a read back path for diagnostics to determine the current operating state of the GPMI controller.

Address: GPMI_DEBUG is 4100_6000h base + C0h offset = 4100_60C0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	WAIT_FOR_READY_END								DMA_SENSE								DMAREQ								CMD_END							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPMI_DEBUG field descriptions

Field	Description
31–24 WAIT_FOR_ READY_END	Read Only view of the Wait_For_Ready End toggle signals to DMA. One per channel
23–16 DMA_SENSE	Read-only view of sense state of the 8 DMA channels. A value of "1" in any bit position indicates that a read and compare command failed or a timeout occured for the corresponding channel.
15–8 DMAREQ	Read-only view of DMA request line for 8 DMA channels. A toggle on any bit position indicates a DMA request for the corresponding channel.
7–0 CMD_END	Read Only view of the Command End toggle signals to DMA. One per channel

31.5.14 GPMI Version Register (GPMI_VERSION)

This register reflects the version number for the GPMI.

Address: GPMI_VERSION is 4100_6000h base + D0h offset = 4100_60D0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	MAJOR								MINOR								STEP															
W																																
Reset	0	0	0	0	0	1	0	1	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

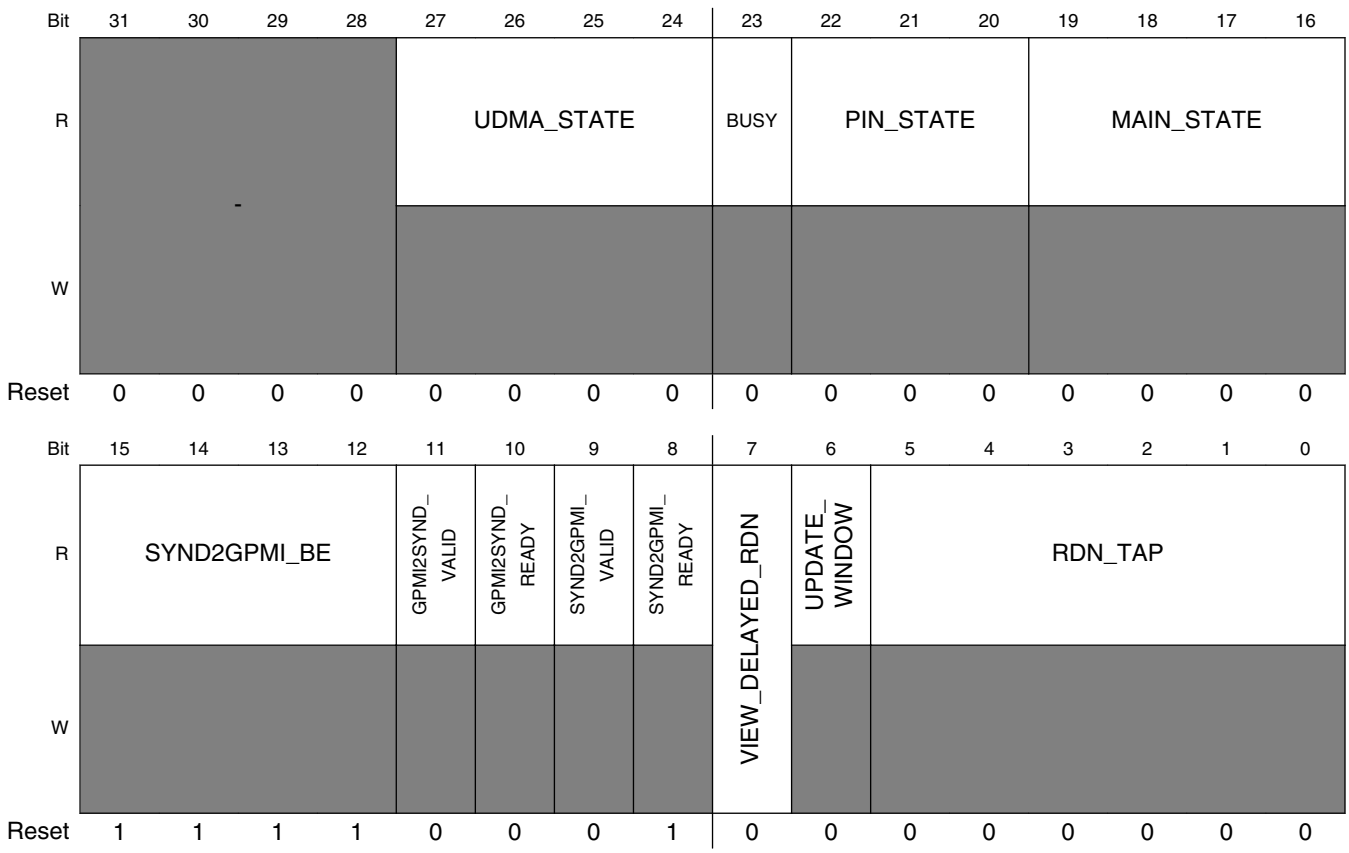
GPMI_VERSION field descriptions

Field	Description
31–24 MAJOR	Fixed read-only value reflecting the MAJOR field of the RTL version.
23–16 MINOR	Fixed read-only value reflecting the MINOR field of the RTL version.
15–0 STEP	Fixed read-only value reflecting the stepping of the RTL version.

31.5.15 GPMI Debug2 Information Register (GPMI_DEBUG2)

The GPMI Debug2 information register provides a read back path for diagnostics to determine the current operating state of the GPMI controller.

Address: GPMI_DEBUG2 is 4100_6000h base + E0h offset = 4100_60E0h



GPMI_DEBUG2 field descriptions

Field	Description
31–28 -	Always write zeroes to this bit field.
27–24 UDMA_STATE	USM_IDLE = 4'h0, idle USM_DMARQ = 4'h1, DMA req USM_ACK = 4'h2, DMA ACK USM_FIFO_E = 4'h3, Fifo empty USM_WPAUSE = 4'h4, WR DMA Paused by device USM_TSTRB = 4'h5, Toggle HSTROBE USM_CAPTUR = 4'h6, Capture Stage, (data sampled with DSTROBE is valid) USM_DATOUT = 4'h7, Change Burst DATAOUT USM_CRC = 4'h8, Source CRC to Device

Table continues on the next page...

GPMI_DEBUG2 field descriptions (continued)

Field	Description
	USM_WAIT_R = 4'h9, Waiting for DDMARDY- USM_END = 4'ha; Negate DMAACK (end of DMA) USM_WAIT_S = 4'hb, Waiting for DSTROBE USM_RPAUSE = 4'hc, Rd DMA Paused by Host USM_RSTOP = 4'hd, Rd DMA Stopped by Host USM_WTERM = 4'he, Wr DMA Termination State USM_RTERM = 4'hf, Rd DMA Termination state
23 BUSY	When asserted the GPMI is busy. Undefined results may occur if any registers are written when BUSY is asserted. 0x0 **DISABLED** — The GPMI is not busy. 0x1 **ENABLED** — The GPMI is busy.
22–20 PIN_STATE	parameter PSM_IDLE = 3'h0, PSM_BYTCNT = 3'h1, PSM_ADDR = 3'h2, PSM_STALL = 3'h3, PSM_STROBE = 3'h4, PSM_ATARDY = 3'h5, PSM_DHOLD = 3'h6, PSM_DONE = 3'h7. 0x0 **PSM_IDLE** — 0x1 **PSM_BYTCNT** — 0x2 **PSM_ADDR** — 0x3 **PSM_STALL** — 0x4 **PSM_STROBE** — 0x5 **PSM_ATARDY** — 0x6 **PSM_DHOLD** — 0x7 **PSM_DONE** —

15–12 SYND2GPMI_BE	Data byte enable Input from BCH.
11 GPMI2SYND_VALID	Data handshake output to BCH.

Table continues on the next page...

GPMI_DEBUG2 field descriptions (continued)

Field	Description
10 GPMI2SYND_ READY	Data handshake output to BCH.
9 SYND2GPMI_ VALID	Data handshake Input from BCH.
8 SYND2GPMI_ READY	Data handshake Input from BCH.
7 VIEW_ DELAYED_RDN	Set to a 1 to select the delayed feedback RDN to drive the GPMI_ADDR[0] (Nand CLE) pin. For debug purposes, this will allow you see if DLL is functioning properly.
6 UPDATE_ WINDOW	A 1 indicates that the DLL is busy generating the required delay.
5–0 RDN_TAP	This is the DLL tap calculated by the DLL controller. The selects the amount of delay form the DLL chain.

31.5.16 GPMI Debug3 Information Register (GPMI_DEBUG3)

The GPMI Debug3 information register provides a read back path for diagnostics to determine the current operating state of the GPMI controller.

Address: GPMI_DEBUG3 is 4100_6000h base + F0h offset = 4100_60F0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	APB_WORD_CNTR																DEV_WORD_CNTR

GPMI_DEBUG3 field descriptions

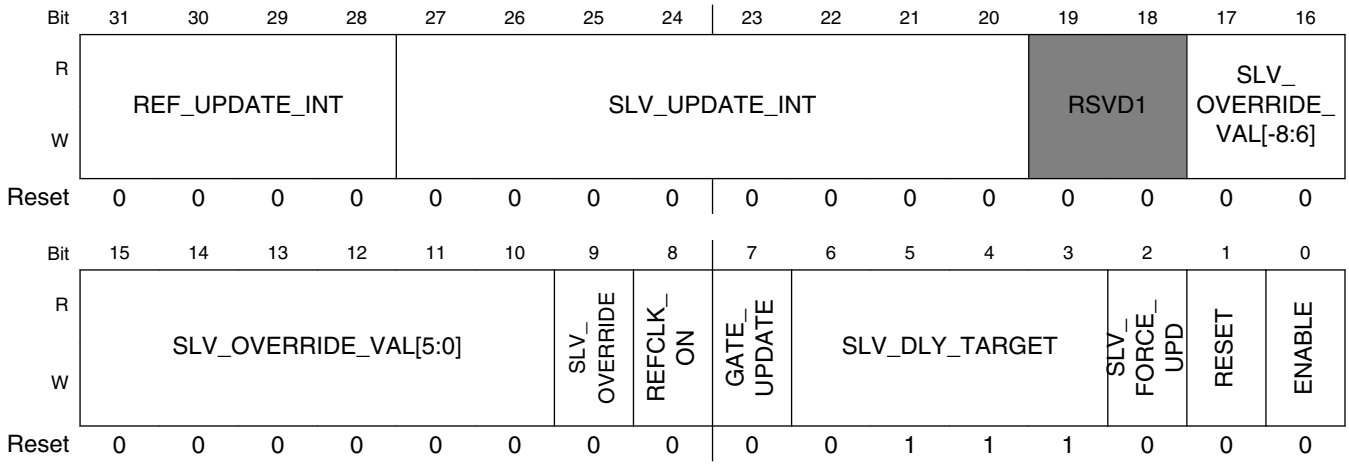
Field	Description
31–16 APB_WORD_ CNTR	Reflects the number of words (16 or 8-bit) remains to be transferred on the APB bus.
15–0 DEV_WORD_ CNTR	Reflects the number of words (16 or 8-bit) remains to be transferred on the ATA/Nand bus.

31.5.17 GPMI Double Rate Read DLL Control Register (GPMI_READ_DDR_DLL_CTRL)

GPMI DDR Read Delay Loop Lock Control Register.

This register provides programmability in DDR mode for data input timing and data formats.

Address: GPMI_READ_DDR_DLL_CTRL is 4100_6000h base + 100h offset = 4100_6100h



GPMI_READ_DDR_DLL_CTRL field descriptions

Field	Description
31–28 REF_UPDATE_ INT	This field allows the user to add additional delay cycles to the DLL control loop (reference delay line control). By default, the DLL control loop shall update every two SSPCLK cycles. Programming this field results in a DLL control loop update interval of (2 + REF_UPDATE_INT) * SSPCLK. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that may effect the delay (such as voltage and temperature)
27–20 SLV_UPDATE_ INT	Setting a value greater than 0 in this field, shall over-ride the default slave delay-line update interval of 256 SSPCLK cycles. A value of 0 results in an update interval of 256 SSPCLK cycles (default setting). A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the slave-delay line using the SLV_FORCE_UPDATE register. Note that the slave delay line will also update automatically when the reference DLL transitions to a locked state (from an un-locked state).
19–18 RSVD1	Reserved
17–10 SLV_ OVERRIDE_VAL	When SLV_OVERRIDE=1 This field is used to select 1 of 256 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 256.
9 SLV_OVERRIDE	Set this bit to 1 to Enable manual override for slave delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to tbe enabled using the ENABLE bit. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE=0
8 REFCLK_ON	set this bit to 1 will turn on the reference clock

Table continues on the next page...

GPMI_READ_DDR_DLL_CTRL field descriptions (continued)

Field	Description
7 GATE_UPDATE	Setting this bit to 1, forces the slave delay line not update
6–3 SLV_DLY_ TARGET	The delay target for the SSP read clock is can be programmed in 1/16th increments of an SSPCLK half-period. So the input read-clock can be delayed relative input data from (SSPCLK/2)/16 to SSPCLK/2.
2 SLV_FORCE_ UPD	Setting this bit to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line shall update automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered).
1 RESET	Setting this bit to 1 force a reset on DLL. This will cause the DLL to lose lock and re-calibrate to detect an SSPCLK half period phase shift. This signal is used by the DLL as edge-sensitive, so in order to create a subsequent reset, RESET must be taken low and then asserted again.
0 ENABLE	Set this bit to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE VAL, the DLL does not need to be enabled.

31.5.18 GPMI Double Rate Write DLL Control Register (GPMI_WRITE_DDR_DLL_CTRL)

GPMI DDR Write Delay Loop Lock Control Register.

This register provides programmability in DDR mode for data output timing and data formats.

Address: GPMI_WRITE_DDR_DLL_CTRL is 4100_6000h base + 110h offset = 4100_6110h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	0	0	0	0	0	0	1	1	1	0	0	0

GPMI_WRITE_DDR_DLL_CTRL field descriptions

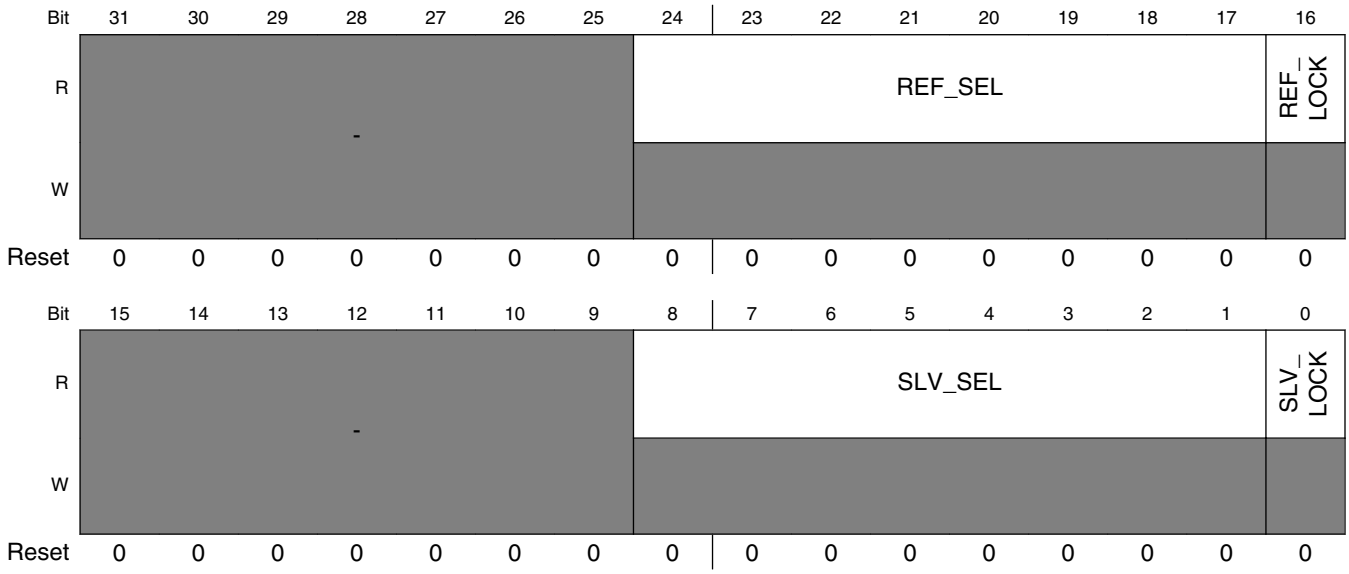
Field	Description
31–28 REF_UPDATE_INT	This field allows the user to add additional delay cycles to the DLL control loop (reference delay line control). By default, the DLL control loop shall update every two SSPCLK cycles. Programming this field results in a DLL control loop update interval of (2 + REF_UPDATE_INT) * SSPCLK. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that may effect the delay (such as voltage and temperature)
27–20 SLV_UPDATE_INT	Setting a value greater than 0 in this field, shall over-ride the default slave delay-line update interval of 256 SSPCLK cycles. A value of 0 results in an update interval of 256 SSPCLK cycles (default setting). A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the slave-delay line using the SLV_FORCE_UPDATE register. Note that the slave delay line will also update automatically when the reference DLL transitions to a locked state (from an un-locked state).
19–18 -	Reserved
17–10 SLV_OVERRIDE_VAL	When SLV_OVERRIDE=1 This field is used to select 1 of 256 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 256.
9 SLV_OVERRIDE	Set this bit to 1 to Enable manual override for slave delay chain using SLV_OVERRIDE_VAL; to set 0 to disable manual override. This feature does not require the DLL to tbe enabled using the ENABLE bit. In fact to reduce power, if SLV_OVERRIDE is used, it is recommended to disable the DLL with ENABLE=0
8 REFCLK_ON	set this bit to 1 will turn on the reference clock
7 GATE_UPDATE	Setting this bit to 1, forces the slave delay line not update
6–3 SLV_DLY_TARGET	The delay target for the SSP read clock is can be programmed in 1/16th increments of an SSPCLK half-period. So the input read-clock can be delayed relative input data from (SSPCLK/2)/16 to SSPCLK/2.
2 SLV_FORCE_UPD	Setting this bit to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line shall update automatically based on the SLV_UPDATE_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV_FORCE_UP is set back to 0 and then asserted again (edge triggered).
1 RESET	Setting this bit to 1 force a reset on DLL. This will cause the DLL to lose lock and re-calibrate to detect an SSPCLK half period phase shift. This signal is used by the DLL as edge-sensitive, so in order to create a subsequent reset, RESET must be taken low and then asserted again.
0 ENABLE	Set this bit to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the slave delay line override feature with SLV_OVERRIDE and SLV_OVERRIDE VAL, the DLL does not need to be enabled.

31.5.19 GPMI Double Rate Read DLL Status Register (GPMI_READ_DDR_DLL_STS)

GPMI Double Rate Read DLL Status Register, Read Only.

GPMI DLL status fields are provided in this register.

Address: GPMI_READ_DDR_DLL_STS is 4100_6000h base + 120h offset = 4100_6120h



GPMI_READ_DDR_DLL_STS field descriptions

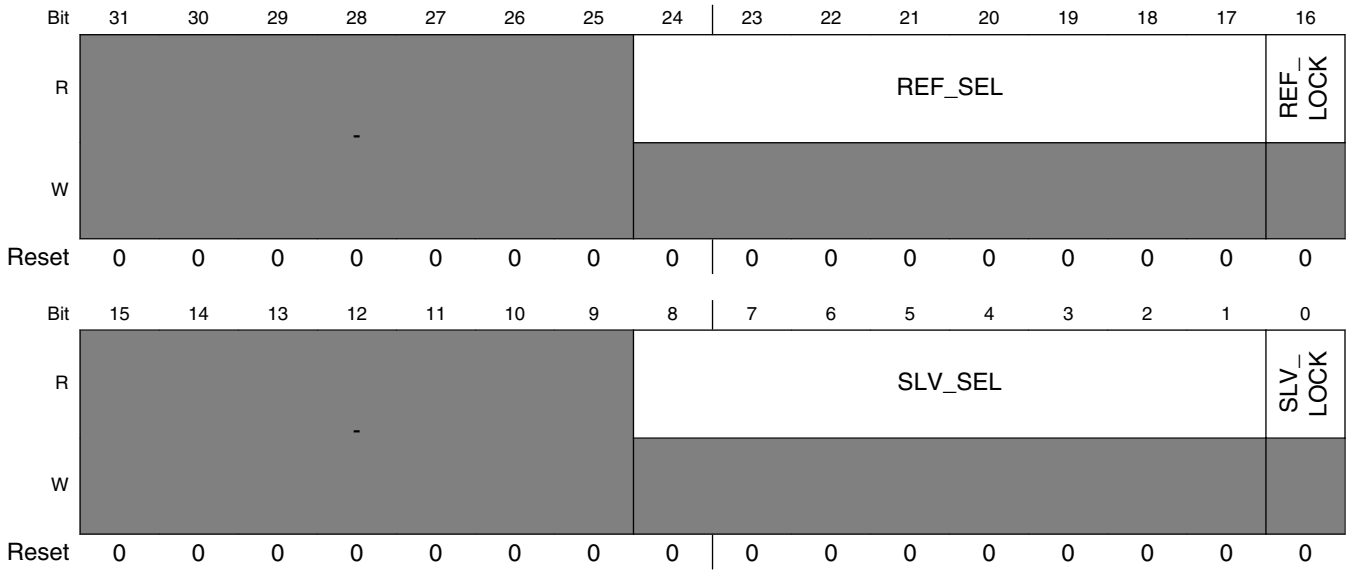
Field	Description
31–25 -	Reserved
24–17 REF_SEL	Reference delay line select status.
16 REF_LOCK	Reference DLL lock status. This signifies that the DLL has detected and locked to a half-phase GPMICLK shift, allowing the slave delay-line to perform programmed clock delays.
15–9 -	Reserved
8–1 SLV_SEL	Slave delay line select status
0 SLV_LOCK	Slave delay-line lock status. This signifies that a valid calibration has been set to the slave-delay line and that the slave-delay line is implementing the programmed delay value.

31.5.20 GPMI Double Rate Write DLL Status Register (GPMI_WRITE_DDR_DLL_STS)

GPMI Double Rate Write DLL Status Register, Read Only.

GPMI DLL status fields are provided in this register.

Address: GPMI_WRITE_DDR_DLL_STS is 4100_6000h base + 130h offset = 4100_6130h



GPMI_WRITE_DDR_DLL_STS field descriptions

Field	Description
31–25 -	Reserved
24–17 REF_SEL	Reference delay line select status.
16 REF_LOCK	Reference DLL lock status. This signifies that the DLL has detected and locked to a half-phase GPMICLK shift, allowing the slave delay-line to perform programmed clock delays.
15–9 -	Reserved
8–1 SLV_SEL	Slave delay line select status
0 SLV_LOCK	Slave delay-line lock status. This signifies that a valid calibration has been set to the slave-delay line and that the slave-delay line is implementing the programmed delay value.

Chapter 32
General Purpose Timer (GPT)

32.1 Overview

This chapter describes the General Purpose Timer (GPT) module interface. It is also a reference for software driver programming. The GPT has a 32-bit up-counter. The timer counter value can be captured in a register using an event on an external pin. The capture trigger can be programmed to be a rising or/and falling edge. The GPT can also generate an event on the DO_CMPOUT*n* pins and an interrupt when the timer reaches a programmed value. The GPT has a 12-bit prescaler, which provides a programmable clock frequency derived from multiple clock sources.

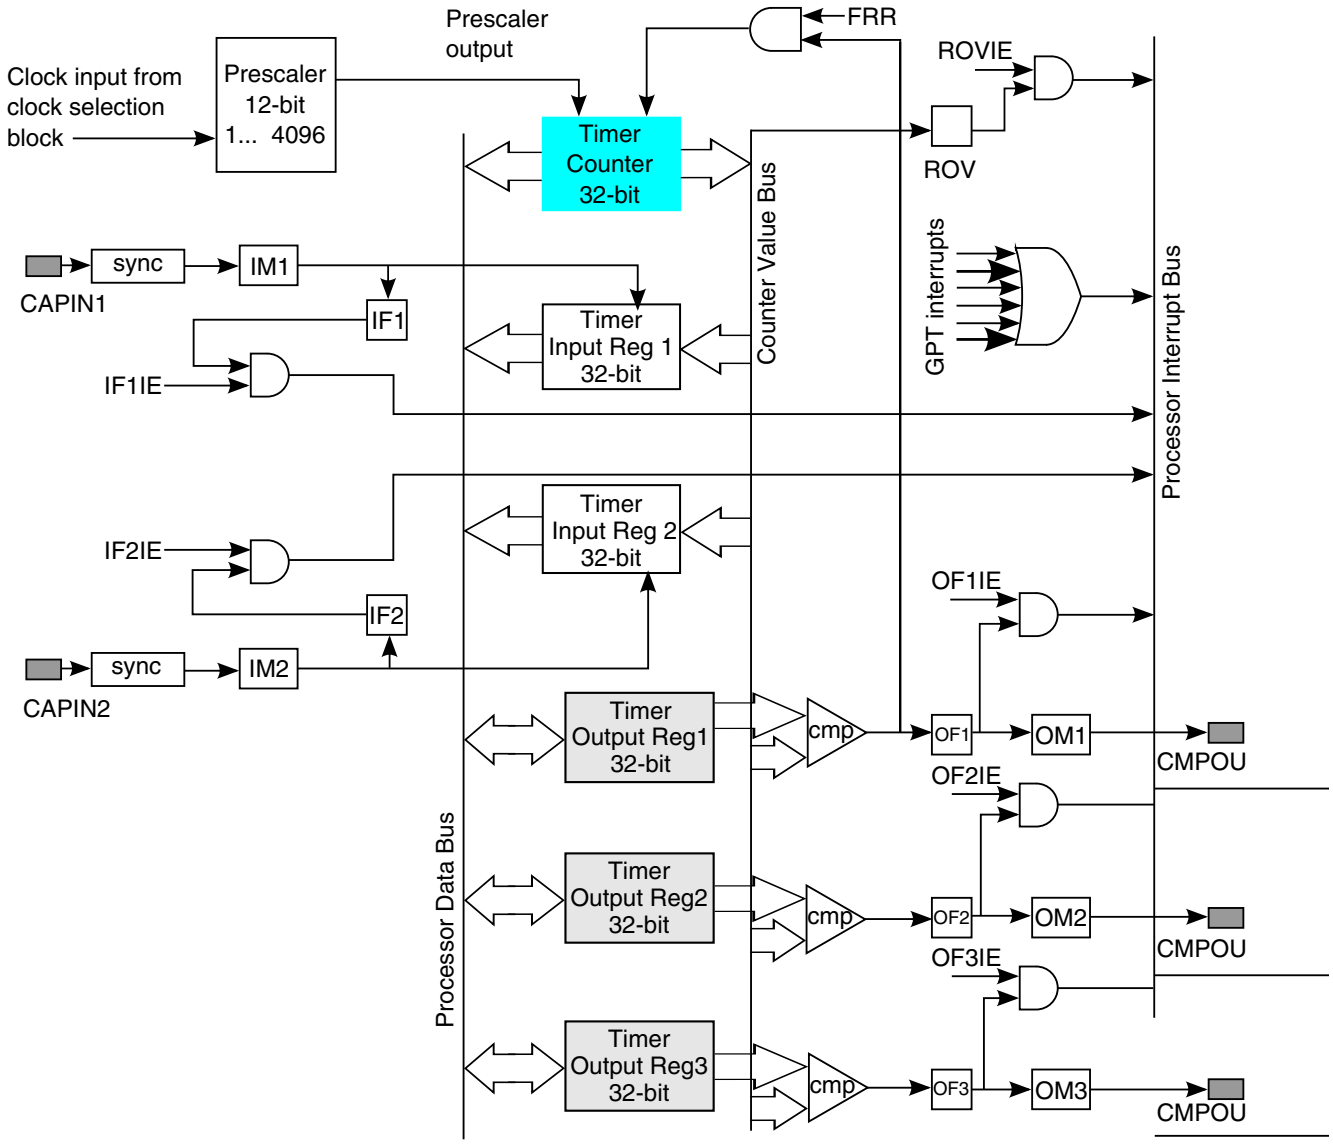


Figure 32-1. GPT Block Diagram

The following figure shows the GPT functional clocking scheme.

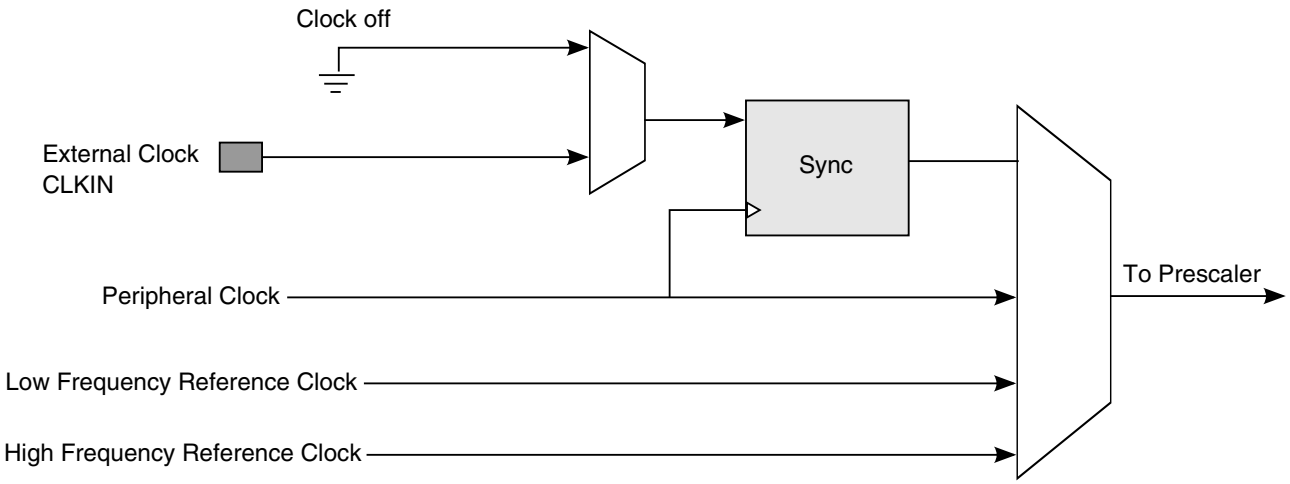

Figure 32-2. GPT Counter Clocks Diagram

32.1.1 Features

- One 32-bit up-counter with clock source selection, including external clock.
- Two input capture channels with a programmable trigger edge.
- Three output compare channels with a programmable output mode. A "forced compare" feature is also available.
- Can be programmed to be *active* in low power and debug modes.
- Interrupt generation at capture, compare, and rollover events.
- Restart or free-run modes for counter operations.

32.1.2 Modes and Operation

The GPT supports the modes described in the indicated sections:

- Operating Modes
  - Restart Mode
  - Free-Run Mode

32.2 External Signals

The GPT follows the IP Bus protocol for interfacing with the processor core. The GPT does not have *any interface signals with any other module inside the chip,* except for the clock and reset inputs (from the clock and reset controller module) and for the interrupt signals *to* the processor interrupt handler. There are functional and clock inputs, and functional output signals going outside the chip boundary.

The following table describes all block signals that connect off-chip.

Table 32-1. Off-Chip Module Signals

Name	Direction	Function	Reset State	Pull-Up
CLKIN	I	Input pin for an external clock that the counter can be operated at.	-	Passive Hysteresis
CAPIN1	I	Input pin for a capture event for Input Capture Channel 1.	-	Passive
CAPIN2	I	Input pin for a capture event for Input Capture Channel 2.	-	Passive
CMPOUT1	O	Output pin that indicates a "compare event" occurrence in Output Compare Channel 1.	0	Passive
CMPOUT2	O	Output pin that indicates a "compare event" occurrence in Output Compare Channel 2.	0	Passive
CMPOUT3	O	Output pin that indicates a "compare event" occurrence in Output Compare Channel 3.	0	Passive

There are six signals (three input, three output) in the GPT module that *can be* connected to the chip pads.

32.2.1 External Clock Input: CLKIN

The GPT counter can be operated using an external clock from outside the device, and this is the input pin used for that purpose. This clock is treated as asynchronous to the peripheral clock. To ensure proper operations of GPT, the external clock input frequency should be less than 1/4 of frequency of the peripheral clock. Hysteresis characteristics on this pad will be required because this is a clock input.

32.2.2 Input Capture Trigger Signals: CAPIN1, CAPIN2

The GPT counter value can be stored in a register, triggered by an event from *outside the device*. A positive or/and negative edge on these signals can trigger this capture event. These signals are treated as asynchronous to the peripheral clock. Only those transitions which occur *at least a single clock cycle* (the clock selected to run the counter) *after the previous recorded transition* are guaranteed to trigger a capture event.

32.2.3 Output Compare Signals: DO_CMPOUT1, DO_CMPOUT2, DO_CMPOUT3

The output compare signals indicate that output compare events have gone through a specified transition.

32.3 Functional Description

This section provides a complete functional description of the GPT.

32.3.1 Operating Modes

The GPT counter can be programmed to work in either of two modes: Restart mode or Free-Run mode.

32.3.1.1 Restart Mode

In Restart mode (selectable through the GPT Control Register GPT_CR), when the counter reaches the compared value, the counter resets and starts again from 0x00000000. The Restart feature is associated only with Compare Channel 1.

Any write access to the Compare register of Channel 1 will reset the GPT counter. This is done to avoid possibly missing a compare event when compare value is changed from a higher value to lower value while counting is proceeding.

For the other two compare channels, when the compare event occurs the counter is *not reset*.

32.3.1.2 Free-Run Mode

In Free-Run mode, when compare events occur for all 3 channels, the counter is *not reset*; instead the counter continues to count until 0xffffffff, and then rolls over (to 0x00000000).

32.3.2 Operation

The General Purpose Timer (GPT) has a single counter (GPT_CNT) that is a 32-bit free-running *up-counter,* which starts counting *after it is enabled by software* (EN=1).

The counter's clock source is the output of the prescaler labelled "Prescaler output" in Figure 32-1.

- If the GPT timer is disabled (EN=0), then the Main Counter *and* Prescaler Counter freeze their current count values. The ENMOD bit determines the value of the GPT counter when the EN bit is set and the Counter is enabled again.
  - If the ENMOD bit is set (=1), then the Main Counter and Prescaler Counter values are reset to 0, when GPT is enabled (EN=1).
  - If ENMOD bit is programmed to 0, then the Main Counter and Prescaler Counter restart counting from their frozen values, when GPT is enabled again (EN=1).
- If GPT is programmed to be disabled in a low power mode (STOP/WAIT), then the Main Counter and Prescaler Counter freeze at their current count values *when* GPT enters low power mode. When GPT exits a low power mode, the Main Counter and Prescaler Counter start counting from their frozen values *regardless* of the ENMOD bit value. Note that the GPT_CNT can be read *at any time* by the processor, and that *both* Input Capture Channels use the *same* counter (GPT_CNT).
- A hardware reset resets all the GPT registers to their respective reset values. All registers except the Output Compare Registers (OCR1, OCR2, OCR3) obtain a value of 0x0. The Compare registers are reset to 0xffffffff.
- The software reset (SWR bit in the GPT_CR control register) resets *all* of the register bits *except* the EN, ENMOD, STOPEN, WAITEN, and DBGEN bits. The state of these bits is not affected by a software reset. Note that a software reset can be given *while the GPT is disabled*.

32.3.2.1 Clocks

The clock that is input to the prescaler can be selected from 4 clock sources:

- High Frequency Clock

Provided by the Clock Controller Module (CCM), the High Frequency Clock is intended to be ON in Normal Power mode when the Peripheral Clock is turned OFF, thereby enabling the GPT to be operated using the High Frequency Clock *in Normal Power mode*. The CCM is expected to provide this clock *after* synchronizing it to the System Bus Clock in Normal functional mode; the CCM is also expected to switch to the *unsynchronized* version of the High Frequency Clock in a Low Power mode.

- Low Reference Clock

  This 32 kHz Low Reference Clock (provided by the CCM) is intended to be ON in Low Power mode when the Peripheral Clock is turned OFF, thereby enabling the GPT to be operated using the Low Reference Clock in Low Power mode. The CCM is expected to provide the Low Reference Clock *after* synchronizing it to the System Bus Clock in Normal functional mode; the CCM is also expected to switch to the *unsynchronized* version of the Low Reference Clock in a Low Power mode.

- External Clock

  The External Clock comes from *outside the device* and can be selected to run the GPT counter. The External Clock is treated as *asynchronous to the Peripheral Clock,* and is synchronized to the Peripheral Clock, *inside* the module. Therefore, the External Clock frequency is limited to < 1/4 frequency of the Peripheral Clock, for proper GPT operations. Note that in Low Power modes, *if* the Peripheral Clock is not available, then the External Clock *cannot be used* to run the counter.

- Peripheral Clock

  If the Peripheral Clock or the External Clock is selected(CLKSRC=001 or 011) as Clock Source, then the Peripheral Clock will be ON in normal GPT operations. In Low Power modes, if the GPT is programmed to be disabled (STOPEN or WAITEN or DOZEN=0), then the Peripheral Clock can be switched OFF.

- Crystal Oscillator Clock

  This 24MHz Crystal Oscillator Clock (provided by the CCM) is intended to be used against frequency change of Peripheral Clock changes to provide a more accruate timer clock for operation system. The CCM is expected to provide the 24M Crystal Oscillator Clock *without* synchronizing it to the System Bus Clock in Normal functional mode. Synchronization is done in GPT module. Before synchronization, the 24M Crystal Oscillator Clock is divided by a 24M clock prescaler, to make sure the clock frequency less than half of System Bus Clock .

The clock input source is configured using the clock source field (CLKSRC, in the GPT_CR control register). The clock input to the prescaler can be disabled by programming the CLKSRC bits (of the GPT_CR control register) to 000. **The CLKSRC field value should be changed** *only after disabling the GPT* (by setting the EN bit in the GPT_CR to 0).

The PRESCALER field selects the divide ratio of the input clock that drives the main counter. The prescaler can divide the input clock by a value (from 1 to 4096) and can be changed *at any time*. A change in the value of the PRESCALER field *immediately affects* the output clock frequency.

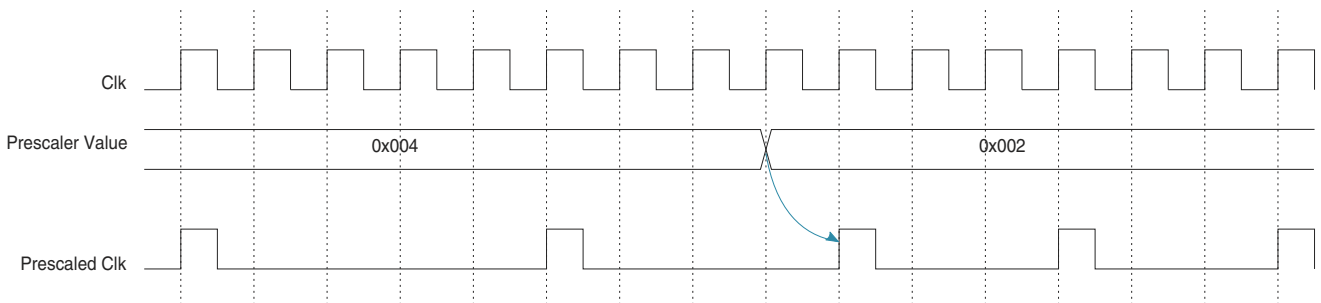

Figure 32-3. Prescaler Value Change Timing Diagram

32.3.2.2 Input Capture

There are two Input Capture Channels, and each Input Capture Channel has a dedicated capture pin, capture register and input edge detection/selection logic. Each input capture function has an associated status flag, and can cause the processor to make an interrupt service request.

When a selected edge transition occurs on an Input Capture pin, the contents of the GPT_CNT is captured on the corresponding capture register and the appropriate interrupt status flag is set. An interrupt request can be generated when the transition is detected *if* its corresponding enable bit is set (in the Interrupt Register). The capture can be programmed to occur on the input pin's rising edge, falling edge, on both rising and falling edges, or the capture can be disabled. The events are synchronized with the clock that was selected to run the counter. Only those transitions that occur at least one clock cycle (clock selected to run the counter) *after* the previous recorded transition will be guaranteed to trigger a capture event. There can be up to one clock cycle of uncertainty in the latching of the input transition. The Input Capture registers can be read *at any time* without affecting their values.

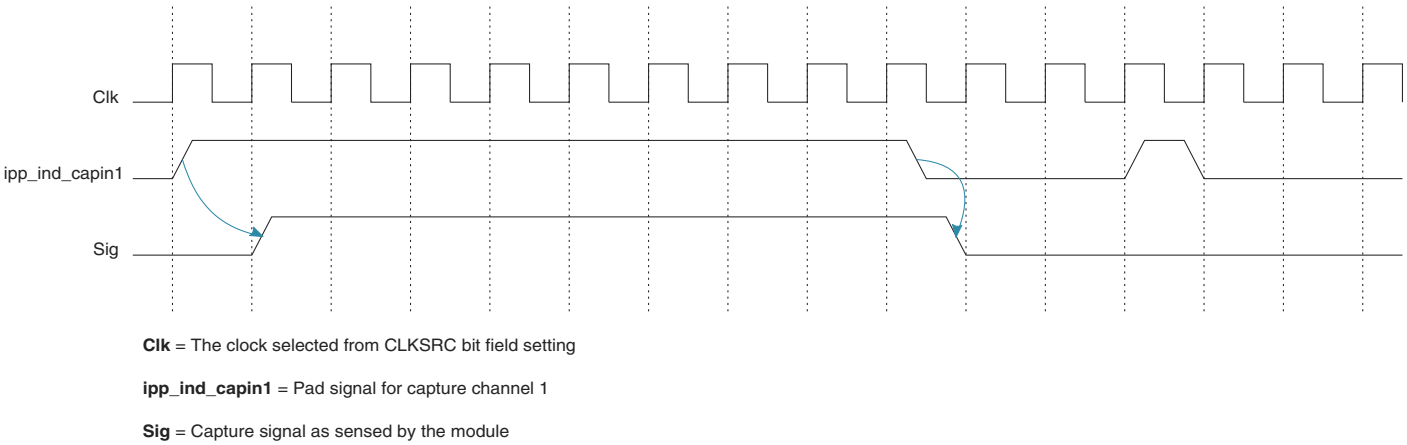

Figure 32-4. Input Capture Event Timing

32.3.2.3 Output Compare

The three Output Compare Channels *use the same counter* (GPT_CNT) as the Input Capture Channels. When the programmed content of an Output Compare register matches the value in GPT_CNT, an output compare status flag is set and an interrupt is generated (if the corresponding bit is set in the interrupt register). Consequently, the Output Compare timer pin will be set, cleared, toggled, not affected at all or provide an active-low pulse for one input clock period (subject to the restriction on the maximum frequency allowed on the pad) according to the mode bits (that were programmed).

There is also a "forced-compare" feature that allows the software to generate a compare event when required, *without the condition of the counter value that is equal to the compare value*. The action taken as a result of a forced compare is the same as when an output compare match occurs, *except that the status flags are not set and no interrupt can be generated*. Forced channels take programmed action immediately after the write to the force-compare bits. These bits are self-negating and always read as zeros.

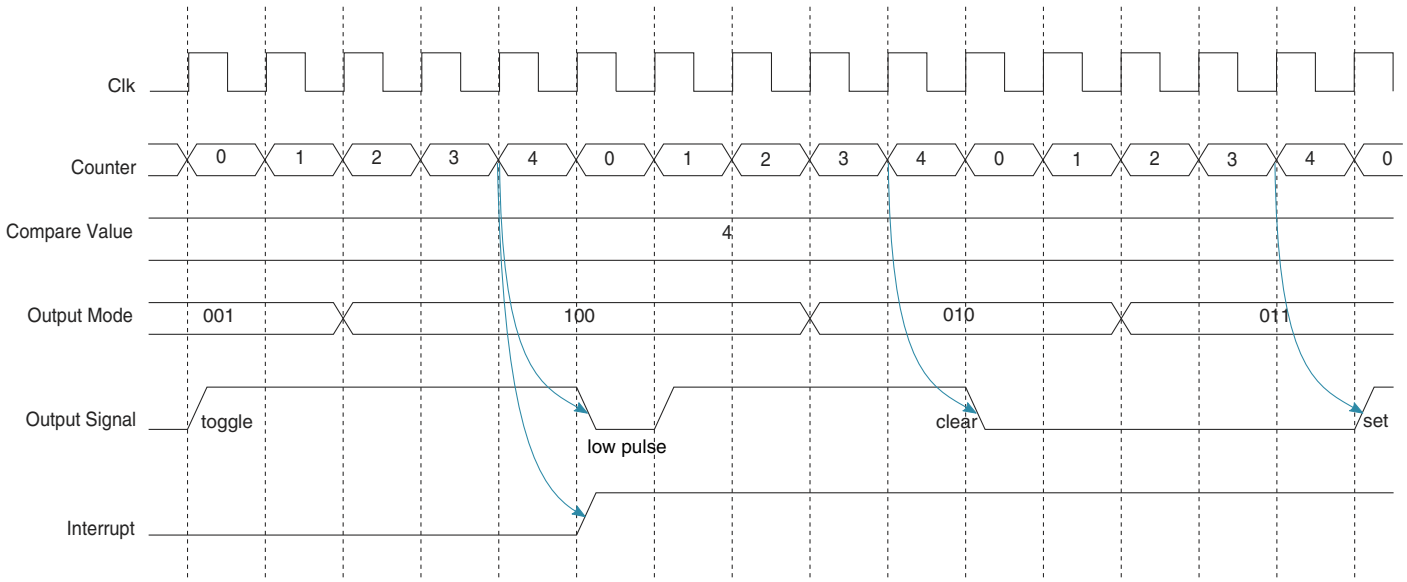

Figure 32-5. Output Compare and Interrupt Timing

32.3.2.4 Interrupts

There are 6 different interrupts that are generated by the GPT. If the selected clock for running the counter is available, then *all interrupts can be generated in Low Power and Debug modes*.

- Rollover Interrupt

  The Rollover Interrupt is generated when the GPT counter reaches 0xffffffff, then resets to 0x00000000 and continues counting. The Rollover Interrupt is enabled by the ROVIE bit in the GPT_IR register; the associated status bit is the ROV bit in the GPT_SR register.

- Input Capture Interrupt 1, 2

  After a capture event occurs, the associated Input Capture Channel generates an interrupt. The "capture event" interrupts are enabled by the IF2IE and IF1IE bits (in the GPT_IR register); the associated status bits are IF2 and IF1 (in the GPT_SR register). The capture of the counter value because of a capture event is *not affected by a pending capture interrupt*. The Capture register is updated with a new counter value when a capture event occurs, regardless of whether that Capture Channels' interrupt has been serviced or not.

- Output Compare Interrupt 1, 2, 3

After a compare event occurs, the associated Output Compare Channel generates an interrupt. The "compare event" interrupts are enabled by the OF3IE, OF2IE, and OF1IE bits (in the GPT_IR register); the associated status bits are OF3, OF2, and OF1 (in the GPT_SR register). A "forced compare" does not generate an interrupt.

A *cumulative* interrupt line is also present, which is asserted whenever any of the above interrupts are posted. The cumulative interrupt line has *no* associated enables or status bits.

32.3.2.5 Low Power Mode Behavior

In Low Power modes, if the clock from the selected clock source is available (except for the External Clock, which can be used *only if* the Peripheral Clock is available), the counter will continue to run depending on whether the control bit for that mode is set. If the clock is not present or if the corresponding low power bit in the GPT_CR control register is 0, the Main Counter and the Prescaler Counter freeze at their current values and resume counting (from their frozen values) when the Low Power mode is exited.

32.3.2.6 Debug Mode Behavior

In Debug mode, the modules in the device have the option of continuing to run or be halted.

- If the DBGEN bit is set, then the GPT timer will continue to run in Debug mode.
- If the DBGEN bit is not set (in the GPT_CR control register), then the GPT timer is halted.

32.4 Programmable Registers

The GPT has 10 user-accessible 32-bit registers, which are used to configure, operate, and monitor the state of the GPT.

An IP bus write access to the GPT Control Register (GPT_CR) and the GPT Output Compare Register1 (GPT_OCR1) results in *one cycle of wait state*, while other valid IP bus accesses incur 0 wait states.

Irrespective of the Response Select signal value, a Write access to the GPT Status Registers (Read-only registers GPT_ICR1, GPT_ICR2, GPT_CNT) will generate a bus exception.

- If the Response Select signal is driven Low, then the Read/Write access to the *unimplemented* address space of GPT (*ips_addr* is greater than or equal to $BASE + $028) will generate a bus exception.
- If the Response Select is driven High, then the Read/Write access to the unimplemented address space of GPT will *not* generate any error response (like a bus exception).

GPT memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
53FA_0000	GPT Control Register (GPT_CR)	32	R/W	0000_0000h	32.4.1/ 1603
53FA_0004	GPT Prescaler Register (GPT_PR)	32	R/W	0000_0000h	32.4.2/ 1606
53FA_0008	GPT Status Register (GPT_SR)	32	R/W	0000_0000h	32.4.3/ 1607

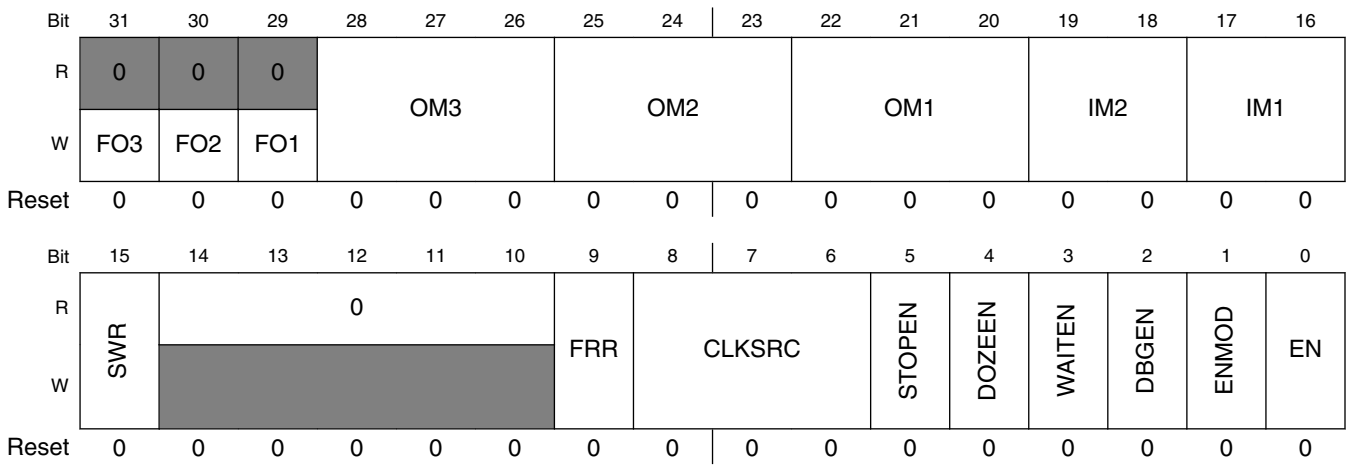
53FA_0024	GPT Counter Register (GPT_CNT)	32	R	0000_0000h	32.4.10/ 1612

32.4.1 GPT Control Register (GPT_CR)

The GPT Control Register (GPT_CR) is used to program and configure GPT operations. An IP Bus Write to the GPT Control Register occurs after one cycle of wait state, while an IP Bus Read occurs after 0 wait states.

Address: GPT_CR is 53FA_0000h base + 0h offset = 53FA_0000h



GPT_CR field descriptions

Field	Description
31 FO3	FO3 Force Output Compare Channel 3 FO2 Force Output Compare Channel 2 FO1 Force Output Compare Channel 1 The FO*n* bit causes the pin action *programmed* for the timer Output Compare *n* pin (according to the OM*n* bits in this register). • The OF*n* flag (OF3, OF2, OF1) in the status register is **not affected**. • This bit is self-negating and always read as zero. 0 Writing a 0 has no effect. 1 Causes the programmed pin action on the timer Output Compare *n* pin; the OF*n* flag is not set.
30 FO2	See F03
29 FO1	See F03
28–26 OM3	OM3 (bits 28-26) controls the Output Compare Channel 3 operating mode. OM2 (bits 25-23) controls the Output Compare Channel 2 operating mode. OM1 (bits 22-20) controls the Output Compare Channel 1 operating mode. The OM*n* bits specify the response that a compare event will generate on the output pin of Output Compare Channel *n*.

Table continues on the next page...

GPT_CR field descriptions (continued)

Field	Description
	• The toggle, clear, and set options cause a change on the output pin *only* if a compare event occurs. • When OM*n* is programmed as 1xx (active low pulse), the output pin is set to one immediately on the next input clock; a low pulse (that is an input clock in width) occurs when there is a compare event. Note that here, "input clock" refers to the clock selected by the CLKSRC bits of the GPT Control Register. 000 Output disconnected. No response on pin. 001 Toggle output pin 010 Clear output pin 011 Set output pin 1xx Generate an active low pulse (that is one input clock wide) on the output pin.
25–23 OM2	See OM3
22–20 OM1	See OM3
19–18 IM2	IM2 (bits 19-18, Input Capture Channel 2 operating mode) IM1 (bits 17-16, Input Capture Channel 1 operating mode) The IM*n* bit field determines the transition on the input pin (for Input capture channel *n*), which will trigger a capture event. 00 capture disabled 01 capture on rising edge only 10 capture on falling edge only 11 capture on both edges
17–16 IM1	See IM2
15 SWR	Software reset. This is the software reset of the GPT module. It is a self-clearing bit. • The SWR bit is set when the module is in reset state. • The SWR bit is cleared when the reset procedure finishes. • Setting the SWR bit resets **all of the registers** to their default reset values, except for the CLKSRC, EN, ENMOD, STOPEN, WAITEN, and DBGEN bits in the GPT Control Register (this control register). 0 GPT is not in reset state 1 GPT is in reset state
14–10 Reserved	This read-only field is reserved and always has the value zero. Reserved bits. • Writing a value to these reserved bits will not affect GPT operations. • These reserved bits are always read as zero. • It is recommended that all writes to these reserved bits be 0 (for forward compatibility).
9 FRR	Free-Run or Restart mode. The FFR bit determines the behavior of the GPT when a compare event in channel 1 occurs. • In Restart mode, after a compare event, the counter resets to 0x00000000 and resumes counting (after the occurrence of a compare event). • In Free-Run mode, after a compare event, the counter continues counting until 0xFFFFFFFF and then rolls over to 0.

Table continues on the next page...

GPT_CR field descriptions (continued)

Field	Description
	0 Restart mode 1 Free-Run mode
8–6 CLKSRC	Clock Source select. The CLKSRC bits select which clock will go to the prescaler (and subsequently be used to run the GPT counter). • The CLKSRC bit field value should only be changed after disabling the GPT by clearing the EN bit in this register (GPT_CR). • A software reset does not affect the CLKSRC bit. 000 No clock 001 Peripheral Clock 010 High Frequency Reference Clock 011 External Clock (CLKIN) 100 Low Frequency Reference Clock 101 Crystal oscillator as Reference Clock others Reserved
5 STOPEN	GPT Stop Mode enable. The STOPEN read/write control bit enables GPT operation *during Stop mode*. • A hardware reset resets the STOPEN bit. • A software reset *does not affect* the STOPEN bit. 0 GPT is disabled in Stop mode. 1 GPT is enabled in Stop mode.
4 DOZEEN	GPT Doze Mode Enable. • A hardware reset resets the DOZEEN bit. • A software reset *does not affect* the DOZEEN bit. 0 GPT is disabled in doze mode. 1 GPT is enabled in doze mode.
3 WAITEN	GPT Wait Mode enable. The WAITEN read/write control bit enables GPT operation *during Wait mode*. • A hardware reset resets the WAITEN bit. • A software reset *does not affect* the WAITEN bit. 0 GPT is disabled in wait mode. 1 GPT is enabled in wait mode.
2 DBGEN	GPT debug mode enable. The DBGEN read/write control bit enables GPT operation *during Debug mode*. • A hardware reset resets the DBGEN bit. • A software reset *does not affect* the DBGEN bit. 0 GPT is disabled in debug mode. 1 GPT is enabled in debug mode.
1 ENMOD	GPT Enable mode.

Table continues on the next page...

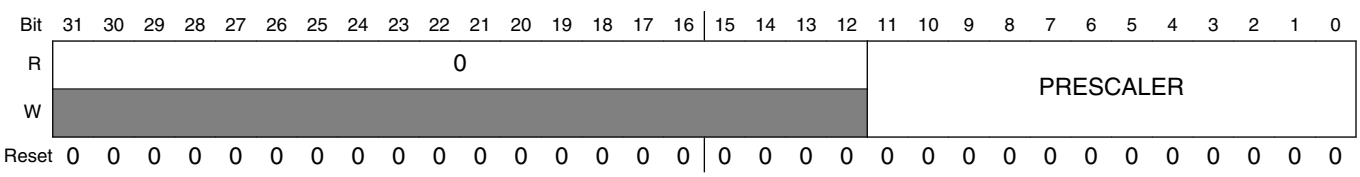
GPT_CR field descriptions (continued)

Field	Description
	When the GPT is disabled (EN=0), then both the Main Counter and Prescaler Counter *freeze their current count values*. The ENMOD bit determines the value of the GPT counter when Counter is enabled again (if the EN bit is set). • If the ENMOD bit is 1, then the Main Counter and Prescaler Counter values are reset to 0 after GPT is enabled (EN=1). • If the ENMOD bit is 0, then the Main Counter and Prescaler Counter restart counting *from their frozen values* after GPT is enabled (EN=1). • If GPT is programmed to be disabled in a low power mode (STOP/WAIT), then the Main Counter and Prescaler Counter *freeze at their current count values* when the GPT enters low power mode. • When GPT exits low power mode, the Main Counter and Prescaler Counter start counting from their frozen values, regardless of the ENMOD bit value. • Setting the SWR bit will clear the Main Counter and Prescaler Counter values, regardless of the value of EN or ENMOD bits. • A hardware reset resets the ENMOD bit. • A software reset *does not affect* the ENMOD bit. 0 GPT counter will retain its value when it is disabled. 1 GPT counter value is reset to 0 when it is disabled.
0 EN	GPT Enable. The EN bit is the GPT module enable bit. **Before setting the EN bit**, we recommend that *all registers be properly programmed*. • A hardware reset resets the EN bit. • A software reset *does not affect* the EN bit. 0 GPT is disabled. 1 GPT is enabled.

32.4.2 GPT Prescaler Register (GPT_PR)

The GPT Prescaler Register (GPT_PR) contains bits that determine the divide value of the clock that runs the counter.

Address: GPT_PR is 53FA_0000h base + 4h offset = 53FA_0004h



GPT_PR field descriptions

Field	Description
31–12 Reserved	This read-only field is reserved and always has the value zero. Reserved bits.

Table continues on the next page...

GPT_PR field descriptions (continued)

Field	Description
	• Writing a value to these reserved bits will not affect GPT operations. • These reserved bits are always read as zero.
11–0 PRESCALER	Prescaler bits. The clock selected by the CLKSRC field is divided by [PRESCALER + 1], and then used to run the counter. • A change in the value of the PRESCALER bits cause the Prescaler counter to reset and a new count period to start immediately. • See Figure 32-3 for the timing diagram. 0x000 Divide by 1 0x001 Divide by 2 ... ... 0xFFF Divide by 4096

32.4.3 GPT Status Register (GPT_SR)

The GPT Status Register (GPT_SR) contains bits that indicate that a counter has rolled over, and if any event has occurred on the Input Capture and Output Compare channels. The bits are cleared by writing a 1 to them.

Address: GPT_SR is 53FA_0000h base + 8h offset = 53FA_0008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

GPT_SR field descriptions

Field	Description
31–6 Reserved	This read-only field is reserved and always has the value zero. Reserved bits. • Writing a value to these reserved bits will not affect GPT operations. • These reserved bits are always read as zero.
5 ROV	Rollover Flag. The ROV bit indicates that the counter has reached its *maximum possible value* and *rolled over* to 0 (from which the counter continues counting). The ROV bit is only set if the counter has reached 0xFFFFFFFF in both Restart and Free-Run modes.

Table continues on the next page...

GPT_SR field descriptions (continued)

Field	Description
	0 Rollover has not occurred. 1 Rollover has occurred.
4 IF2	IF2 Input capture 2 Flag IF1 Input capture 1 Flag The IF*n* bit indicates that a capture event has occurred on Input Capture channel *n*. 0 Capture event has not occurred. 1 Capture event has occurred.
3 IF1	See IF2
2 OF3	OF3 Output Compare 3 Flag OF2 Output Compare 2 Flag OF1 Output Compare 1 Flag The OF*n* bit indicates that a compare event has occurred on Output Compare channel *n*. 0 Compare event has not occurred. 1 Compare event has occurred.
1 OF2	See OF3
0 OF1	See OF3

32.4.4 GPT Interrupt Register (GPT_IR)

The GPT Interrupt Register (GPT_IR) contains bits that control whether interrupts are generated after rollover, input capture and output compare events.

Address: GPT_IR is 53FA_0000h base + Ch offset = 53FA_000Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

2 OF3IE	OF3IE Output Compare 3 Interrupt Enable OF2IE Output Compare 2 Interrupt Enable OF1IE Output Compare 1 Interrupt Enable The OF*n*IE bit controls the Output Compare Channel *n* interrupt. 0 Output Compare Channel *n* interrupt is disabled. 1 Output Compare Channel *n* interrupt is enabled.
1 OF2IE	See OF3IE
0 OF1IE	See OF3IE

32.4.5 GPT Output Compare Register 1 (GPT_OCR1)

The GPT Compare Register 1 (GPT_OCR1) holds the value that determines when a compare event will be generated on Output Compare Channel 1. Any write access to the Compare register of Channel 1 while in Restart mode (FRR=0) will reset the GPT counter.

An IP Bus Write access to the GPT Output Compare Register1 (GPT_OCR1) occurs *after* one cycle of wait state; an IP Bus Read access occurs *immediately* (0 wait states).

Address: GPT_OCR1 is 53FA_0000h base + 10h offset = 53FA_0010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

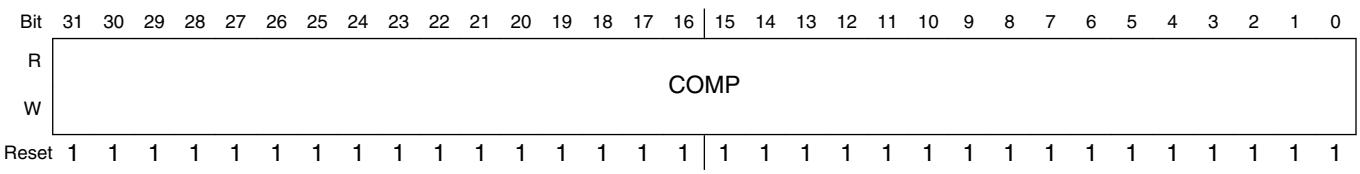
GPT_OCR1 field descriptions

Field	Description
31–0 COMP	Compare Value. When the counter value equals the COMP bit field value, a compare event is generated on Output Compare Channel 1.

32.4.6 GPT Output Compare Register 2 (GPT_OCR2)

The GPT Compare Register 2 (GPT_OCR2) holds the value that determines when a compare event will be generated on Output Compare Channel 2.

Address: GPT_OCR2 is 53FA_0000h base + 14h offset = 53FA_0014h



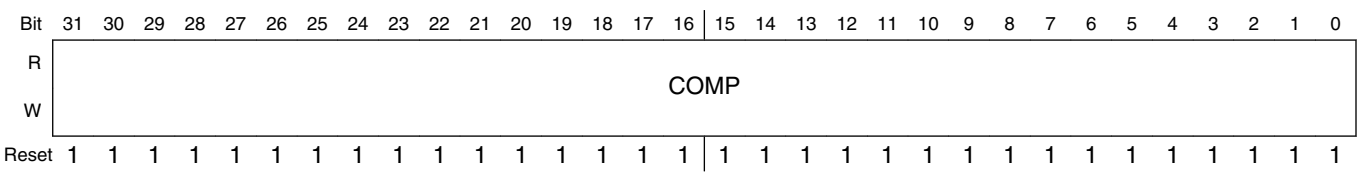
GPT_OCR2 field descriptions

Field	Description
31–0 COMP	Compare Value. When the counter value equals the COMP bit field value, a compare event is generated on Output Compare Channel 2.

32.4.7 GPT Output Compare Register 3 (GPT_OCR3)

The GPT Compare Register 3 (GPT_OCR3) holds the value that determines when a compare event will be generated on Output Compare Channel 3.

Address: GPT_OCR3 is 53FA_0000h base + 18h offset = 53FA_0018h



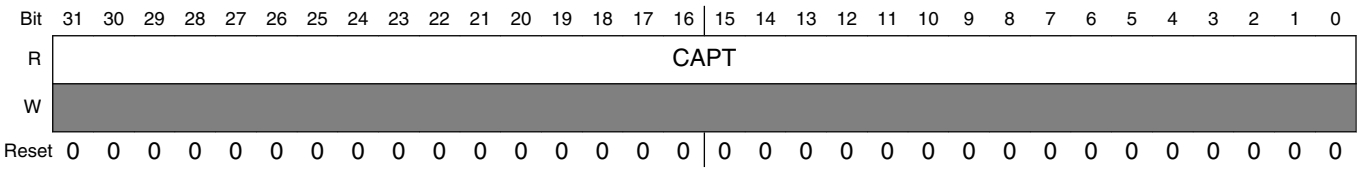
GPT_OCR3 field descriptions

Field	Description
31–0 COMP	Compare Value. When the counter value equals the COMP bit field value, a compare event is generated on Output Compare Channel 3.

32.4.8 GPT Input Capture Register 1 (GPT_ICR1)

The GPT Input Capture Register 1 (GPT_ICR1) is a read-only register that holds the value that was in the counter during the last capture event on Input Capture Channel 1.

Address: GPT_ICR1 is 53FA_0000h base + 1Ch offset = 53FA_001Ch



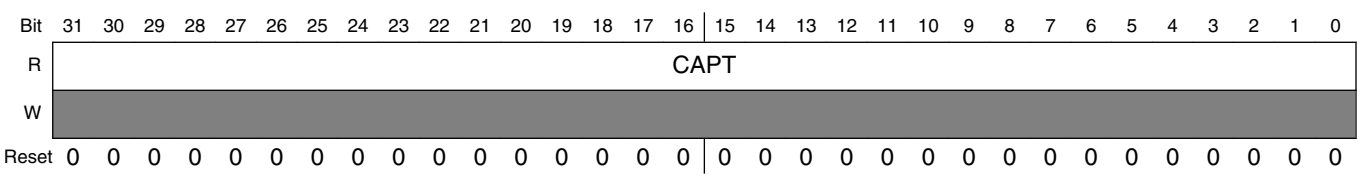
GPT_ICR1 field descriptions

Field	Description
31–0 CAPT	Capture Value. After a capture event on Input Capture Channel 1 occurs, the current value of the counter is loaded into GPT Input Capture Register 1.

32.4.9 GPT Input Capture Register 2 (GPT_ICR2)

The GPT Input capture Register 2 (GPT_ICR2) is a read-only register which holds the value that was in the counter during the last capture event on input capture channel 2.

Address: GPT_ICR2 is 53FA_0000h base + 20h offset = 53FA_0020h



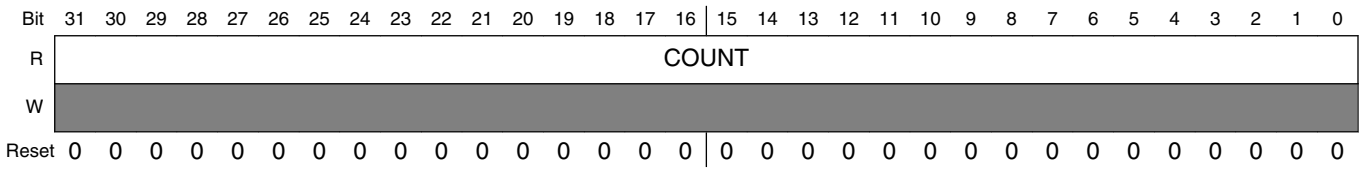
GPT_ICR2 field descriptions

Field	Description
31–0 CAPT	Capture Value. After a capture event on Input Capture Channel 2 occurs, the current value of the counter is loaded into GPT Input Capture Register 2.

32.4.10 GPT Counter Register (GPT_CNT)

The GPT Counter Register (GPT_CNT) is the main counter's register. GPT_CNT is a read-only register and can be read without affecting the counting process of the GPT.

Address: GPT_CNT is 53FA_0000h base + 24h offset = 53FA_0024h



GPT_CNT field descriptions

Field	Description
31–0 COUNT	Counter Value. The COUNT bits show the current count value of the GPT counter.

Chapter 33
2D Graphics Processing Unit (GPU2D)

33.1 Overview

This block guide describes key architectural features of the G12 OpenVG core as well as details of the G12 OpenVG IP customizing and integration in the i.MX50.

The ATI^{TM} Z160(G12) IP is an embedded, 2D and vector graphics accelerator targeting the OpenVG 1.0.1 graphics API and feature set.

It accelerates 2D bitmap graphics operations, such as BitBlt, fill and raster operations using a separate 2D graphics acceleration unit.

Vector graphics rendering is accelerated by a separate anti-aliasing polygon rasterizer, which is connected to the 2D graphics acceleration unit.

The core has a rich, but well-chosen set of features, with emphasis being on very high image quality and low memory bandwidth consumption.

The GPU top level block diagram is presented at GPU2D Block Diagram.

33.2 GPU2D Feature List

The following chapters describe the functional features of the graphics processor.

33.2.1 Frame Buffer

- Frame buffer sizes supported up-to 2048x2048
- ARGB4444, RGB565, ARGB1555, ARGB5551, ARGB8888 frame buffer modes
- Configurable ARGB order in frame buffer: ARGB, BGRA, ABGR, RGBA
- Linear and block-based (4x4 pixels) frame buffer modes
- Fast buffer clears
- Support for OpenVG render to Image

33.2.2 2D Bitmap Graphics (Separate 2D Unit)

- Parallel operation with the 3D pipeline, independent command input
- BitBlt (surface-to-surface copy)
  - Format conversion from monochrome/ARGB/YUV to ARGB during BitBlt
- Block fill
- Internal 32-bit color precision
- Source bitmap format:
  - 1/4/8-bit monochrome
  - ARGB4444, RGB565, ARGB1555, ARGB5551, ARGB8888
  - Configurable ARGB order: ARGB, BGRA, ABGR, RGBA
  - Packed YUV 4:2:2 formats (FOURCC codes YUY2, UYVY, YVYU), two pixels per 32 bits of data.
  - 1-bit bitmap maps to foreground and background colors.
  - 4-bit bitmap is optionally gamma corrected to 8-bit alpha values and can be combined with foreground color to draw anti-aliased fonts.
- Destination bitmap format:
  - ARGB4444, RGB565, ARGB1555, ARGB5551, ARGB8888, B8, A8, AB88
  - Configurable ARGB order: ARGB, BGRA, ABGR, RGBA
- Supports three source bitmaps for separate mask/pattern/alpha bitmap support plus reading destination for ROP, blend and color key operations
- Supports masking source coordinates for wrapping patterns
- Supports ROP4 (ROP3 with separate ROPs for masked and unmasked pixels) logical operations
- Supports inverting mask and alpha values from source
- Supports destination rotation by 0/90/180/270 degrees Supports programmable blending with optional alpha un-premultiply
- Supports per pixel and constant alpha with optional modulation by source color alpha for OpenVG alpha masking Supports color keying by source and destination colors, with optional ignoring of alpha channel
- Supports one scissor rectangle for destination coordinates
- Dithering (ordered)
- Color component masking
- RGB reads and writes
- Non-power of two source and destination bitmap sizes supported (stride must be a multiple of 32-bits)
- BitBlt with scaling implemented with the 3D rendering pipeline, bilinear filtering with texture lookups, programmable filter kernels possible with the programmable Pixel processor

33.2.3 Vector Graphics

- Parallel operation with the 3D pipeline, independent command input
- Rasterization of convex and concave polygons with anti-aliasing
- Efficient native polygon rendering (no tessellation to triangles)
- Non-zero and odd-even fill rules
- Primitives supported:
  - Polygons
  - OpenVG path primitives (except Elliptical Arcs): Horizontal/vertical lines, generic lines, curves, smooth curves, moveto, path closing
  - Curve types supported: cubic and quadratic BÈzier
  - Strokes with thickness, joints and end caps, unlimited stroke thickness
  - Special case handling of singularities for thick strokes
  - Supports paths with a maximum of 256 crossings along a horizontal or a vertical line
- Input coordinates:
  - Absolute and relative coordinate input in floating point
  - Fixed-point (byte, short, int) and floating-point coordinate input - 0.8, 0.16, 16.16 formats
  - Little- and Big-endian support separately selectable for command stream and data.
- Geometry
  - User to surface transform for vertices and stroke shape
  - Hardware curve tessellation
  - Adjustable accuracy for curve and round cap splitting
  - OpenVG/SVG join types: Miter (with miter limit), round, bevel
  - OpenVG/SVG cap types: Butt, round, square
- Pixel processing:
  - Programmable gradient and texturing processor
  - Linear and radial gradients (with focal point)
  - Perspective texture mapping with filtering
  - Two textures supported
  - sRGB and pre-multiply support for textures
  - 16-sample anti-aliasing
  - 4x RGSS AA (Rotated Grid Super Sample)
  - Per-pixel alpha-masking
  - Maximum texture size: 1024x1024 pixels
- Vector graphics rendering system ARM platform load:
  - Display list generation during path creation ñ commands and vertices are stored to an internal format/buffer, no format conversion is performed

- Filling or stroking a path only requires a few register writes to start the operation in hardware
- Display lists are transferred to the vector graphics rasterizer using DMA without ARM platform interaction

33.3 GPU2D Block Diagram

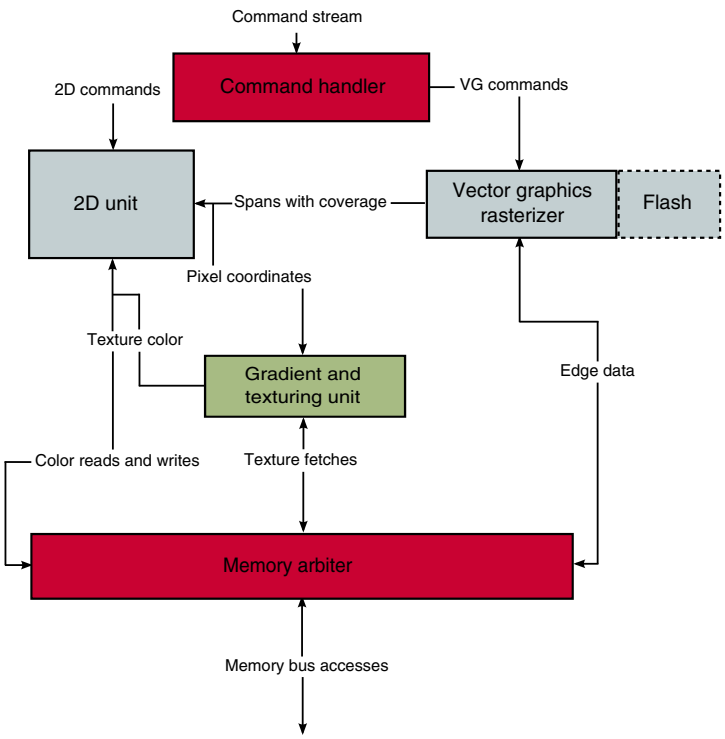


Figure 33-1. GPU2D Block Diagram

33.4 GPU SoC Interface

33.4.1 GPU2D Top Level Diagram

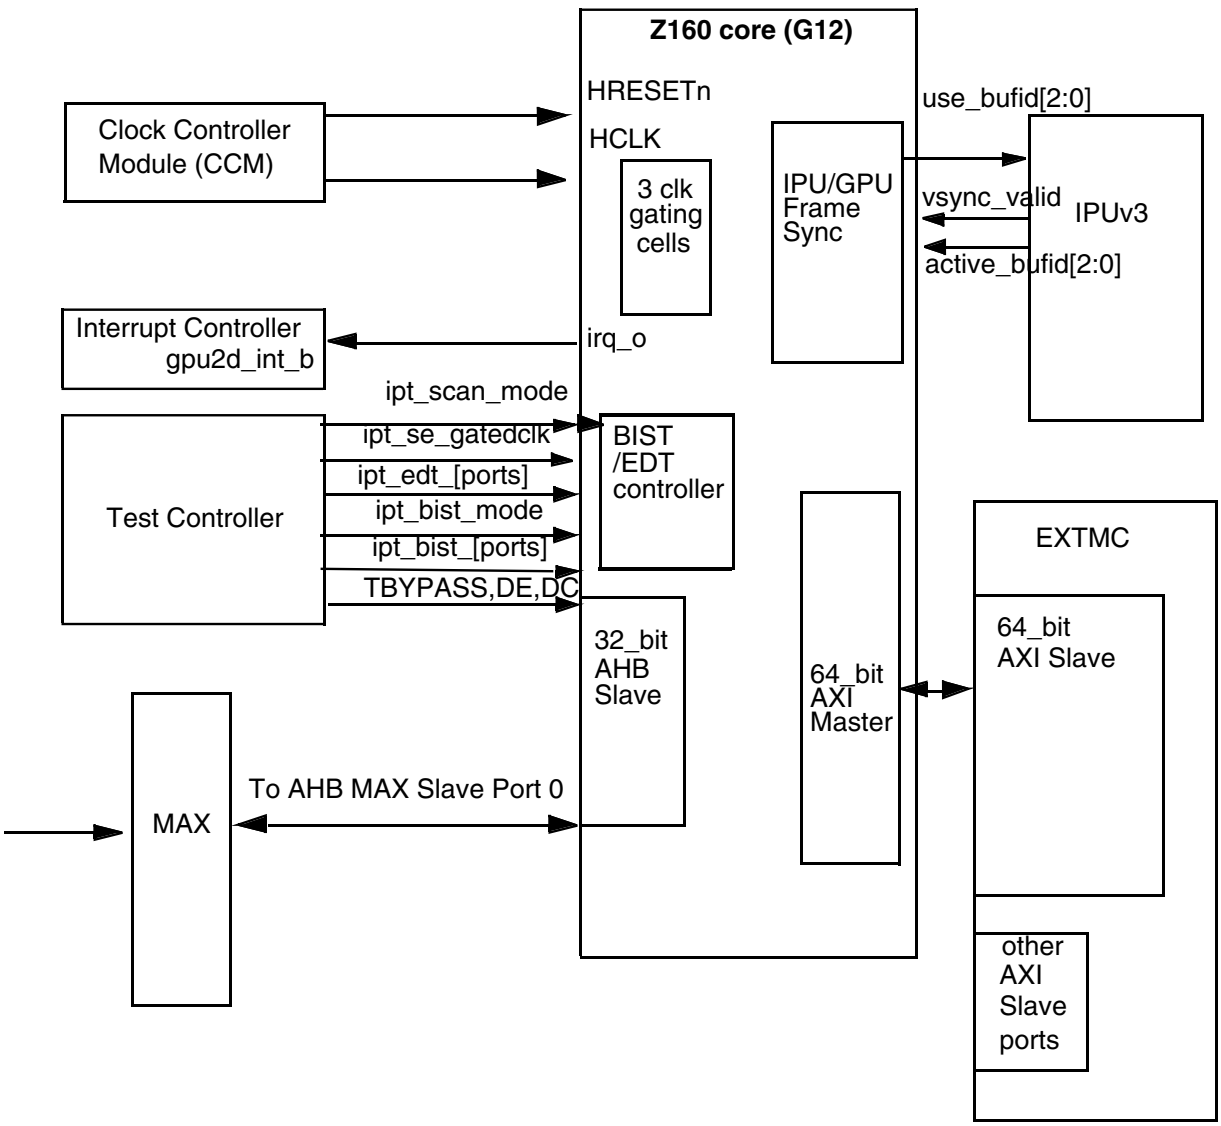

Figure 33-2. GPU2D System Connectivity

33.4.2 SoC Bus Connection

The GPU2D has the following two bus interfaces in SoC:

- 32_bit AHB slave bus.

This port is connected to ARM through MAX slave port 0, it allows access to the control registers and is the command stream input to Z160 core. The AHB interface is a fully compliant ARM AMBA AHB bus interface. It has been designed to comply with Rev 2.0 of the AMBA specification and it implements the Retry capable Slave part of the specification

- 64_bit AXI master bus

The external memory master bus is a standard 64_bit AMBA AXI master bus.

33.5 Other Signals Connection

Table 33-1. Z160(G12) miscellaneous signals

Name	Type	Source/ destination	Description
gpu2d_int_b	Output	Interrupt controller	Interrupt output from the Z160 (G12) OpenVG Graphics Core. Active LOW.
gpu2d_use_bufid[2:0]	Output	Image Processing Unit (IPU) frame sync	Tell IPU which buffer can be displayed
ipu_vsync_valid	Input	IPU frame sync	Tell GPU2D one frame is finished
ipu_active_bufid[2:0]	Input	IPU frame sync	Tell GPU2D which frame is free to be overwritten

33.6 Clocking Architecture

There is one clock input to the GPU2D, namely HCLK. In fact Z160(G12) core needs 5 clock inputs, named bus_clk, clk_0,clk_1,clk_2,clk_3, which are divided from HCLK but balanced and therefore, count as only one clock domain.

33.7 Power Management

Table 33-2. GPU2D miscellaneous signals

Clock name	Enable signal	Clocked sub-blocks	Related area
bus_clk(hclk)		Busif	4%
clk_0(hclk)	Input	Arbiter, Input	1%
clk_1	clock1_ena	Bcache	20%

Table continues on the next page...

Table 33-2. GPU2D miscellaneous signals (continued)

Clock name	Enable signal	Clocked sub-blocks	Related area
clk_2	clock2_ena	2D, V3	45%
clk_3	clock3_ena	V1, V2	30%

The different use cases and the associated clock settings are presented at the following table. For the use-cases where the core is not used at all, also bus_clk and clk_0 should be gated off to maximize the power savings. This cannot be controlled by the core itself.

Use case	bus clk	clk 0	clk 1	clk 2	clk 3
Idle	on	on	off	off	off
Bitmap case - standalone	on	on	on	on	off
Vector graphics	on	on	on	on	on

Figure 33-3. Graphics Core Operating Mode

If the whole chip go into low power mode, all clk source will be shut down by CCM.

33.8 Modes of Operation

The GPU2D supports

- 2D bitmap acceleration mode
- Vector Graphic acceleration mode
- low power mode

33.9 Reset

The GPU2D has only 1 reset port named HRESETn. The internal Z160 core (G12) contains asynchronous reset signals for each corresponding clock domain - namely rst_n for the clk clocks and bus_rst_n for the busclk clock, which are directly connected to HRESETn.

Resets are active low. The reset signals asynchronously reset all of the DFFs in the design.

33.10 Interrupts

The Z160 Core (G12) generates individual interrupts internally. Each interrupt can be enabled or disabled by changing its own enable bit. Setting the enable bit HIGH enables the corresponding interrupt.

The interrupts from all sources in the Z160 Core (G12) are combined (ORed) and output as the active LOW **gpu2d_int_b** interrupt.

33.11 DMA

GPU2D is a DMA master in fact, it read command and write data to system memory through EXTMC.

GPU2D also can be feed by DMA through MAX slave port 0.

33.12 Memory Map

The Z160 Graphics Core (G12) memory map is described in the following sections:

- AHB slave interface
- AXI master memory interface (EXTMC port).

33.12.1 AHB Slave Interface

This is based on the GPU2D occupying slave port 0 of the crossbar., whose base address is 0x20000000. GPU2D has 2 kinds of registers, one is "Interface" registers which can be read/write accessible, the others are "Internal" registers which only can be written through Z160's slave ports.

GPU2D Memory Map

Description	Memory Address Base	Memory Address End
Registers	0x2000 0000	0x200007FC

Description of all user-accessible registers in the design can be found from regs.html

Interface registers can only be accessed by status read / write channel directly through the slave port, which is mapped to 0x400 - 0x7fc address range. These registers are used to read and clear interrupts by the ARM platform, for example.

Internal 2D / VG registers are write only. They can only be accessed by two writing commands through the slave port (GPU2D's base address). The first command is a register address write, followed by a data write command.

In practice, this means that the command stream, which is prepared by the software driver is written through the 0x000-0x3ff address range either directly, or through the DMA operation by the core. These registers are not accessible directly by slave ports channel, like interface registers are not accessible through this channel.

33.12.2 AXI Master Memory Interface (EXTMC Port)

The Z160 Graphics Core (G12 or GPU2D) can access memory with or without a *Memory Management Unit* (MMU):

Translation is performed using a table with 8KB entries, one for each 4KB page in a 32MB linear address space.

Chapter 34
I2C Controller (I2C)

34.1 Overview

This chapter describes block-level operation and programming of I2C. The chapter is intended for a block driver software developer. To understand how the block is integrated at the SoC level, a system software developer can refer to discussions of the block in the appropriate SoC-level chapter(s).

References: This document assumes an understanding of the following reference:

1. The I2C Bus Specification, Version 2.1

The Inter IC (I2C) provides functionality of a standard I2C slave and master. The I2C is designed to be compatible with the standard Philips I2C bus protocol.

I2C is a two-wire, bidirectional serial bus that provides a simple, efficient method of data exchange, minimizing the interconnection between devices. This bus is suitable for applications requiring occasional communications over a short distance between many devices. The flexible I2C standard allows additional devices to be connected to the bus for expansion and system development. See the connection diagram in the figure below.

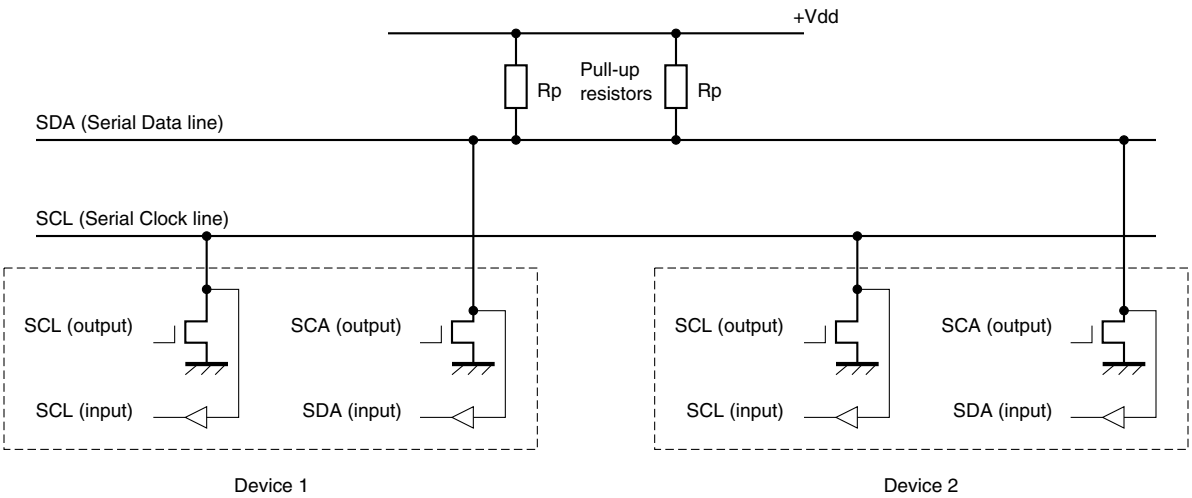

Figure 34-1. Connection of Devices to I2C Bus

The I2C interface operates up to 400 kbps, but it depends on the pin loading and timing characteristics. For pin requirement details, refer to Philips I2C Bus Specification, Version 2.1. The I2C system is a true multiple-master bus including arbitration and collision detection that prevents data corruption if multiple devices attempt to control the bus simultaneously. This feature supports complex applications with multiprocessor control and can be used for rapid testing and alignment of end products through external connections to an assembly-line computer. The figure below shows the block diagram of I2C.

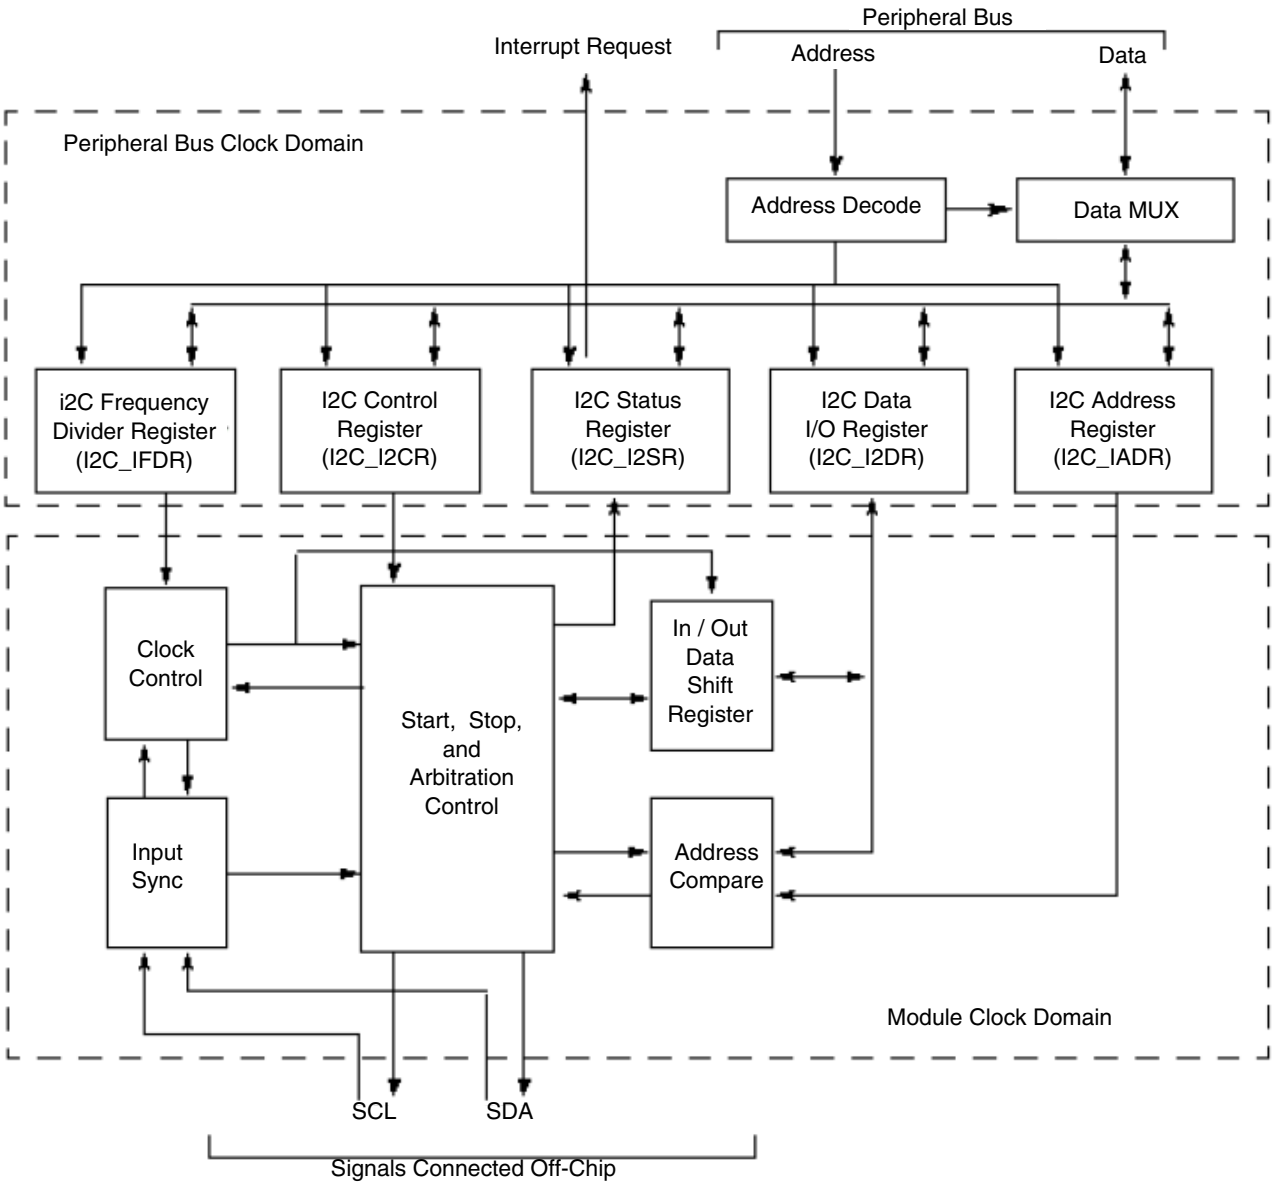

Figure 34-2. I2C Block Diagram

34.1.1 Features

The I2C has the following key features:

- Compatibility with I2C bus standard
- Multiple-master operation
- Software-programmable for one of 64 different serial clock frequencies
- Software-selectable acknowledge bit
- Interrupt-driven, byte-by-byte data transfer
- Arbitration-lost interrupt with automatic mode switching from master to slave

- Calling address identification interrupt
- Start and stop signal generation/detection
- Repeated START signal generation
- Acknowledge bit generation/detection
- Bus-busy detection

34.1.2 Modes and Operations

The I2C primarily operates in two different functional modes.

34.1.2.1 Standard Mode

In Standard mode, I2C supports the data transfer rates up to 100 Kbits/s.

34.1.2.2 Fast Mode

In Fast Mode, data transfer rates up to 400 Kbits/s can be achieved.

As per block operation, there is no special configuration required for Fast and Standard mode. It is the data transfer rate which distinguishes Standard and Fast mode.

34.2 External Signals

The table below describes all I2C signals that connect off-chip.

For I2C compliance, all devices connected to the SCL and SDA signals must have open-drain or open-collector outputs. The logic AND function is exercised on both lines with external pull-up resistors.

Input of SCL and SDA also need to be manually opened by set SION bit in IOMUX after corresponding PADs were selected as I2C function.

Table 34-1. Off-Chip Block Signals

Signal	I/O	Description	Reset State[1]	Pull-Up/Down[1]
SCL	I/O	Serial Clock	1	Active
SDA	I/O	Serial Data	1	Active

1. The reset state values and pull-up/down requirements provided in this table are from the block-level perspective. To understand how the block is integrated at the SoC level, the system software developer must see discussions of the block in the appropriate SoC-level chapter(s). For example, a block signal that requires a pull-up could be integrated with a pull-

up option built into the SoC. In this case, the system software developer must ensure the proper programming at the SoC level.

34.3 Functional Description

34.3.1 I2C System Configuration

Out of a reset, the I2C defaults to slave receive operations. Thus, when not operating as a master or responding to a slave transmit address, the I2C will default to the slave receiver state.

For exceptions, see Initialization Sequence.

NOTE

The I2C is designed to be compatible with the Philips™ I2C bus protocol. For information on system configuration, protocol, and restrictions, refer to the I2C Bus Specification, Version 2.1. The I2C supports Standard and Fast modes only.

34.3.2 I2C Protocol

The I2C communication protocol consists of six components, as follows:

- START
- Data Source/Recipient
- Data Direction
- Slave Acknowledge
- Data Acknowledge
- STOP

See the figure below for the I2C standard communication protocol, as defined in the following sections.

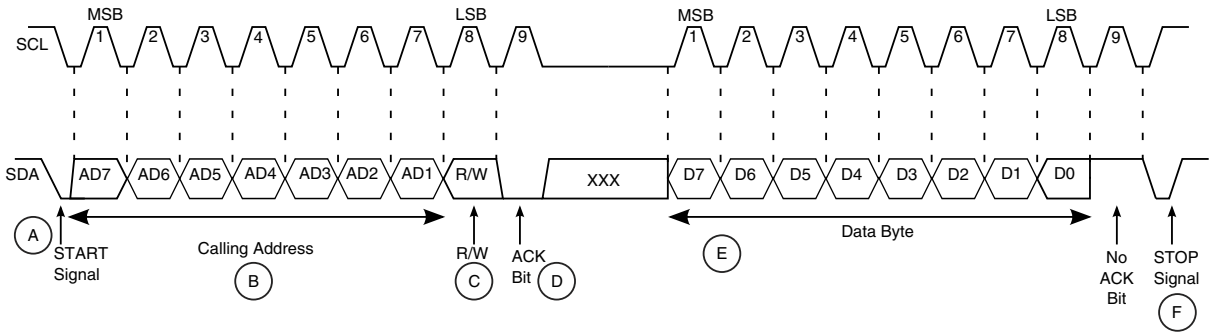

Figure 34-3. I2C Standard Communication Protocol

34.3.2.1 START Signal

When no other device is a bus master (both SCL and SDA lines are at logic high), a device can initiate communication by sending a START signal (see A in Figure 34-3).

A START signal is defined as a high-to-low transition of SDA while SCL is high. This signal denotes the beginning of a data transfer (each data transfer can be several bytes long) and awakens all slaves.

34.3.2.2 Slave Address Transmission

The master sends the slave address in the first byte after the START signal (B). After the seven-bit calling address, it sends the R/W bit (C), which tells the slave data transfer direction.

Each slave must have a unique address. An I2C master must not transmit an address that is the same as its slave address; it cannot be master and slave at the same time.

The slave whose address matches that sent by the master pulls SDA low at the ninth clock (D) to return an acknowledge bit.

34.3.2.3 Data Transfer

When successful slave addressing is achieved, the data transfer can proceed (E) on a byte-by-byte basis in the direction specified by the R/W bit sent by the calling master.

Data can be changed only while SCL is low and must be held stable while SCL is high, as shown in Figure 34-3. SCL is pulsed once for each data bit, most-significant bit first. The receiving device must acknowledge each byte by pulling SDA low at the ninth clock; therefore, a data byte transfer takes nine clock pulses.

If it does not acknowledge the master, the slave receiver must leave SDA high. The master can then generate a STOP signal to abort the data transfer or generate a START signal (a repeated start, as shown in Figure 34-4) to start a new calling sequence.

If the master receiver does not acknowledge the slave transmitter after a byte transmission, it means end-of-data to the slave. The slave releases SDA for the master to generate a STOP or START signal.

NOTE

Writing to the data register triggers transmit operation.

Transmit data should always be written after MTX bit is programmed. Transmit data is not latched inside until the transfer is initiated on the interface bus.

After the transmit data write in I2C, software can either wait for a transfer-done interrupt or it can poll for ICF bit for zero, if new data has to be written during the previous data transfer. The IIF bit may not be polled if the IIEN bit is set because the I2C will generate an interrupt when IIF is set.

34.3.2.4 STOP Signal

The master can terminate communication by generating a STOP signal to free the bus. A STOP signal is defined as a low-to-high transition of SDA while SCL is at logical high (F).

NOTE

A master can generate a STOP even if the slave has made an acknowledgment, at which point the slave must release the bus.

34.3.2.5 Repeat Start

Instead of signalling a STOP, the master can repeat the START signal, followed by a calling command

(see A in the figure below). A repeated START occurs when a START signal is generated without first generating a STOP signal to end the communication. The master uses a repeated START to communicate with another slave or with the same slave in a different mode (transmit/receive mode) without releasing the bus.

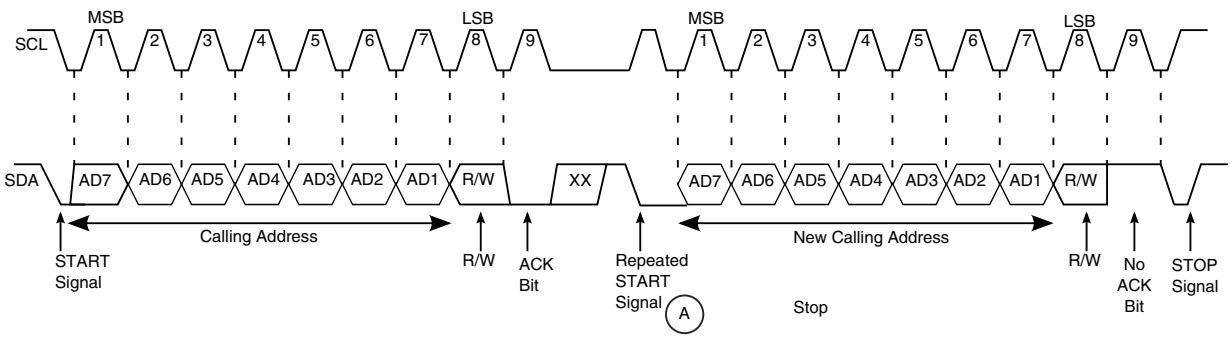

Figure 34-4. Repeated START

34.3.3 Arbitration Procedure

If multiple devices simultaneously request the bus, the bus clock is determined by a synchronization procedure in which the low period equals the longest clock-low period among the devices, and the high period equals the shortest. A data arbitration procedure determines the relative priority of competing devices.

A device loses arbitration if it sends logic high while another sends logic low; it immediately switches to slave-receive mode and stops driving SDA. In this case, the transition from master to slave mode does not generate a STOP condition. Meanwhile, hardware sets the arbitration lost bit in the I2C Status register (I2C_I2SR[IAL] to indicate loss of arbitration).

34.3.4 Clock Synchronization

Because wire-AND logic is used, a high-to-low transition on SCL affects devices connected to the bus. Devices start counting their low period when the master drives SCL low. When a device clock goes low, it holds SCL low until the clock high state is reached. However, the low-to-high change in this device clock may not change the state of SCL if another device clock is still in its low period. Therefore, the device with the longest low period holds the synchronized clock SCL low.

Devices with shorter low periods enter a high wait state during this time (see the figure below). When all devices involved have counted off their low period, the synchronized clock SCL is released and pulled high. There is then no difference between device clocks and the state of SCL, so all of the devices start counting their high periods. The first device to complete its high period pulls SCL low again.

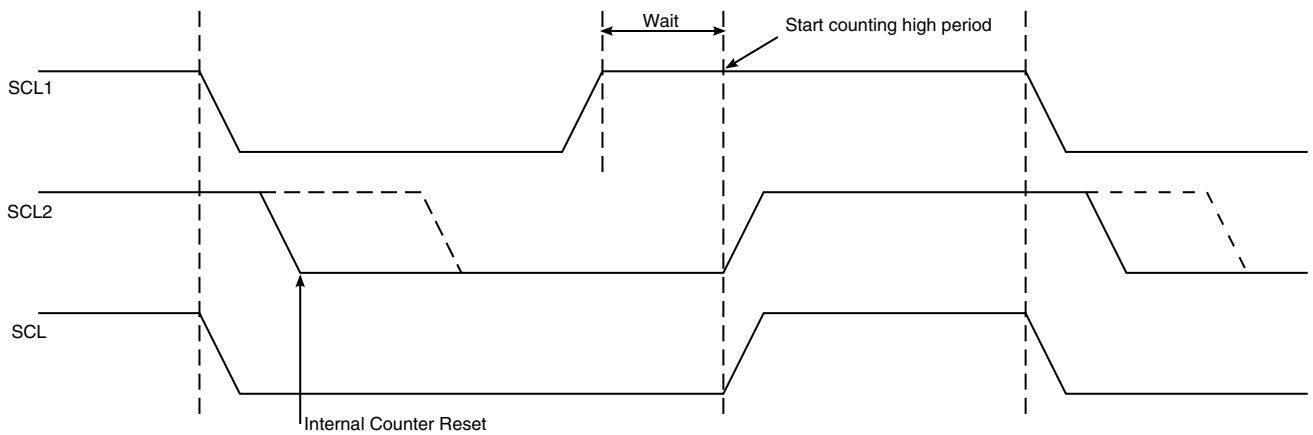

Figure 34-5. Synchronized Clock SCL

34.3.5 Handshaking

The clock synchronization mechanism can be used as a handshake in data transfers. Slave devices can hold SCL low after completing one byte transfer (9 bits). In such a case, the clock mechanism halts the bus clock and forces the master clock into a wait state until the slave releases SCL.

34.3.6 Clock Stretching

Slaves can use the clock synchronization mechanism to slow down the transfer bit rate. After the master has driven SCL low, the slave can drive SCL low for the required period and then release it. If the slave SCL low period is longer than the master SCL low period, the resulting SCL bus signal low period is stretched.

34.3.7 Peripheral Bus Accesses

I2C is a 16-bit block. Only half-word accesses should be performed to the block.

34.3.8 Generation of Transfer Error on IP Bus

If an address is received on the Peripheral slave bus interface that is not implemented, an access error is generated.

34.3.9 Clocks

There are two input clocks for I2C.

1. Peripheral Clock:The clock is used for Peripheral bus register read/writes.
2. Module Clock:This is the functional clock of the I2C. The serial bit clock frequency is derived from the module clock. The module clock and peripheral clocks are synchronous to each other. The minimum frequency of module clock should be 12.8 MHz for Fast Mode to achieve 400 Kbps operation.

34.3.10 Reset

The I2C can be reset in two ways.

1. Global reset: A hard asynchronous reset of the whole I2C.
2. Software reset: An internal reset for whole I2C, except I2C_IADR and I2C_IFDR registers, is initiated by deasserting the I2C_I2CR[IEN] bit.

34.3.11 Interrupts

There is only one interrupt from the block. The interrupt is enabled by setting the I2C_I2CR[IIEN] bit.

The interrupt is generated in any one of the following conditions.

- One byte transfer is completed (the interrupt is set at the falling edge of the ninth clock).
- An address is received that matches its own specific address in slave-receive mode.
- Arbitration is lost.

34.3.12 Byte Order

The block only supports the little endian mode.

34.4 Initialization

34.4.1 Initialization Sequence

Before the interface can transfer serial data, registers must be initialized, as follows:

1. Set the data sampling rate (I2C_IFDR[IC] to obtain SCL frequency from the system bus clock.
2. Update the address in the (I2C_IADR) to define its slave address (address can range from 0 to 0x7f).
3. Set the I2C enable bit (I2C_I2CR[IEN]) to enable the I2C bus interface system.
4. Modify the bits in the I2C_I2CR to select master/slave mode, transmit/receive mode, and interrupt-enable or not.

34.4.2 Generation of START

After completion of the initialization procedure, serial data can be transmitted by selecting the master transmitter mode. On a multiple-master bus system, the busy bus (I2C_I2SR[IBB]) must be tested to determine whether the serial bus is free. If the bus is free (IBB = 0), the START signal and the first byte (the slave address) can be sent. The data written to the data register comprises the address of the desired slave and the LSB indicates the transfer direction.

The free time between a STOP and the next START condition is built into the hardware that generates the START cycle. Depending on the relative frequencies of the system clock and the SCL period, it may be necessary to wait until the I2C is busy after writing the calling address to the data register (I2C_I2DR) before proceeding to load data into the data register (I2C_I2DR).

34.4.3 Post-Transfer Software Response

Sending or receiving a byte sets the data transferring bit (I2C_I2SR[ICF]), which indicates one byte communication is finished. Upon completion, the interrupt status (I2C_I2SR[IIF]) is also set. An external interrupt is generated if the interrupt enable (I2C_I2CR[IIEN]) is set. The software must first clear the interrupt status (I2C_I2SR[IIF]) in the interrupt routine.

(See the flow chart in Figure 34-7.) The data transferring bit (I2C_I2SR[ICF]) is cleared either by reading from I2C_I2DR in receive mode or by writing to this register in transmit mode.

The software can service the I2C I/O in the main program by monitoring the interrupt status (I2C_I2SR[IIF]) if the interrupt enable is deasserted. In this case, the interrupt status should be polled of the data transferring bit (I2C_I2SR[ICF]) because the operation is different when arbitration is lost.

When an interrupt occurs at the end of the address cycle, the master is always in transmit mode; that is, the address is sent. If master receive mode is required, then I2C_I2CR[MTX] should be toggled and dummy read of I2C_I2DR register has to be done for triggering receive data.

During slave-mode address cycles (I2C_I2SR[IAAS] = 1), the slave read/write bit I2C_I2SR[SRW] is read to determine the direction of the next transfer. The transmit/receive bit (I2C_I2CR[MTX]) should also be programmed accordingly. For slave-mode data cycles (IAAS = 0), SRW is invalid. MTX should be read to determine the current transfer direction.

34.4.4 Generation of STOP

A data transfer ends when the master signals a STOP, which can occur after all data is sent.

For a master receiver to terminate a data transfer, it must inform the slave transmitter by not acknowledging the last data byte. This is done by setting the transmit acknowledge bit (I2C_I2CR[TXAK]) before reading the next-to-last byte. Before the last byte is read, a STOP signal must be generated.

34.4.5 Generation of Repeated START

After the data transfer, if the master still wants the bus, it can signal another START followed by another slave address without signalling a STOP.

34.4.6 Slave Mode

In the slave interrupt service routine (see Figure 34-7), the block addressed as slave bit (IAAS) should be tested to check if a calling of its own address has just been received. If IAAS is set, software should set the transmit/receive mode select bit (I2C_I2CR[MTX]) according to the I2C_I2SR[SRW]. Writing to the I2C_I2CR clears the IAAS automatically. The only time IAAS is read as set is from the interrupt at the end of the address cycle where an address match occurred; interrupts resulting from subsequent data transfers will have IAAS cleared. A data transfer can now be initiated by writing information to I2C_I2DR for slave transmits, or read from I2C_I2DR in slave-receive mode. A dummy read of I2C_I2DR in slave/receive mode releases SCL, allowing the master to send data.

In the slave transmitter routine, the receive acknowledge bit (I2C_I2SR[RXAK]) must be tested before sending the next byte of data. Setting RXAK means an end-of-data signal from the master receiver, after which the software must switch it from transmitter to receiver mode. Reading the data register (I2C_I2DR) then releases SCL so that the master can generate a STOP signal.

34.4.7 Arbitration Lost

If several devices try to engage the bus at the same time, one becomes master. Hardware immediately switches devices that lose arbitration to slave receive mode. Data output to SDA stops, but SCL is still generated until the end of the byte during which arbitration is lost. An interrupt occurs at the falling edge of the ninth clock of this transfer if the arbitration is lost (I2C_I2SR[IAL] = 1), and the slave mode is selected (I2C_I2CR[MSTA] = 0).

See the flow chart in Figure 34-7.

If a device that is not a master tries to transmit or do a START, hardware inhibits the transmission, clears MSTA without signalling a STOP, generates an interrupt to the ARM platform, and sets I2C_I2SR[IAL] to indicate a failed attempt to engage the bus. When considering these cases, the slave service routine should first test I2C_I2SR[IAL], and the software should clear it if it is set.

For Multi-master mode, when an I2C is enabled when the bus is busy and asserts START, the I2C_I2SR[IAL] bit gets set only for SDA=0, SCL=0/1, SDA=1, and SCL=0, but not for SDA=1 and SCA=1, which is the same as bus idle state.

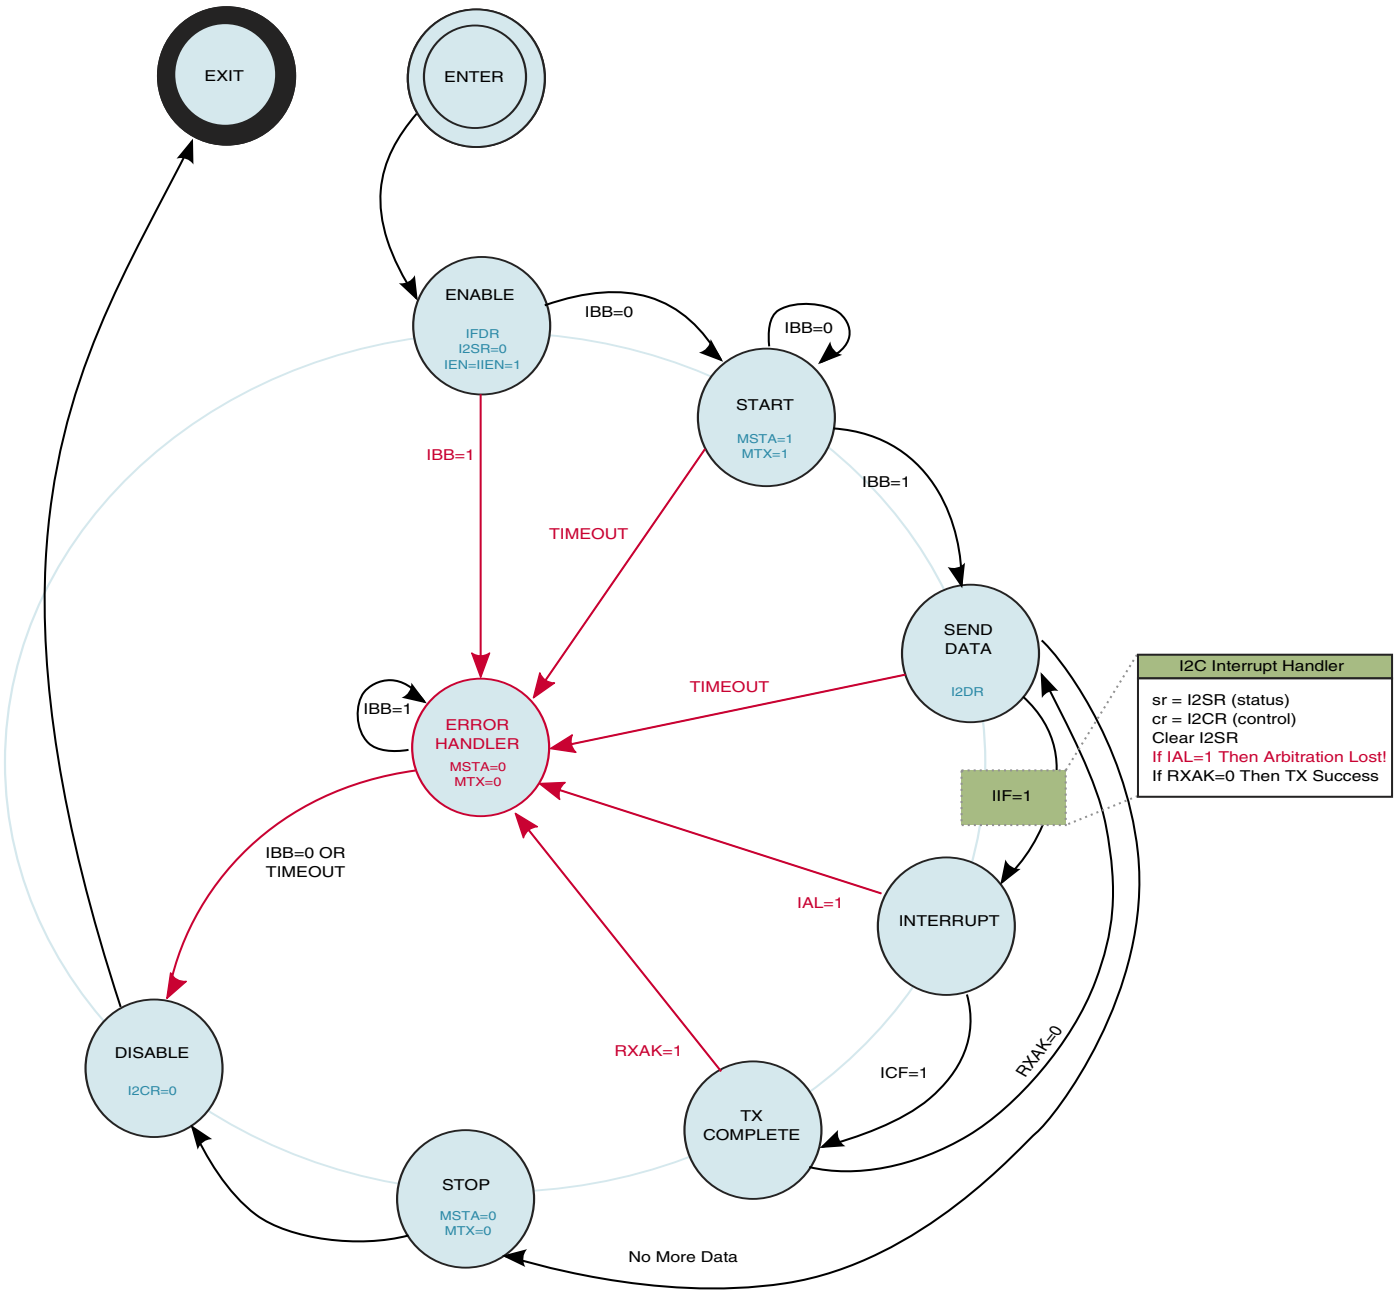

Figure 34-6. I2C Programming State Diagram

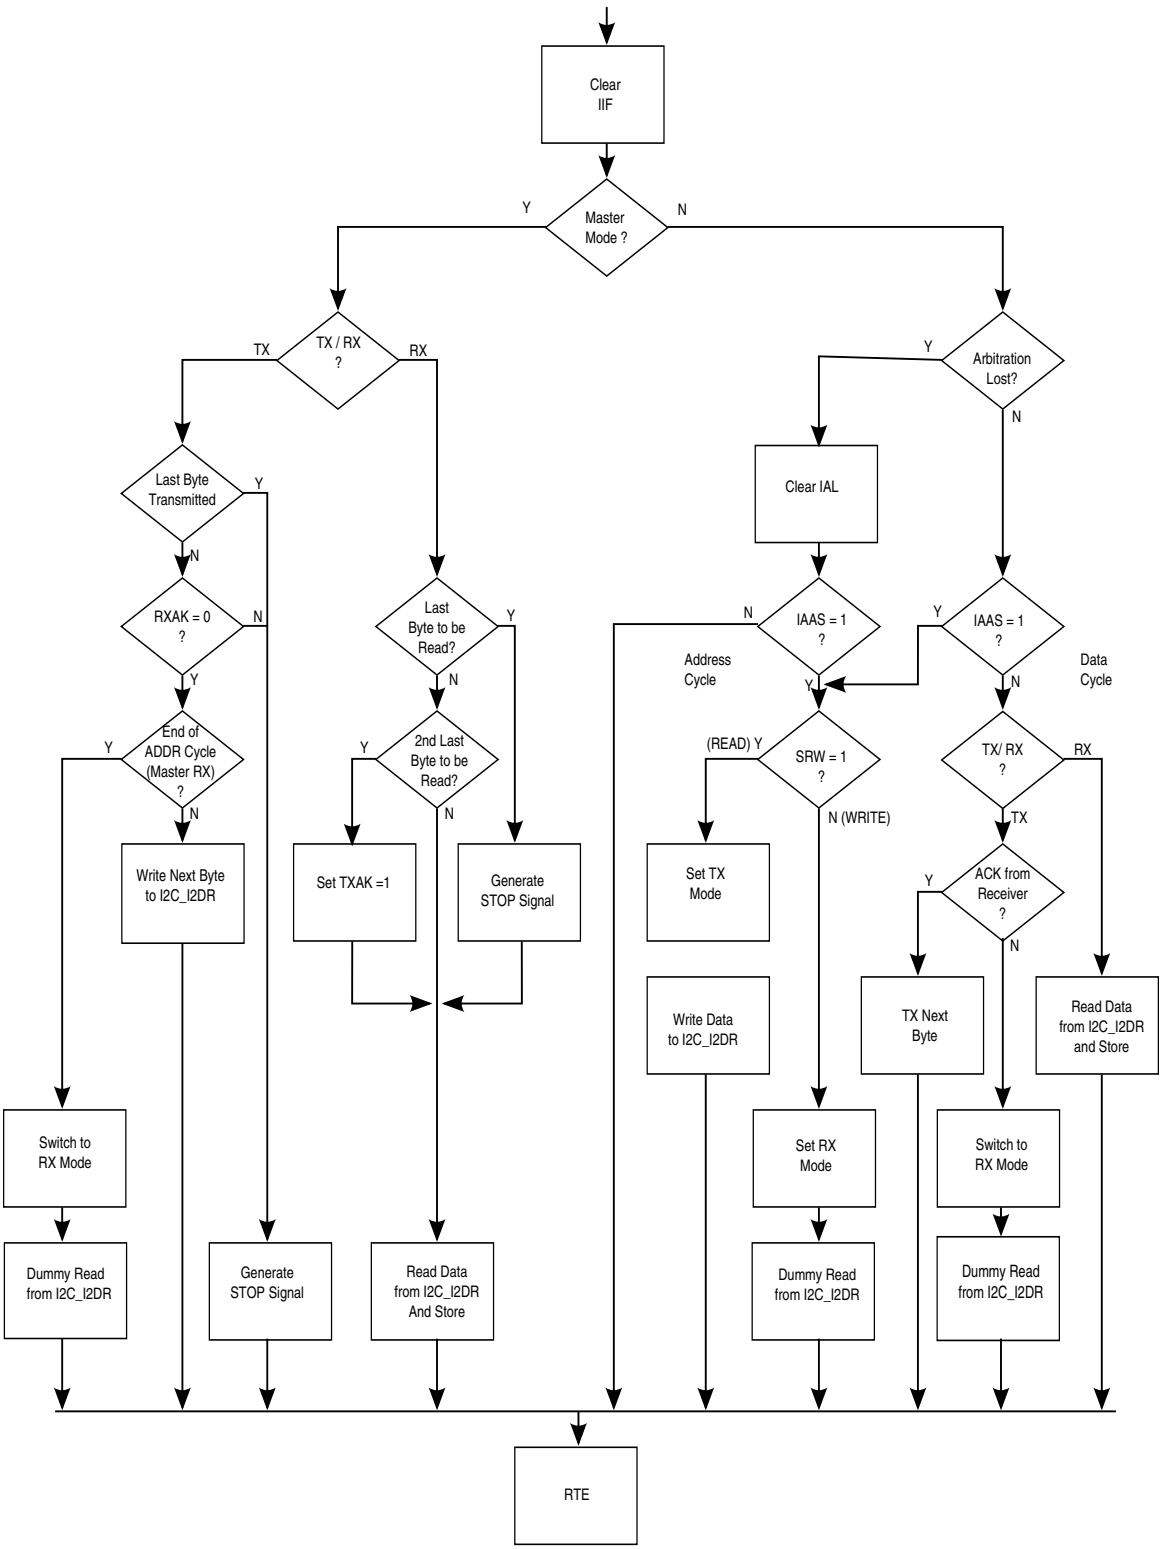

Figure 34-7. Flow-Chart of Typical I2C Interrupt Routine

NOTE

For a repeated start-only, the stop generation stage will not occur in master mode. A loop will repeat itself without stopping for the next start.

For Master Rx mode, I2C is programmed as master transmit during address mode and after slave address transfer, MTX bit should be cleared and Dummy read on I2C_I2DR register should be performed so that I2C can read the next receive data.

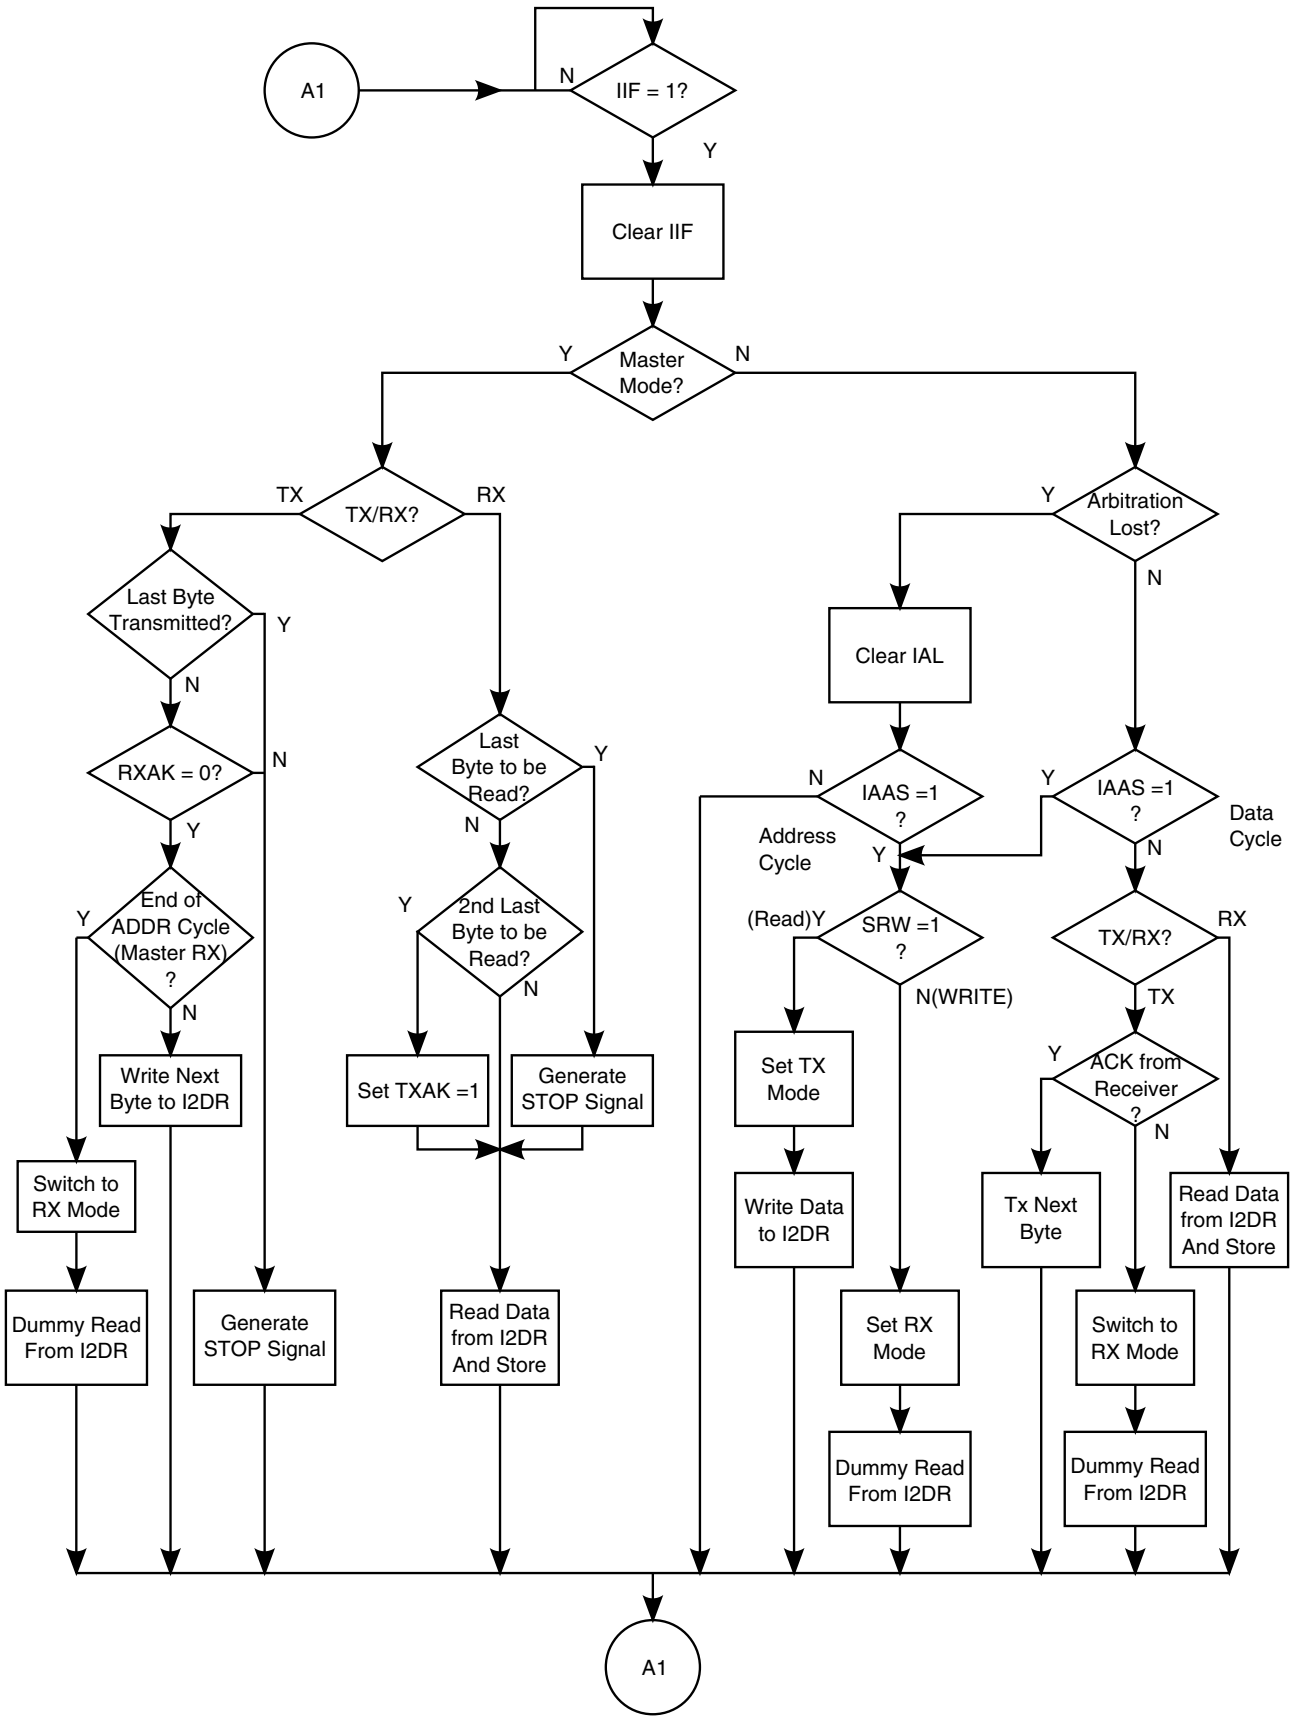

Figure 34-8. Flow Chart for Typical I2C Polling Routine

NOTE

The time-out value will depend on the bus frequency at which I2C is operating. The Min. Time-out for polling IIF bit at I2C Max bus frequency of 400KHz is, T_{min} = 25 μs (= 2.5*10 μs). This value can be interpolated for any bus frequency.

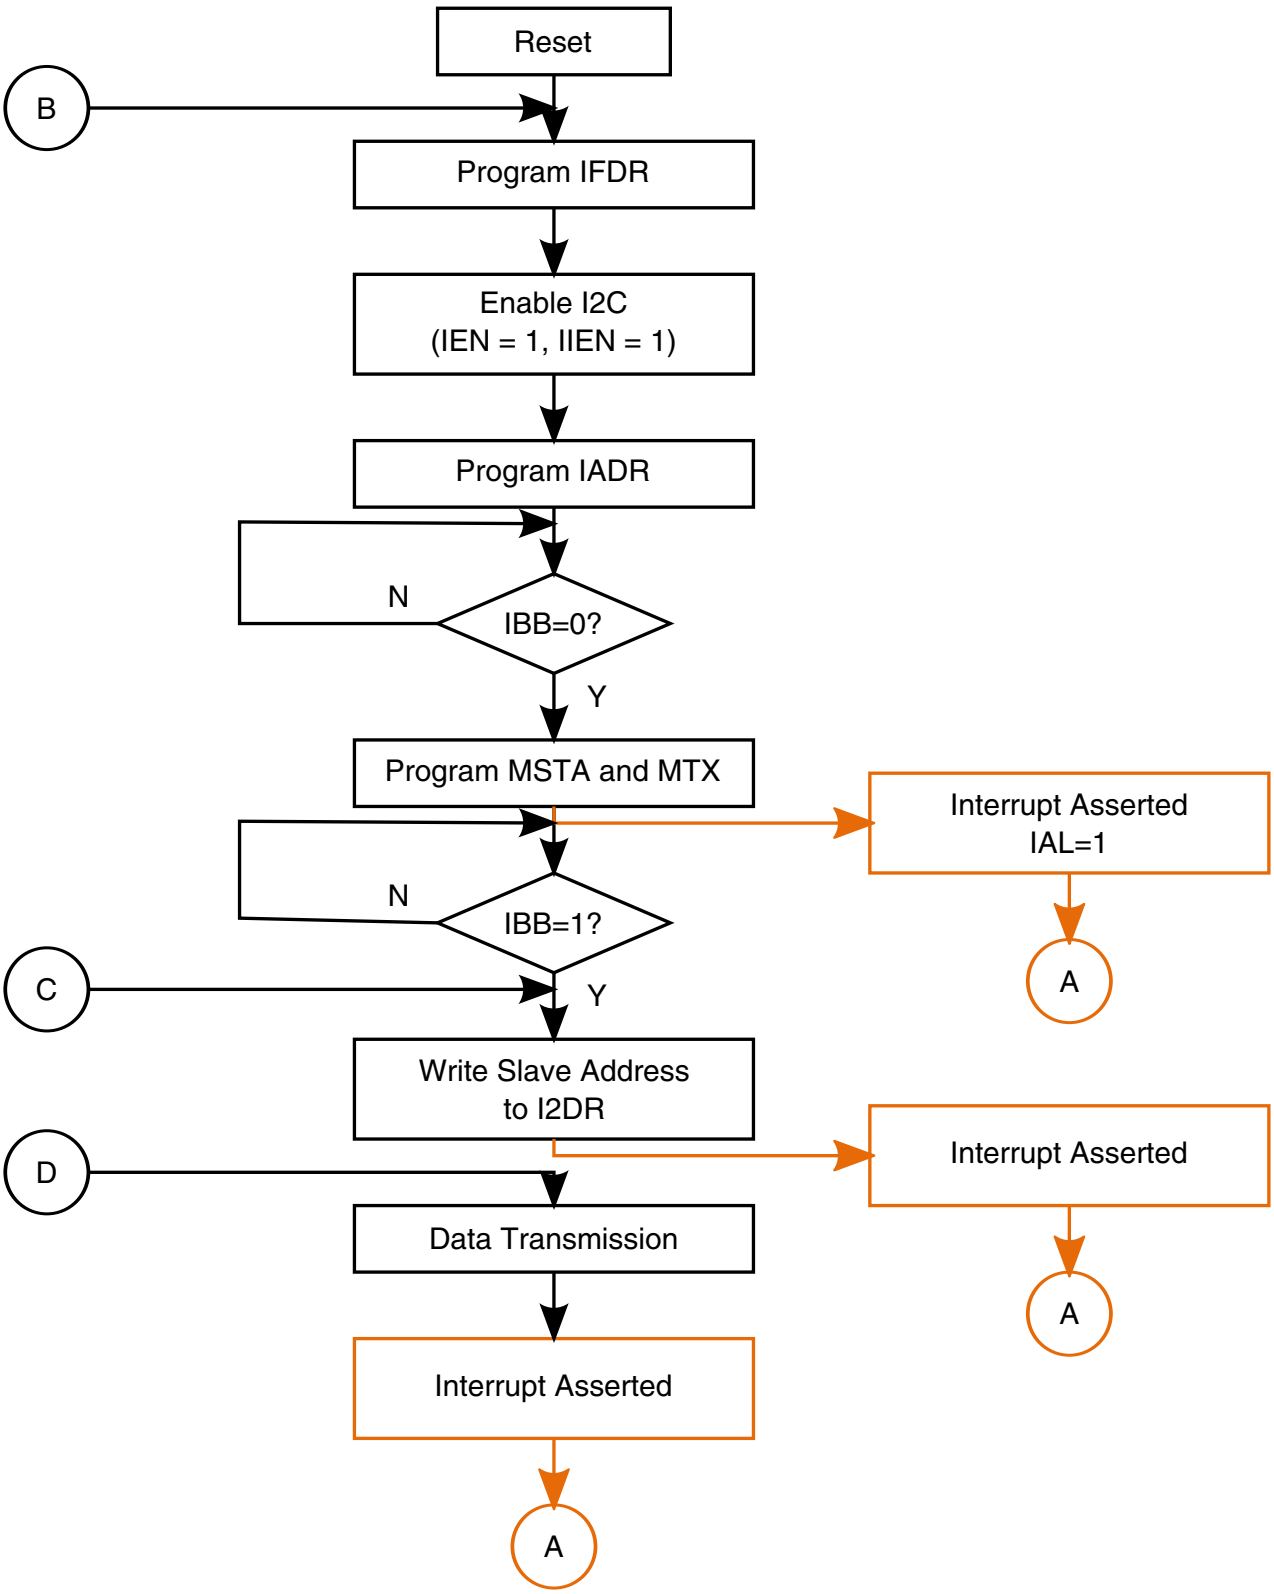

Figure 34-9. Detailed Flow Chart of a Typical I2C Master Tx Mode, Part 1

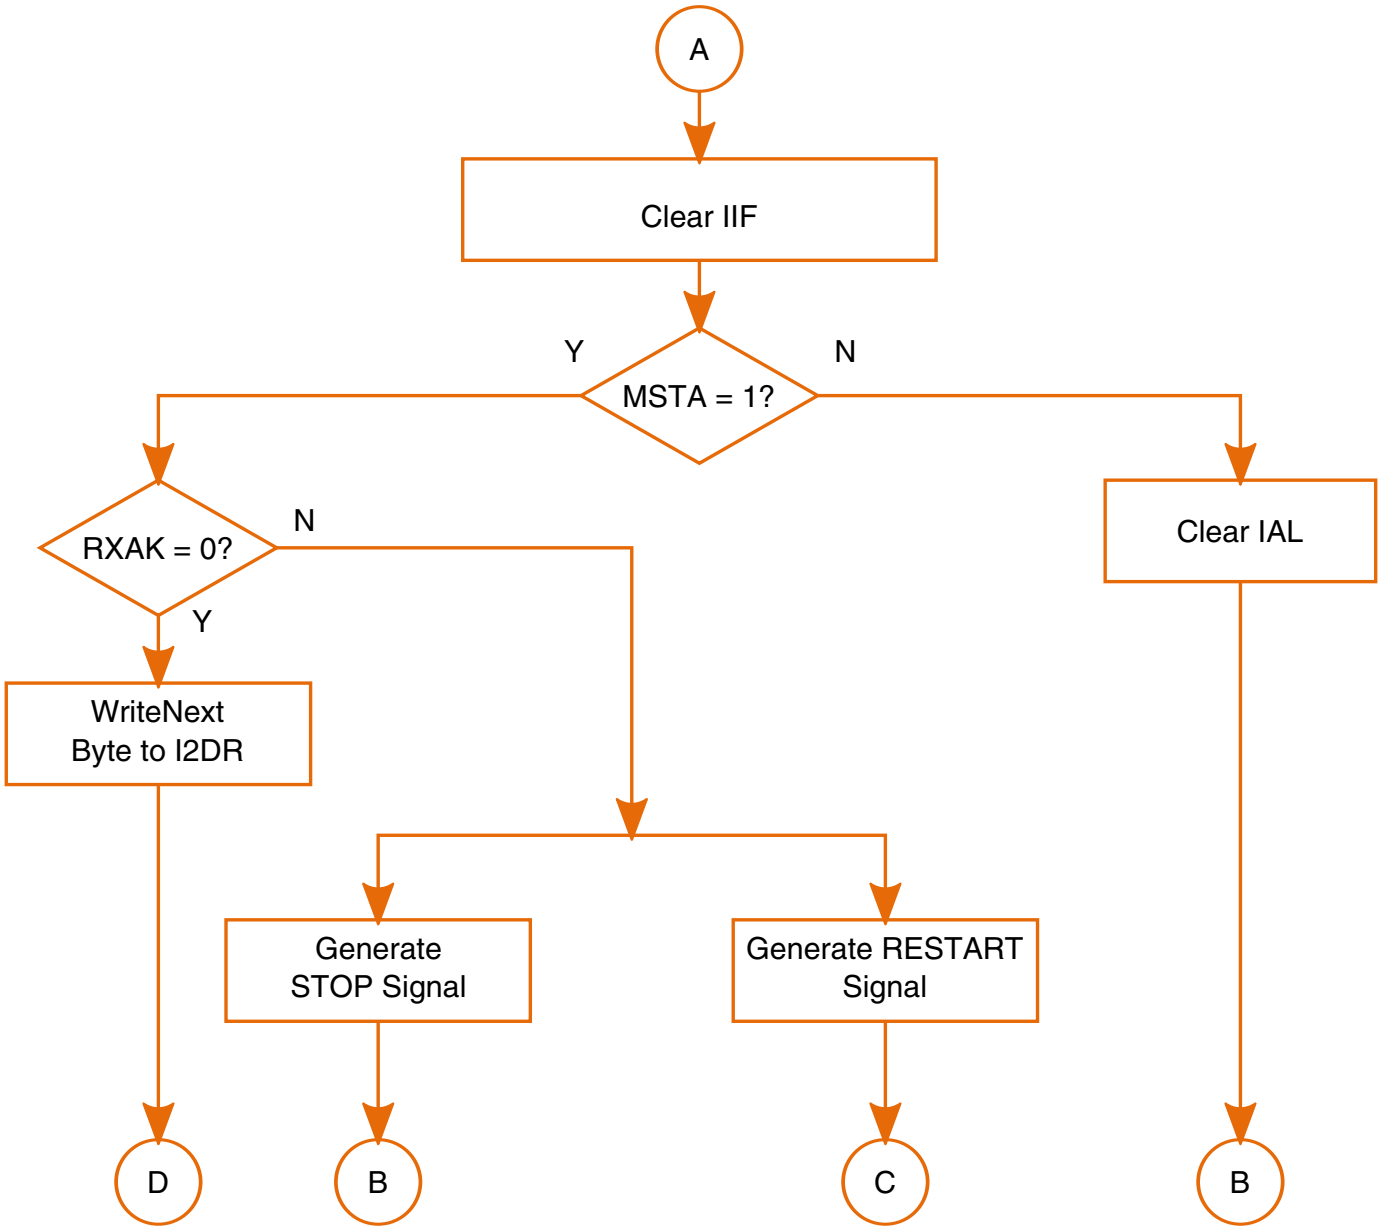

Figure 34-10. Detailed Flow Chart of a Typical I2C Master Tx Mode, Part 2

Figure 34-9 and Figure 34-10 show the Master Transmit mode operation with interrupt sub-routine. In case interrupt is generated and the MSTA bit is 0, then bus arbitration is lost and IAL is set. Software can clear IAL bit and re-program I2C. If MSTA bit is 1, then it will be a transfer done interrupt and software can check RXAK bit for data receive acknowledgement by slave and accordingly decide to either generate STOP, REPEAT START by writing in I2C_I2CR register or next data transfer by writing into I2C_I2DR register.

NOTE

The IBB bit is asserted by START condition on the bus, and it is deasserted by STOP condition on bus. Therefore, if arbitration is lost due to an unexpected STOP condition during transfer, then IBB is cleared. If arbitration is lost due to data mismatch, then it will not be cleared. Software should always clear the IEN bit and then set it if arbitration is lost.

34.5 Software Restriction

Software should take care that there is a delay of at least two Module Clock cycles after it sets the I2C_I2CR[RSTA] bit before writing to the I2C_I2DR register. Maximum possible clock period of Module Clock is 78 ns.

34.6 Programmable Registers

34.6.1 I2C Memory Map/Register Definition

The I2C contains five 16-bit registers.

NOTE

Registers at offsets 0x0002, 0x0006, 0x000A, and 0x000E are reserved for future additions.

I2C memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
53FE_C000	I2C Address Register (I2C-3_IADR)	16	R/W	0000h	34.61.1/ 1645
53FE_C004	I2C Frequency Divider Register (I2C-3_IFDR)	16	R/W	0000h	34.61.2/ 1646

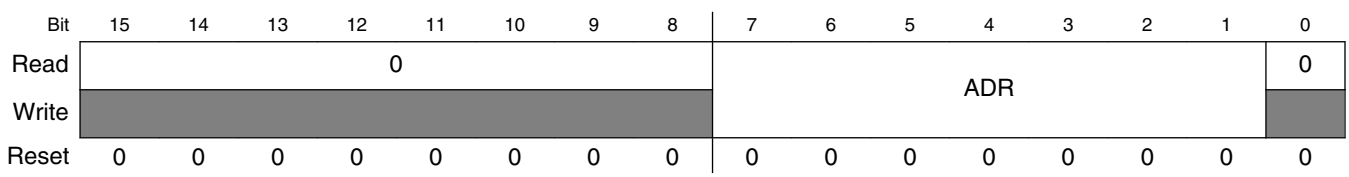
63FC_8004	I2C Frequency Divider Register (I2C-1_IFDR)	16	R/W	0000h	34.61.2/ 1646
63FC_8008	I2C Control Register (I2C-1_I2CR)	16	R/W	0000h	34.61.3/ 1647
63FC_800C	I2C Status Register (I2C-1_I2SR)	16	R/W	0081h	34.61.4/ 1649
63FC_8010	I2C Data I/O Register (I2C-1_I2DR)	16	R/W	0000h	34.61.5/ 1650

34.61.1 I2C Address Register (I2Cx_IADR)

Addresses: I2C-3_IADR is 53FE_C000h base + 0h offset = 53FE_C000h
I2C-2_IADR is 63FC_4000h base + 0h offset = 63FC_4000h
I2C-1_IADR is 63FC_8000h base + 0h offset = 63FC_8000h



I2Cx_IADR field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7–1 ADR	Slave address. Contains the specific slave address to be used by the I2C. Slave mode is the default I2C mode for an address match on the bus.

Table continues on the next page...

I2Cx_IADR field descriptions (continued)

Field	Description
	NOTE: The I2C_IADR holds the address the I2C responds to when addressed as a slave. The slave address is not the address sent on the bus during the address transfer. The register is not reset by a software reset.
0 Reserved	This read-only field is reserved and always has the value zero. Reserved

34.61.2 I2C Frequency Divider Register (I2Cx_IFDR)

The I2C_IFDR provides a programmable prescaler to configure the clock for bit-rate selection. The register does not get reset by software reset. The following table describes the Divider values for register field "IC". Table below describes the register values for field "IC".

Table 34-12. I2C_IFDR Register Field Values

IC	Divider		IC	Divider		IC	Divider		IC	Divider
0x00	30		0x10	288		0x20	22		0x30	160

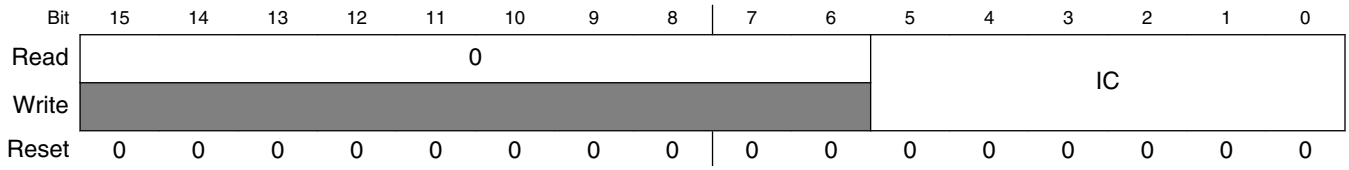
Addresses: I2C-3_IFDR is 53FE_C000h base + 4h offset = 53FE_C004h
I2C-2_IFDR is 63FC_4000h base + 4h offset = 63FC_4004h
I2C-1_IFDR is 63FC_8000h base + 4h offset = 63FC_8004h



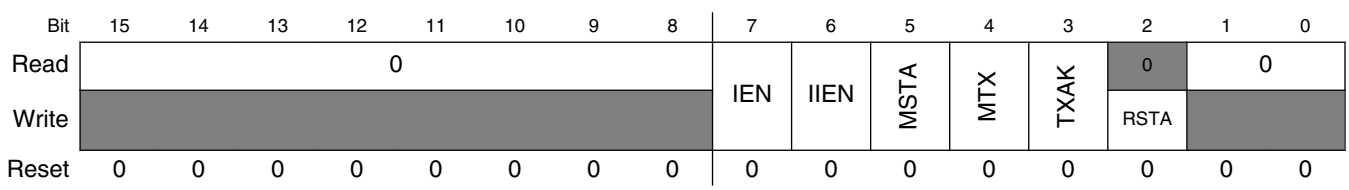
I2Cx_IFDR field descriptions

Field	Description
15–6 Reserved	This read-only field is reserved and always has the value zero. Reserved
5–0 IC	I2C clock rate. Pre scales the clock for bit-rate selection. Due to potentially slow SCL and SDA rise and fall times, bus signals are sampled at the prescaler frequency. The serial bit clock frequency is equal to IPG_CLK_ROOT divided by the divider shown in I2C Data I/O Register . **NOTE:** The IC value should not be changed during the data transfer, however, it can be changed before REPEAT START or START programming sequence in I2C. The I2C protocol supports bit rates up to 400 kbps. The IC bits need to be programmed in accordance with this constraint.

34.61.3 I2C Control Register (I2Cx_I2CR)

The I2C_I2CR is used to enable the I2C and the I2C interrupt. It also contains bits that govern operation as a slave or a master.

Addresses: I2C-3_I2CR is 53FE_C000h base + 8h offset = 53FE_C008h
I2C-2_I2CR is 63FC_4000h base + 8h offset = 63FC_4008h
I2C-1_I2CR is 63FC_8000h base + 8h offset = 63FC_8008h



I2Cx_I2CR field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7 IEN	I2C enable. Also controls the software reset of the entire I2C. Resetting the bit generates an internal reset to the block. If the block is enabled in the middle of a byte transfer, slave mode ignores the current bus transfer and starts operating when the next start condition is detected. Master mode is not aware that the bus is busy so initiating a start cycle may corrupt the current bus cycle, ultimately causing either the current master or the I2C to lose arbitration. After which, bus operation returns to normal.

Table continues on the next page...

I2Cx_I2CR field descriptions (continued)

Field	Description
	0 The block is disabled, but registers can still be accessed. 1 The I2C is enabled. This bit must be set before any other I2C_I2CR bits have any effect.
6 IIEN	I2C interrupt enable. **NOTE:** If data is written during the START condition, that is, just after setting the I2C_I2CR[MSTA] and I2C_I2CR[MTX] bits, then the ICF bit is cleared at the falling edge of SCLK after START. If data is written after the START condition and falling edge of SCLK, then ICF bit is cleared as soon as data is written. 0 I2C interrupts are disabled, but the status flag I2C_I2SR[IIF] continues to be set when an interrupt condition occurs. 1 I2C interrupts are enabled. An I2C interrupt occurs if I2C_I2SR[IIF] is also set.
5 MSTA	Master/slave mode select bit. If the master loses arbitration, MSTA is cleared without generating a STOP signal. **NOTE:** Module clock should be on for writing to the MSTA bit. **NOTE:** The MSTA bit is cleared by software to generate a STOP condition; it can also be cleared by hardware when the I2C loses the bus arbitration. 0 Slave mode. Changing MSTA from 1 to 0 generates a STOP and selects slave mode. 1 Master mode. Changing MSTA from 0 to 1 signals a START on the bus and selects master mode.
4 MTX	Transmit/receive mode select bit. Selects the direction of master and slave transfers. 0 Receive. When a slave is addressed, the software should set MTX according to the slave read/write bit in the I2C status register (I2C_I2SR[SRW]). 1 Transmit. In master mode, MTX should be set according to the type of transfer required. Therefore, for address cycles, MTX is always 1.
3 TXAK	Transmit acknowledge enable. Specifies the value driven onto SDA during acknowledge cycles for both master and slave receivers. **NOTE:** Writing TXAK applies only when the I2C bus is a receiver. 0 An acknowledge signal is sent to the bus at the ninth clock bit after receiving one byte of data. 1 No acknowledge signal response is sent (that is, the acknowledge bit = 1).
2 RSTA	Repeat start. Always reads as 0. Attempting a repeat start without bus mastership causes loss of arbitration. 0 No repeat start 1 Generates a repeated START condition
1–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

34.61.4 I2C Status Register (I2Cx_I2SR)

The I2C_I2SR contains bits that indicate transaction direction and status.

Addresses: I2C-3_I2SR is 53FE_C000h base + Ch offset = 53FE_C00Ch
I2C-2_I2SR is 63FC_4000h base + Ch offset = 63FC_400Ch
I2C-1_I2SR is 63FC_8000h base + Ch offset = 63FC_800Ch

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0								ICF	IAAS	IBB	IAL	0	SRW	IIF	RXAK
Write																
Reset	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	1

I2Cx_I2SR field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7 ICF	Data transferring bit. While one byte of data is transferred, ICF is cleared. 0 Transfer is in progress. 1 Transfer is complete. This bit is set by the falling edge of the ninth clock of the last byte transfer.
6 IAAS	I2C addressed as a slave bit. The ARM platform is interrupted if the interrupt enable (I2C_I2CR[IIEN]) is set. The ARM platform must check the slave read/write bit (SRW) and set its TX/RX mode accordingly. Writing to I2C_I2CR clears this bit. 0 Not addressed 1 Addressed as a slave. Set when its own address (I2C_IADR) matches the calling address.
5 IBB	I2C bus busy bit. Indicates the status of the bus. **NOTE:** When I2C is enabled (I2C_I2CR[IEN] = 1), it continuously polls the bus data (SDAK) and clock (SCLK) signals to determine a START or STOP condition. 0 Bus is idle. If a STOP signal is detected, IBB is cleared. 1 Bus is busy. When START is detected, IBB is set.
4 IAL	Arbitration lost. Set by hardware in the following circumstances (IAL must be cleared by software by writing a "0" to it at the start of the interrupt service routine): • SDA input sampled low when the master drives high during an address or data-transmit cycle. • SDA input sampled low when the master drives high during the acknowledge bit of a data-receive cycle. For the above two cases, the bit is set at the falling edge of 9th SCL clock during the ACK cycle. • A start cycle is attempted when the bus is busy. • A repeated start cycle is requested in slave mode. • A stop condition is detected when the master did not request it. **NOTE:** Software cannot set the bit. 0 No arbitration lost. 1 Arbitration is lost.

Table continues on the next page...

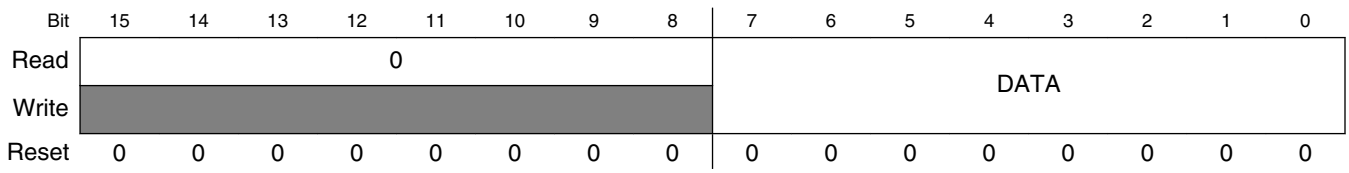
I2Cx_I2SR field descriptions (continued)

Field	Description
3 Reserved	This read-only field is reserved and always has the value zero. Reserved
2 SRW	Slave read/write. When the I2C is addressed as a slave, IAAS is set, and the slave read/write bit (SRW) indicates the value of the R/W command bit of the calling address sent from the master. SRW is valid only when a complete transfer has occurred, no other transfers have been initiated, and the I2C is a slave and has an address match. 0 Slave receive, master writing to slave 1 Slave transmit, master reading from slave
1 IIF	I2C interrupt. Must be cleared by the software by writing a "0" to it in the interrupt routine. **NOTE:** The software cannot set the bit. 0 No I2C interrupt pending. 1 An interrupt is pending. This causes a processor interrupt request (if the interrupt enable is asserted [IIEN = 1]). The interrupt is set when one of the following occurs: • One byte transfer is completed (the interrupt is set at the falling edge of the ninth clock). • An address is received that matches its own specific address in slave-receive mode. • Arbitration is lost.
0 RXAK	Received acknowledge. This is the value received of the SDA input for the acknowledge bit during a bus cycle. 0 An "acknowledge" signal was received after the completion of an 8-bit data transmission on the bus. 1 A "No acknowledge" signal was detected at the ninth clock.

34.61.5 I2C Data I/O Register (I2Cx_I2DR)

In master-receive mode, reading the data register allows a read to occur and initiates the next byte to be received. In slave mode, the same function is available after it is addressed.

Addresses: I2C-3_I2DR is 53FE_C000h base + 10h offset = 53FE_C010h
I2C-2_I2DR is 63FC_4000h base + 10h offset = 63FC_4010h
I2C-1_I2DR is 63FC_8000h base + 10h offset = 63FC_8010h



I2Cx_I2DR field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7–0 DATA	Data Byte. Holds the last data byte received or the next data byte to be transferred. Software writes the next data byte to be transmitted or reads the data byte received. **NOTE:** The core-written value in I2C_I2DR cannot be read back by the core. Only data written by the I2C bus side can be read.

Chapter 35
IOMUXC

35.1 Overview

The IOMUX Controller (IOMUXC), together with the IOMUX, enables the IC to share one PAD to several functional blocks. The sharing is done by multiplexing the PAD input/output signals. For each PAD there are up to 8 muxing options (called ALT modes). Since different modules require different PAD settings (like pull up, keeper, and so on) the IOMUXC controls also the PAD settings parameters.

The IOMUX consist of only combinatorial logic combined from several basic iomux cells, each basic iomux cell handles only one pad signals muxing.

Figure 35-1 illustrates the IOMUX/IOMUXC connectivity in the system.

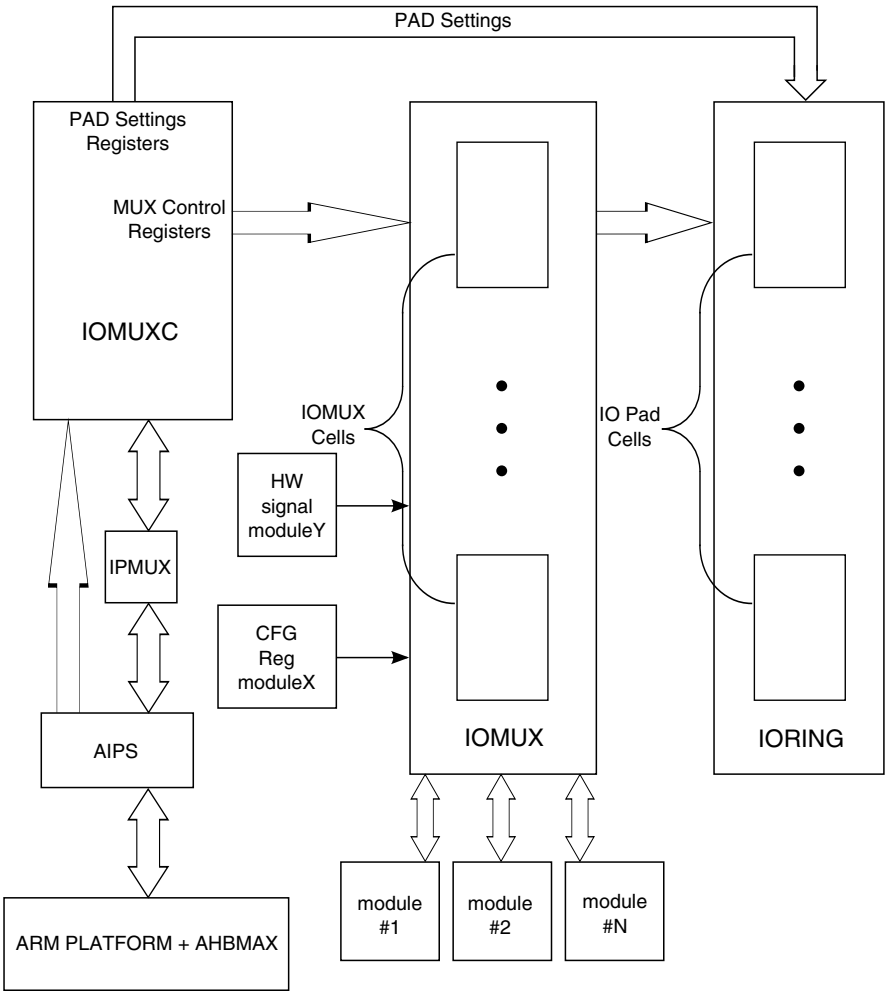


Figure 35-1. IOMUX SoC Level Block Diagram

35.1.1 Features

The IOMUXC features are:

- 32 bits SW Mux control registers (IOMUXC_SW_MUX_CTL_PAD_<PAD NAME> or IOMUXC_SW_MUX_CTL_GRP_<GROUP NAME>) to configure a specific mux mode of each pad or a predefined group of pads and to enable forcing the input path of the pad/s (SION bit).
- 32 bits SW Pad control registers (IOMUXC_SW_PAD_CTL_PAD_<PAD_NAME> or IOMUXC_SW_PAD_CTL_GRP_<GROUP NAME>) to configure specific pad settings of each pad or a predefined group of pads.
- 32 bits General Purpose Registers-Two 32 bits registers according to SOC requirements for any usage.

- 32 bits "Daisy Chain" Control registers-register to control the input path to a module when more than one pad may drive this module input.
- IPS Interface-Sky Blue peripheral bus to allow registers configuration and readiness (all registers are read/write registers).

Each SW MUX/PAD CTL IOMUXC register handles only one pad or one pads group.

Only the minimum number of registers required by SW will be implemented by HW, for example, if only ALT0 and ALT1 modes are used on Pad X then only one bit register will be generated as the MUX_MODE control field in the SW Mux control register of Pad X.

The SW Mux control registers may allow also forcing the pads to become input (input path enabled) regardless of the functional direction driven. This may be useful for loopback and GPIO data capture.

35.1.2 Modes of Operation

There is only one mode of operation-normal mode.

35.2 External Signal Description

There are no signals in the IOMUX that connect off chip (they all control the PADS functionality).

35.3 Functional Description

The IOMUXC Detailed Block Diagram is illustrated in Figure 35-2.

The IOMUXC is consist of 2 sub blocks:

- IOMUXC_REGISTERS: includes all the IOMUXC registers (6 main types are illustrated).
- IOMUXC_LOGIC: includes all the IOMUXC combinatorial logic (IP interface controls, address decoder, observability muxes).

The IOMUXC external signals and the IOMUXC sub blocks connections internal signals are also detailed in this diagram. The following are the naming conventions used along with some explanation:

- <PAD>-any PAD logic name.

- <GRP>-any PAD group logic name.
- <FUNC>-one of the following pad control functions:
  - SRE (1 bit slew rate control).
  - DSE (2 bits drive strength control).
  - ODE (1 bit open drain control).
  - HYS (1 bit hysteresis control).
  - PULL_KEEP_CTL (4 bits pull up/down and keeper controls)
  - PUS (2 bits pull up/down configuration value)
  - PUE (1 bit pull/keep select)
  - PKE (1 bit enable/disable pull up, pull down or keeper capability)
  - DDR_MODE_SEL (1 bit ddr_mode control)
  - DDR_INPUT (1 bit ddr_input control)
- ips_addr[X:2] - since the IOMUXC registers are all 32 bits width address lines 0,1 are not used. X will be calculated automatically by the tool according to the final register number: X is smallest integer value which satisfy the constraint: 2^(X-1) >= (Total number of IOMUXC registers).

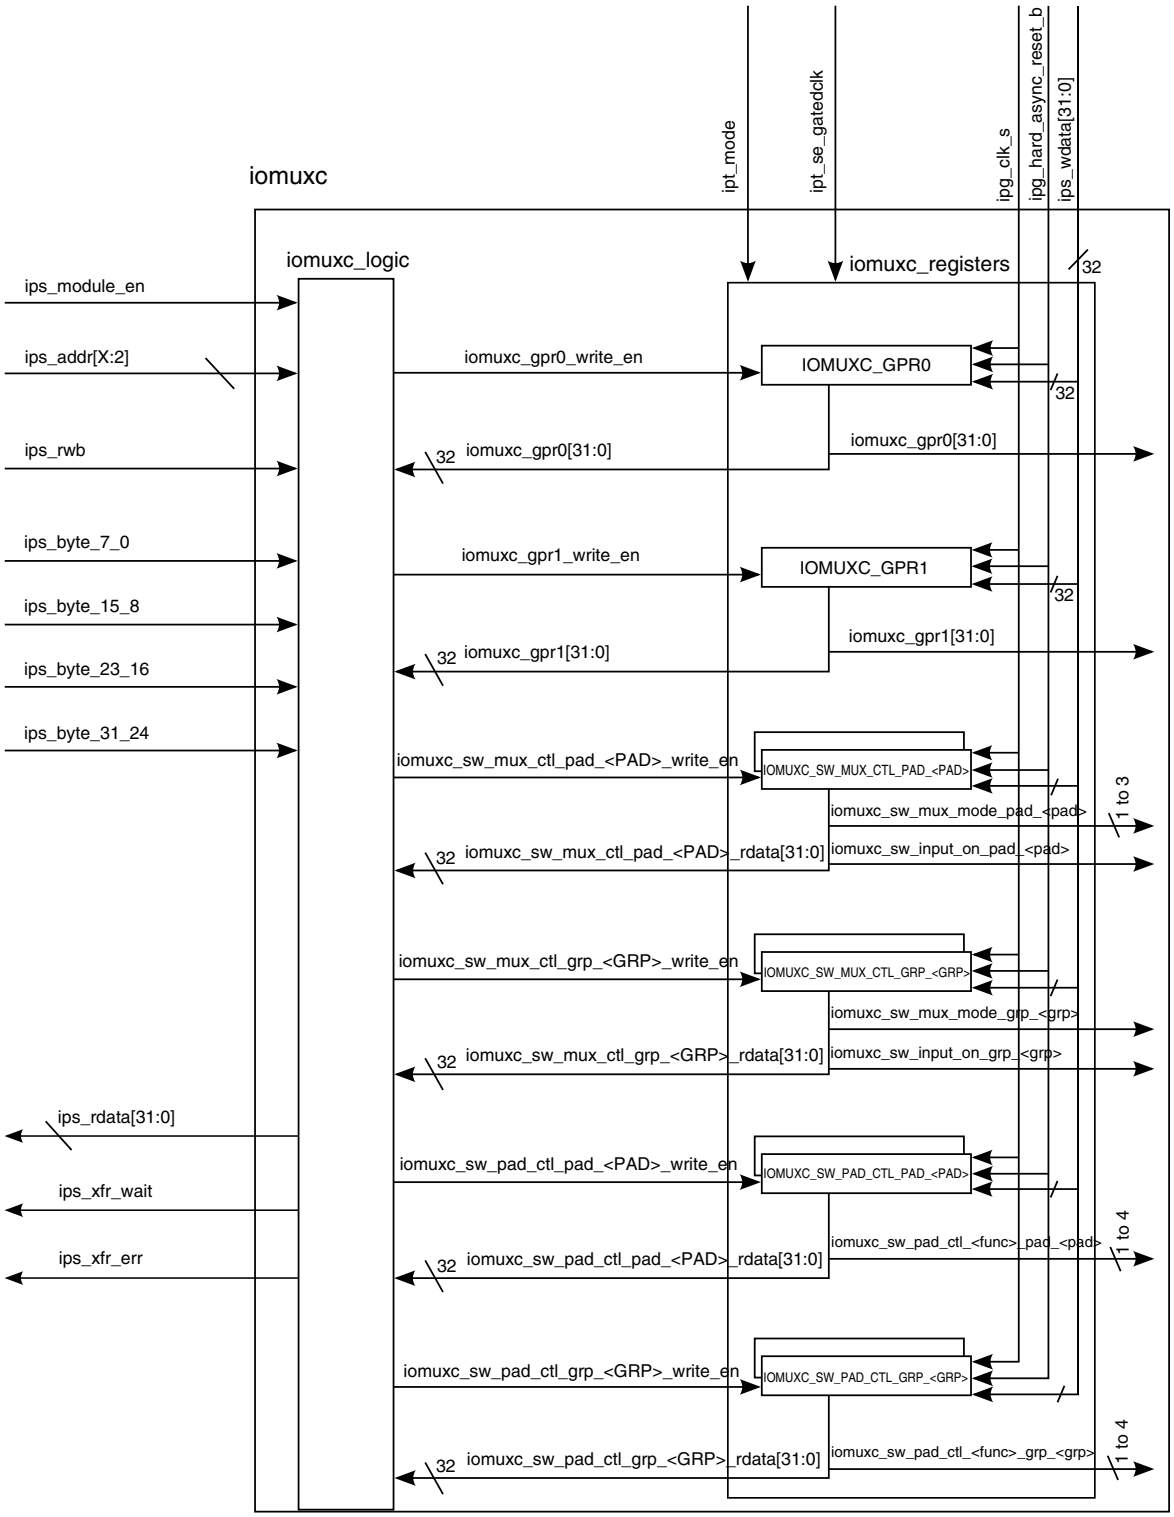

Figure 35-2. IOMUXC Block Diagram

The IOMUX consist of a number (about the number of pads in the SoC) of basic iomux_cell units. If only one functional mode is required for a specific pad then there is no need for IOMUXing and the signals can be connected directly from the module to the IORING. IOMUX cell is required whenever 2 or more functional modes are required for a specific pad or when one functional mode and the one test mode are required.

The basic iomux_cell design, which allows 2 levels of HW signal control (in ALT6 and ALT7 modes - ALT7 gets highest priority) is shown in Figure 35-3.

35.3.1 ALT6 and ALT7 Extended Muxing Modes

The ALT7 and ALT6 Extended Muxing Modes allows any signal in the system (Fuse, Pad input, JTAG, SW register, etc) to override any SW configuration and to force the ALT6/ALT7 Muxing Mode. It also allows an IOMUX SW register to control a group of pads.

35.3.2 SW Loopback through SION Bit

A limited but satisfying option exist to override the regular pad functionality and force the input path to be active (ipp_ibe=1'b1) regardless of the value driven by the corresponding module. This can be done by setting the SION (SW Input On) bit in the IOMUXC_SW_MUX_CTL register (when available) to "1" and can be used for:

- LoopBack-Module X drives the pad and also receive pad value as an input.
- GPIO Capture-Module X drives the pad and the value is captured by GPIO.

NOTE

Software loopback is not affecting DRAM MC PADS.

35.3.3 "Daisy Chain"-Multi Pads Driving Same Module Input Pin

In some cases, more than one pad may drive a single module input pin.

Such cases require adding one more level of IOMUXing: all these input signals are muxed and a dedicated SW controlled register controls the mux in order to select the required input path. This means that a pad involved in such "Daisy Chain" situation may require 2 SW configuration commands: one for selecting the mode for this pad and one for defining it as the input path.

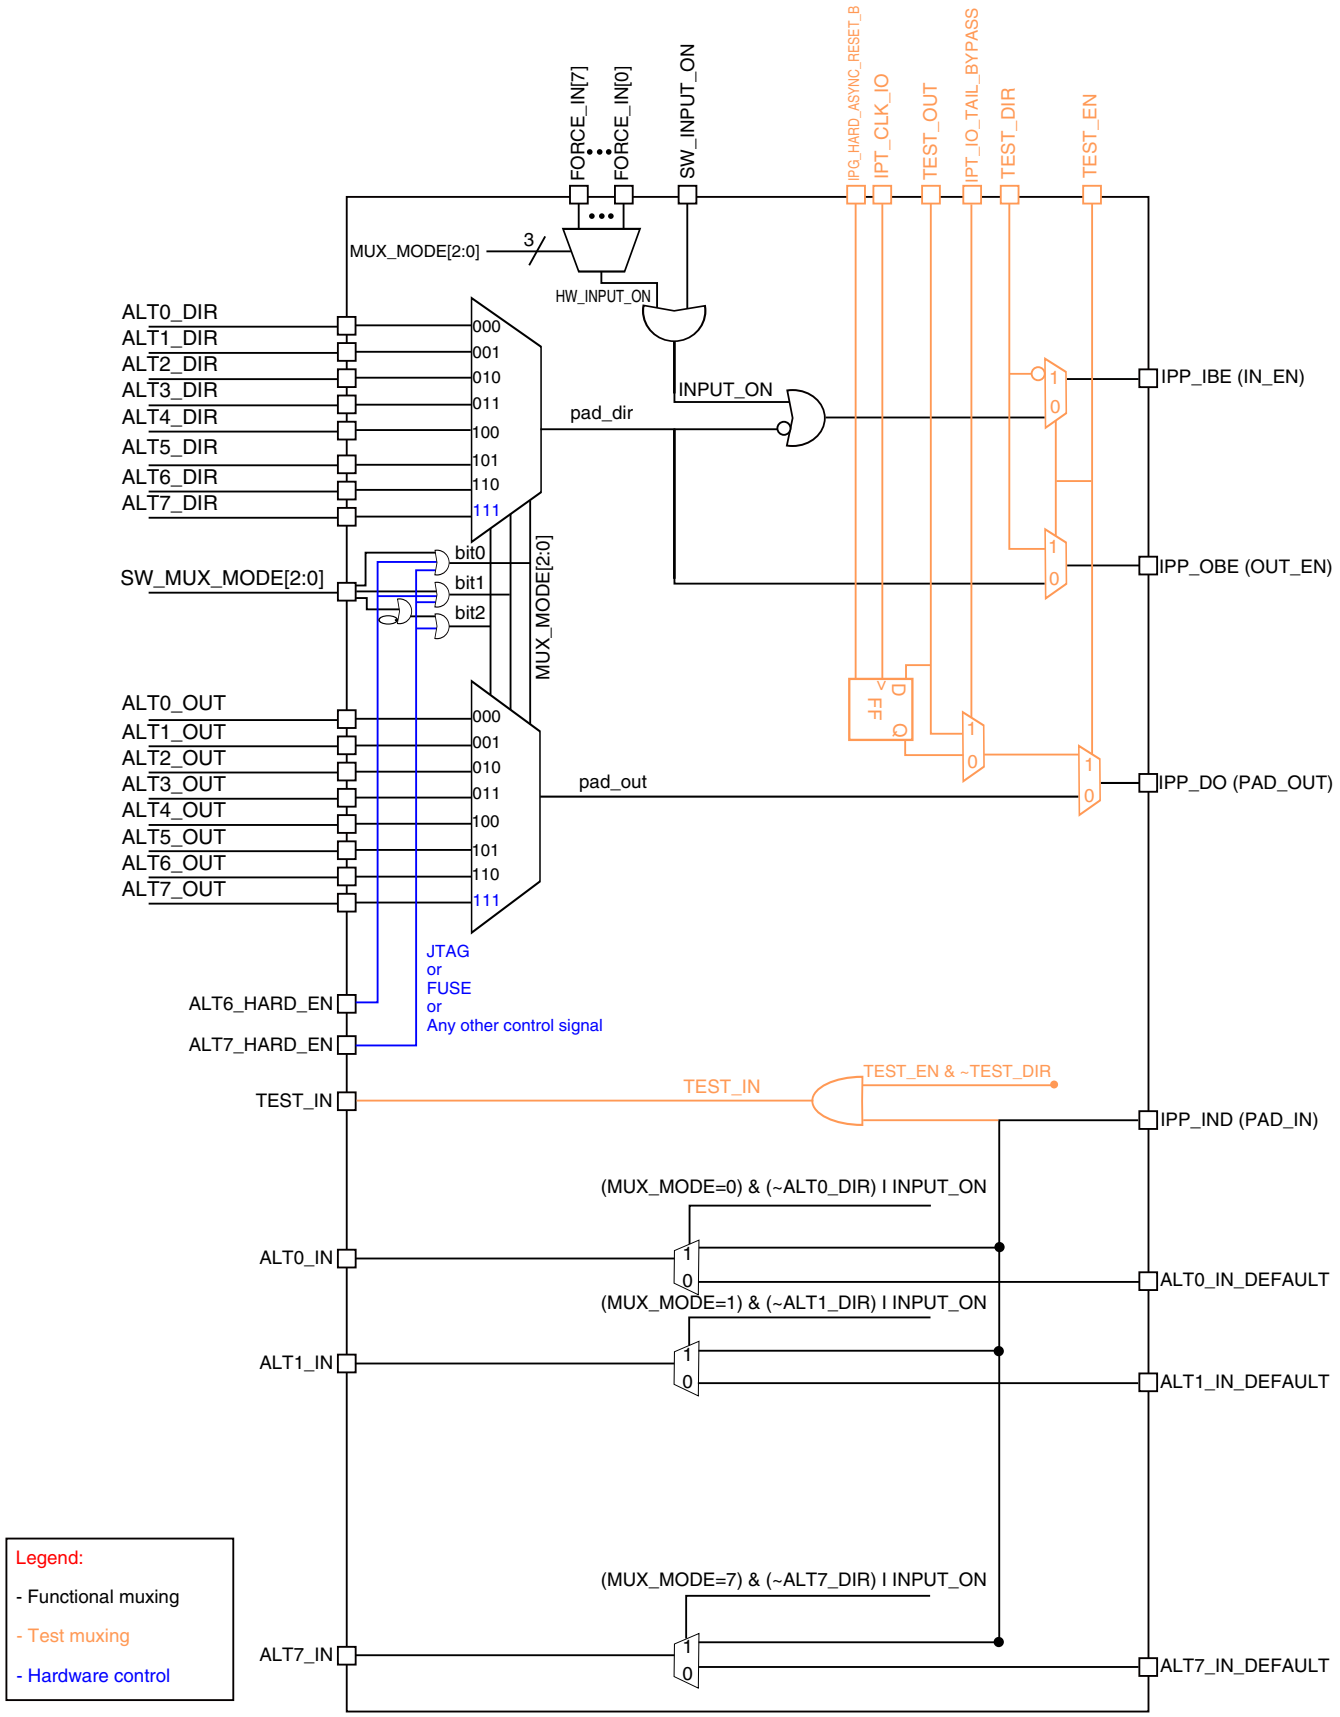

Figure 35-3. IOMUX Cell Block Diagram

35.3.4 Interrupts

There are no interrupts that are generated by the IOMUX controller.

35.4 Programmable Registers

IOMUXC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
53FA_8000	GPR0 (IOMUXC_GPR0)	32	R/W	0000_0000h	35.4.1/ 1686
53FA_8004	GPR1 (IOMUXC_GPR1)	32	R/W	0019_0005h	35.4.2/ 1687
53FA_8008	GPR2 (IOMUXC_GPR2)	32	R/W	0000_0000h	35.4.3/ 1688
53FA_800C	OBSERVE_MUX_0 (IOMUXC_OBSMUX0)	32	R/W	0000_0000h	35.4.4/ 1689
53FA_8010	OBSERVE_MUX_1 (IOMUXC_OBSMUX1)	32	R/W	0000_0000h	35.4.5/ 1690
53FA_8014	OBSERVE_MUX_2 (IOMUXC_OBSMUX2)	32	R/W	0000_0000h	35.4.6/ 1691
53FA_8018	OBSERVE_MUX_3 (IOMUXC_OBSMUX3)	32	R/W	0000_0000h	35.4.7/ 1692
53FA_801C	OBSERVE_MUX_4 (IOMUXC_OBSMUX4)	32	R/W	0000_0000h	35.4.8/ 1693
53FA_8020	SW_MUX_CTL_PAD_KEY_COL0 (IOMUXC_SMUXC_PKC0)	32	R/W	0000_0001h	35.4.9/ 1695
53FA_8024	SW_MUX_CTL_PAD_KEY_ROW0 (IOMUXC_SMUXC_PKR0)	32	R/W	0000_0001h	35.4.10/ 1696
53FA_8028	SW_MUX_CTL_PAD_KEY_COL1 (IOMUXC_SMUXC_PKC1)	32	R/W	0000_0001h	35.4.11/ 1697
53FA_802C	SW_MUX_CTL_PAD_KEY_ROW1 (IOMUXC_SMUXC_PKR1)	32	R/W	0000_0001h	35.4.12/ 1698
53FA_8030	SW_MUX_CTL_PAD_KEY_COL2 (IOMUXC_SMUXC_PKC2)	32	R/W	0000_0001h	35.4.13/ 1699
53FA_8034	SW_MUX_CTL_PAD_KEY_ROW2 (IOMUXC_SMUXC_PKR2)	32	R/W	0000_0001h	35.4.14/ 1700
53FA_8038	SW_MUX_CTL_PAD_KEY_COL3 (IOMUXC_SMUXC_PKC3)	32	R/W	0000_0001h	35.4.15/ 1701

Chapter 36
Keypad Port (KPP)

36.1 Overview

The Keypad Port (KPP) is a 16-bit peripheral that can be used as a keypad matrix interface or as general purpose input/output (I/O). The figure below shows the KPP block diagram. The KPP provides interface for the keypad matrix with 2-point contact or 3-point contact keys. The KPP is designed to simplify the software task of scanning a keypad matrix. With appropriate software support, the KPP is capable of detecting, debouncing, and decoding one or multiple keys pressed simultaneously on the keypad.

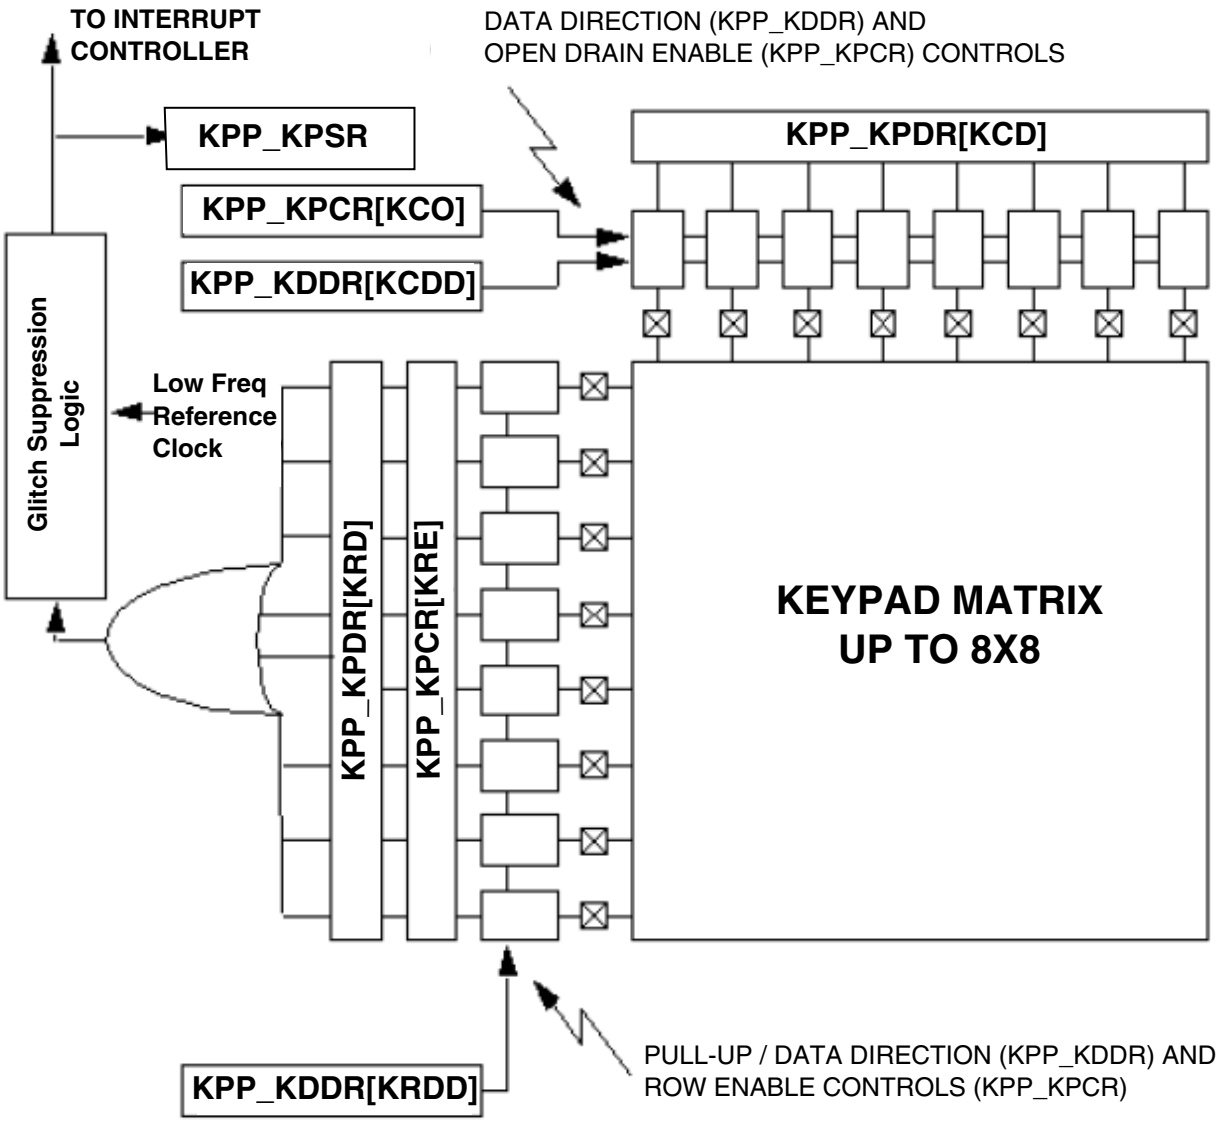

Figure 36-1. KPP Peripheral Block Diagram

36.1.1 Features

The KPP includes these distinctive features:

- Supports up to an 8 x 8 external key pad matrix
- Port pins can be used as general purpose I/O
- Open drain design
- Glitch suppression circuit design
- Multiple-key detection
- Long key-press detection

- Standby key-press detection
- Synchronizer chain clear
- Supports a 2-point and 3-point contact key matrix

36.1.2 Modes and Operations

This block supports the following modes:

- Run Mode-This is the normal functional mode in which the KPP can detect any key press event.
- Low Power Mode-The keypad can detect any key press even in low power modes (when there is no MCU clock).

36.2 External Signals

36.2.1 External Signals Overview

There are 16 pins dedicated to the KPP. Keypads of any configuration up to eight rows and eight columns are supported through the software configuration of the peripheral pins. Any pins not used for the keypad are available as general purpose I/O. The registers are configured such that the pins can be treated as an I/O port up to 16 bits wide.

See the table below for the list of external signals.

Table 36-1. Block Signals

Name	Function	Reset State	Pull up	
KPCOL[7:0]	Column input or output pin, from chip	0	Active[1]	
KPROW[7:0]	Row input or output pin, from chip	1	Active[2]	

1. The corresponding pads are required to be pull-up enabled.
2. The corresponding pads are required to be pull-up enabled.

36.2.1.1 Input Pins

Any of the 16 pins associated with the KPP can be configured as inputs by writing a "0" to the appropriate bits in the KPP_KDDR. Additionally, the least significant 8 bits (ROW inputs) corresponding to KPP_KDDR[KRDD] have internal pull-ups, which are enabled when the pin is used as an input.

36.2.1.2 Output Pins

Any of the 16 pins associated with the KPP can be configured as outputs by writing the appropriate bits in the KPP_KDDR to a "1". Additionally, the 8 most significant bits (15-8) can be designated as open drain outputs by writing a "1" to the appropriate bits in the KPP_KPCR. The lower 8 bits (7-0) are always in "totem pole" style, driven when configured as outputs.

See the table below.

Table 36-2. Keypad Port Column Modes

KPP_KDDR (15:8)	KPP_KPCR (15:8)	Pin Function
0	x	Input
1	0	Totem-Pole Output
1	1	Open-Drain Output

NOTE

Totem pole capability should be provided for column pins. Totem pole configuration helps for a faster discharge of keypad capacitance when all columns need to be quickly brought to a "1" during the scan routine. With this configuration, delay between the scanning of two subsequent columns is reduced.

36.2.1.3 Generation of Transfer Error Signal on Peripheral Bus

If there is an access to an address which is not implemented, then the KPP asserts a transfer error signal on Peripheral Bus.

36.3 Functional Description

The Keypad Port (KPP) is designed to simplify the software task of scanning a keypad matrix. With appropriate software support and matrix organization, the KPP is capable of detecting, debouncing, and decoding one or more keys pressed simultaneously on the keypad.

Logic in the KPP is capable of detecting a key press even while the processor is in one of the low power standby modes provided that a low frequency reference clock is on. The KPP may generate an ARM platform interrupt any time a key press or key release is detected. This interrupt is capable of forcing the processor out of a low power mode.

36.3.1 Keypad Matrix Construction

The KPP is designed to interface to a keypad matrix, which shorts the intersecting row and column lines together whenever a key is depressed. The interface is not optimized for any other switch configuration.

36.3.2 Keypad Port Configuration

The software must initialize the KPP for the size of the keypad matrix. Pins connected to the keypad columns should be configured as open-drain outputs. Pins connected to the keypad rows should be configured as inputs. On-chip, pull-up resistors should be implemented for active keypad rows.

In addition to enabled row inputs in the Keypad Control register, corresponding interrupt (depress or/and release) must also be enabled to generate an interrupt.

Discrete switches that are not part of the matrix may be connected to any unused row inputs. The second terminal of the discrete switch is connected to ground. The hardware detects closures of these switches without the need for software polling.

36.3.3 Keypad Matrix Scanning

Keypad scanning is performed by a software loop that walks a zero across each of the keypad columns, reading the value on the rows at each step. The process is repeated several times in succession, with the results of each pass optionally compared to those

from the previous pass. When several (3 or 4) consecutive scans yield the same key closures, a valid key press has been detected. Software then can decode exactly which switch was depressed and pass the value up to the next higher software layer.

The basic debouncing period, which must be defined in the software routine, may be controlled with an internal timer. The basic period is the period between the scan of two consecutive columns, so the debouncing time between two consecutive scans of the whole matrix shall be the number of columns multiplied by the basic period.

36.3.4 Keypad Standby

There is no need for the ARM platform to continually scan the keypad. Between key presses, the keypad can be left in a state that requires no software intervention until the next key press is detected. To place the keypad in a standby state, software should write all column outputs low. Row inputs are left enabled. At this point, the ARM platform can attend to other tasks or revert to a low power standby mode. The KPP will interrupt the ARM platform if any key is pressed.

Upon receiving a keypad interrupt, the ARM platform should set all the column strobes high, and begin a normal keypad scanning routine to determine which key was pressed. It is important that open-drain drivers be used when scanning to prevent a possible DC path between power and ground through two or more switches.

36.3.5 Glitch Suppression on Keypad Inputs

A glitch suppression circuit qualifies the keypad inputs to prevent noise from inadvertently interrupting the ARM platform. The circuit is a 4-state synchronizer clocked from a low frequency reference clock source.

This clock must continue to run in any low power mode where the keypad is a wake-up source, as the ARM platform interrupt is generated from the synchronized input. An interrupt is not generated until all four synchronizer stages have latched a valid key assertion. This guarantees the filtering out of any noise less than three clock periods in duration of a low frequency reference clock. Noise filtering of the duration between three to four clock periods cannot be guaranteed. The interrupt output is latched in an S-R latch and remains asserted until cleared by the software. The Set input of the latch is rising-edge clocked. See the figure below.

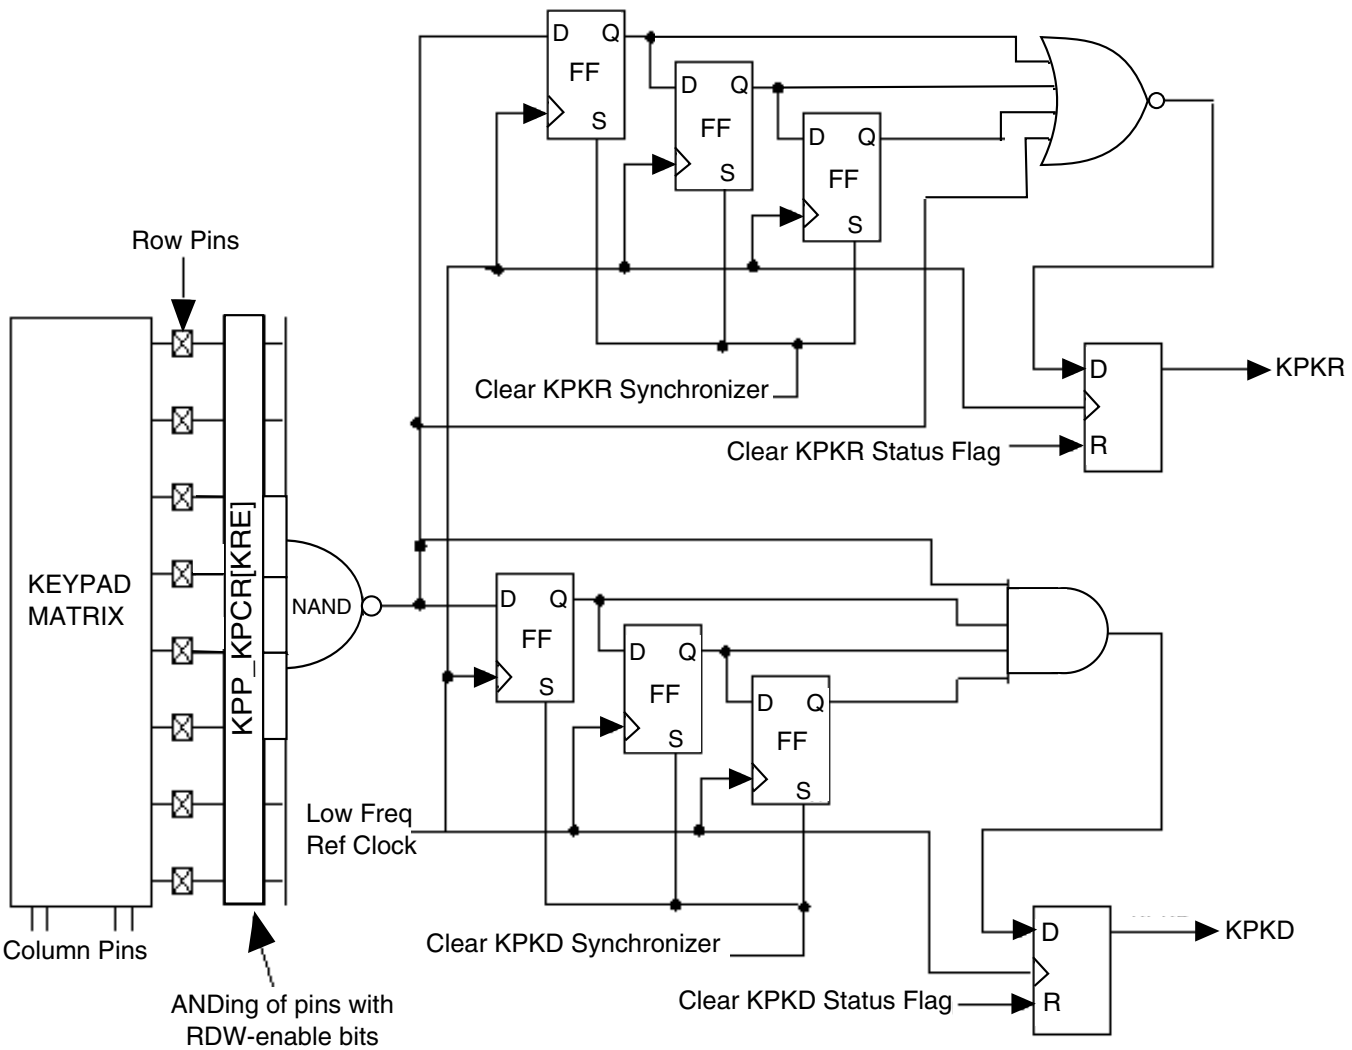

Figure 36-2. Keypad Synchronizer Functional Diagram

36.3.6 Multiple Key Closures

Using the key press and Key release interrupts, the software can detect multiple keys or achieve n key rollover. The key scanning routine can be programmed accordingly.

See the following figures for illustrations of the interfacing of a 2-contact keypad matrix with the KPP controller. With proper enabling of row lines and the performing scan-routine, multiple key presses can be detected. When keys present on the same row are pressed, corresponding row lines (multiple lines) become low when the column is driven low during a scan-routine. By reading the data-register, pressed keys can be detected. Similarly, when keys present on same row line are pressed, the corresponding row line (only one line) becomes low when logic "0" is driven on the column line during a scan-routine.

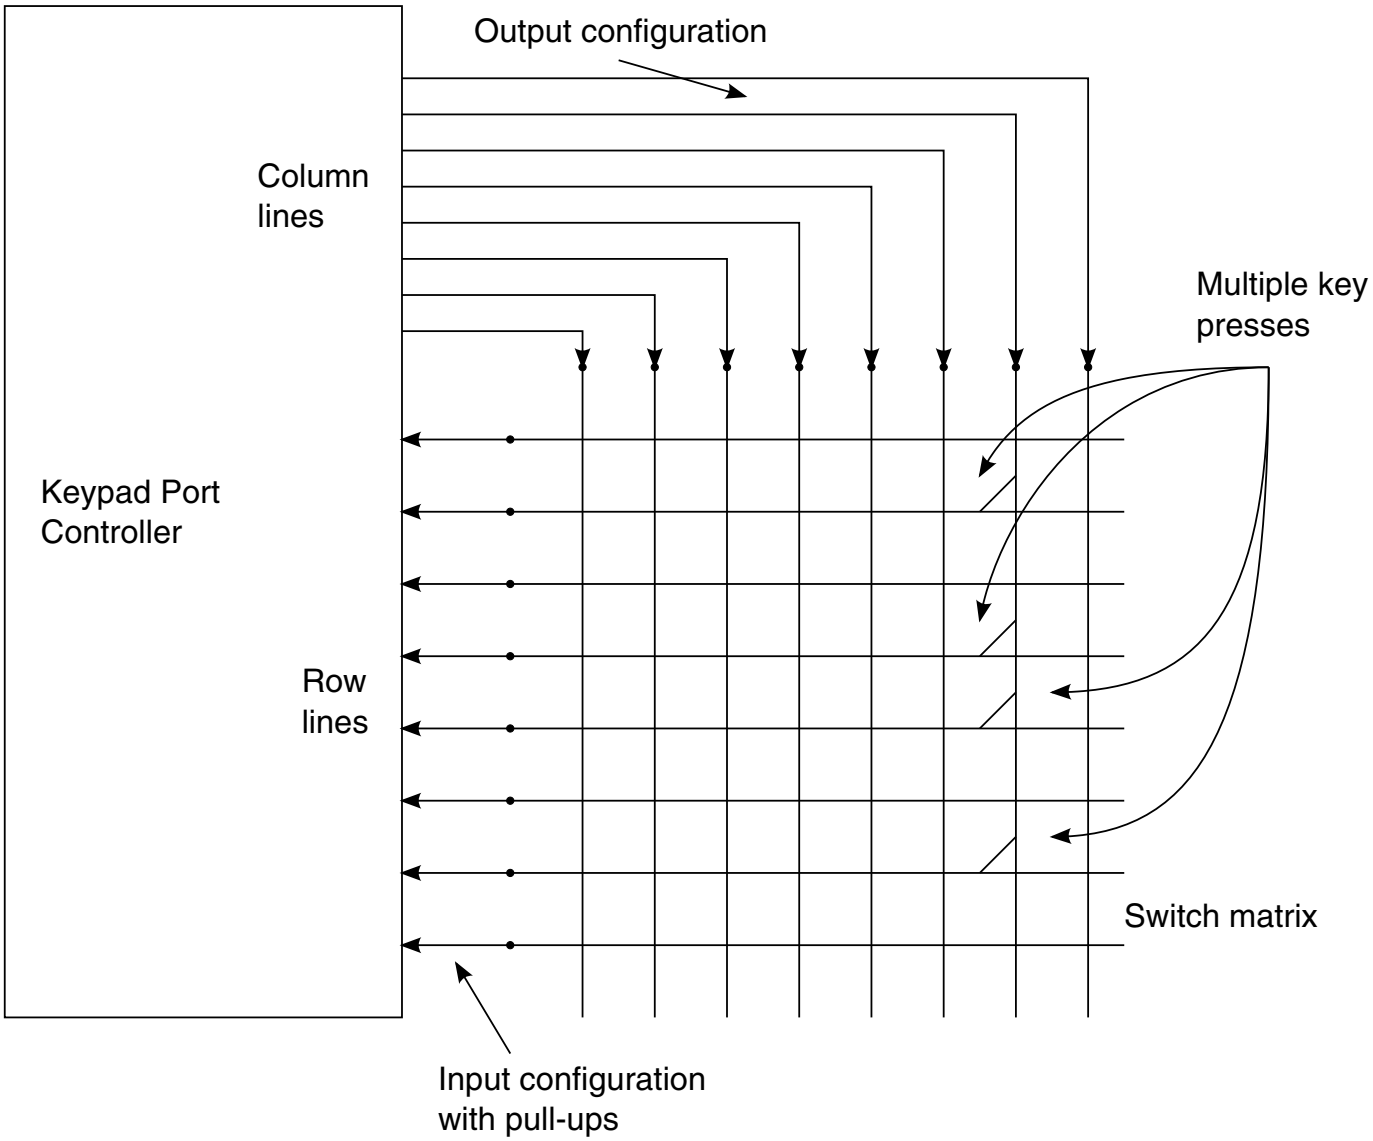

Figure 36-3. Multiple Key Presses on Same Column Line (Simplified View)

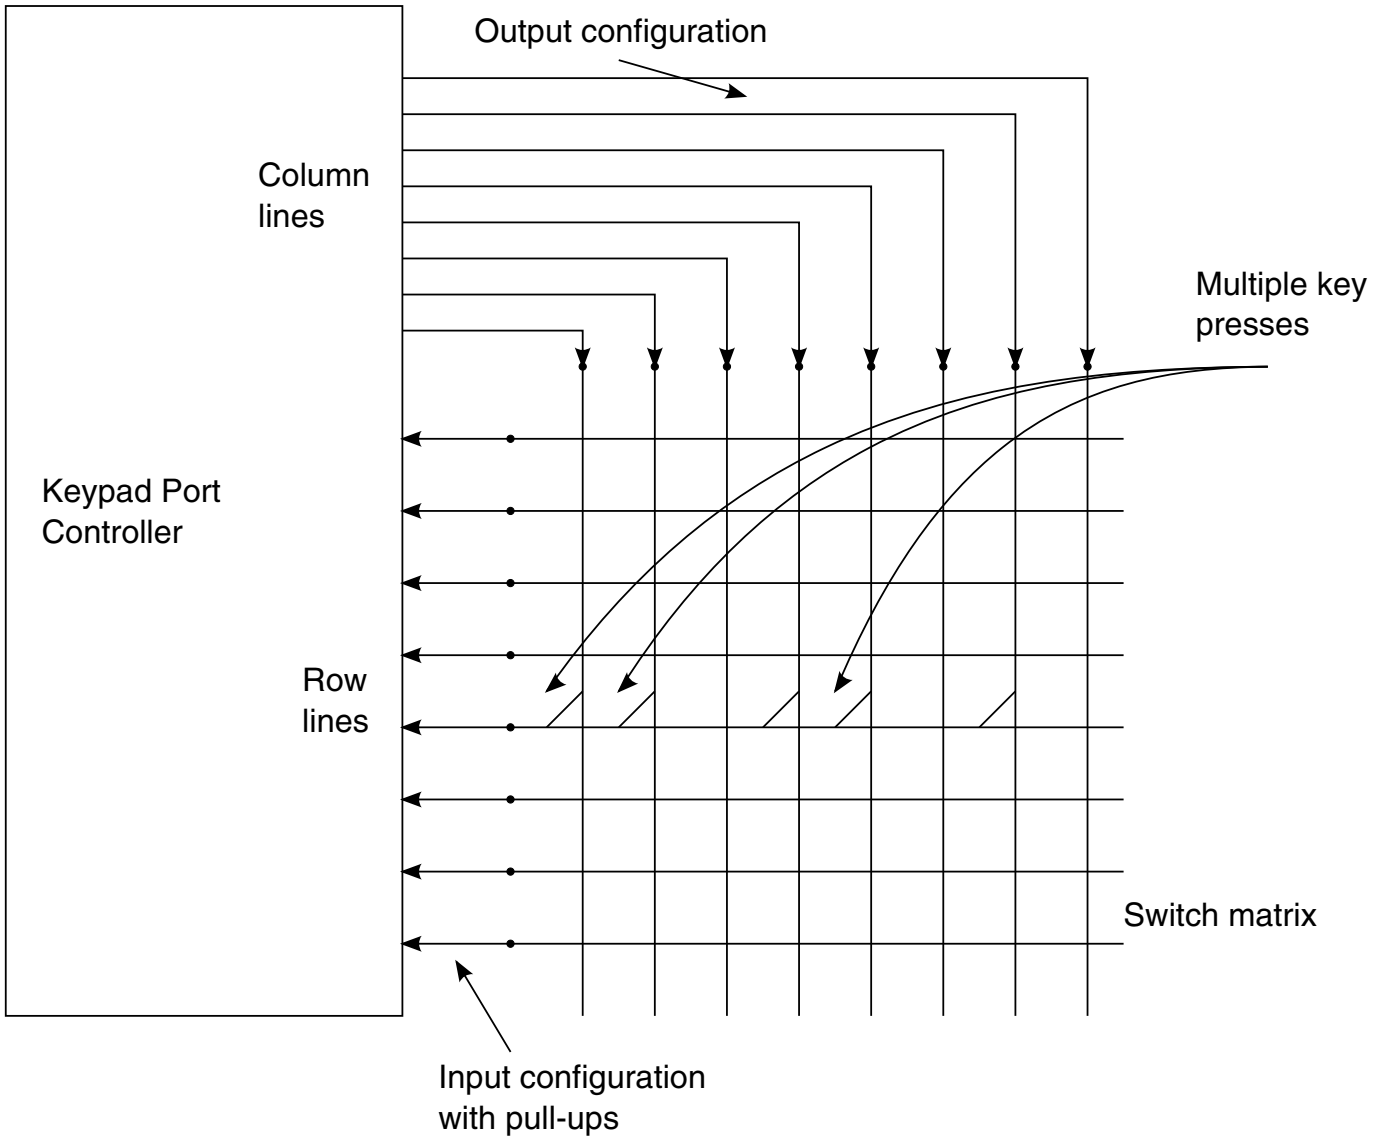

Figure 36-4. Multiple Key Presses on Same Row Line (Simplified View)

NOTE

An n key rollover is a technique with which the system can recognize the order in which keys are pressed.

36.3.6.1 Ghost Key Problem and Correction

The KPP detects if one or multiple keys are pressed or released. In the case where a simple keypad matrix with two-contact switches is used, there is a chance of "ghost" key detection when three or more keys are pressed. This is a limitation imposed by such a keypad matrix.

As can be seen in Figure 36-5, three keys pressed simultaneously can cause a short between the column currently "scanned" by the software and another column. Depending on the location of the third key pressed, a "ghost" key press may be detected.

However, this can be corrected by using a keypad matrix that provides "ghost" key protection. Such a matrix implements a one-way "diode" at all keypad points between rows and columns. This way, the multiple pressing of three keys will not cause a short at a fourth key (see Figure 36-6).

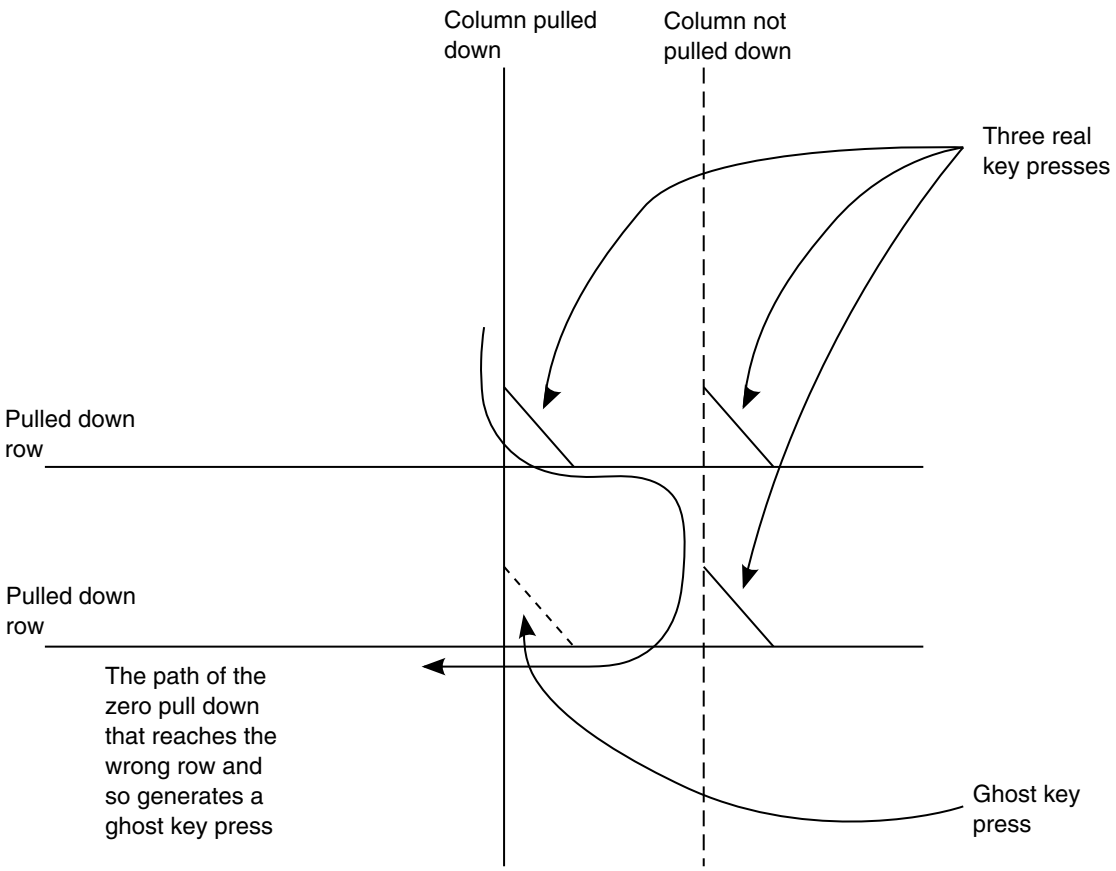

Figure 36-5. Decoding Wrong Three- Key-Presses

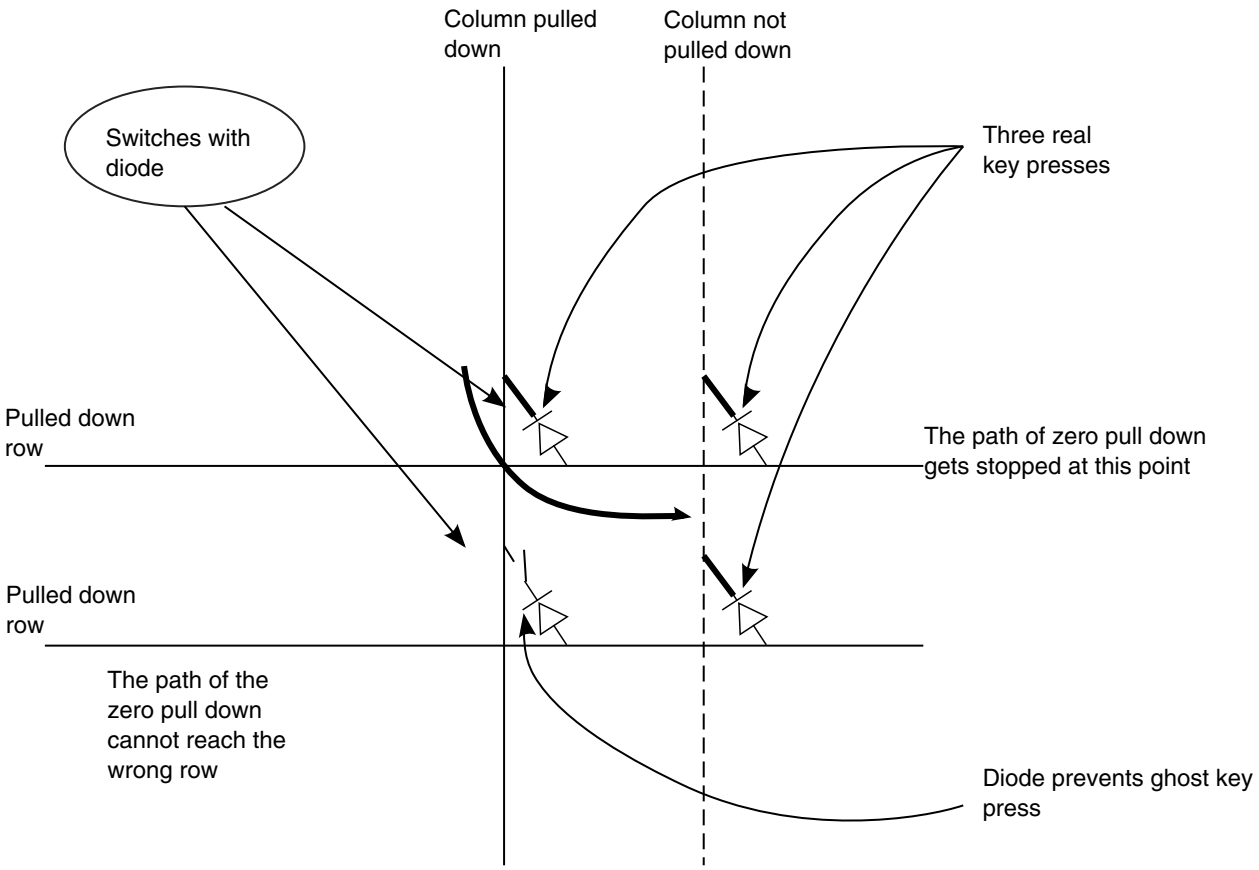

Figure 36-6. Matrix with "Ghost" Key Protections

36.3.7 3-Point Contact Keys Support

The KPP supports interfacing to a matrix consisting of 3-point contact keys. As shown in Figure 36-7, two points of such a key are connected to keypad lines, while a third point is connected to ground (low logic).

The keypad lines should be configured as input and a pull-up should to be present on these lines. When such a key is pressed, corresponding keypad lines go low and an interrupt is generated. There is no need to perform a scanning routine for identification of pressed key as it can be done by reading the keypad data-register. A limitation with such a matrix is that for every key at least one keypad row line should be used.

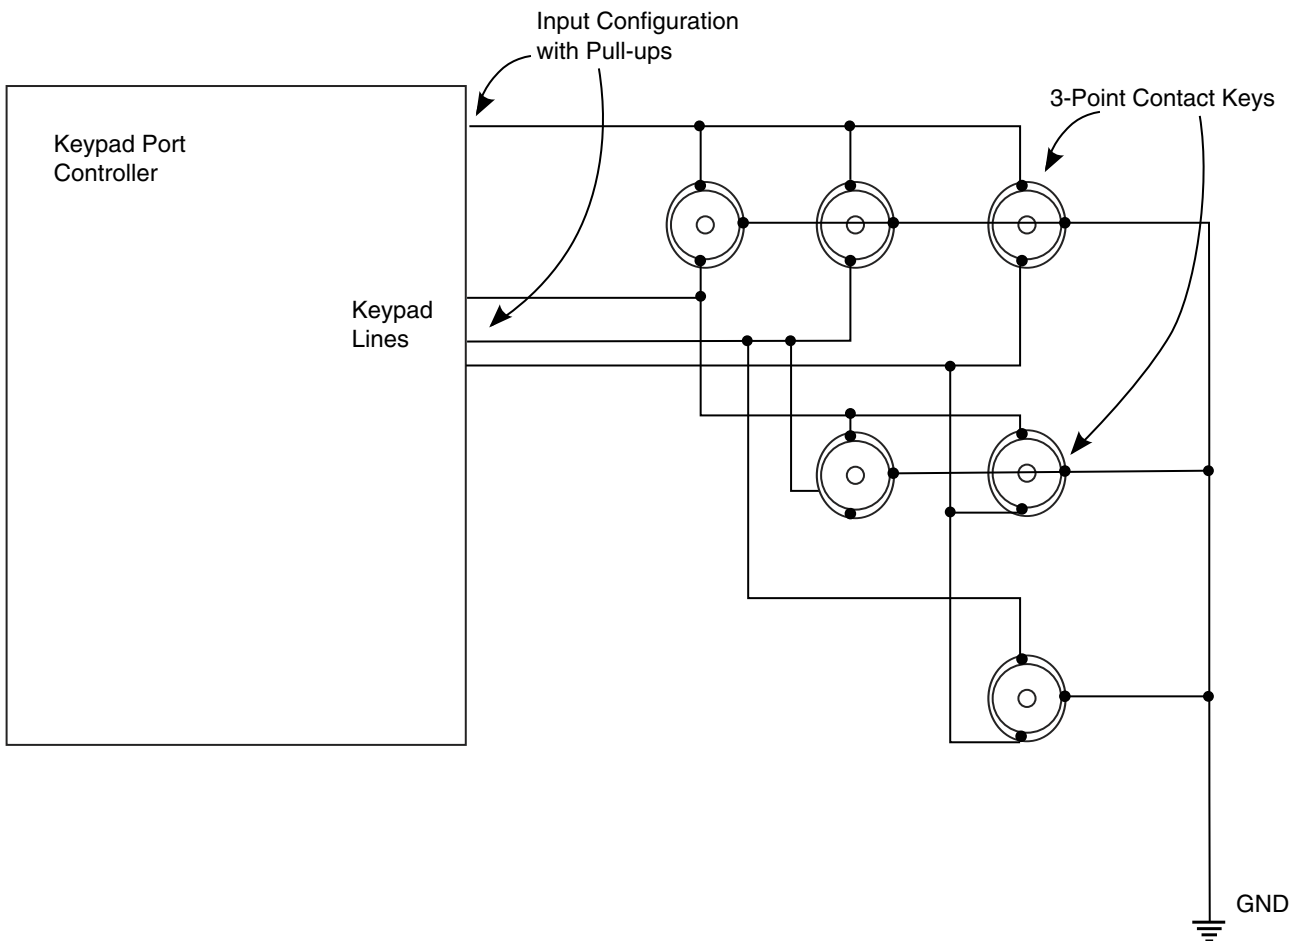

Figure 36-7. KPP Interface with 3-point Contact Key Matrix (Simplified View)

36.4 Initialization/Application Information

36.4.1 Typical Keypad Configuration and Scanning Sequence

Perform the following steps to configure the keypad:

1. Enable the number of rows in the keypad (KPP_KPCR[KRE]).
2. Write 0s to KPP_KPDR[KCD].
3. Configure the keypad columns as open-drain (KPP_KPCR[KCO]).
4. Configure columns as output (KPP_KDDR[KCDD]) and rows as input (KPP_KDDR[KRDD]).
5. Clear the KPKD Status Flag and Synchronizer chain.
6. Set the KDIE control bit, and clear the KRIE control bit (avoid false release events).
7. (The system is now in standby mode, and awaiting a key press.)

36.4.2 Key Press Interrupt Scanning Sequence

Perform the following steps to perform a keypad scanning routine:

1. Disable both (depress and release) keypad interrupts.
2. Write 1s to KPP_KPDR[KCD], setting column data to 1s.
3. Configure columns as totem pole outputs (for quick discharging of keypad capacitance).
4. Configure columns as open-drain.
5. Write a single column to 0, and other columns to 1.
6. Sample row inputs and save data. Multiple key presses can be detected on a single column.
7. Repeat Steps 2-6 for remaining columns.
8. Return all columns to 0 in preparation for standby mode.
9. Clear KPKD and KPKR status bit(s) by writing to a "1"; set the KPKR synchronizer chain by writing a "1" to the KPP_KRSS register; and clear the KPKD synchronizer chain by writing a "1" to the KDSC register.
10. Re-enable the appropriate keypad interrupt(s) so that the KDIE detects a key hold condition, or the KRIE detects a key-release event.

36.4.3 Additional Comments

The order of key press detection can be done in software only. Therefore, the software may need to run the scan routines at very short intervals of time per the application's demands. The reason that such functionality cannot be put in the KPP is that the block is limited by the number of external pins.

For the keys that require a very precise order (such as game keys), individual GPIO pins may be more useful.

36.5 Programmable Registers

The KPP contains four registers.

KPP memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
53F9_4000	Keypad Control Register (KPP_KPCR)	16	R/W	0000h	36.5.1/ 2243
53F9_4002	Keypad Status Register (KPP_KPSR)	16	R/W	0400h	36.5.2/ 2244
53F9_4004	Keypad Data Direction Register (KPP_KDDR)	16	R/W	0000h	36.5.3/ 2246
53F9_4006	Keypad Data Register (KPP_KPDR)	16	R/W	0000h	36.5.4/ 2246

36.5.1 Keypad Control Register (KPP_KPCR)

The Keypad Control Register determines which of the eight possible column strobes are to be open drain when configured as outputs, and which of the eight row sense lines are considered in generating an interrupt to the core.

It is up to the programmer to ensure that pins being used for functions other than the keypad are properly disabled. The KPP_KPCR register is byte- or half-word-addressable.

Address: KPP_KPCR is 53F9_4000h base + 0h offset = 53F9_4000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read / Write	KCO								KRE							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

KPP_KPCR field descriptions

Field	Description
15–8 KCO	Keypad Column Strobe Open-Drain Enable. Setting a column open-drain enable bit (KCO7-KCO0) disables the pull-up driver on that pin. Clearing the bit allows the pin to drive to the high state. This bit has no effect when the pin is configured as an input.

Table continues on the next page...

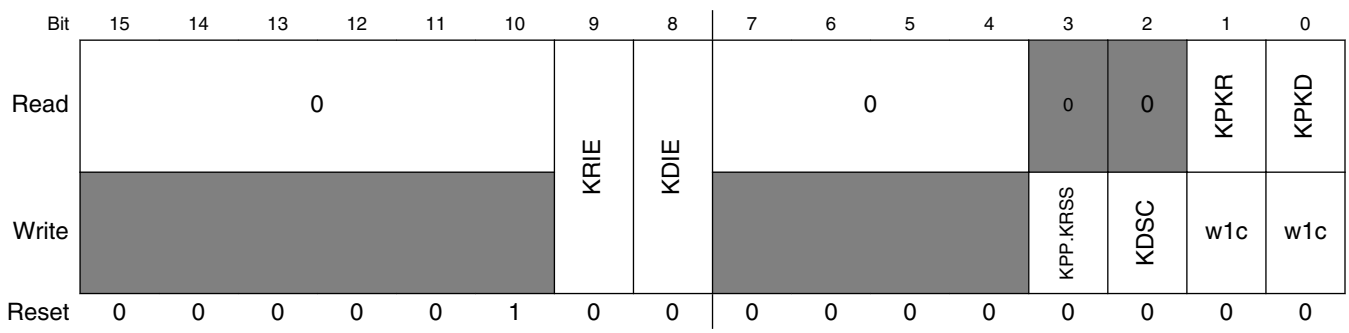
KPP_KPCR field descriptions (continued)

Field	Description
	NOTE: Configuration of external port control logic (for example, IOMUX) should be done properly so that the KPP controls an open-drain enable of the pin. 0 Column strobe output is totem pole drive. 1 Column strobe output is open drain.
7–0 KRE	Keypad Row Enable. Setting a row enable control bit in this register enables the corresponding row line to participate in interrupt generation. Likewise, clearing a bit disables that row from being used to generate an interrupt. This register is cleared by a reset, disabling all rows. The row-enable logic is independent of the programmed direction of the pin. Writing a "0" to the data register of the pins configured as outputs will cause a keypad interrupt to be generated if the row enable associated with that bit is set. 0 Row is not included in the keypad key press detect. 1 Row is included in the keypad key press detect.

36.5.2 Keypad Status Register (KPP_KPSR)

The Keypad Status Register reflects the state of the key press detect circuit. The KPP_KPSR register is byte- or half-word-addressable.

Address: KPP_KPSR is 53F9_4000h base + 2h offset = 53F9_4002h



KPP_KPSR field descriptions

Field	Description
15–10 Reserved	This read-only field is reserved and always has the value zero. Reserved
9 KRIE	Keypad Release Interrupt Enable. The software should ensure that the interrupt for a Key Release event is masked until it has entered the key pressed state, and vice versa, unless this activity is desired (as might be the case when a repeated interrupt is to be generated). The synchronizer chains are capable of being initialized to detect repeated key presses or releases. If they are not initialized when the corresponding event flag is cleared, false interrupts may be generated for depress (or release) events shorter than the length of the corresponding chain. 0 No interrupt request is generated when KPKR is set. 1 An interrupt request is generated when KPKR is set.

Table continues on the next page...

KPP_KPSR field descriptions (continued)

Field	Description
8 KDIE	Keypad Key Depress Interrupt Enable. Software should ensure that the interrupt for a Key Release event is masked until it has entered the key pressed state, and vice-versa, unless this activity is desired (as might be the case when a repeated interrupt is to be generated). The synchronizer chains are capable of being initialized to detect repeated key presses or releases. If they are not initialized when the corresponding event flag is cleared, false interrupts may be generated for depress (or release) events shorter than the length of the corresponding chain. 0 No interrupt request is generated when KPKD is set. 1 An interrupt request is generated when KPKD is set.
7–4 Reserved	This read-only field is reserved and always has the value zero. Reserved, should be cleared
3 KPP.KRSS	Key Release Synchronizer Set. Self-clear bit. The Key release synchronizer is set by writing a logic one into this bit. Reads return a value of "0". 0 No effect 1 Set bits which sets keypad release synchronizer chain
2 KDSC	Key Depress Synchronizer Clear. Self-clear bit. The Key depress synchronizer is cleared by writing a logic "1" into this bit. Reads return a value of "0". 0 No effect 1 Set bits that clear the keypad depress synchronizer chain
1 KPKR	Keypad Key Release. The keypad key release (KPKR) status bit is set when all enabled rows are detected high after synchronization (the KPKR status bit will be set when cleared by a reset). The KPKR bit may be used to generate a maskable key release interrupt. The key release synchronizer may be set high by software after scanning the keypad to ensure a known state. Due to the logic function of the release and depress synchronizer chains, it is possible to see the re-assertion of a status flag (KPKD or KPKR) if it is cleared by software prior to the system exiting the state it represents. Reset value of register is "0" as long as reset is asserted. However when reset is de-asserted, the value of the register depends upon the external row pins and can become "1". 0 No key release detected 1 All keys have been released
0 KPKD	Keypad Key Depress. The keypad key depress (KPKD) status bit is set when one or more enabled rows are detected low after synchronization. The KPKD status bit remains set until cleared by the software. The KPKD bit may be used to generate a maskable key depress interrupt. If desired, the software may clear the key press synchronizer chain to allow a repeated interrupt to be generated while a key remains pressed. In this case, a new interrupt will be generated after the synchronizer delay (4 cycles of the low frequency reference clock elapses if a key remains pressed. This functionality can be used to detect a long key press. This allows detection of additional key presses of the same key or other keys. Due to the logic function of the release and depress synchronizer chains, it is possible to see the re-assertion of a status flag (KPKD or KPKR) if it is cleared by the software prior to the system exiting the state it represents. 0 No key presses detected 1 A key has been depressed

36.5.3 Keypad Data Direction Register (KPP_KDDR)

The bits in the KPP_KDDR control the direction of the keypad port pins. The upper eight bits in the register affect the pins designated as column strobes, while the lower eight bits affect the row sense pins. Setting any bit in this register configures the corresponding pin as an output. Clearing any bit in this register configures the corresponding port pin as an input. For the Keypad Row DDR, an internal pull-up is enabled if the corresponding bit is clear. This register is cleared by a reset, configuring all pins as inputs. The KPP_KDDR register is byte- or half-word addressable.

NOTE

When a pin is used as row pin for keypad purposes, all corresponding pull-ups should be enabled at the upper level (for example, IOMUX) when the bit in row DDR is cleared.

Address: KPP_KDDR is 53F9_4000h base + 4h offset = 53F9_4004h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read / Write	KCDD								KRDD							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

KPP_KDDR field descriptions

Field	Description
15–8 KCDD	Keypad Column Data Direction Register. Setting a bit configures the corresponding COL*n* pin as an output (where *n* = 7 through 0). 0 COLn pin is configured as an input. 1 COLn pin is configured as an output.
7–0 KRDD	Keypad Row Data Direction. Setting a bit configures the corresponding ROW*n* pin as an output (where *n* = 7 through 0). 0 ROWn pin configured as an input. 1 ROWn pin configured as an output.

36.5.4 Keypad Data Register (KPP_KPDR)

This 16-bit register is used to access the column and row data. Data written to this register is stored in an internal latch, and for each pin configured as an output, the stored data is driven onto the pin. A read of this register returns the value on the pin for those bits configured as inputs. Otherwise, the value read is the value stored in the register.

The KPP_KPDR register is byte- or half-word addressable. This register is not initialized by a reset. Valid data should be written to this register before any bits are configured as outputs.

Address: KPP_KPDR is 53F9_4000h base + 6h offset = 53F9_4006h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read Write	KCD								KRD							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

KPP_KPDR field descriptions

Field	Description
15–8 KCD	Keypad Column Data. A read of these bits returns the value on the pin for those bits configured as inputs. Otherwise, the value read is the value stored in the register. 0 Read/Write "0" from/to column ports 1 Read/Write "1" from/to column ports
7–0 KRD	Keypad Row Data. A read of these bits returns the value on the pin for those bits configured as inputs. Otherwise, the value read is the value stored in the register. 0 Read/Write "0" from/to row ports 1 Read/Write "1" from/to row ports

Chapter 37
Enhanced LCD Interface (eLCDIF)

37.1 Overview

The eLCDIF is a general purpose display controller used to drive a wide range of display devices varrying in size and capability. Many of these displays have had an asynchronous parallel MPU interface for command and data transfer to an integrated frame buffer. There are other popular displays that support moving pictures and require the RGB interface mode (called DOTCLK interface in this document) or the VSYNC mode for high-speed data transfers. In addition to these displays, it is also common to provide support for digital video encoders that accept ITU-R BT.656 format 4:2:2 YCbCr digital component video and convert it to analog TV signals. The eLCDIF block supports these interfaces by providing fully programmable functionality.

The block has several major features:

- Bus master interface to source frame buffer data for display refresh and a DMA interface to manage input data transfers from the LCD requiring minimal ARM platform overhead.
- 8/16/18/24/32 bit LCD data bus support available depending on I/O mux options.
- Programmable timing and parameters for MPU, VSYNC and DOTCLK LCD interfaces to support a wide variety of displays.
- ITU-R BT.656 mode (called Digital Video Interface or DVI mode here) including progressive-to-interlace feature and RGB to YCbCr 4:2:2 color space conversion to support 525/60 and 625/50 operation.

37.2 Operation

Bus Interface Mechanisms through Initializing the eLCDIF, describe the internal pipeline for the MPU write/read interface, VSYNC, DOTCLK, and DVI interfaces. Differences for each mode are then described in separate sections, as follows:

- MPU Interface
- VSYNC Interface
- DOTCLK Interface
- ITU-R BT.656 Digital Video Interface (DVI)

eLCDIF pin usage by interface mode is described in eLCDIF Pin Usage by Interface Mode.

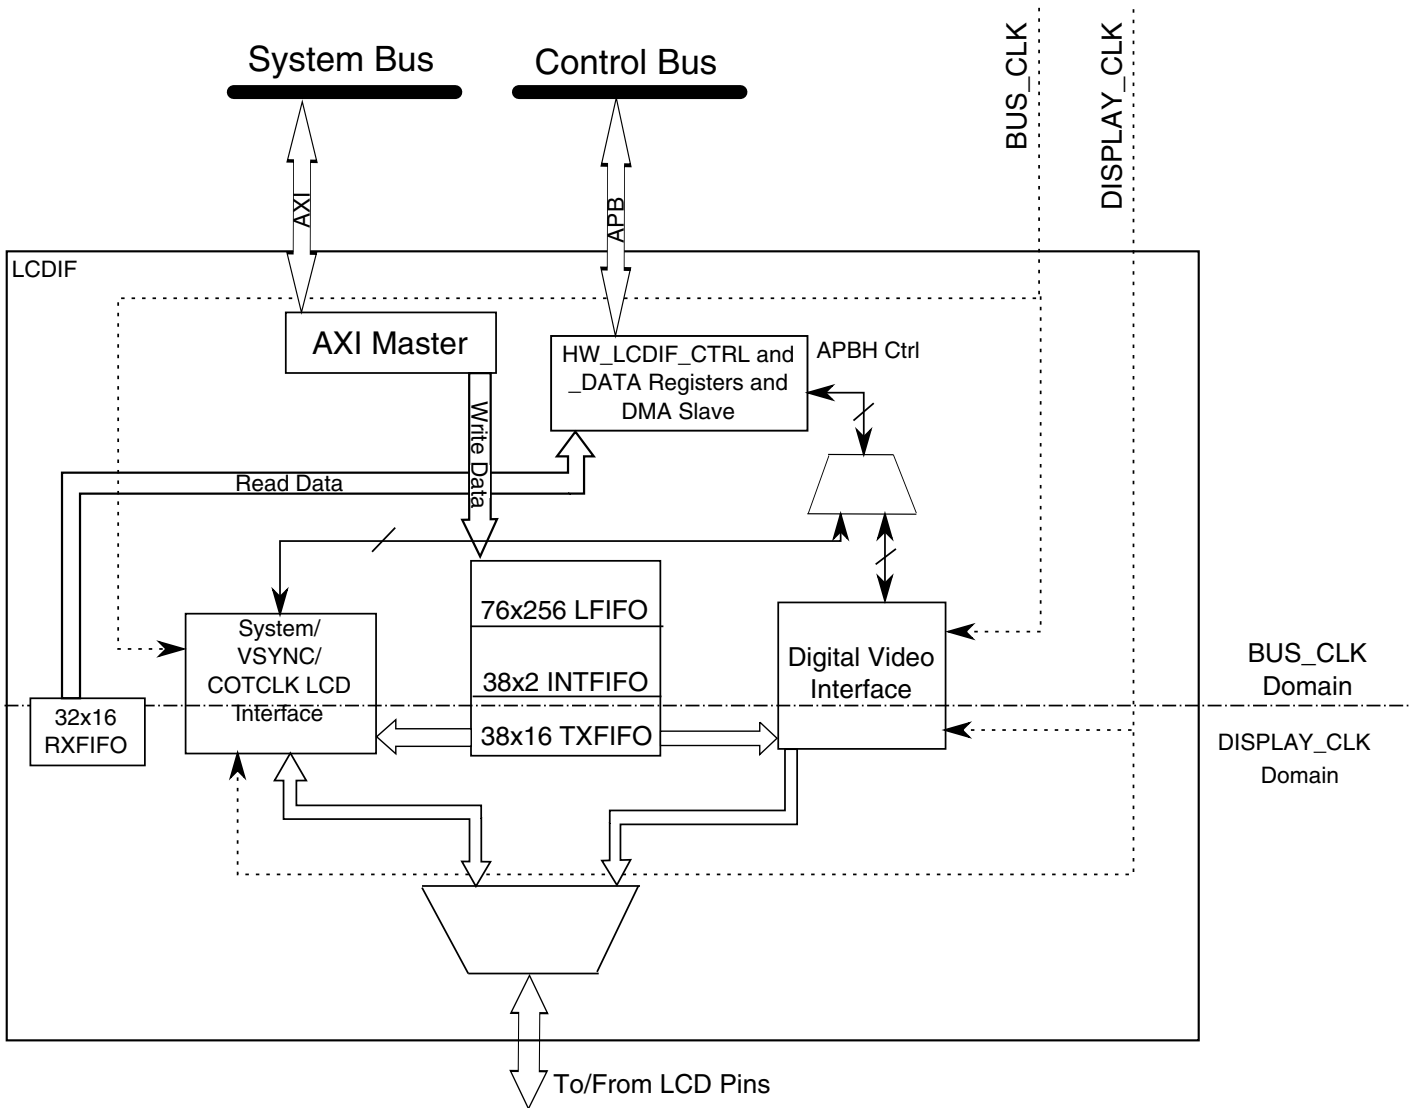


Figure 37-1. Top-Level Block Diagram of eLCDIF subsystem

37.2.1 Bus Interface Mechanisms

The eLCDIF block has memory-mapped control, data and status registers. It provides two efficient methods of transferring data to/from an external display or digital video encoder, the APB DMA slave for reads and AXI bus master for writes. The bus interface runs off

the BUS_CLK domain, while the display interface runs on the DISPLAY_CLK domain. There are three main FIFOs in the block datapath. The LFIFO in the write datapath is a 2K byte synchronous FIFO to manage external DRAM access latency. The TXFIFO is a 16 word deep asynchronous FIFO that provides data crossing between the two clock domains. In the read datapath, there is a 16-deep asynchronous RXFIFO that is read by DMA operation. The following sub-sections describe the two system bus interface mechanisms.

37.2.1.1 Bus Master Operation in Write/Display Modes

The eLCDIF block has a bus master interface that initiates requests for data to drive the display. The LCDIF_MASTER bit must be set to 1 to enable the bus master interface. Software should program all control registers required to transfer the frame sequence.

In the MPU and VSYNC modes, single frames are transferred. When a complete frame is transferred, eLCDIF enters idle and clears the RUN bit in the CTRL register. For subsequent frame transmission, the eLCDIF setup sequence should be repeated.

The DOTCLK and DVI modes are used to refresh the display at the desired refresh rate and resolution. These modes are used to drive displays that do not integrate a display buffer memory. When the display is refreshed, the eLCDIF will automatically update the LCDIF_CUR_BUF_ADDR register with the value in LCDIF_NEXT_BUF_ADDR at the end of current frame and start fetching the next frame from the new address. If the LCDIF_NEXT_BUF_ADDR register was not updated within a frame refresh cycle, eLCDIF will keep transmitting the last frame until a new value is programmed into that register.

eLCDIF also provides the capability of interlacing a progressive frame by fetching odd lines in the first field and then fetching even lines in the second field. This feature can be used in the DVI mode and can be turned on by setting the INTERLACE_FIELDS bit in the LCDIF_CTRL1 register.

37.2.1.2 System Bus Master Performance

The performance of the eLCDIF block can be controlled by changing the burst length and the outstanding cycle issuing capability depending on the memory bandwidth requirements. Two fields in the LCDIF_CTRL2 register will throttle system memory requests. The LCDIF_CTRL2_OUTSTANDING_REQS field will control how many requests the eLCDIF can have in flight on any given clock cycle. This should be programmed based on the expected system bus latency for returned read data. Also, the LCDIF_CTRL2_BURST_LEN_8 bit will set the number of 64 bit words requested for

each eLCDIF system bus request to either 8 or 16 QWORDS. Generally, 4 outstanding requests of length 16 will provide enough performance to drive any standard display resolution. These configuration bits are intended to change the access pattern of the eLCDIF to optimize system bus throughput when other system masters will contend for system memory resources.

The LCDIF_THRES register can also be used to optimize bus throughput and power consumption. The LCDIF_THRES_FASTCLOCK value can be used to change the BUS_CLK frequency when the number of pixels in the LFIFO is below this programmed threshold. The BUS_CLK should be set to a frequency that will exceed the bandwidth requirements of the desired display. In systems supporting the dynamic frequency modulation of the bus clock frequency, the BUS_CLK will be driven at the desired frequency when the number of pixels is below the FASTCLOCK threshold. When the number of pixels is above this threshold, the BUS_CLK will be reduced by a divide factor selected in the centralized clock control module. This will provide an average clock frequency that will exactly meet the pixel bandwidth requirements over time, and minimize power consumption to meet the display bandwidth requirements. During horizontal or vertical blanking intervals, when the LFIFO is full with data for the next active display interval, the clock can be reduced to a slow frequency for extended periods to reduce power consumption.

The LCDIF_THRES_PANIC value can be used to raise the priority of requests initiated by the eLCDIF to alter how the eLCDIF requests are arbitrated by the system bus infrastructure. The panic output control signal is raised when the number of 32bpp pixel equivalents in the LFIFO is less than this programmed value. Since the LFIFO is arranged as a 256x64bit quadword FIFO, it contains two 32bpp pixels per quadword, or 512 32bpp pixels total. To set the panic output when 3/4s of the LFIFO is empty, set the LCDIF_THRES_PANIC value to 3/4 * 512, or 128. The panic signal output is used to assess higher priority to eLCDIF system requests to avoid eLCDIF under run errors during periods of high system bandwidth utilization.

The features available with the LCDIF_THRES register require support from system clocking and dynamic priority control. Refer to the appropriate block documentation to assess the system support for these features.

37.2.1.3 DMA Operation in MPU Read Mode

Data can be read from an external display using the APBDMA interface. A bus master mode is not available to read data via the display interface. The read data interface is typically used with MPU type interfaces.

The eLCDIF block has a DMA slave interface that uses the APBDMA to manage read data transfers. The data transfers are managed by a linked data descriptor chain executed by the APBDMA engine and the DMA master/slave interface between the eLCDIF and the APBDMA engine. This mode is enabled by setting the LCDIF_MASTER bit to 0.

37.2.2 Write Data Path

eLCDIF supports raster based frame buffers and there is no support for tiled buffers. There are several options to accommodate endianness of display buffers in memory before the data is processed for the external display. The INPUT_DATA_SWIZZLE field in the LCDIF_CTRL register provides the following options for data word multiplexing:

```
00 (0): No swizzle (little-endian)
01 (1): Swap bytes 0 and 3, swap bytes 1 and 2 (big-endian)
10 (2): Swap half-words
11 (3): Swap bytes within each half-word
```

The WORD_LENGTH field of LCDIF_CTRL register indicates the input data/pixel format. LCDIF_TRANSFER_COUNT register denotes how much data is contained in each frame. The H_COUNT field of this register indicates the number of pixels per line and V_COUNT indicates the total number of lines per frame. A special bit field in the LCDIF_CTRL1 register, called the BYTE_PACKING_FORMAT, can be used to specify which bytes within the 32-bit word are going to be valid. For example, if the entire 32-bit word is valid, BYTE_PACKING_FORMAT should be set to 0xF, if only lower 3 bytes of each word in the frame buffer are valid, then BYTE_PACKING_FORMAT should be set to 0x7.

The LCD_DATABUS_WIDTH field in LCDIF_CTRL register suggests the width of the bus going to the external display controller. There is an option to source all 32 bits of the input word and transfer it to the output I/O display interface. Refer to the system I/O muxing options for support of this feature. If the LCD_DATABUS_WIDTH is not the same as WORD_LENGTH, eLCDIF will perform RGB to RGB color space conversion. For example, if the input frame has fewer bits per pixel than the display, as in a 16 bpp input frame going to 24 bpp LCD, eLCDIF will pad the MSBs of each color to the LSBs of the same color for each pixel. If the input frame has more bits per pixel than the display, for example, 24 bpp input frame going to 16 bpp LCD, eLCDIF will drop the LSBs of each color channel to convert to the lower color depth. eLCDIF also has the capability to support delta pixel displays by swizzling the R, G and B colors of each pixel in the odd and even lines of the frame separately by programming the ODD_LINE_PATTERN and the EVEN_LINE_PATTERN bit fields. This operation occurs after the RGB-to-RGB color space conversion operation.

eLCDIF also supports RGB to YCbCr 4:2:2 color space conversion. This is useful in the DVI mode since the TV encoder requires input in YCbCr 4:2:2 format. The LCDIF_CSC* registers have complete programmability over the CSC coefficients and offsets. The values must be written into these registers in the signed two's complement format.

The following list shows how the different input/output combinations can be obtained:

- WORD_LENGTH=1 indicates that the input is 8-bit data. This is most likely going to be used for sending commands in MPU interface, or maybe a gray scale image. Any combination of BYTE_PACKING_FORMAT [3:0] is permissible.

  Limitation: H_COUNT must be a multiple of the sum of BYTE_PACKING_FORMAT [3], BYTE_PACKING_FORMAT [2], BYTE_PACKING_FORMAT [1] and BYTE_PACKING_FORMAT [0]. LCD_DATABUS_WIDTH must be 1, indicating an 8-bit data bus.

- WORD_LENGTH=0 implies the input frame buffer is RGB 16 bits per pixel. DATA_FORMAT_16_BIT field determines the pixels are RGB 555 or RGB 565.

  Limitation: BYTE_PACKING_FORMAT [3:0] should be 0x3 or 0xC if there is only one pixel per word. If there are two pixels per word, it should be 0xF and H_COUNT will be restricted to be a multiple of 2 pixels.

- WORD_LENGTH=2 indicates that input frame buffer is RGB 18 bits per pixel, that is, RGB 666. The valid RGB values can be left-aligned or right-aligned within a 32-bit word. The alignment of the valid 18 bits within a word is indicated by the DATA_FORMAT_18_BIT bit.

  Limitation: BYTE_PACKING_FORMAT can be 0x7, 0xE or 0xF. Packed pixels are not supported in this case. H_COUNT can be any number.

- WORD_LENGTH=3 indicates that the input frame-buffer is RGB 24 bits per pixel (RGB 888). If BYTE_PACKING_FORMAT [3:0] is 0x7, it indicates that there is only one pixel per 32-bit word and there is no restriction on H_COUNT. This is also the option that provides 32 bit output depending on the I/O muxing options available. The fourth byte, or bits [31:24], and connected to the I/Os if this muxing is available in the chip package.

  Limitation: If BYTE_PACKING_FORMAT [3:0] is 0xF, it indicates that the pixels are packed, that is, there are 4 pixels in 3 words or 12 bytes and H_COUNT must be a multiple of 4 pixels.

- YCBCR422_INPUT=1 implies that the input frame is in YCbCr 4:2:2 format. BYTE_PACKING_FORMAT must be 0xF.

Limitation: LCD_DATABUS_WIDTH must be 8-bit and H_COUNT must be a multiple of 2 pixels.

ODD_LINE_PATTERN and EVEN_LINE_PATTERN must be 0 when any of RGB_TO_YCBCR422_CSC or INTERLACE_FIELDS or YCBCR422_INPUT bits is 1.

After the RGB to RGB or RGB to YCbCr 4:2:2 color space conversions, there is one more opportunity to swizzle the data before sending it out to the display or the encoder. This can be done with the CSC_DATA_SWIZZLE field in the LCDIF_CTRL register, and it provides the same options as the INPUT_DATA_SWIZZLE register.

Finally, there is an option to shift the output data before sending it out to the display. This is done based on the SHIFT_DIR and SHIFT_NUM_BITS fields in LCDIF_CTRL register.

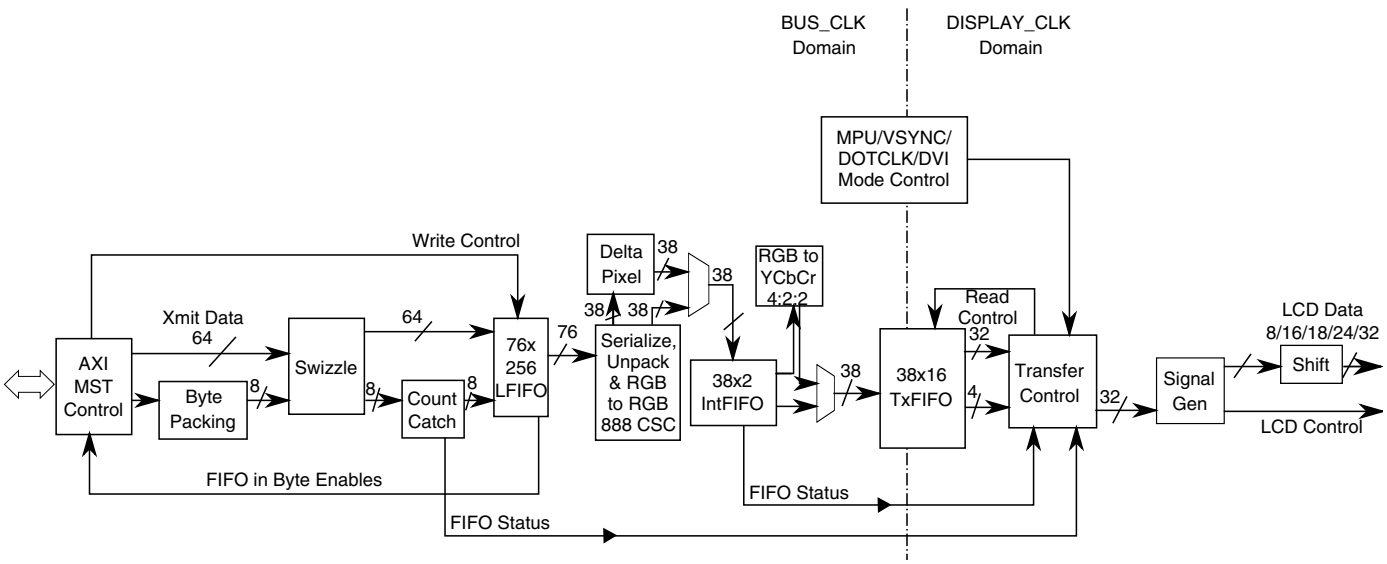

Figure 37-2. General Operations in Write Data Path

The examples in the following figures illustrate some different combinations of register programming for write mode. Assume that the data transferred over the system bus within a 32 bit word is organized as {A7-A0, B7-B0, C7-C0, D7-D0} in 8-bit mode and {A15-A0, B15-B0} in 16-bit mode.

In this example, all 32 bits of the input word are transferred out over an 8 bit display bus. Each byte within the 32 bit word is shifted to the right with zeros appended to I/O bits D[7:6]. The input data bits [7:2] are shifted to the right by 2 bits and presented on the D[5:0].

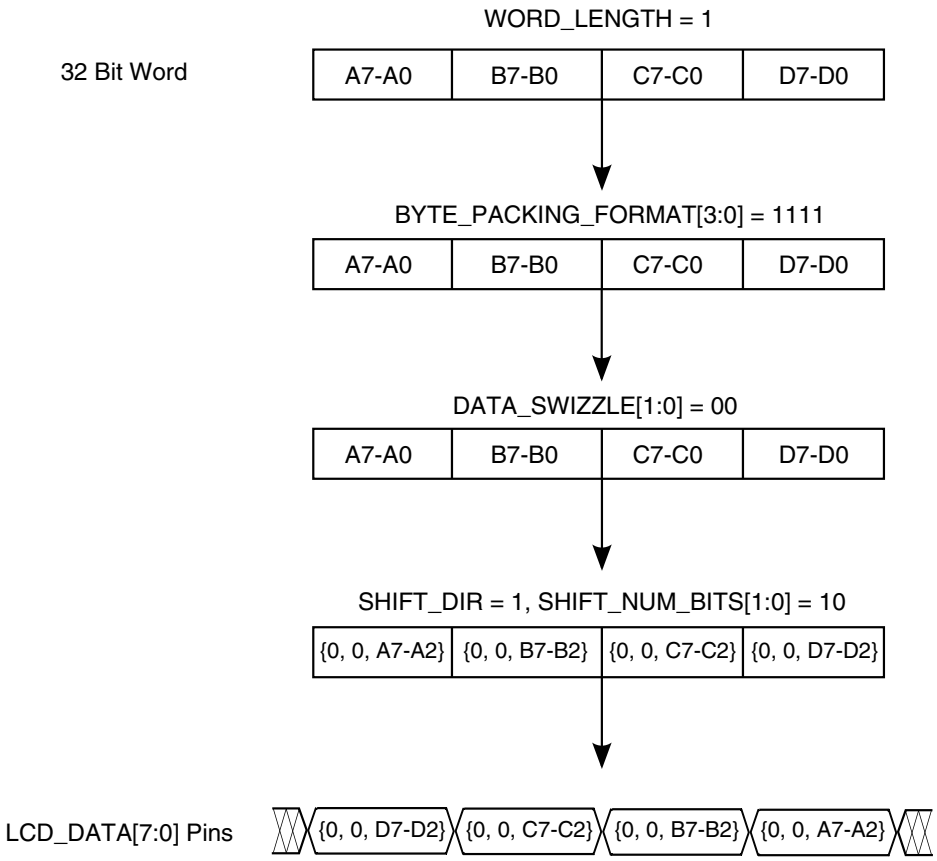

Figure 37-3. Register programming for write mode

In this 8 bit display interface example, one byte of the input word is deleted and not transferred over the external 8 bit display interface. This mode could be used to transfer 24bpp pixels over the 8 bit interface. In this case, the 4th unused byte is not transferred.

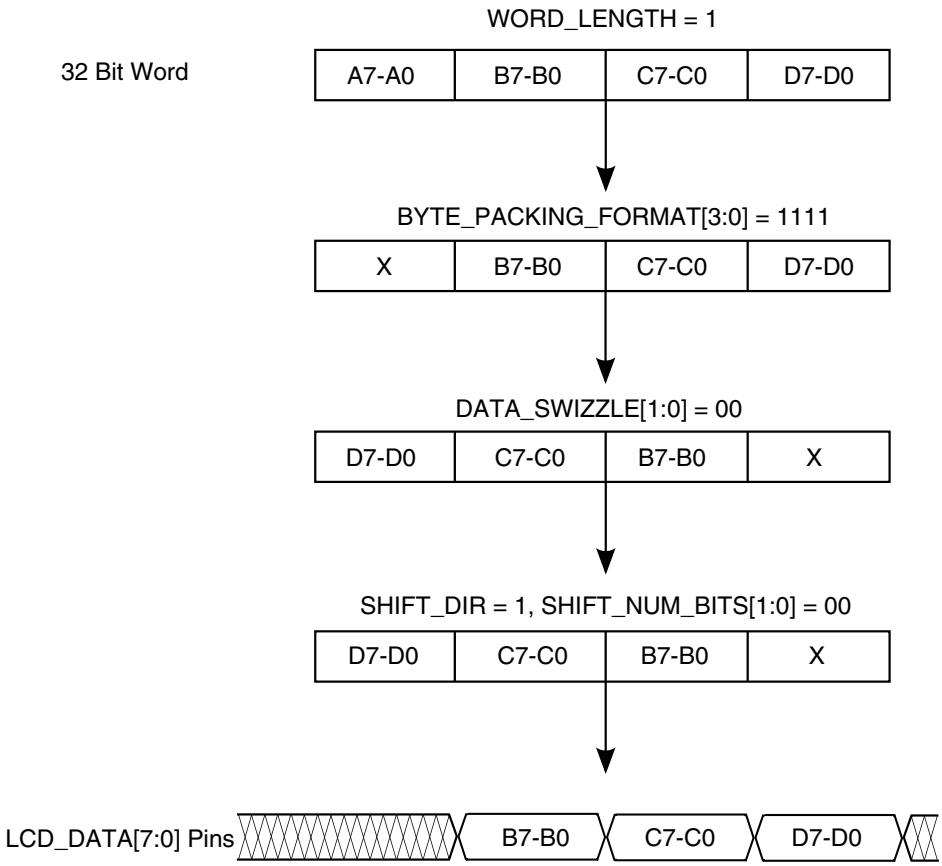

Figure 37-4. Register programming for write mode

The following example uses a 16 bit display interface. Each 16 bit half word is shifted to the right by two bits with zeros appended to the most significant two bits.

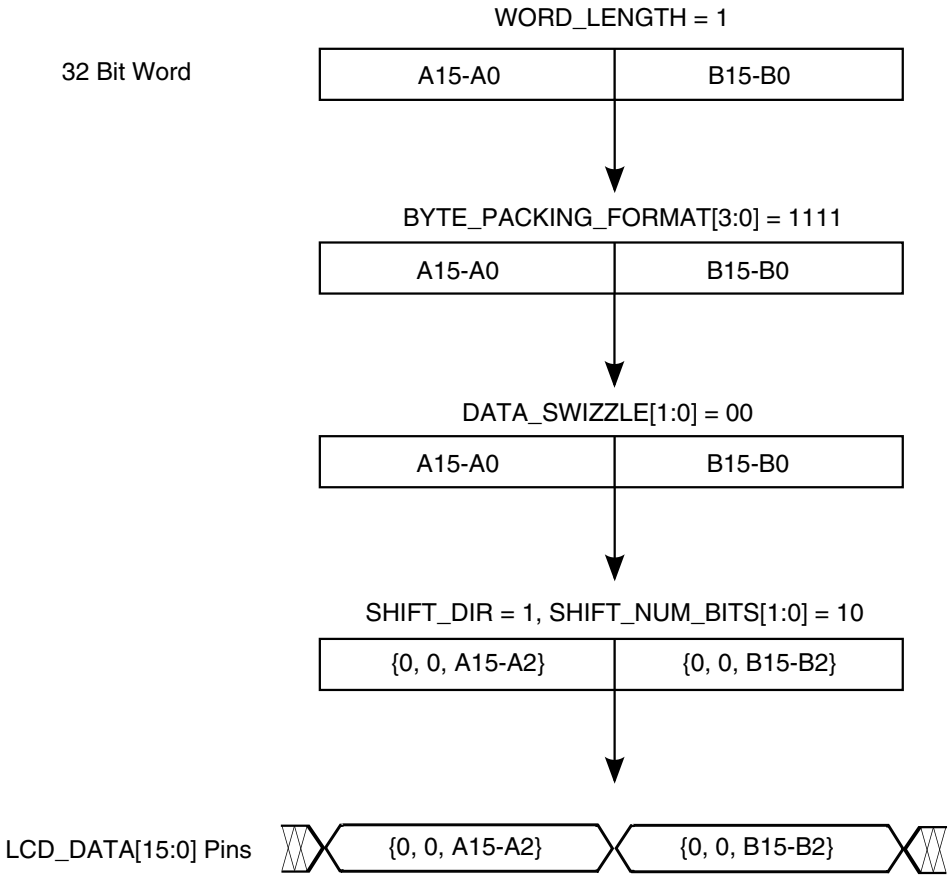

Figure 37-5. Register programming for write mode

This example indicates how an unpacked frame buffer can sourced for display. Only a single 16 bit half word within the 32 bit word is tranferred out via the 16 display bus.

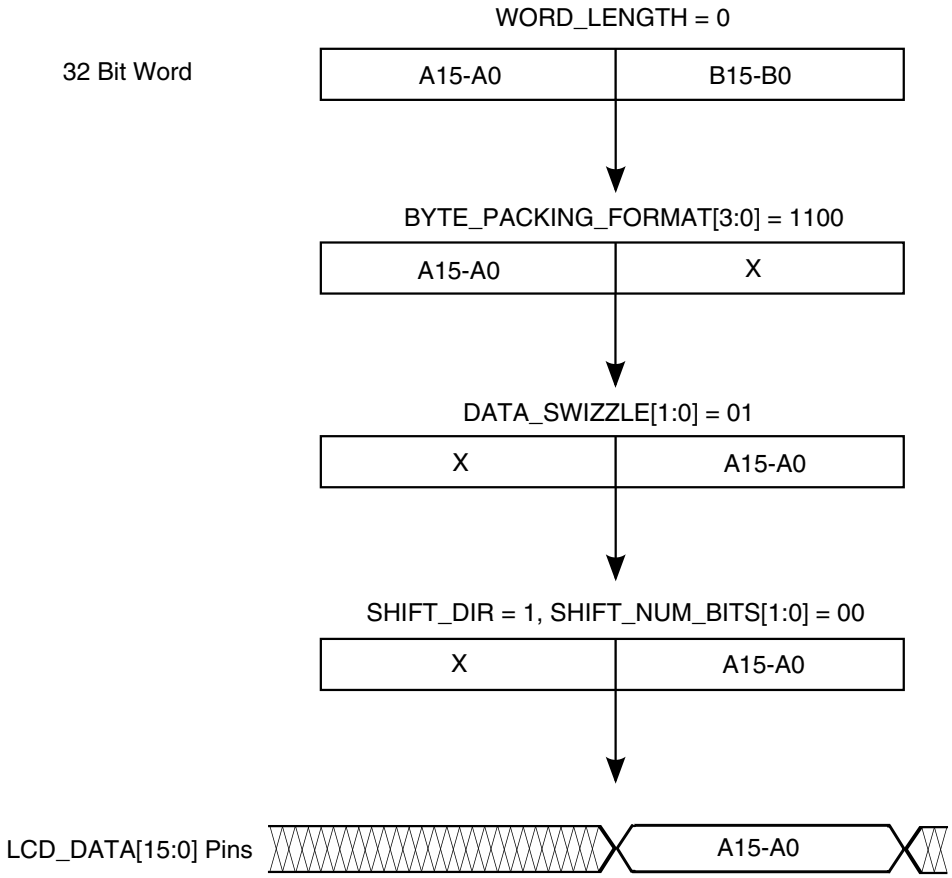

Figure 37-6. Register programming for write mode

37.2.3 Read Data Path

Figure 37-7 shows the MPU read data path in detail. eLCDIF can read from an external display that follows the 6800/8080 MPU protocol. The display bus width is determined by the LCD_DATABUS_WIDTH bit field. The data sampled at every read strobe is called a subword and the number of subwords that can be packed in a 32-bit word is given by the READ_MODE_NUM_PACKED_SUBWORDS bit field. The INITIAL_DUMMY_READ bit field directs the eLCDIF to skip the number of programmed subwords before starting to process read data. This feature is useful in the case of an LCD controller that returns the last written data the first time a read is issued, and then sends the correct data thereafter. SHIFT_DIR and SHIFT_NUM_BITS bit fields indicate whether the data needs to be shifted before getting stored in the internal registers. For example, a value of 2 in READ_MODE_NUM_PACKED_SUBWORDS if lcd databus width is 8 bits indicates two bytes should be packed in a 32-bit word, while if the lcd databus width is 16 bits, it indicates that two half words (or 4 bytes) should be packed.

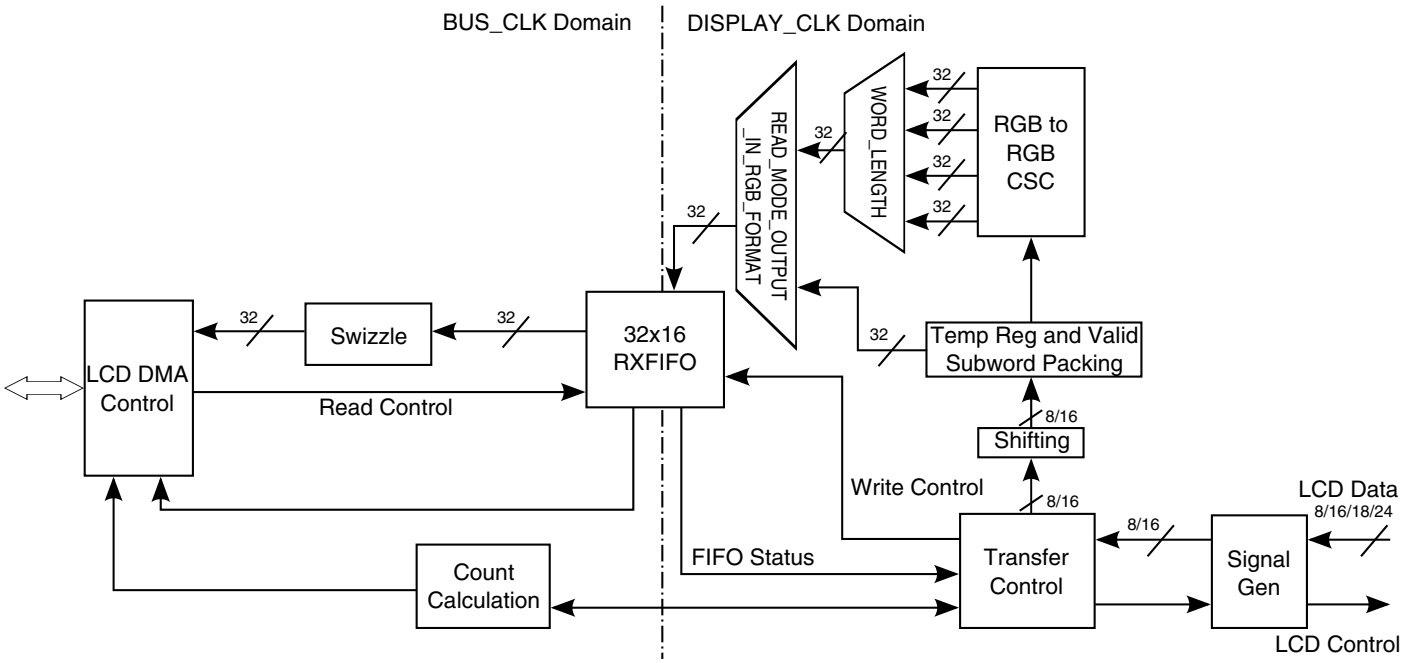

Figure 37-7. MPU Read Data Path

After the last subword within a word is reached, the block looks at the READ_PACK_DIR in the HW_LCDIF_CTRL2 register. If this bit is set, the block will swizzle the data, but only within the valid bytes, unlike in the write mode, where swizzle occurs across all 4 bytes. If the READ_MODE_OUTPUT_IN_RGB_FORMAT bit is set, eLCDIF will convert the data obtained from the READ_PACK_DIR operation into 24-bit unpacked RGB and then re-convert it into 16/18/24 bpp RGB depending on the WORD_LENGTH field. The DATA_FORMAT_16/18/24_BIT bit fields are also considered while converting to 24-bit unpacked RGB format. For example, if DATA_FORMAT_18_BIT is 1, the RGB666 data will be packed in the upper bits [31:4]of a 32-bit word, and that bit is 0, the data will be packed in the lower bits [17:0]. After all these operations, the data gets written into the RXFIFO.

The following figures show some examples of how data is handled in different MPU read modes.

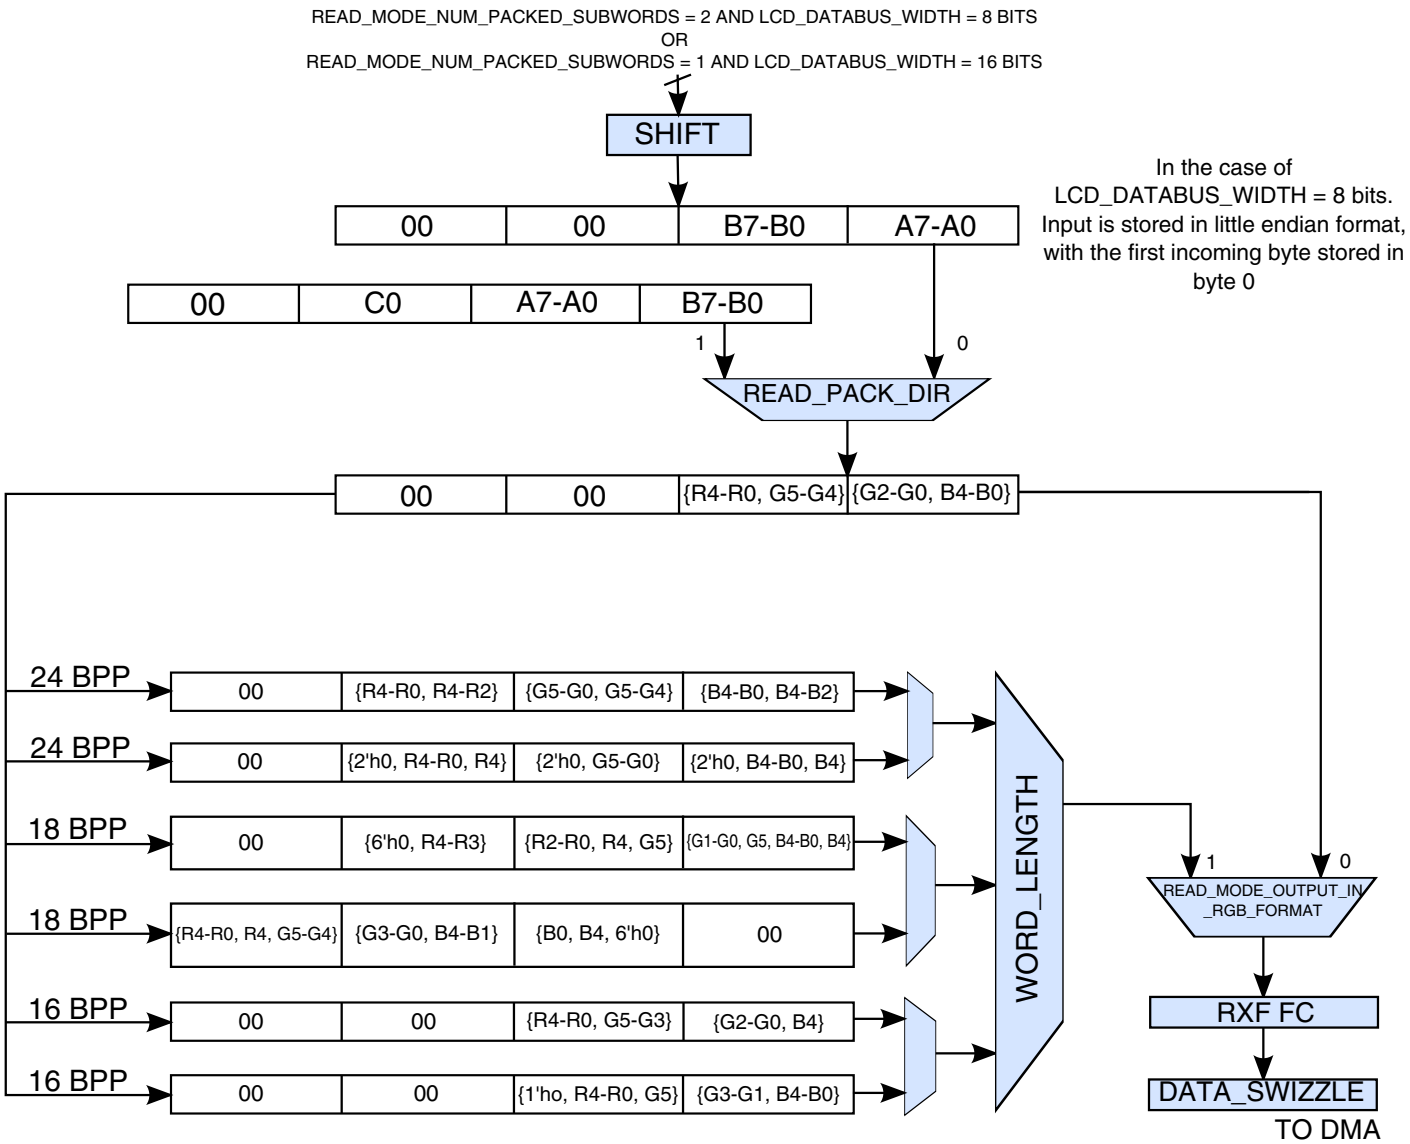

Figure 37-8. Data in MPU read mode

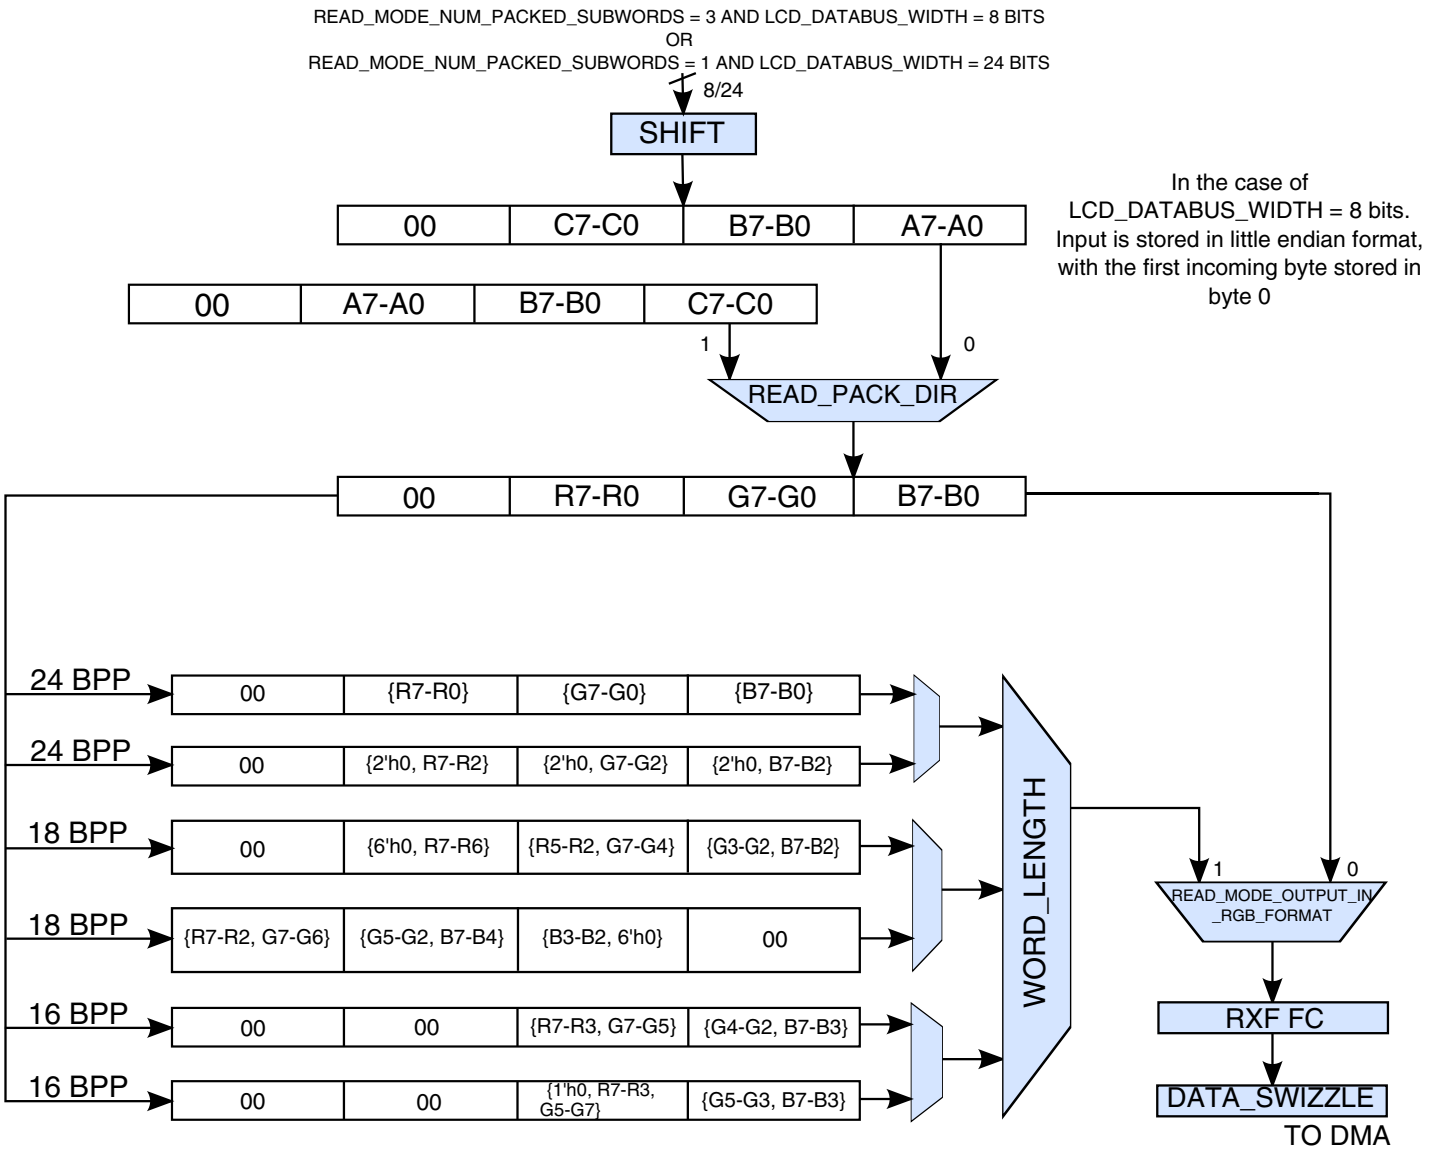

Figure 37-9. Data in MPU read mode

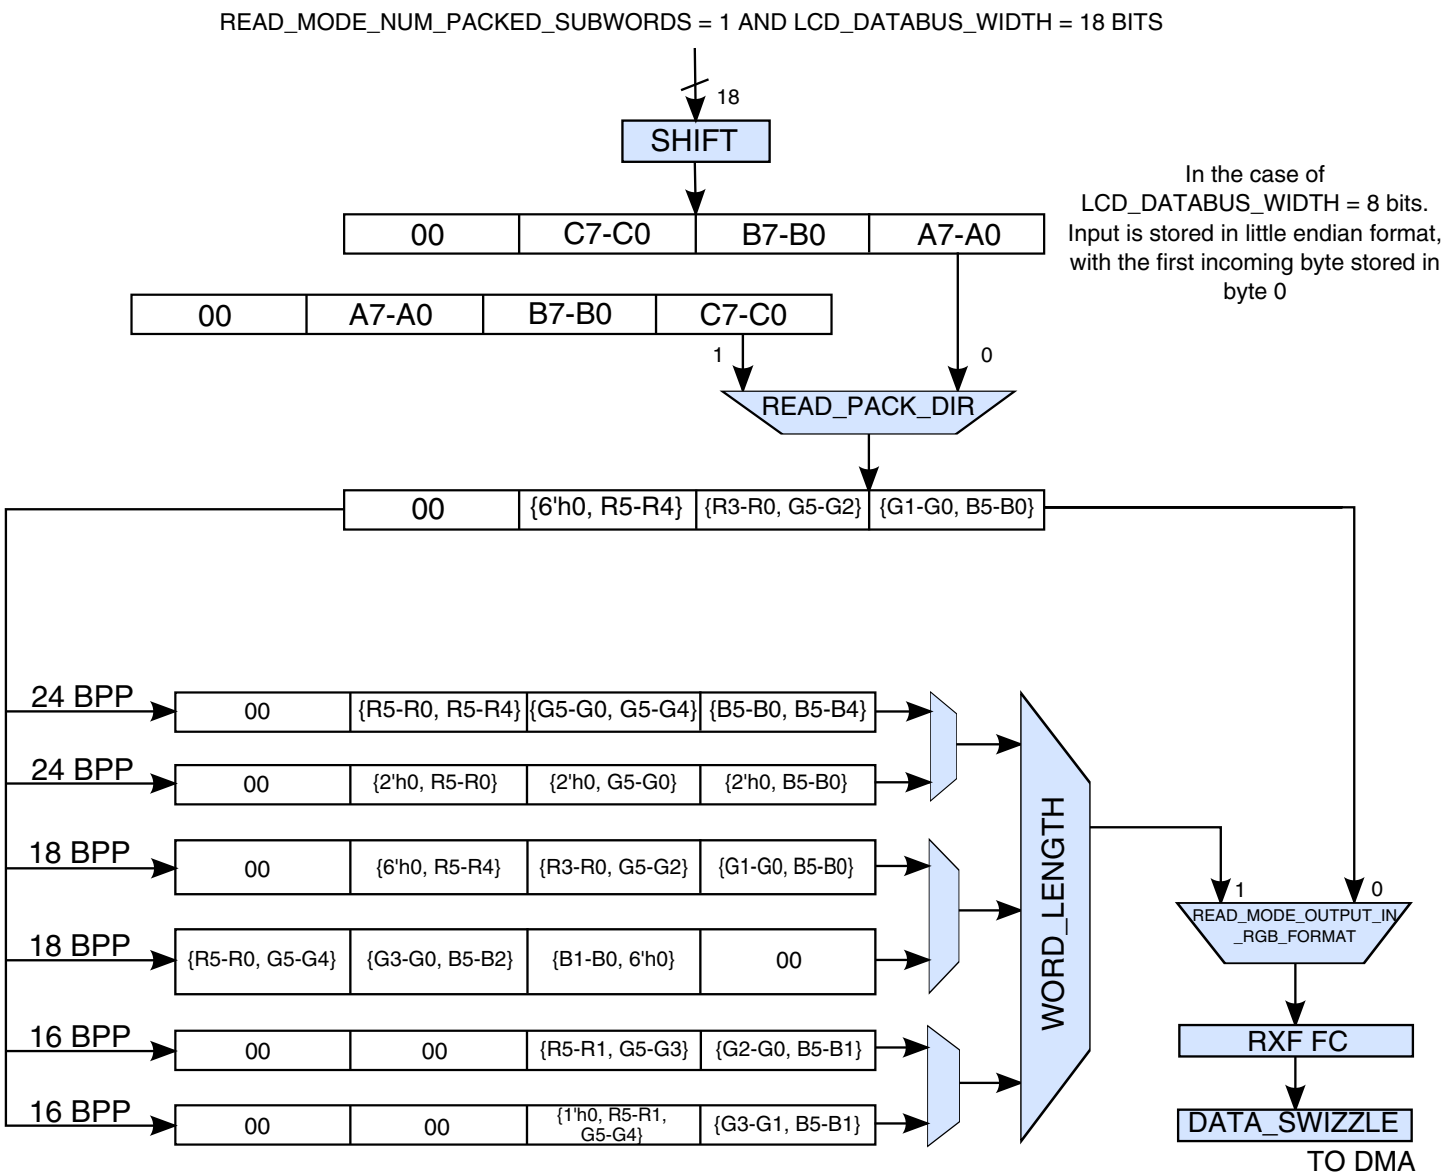

Figure 37-10. Data in MPU read mode

Restrictions:

READ_PACK_DIR should only be used if it is required to swizzle the subwords before doing RGB to RGB CSC, otherwise the DATA_SWIZZLE field should be used to swizzle across bytes.

READ_PACK_DIR must be 0 if LCD_DATABUS_WIDTH is 8 bits and READ_MODE_NUM_PACKED_SUBWORDS =1

If READ_MODE_OUTPUT_IN_RGB_FORMAT bit is set, the following restrictions should be followed:

- If LCD_DATABUS_WIDTH = 8 bits, then READ_MODE_NUM_PACKED_SUBWORDS <= 3.
- If LCD_DATABUS_WIDTH = 16/18/24 bits, then READ_MODE_NUM_PACKED_SUBWORDS = 1.

37.2.4 eLCDIF Interrupts

eLCDIF supports a number of interrupts to aid controlling and status reporting of the block. All the interrupts have individual mask bits for enabling or disabling each of them. They all get funneled through a single interrupt line connected to the interrupt collector (ICOLL).

The following list describes the different interrupts supported by eLCDIF:

- Underflow interrupt is asserted when the clock domain crossing FIFO (TXFIFO) becomes empty but the block is in active display portion during that time. Software should take corrective action to make sure that this does not happen.
- In the bus master mode, the overflow interrupt will be asserted if the block has requested more data than it's FIFOs could hold. In the read mode, it will be asserted if the RxFIFO becomes full and the block reads more data.
- VSYNC edge interrupt will be asserted every time a leading VSYNC edge occurs.
- Cur_frame_done interrupt occurs at the end of every frame in all modes except DVI. In DVI mode, if IRQ_ON_ALTERNATE_FIELDS bit is set, it will occur at the end of every frame, otherwise it will occur at the end of every field.

37.2.5 Initializing the eLCDIF

This section describes write modes and MPU read mode.

37.2.5.1 Write Modes

The following initialization steps are common to all eLCDIF write modes of operation before entering any particular mode.

Initialization steps:

1. Configure the external I/Os to correctly interface the external display.
2. Start the DISPLAY_CLK clock and set the appropriate frequency by programming the registers in CCM.

3. Start the BUS_CLK and set the appropriate frequency by programming the registers in CCM.
4. Bring the eLCDIF out of soft reset and disable the clock gate bit.
5. Reset the LCD controller by setting LCDIF_CTRL1_RESET bit appropriately, being careful to observe the reset requirements of the controller. See Behavior During Reset for more information on Reset requirements.
6. Make sure READ_WRITEB bit in HW_LCDIF_CTRL register is 0.
7. Select bus master mode by setting the LCDIF_MASTER bit in HW_LCDIF_CTRL register to 1. This is required when writing to the display.
8. Set the INPUT_DATA_SWIZZLE according to the endianness of the LCD controller. Also, set the DATA_SHIFT_DIR and SHIFT_NUM_BITS if it is required to shift the data left or right before it is output.
9. Set the WORD_LENGTH field appropriately: 0 = 16-bit input, 1 = 8-bit input, 2 = 18-bit input, 3 = 24/32-bit input. Also, select the correct 16/18/24 bit data format with the corresponding fields in HW_LCDIF_CTRL register.
10. Set the BYTE_PACKING_FORMAT field in HW_LCDIF_CTRL1 according to the input frame.
11. Set the LCD_DATABUS_WIDTH appropriately: 0 = 16-bit output, 1 = 8-bit output, 2 = 18-bit output, 3 = 24/32-bit output.
12. Enable the necessary IRQs.

37.2.5.2 MPU Read Mode

The following initialization steps should be done to enter the MPU read mode of operation:

Initialization steps:

1. Configure the external I/Os to correctly interface the external display.
2. Start the DISPLAY_CLK and set the appropriate frequency by programming the registers in CCM.
3. Start the BUS_CLK and set the appropriate frequency by programming the registers in CCM.
4. Bring the eLCDIF out of soft reset and clock gate.
5. Reset the LCD controller by setting LCDIF_CTRL1_RESET bit appropriately, being careful to observe the reset requirements of the controller.
6. Set the READ_WRITEB bit in LCDIF_CTRL register to 1.
7. Select the DMA mode by making the LCDIF_MASTER bit in LCDIF_CTRL register 0.
8. Also, set the DATA_SHIFT_DIR and SHIFT_NUM_BITS if it is required to shift the data left or right before it is output.

9. Indicate if the read data needs to color-space-converted and stored in a different RGB format by setting the READ_MODE_OUTPUT_IN_RGB_FORMAT field accordingly.
10. Set the WORD_LENGTH field appropriately: 0 = 16-bit input, 1 = 8-bit input, 2 = 18-bit input, 3 = 24-bit input if READ_MODE_OUTPUT_IN_RGB_FORMAT is required. Also, select the correct 16/18/24 bit data format with the corresponding fields in LCDIF_CTRL register.
11. Set the READ_MODE_NUM_PACKED_SUBWORDS field in LCDIF_CTRL2 according to the number of subwords per word required to be packed.
12. Set the READ_PACK_DIR to 1 if it is required to store the data in big-endian format.
13. Set the LCD_DATABUS_WIDTH appropriately: 0 = 16-bit output, 1 = 8-bit output, 2 = 18-bit output, 3 = 24-bit output.
14. Enable the necessary IRQs.

37.2.6 MPU Interface

The MPU interface is used to transfer data and commands between the internal buffer of LCD controller/display and the MPU or vice versa at relatively lower speeds. eLCDIF can support the 6800 as well as the 8080 MPU protocol. If DOTCLK_MODE, DVI_MODE and VSYNC_MODE bits in LCDIF_CTRL registers are 0, it implies that the block is in MPU interface mode of operation. The LCDIF MPU mode has four basic timing parameters: Setup and Hold for the Command/Data register selection (TCS, TCH) and Setup and Hold for the Data bus (TDS, TDH). These parameters are expressed in DISPLAY_CLK cycles. The LCD_WR signal is used as the write strobe while LCD_RS signal is typically used to switch between command and data modes.

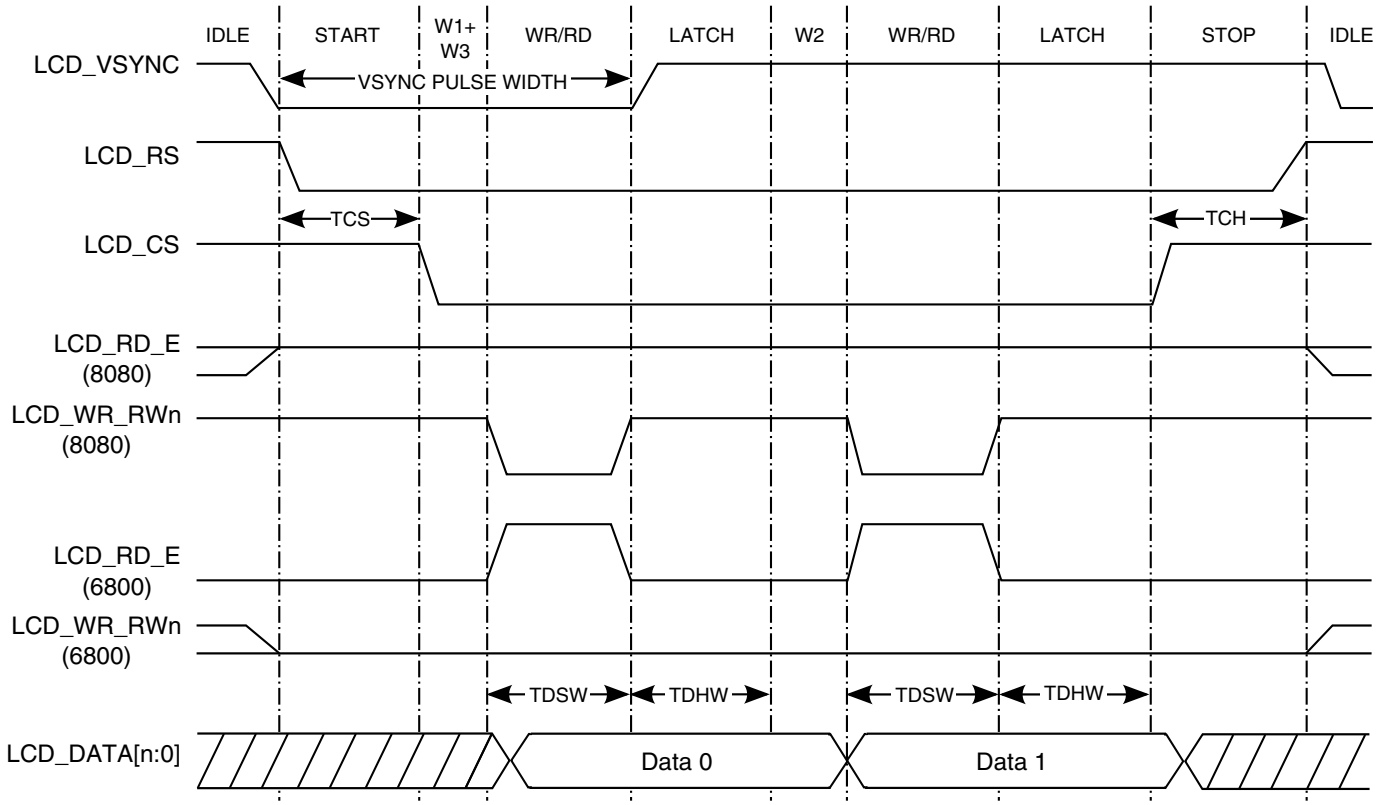

Figure 37-11. Timing in write mode of 6800 and 8080 protocols

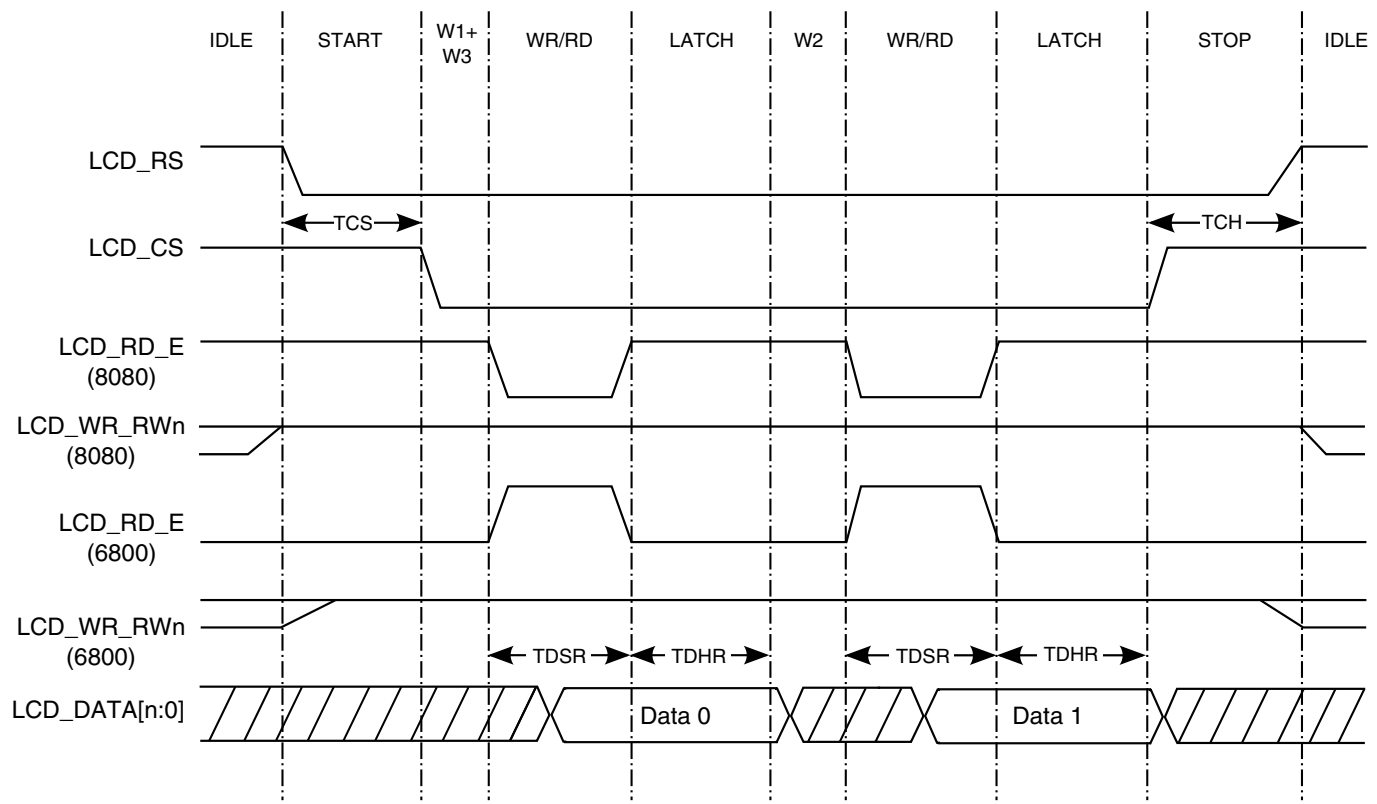

Figure 37-12. Read timing interface in 6800 and 8080 protocols

The eLCDIF has flexible pin and strobe timings which enable it to optimally support a wide range of LCDs. The minimum cycle time is two DISPLAY_CLK cycles (TDS=TDH=1). For example, this results in a maximum LCD data rate of 12 MB/s when DISPLAY_CLK is 24 MHz. TDS and TDH are 8-bit values, so the minimum eLCDIF period is 510 DISPLAY_CLK cycles (47 KHz with a 24 MHz DISPLAY_CLK). The timings are not automatically adjusted if the DISPLAY_CLK frequency changes, so it may be necessary to adjust the timings if DISPLAY_CLK changes.

In the MPU interface mode, the LCDIF_CTRL_ BYPASS_COUNT bit must be 0. The RUN bit is cleared automatically once the eLCDIF has received/transmitted all the data as per the LCDIF_TRANSFER_COUNT register and has completed the transfer to the panel. The current transfer can be cancelled/aborted if the RUN bit is manually made 0.

37.2.6.1 Code Example to Initialize the eLCDIF in MPU Write Mode

```
// Note: Common initialization steps in Initializing the eLCDIF must also be
// executed along with the following code
BF_CS1(LCDIF_CTRL, DATA_SELECT, 1); // 0 if sending command, 1 if sending data. Note that the
                                    // idle state for LCD_RS signal is high, regardless of the
                                     // programming of the DATA_SELECT register.
BF_CS1 (LCDIF_CTRL, MODE86, 8080_MODE);
BF_CS1 (LCDIF_CTRL, READ_WRITEB, 0);
BF_CS1 (LCDIF_CTRL, BYPASS_COUNT, 0); //Must be 0 in MPU mode
BF_CS1 (LCDIF_CTRL1, BUSY_ENABLE, 1);//Only if LCD controller implements a busy line
BF_CS4 (LCDIF_TIMING, CMD_HOLD, 2, CMD_SETUP, 2, DATA_HOLD, 2, DATA_SETUP, 2);  //Values
based
                               // on DISPLAY_CLK frequency and timing requirements of
controller.
                              // Note that these register must be non-zero for correct
operation.
BF_CS2 (LCDIF_TRANSFER_COUNT, H_COUNT, 320, V_COUNT, 240); //For a 320 RGB x 240 display
BF_CS1 (LCDIF_CTRL, RUN, 1);
```

The eLCDIF is now ready to receive data through DMA writes to the LCDIF_DATA register or fetch data directly from memory as a bus master. Also, note that, while in soft DMA mode, the software will need to poll the FIFO STATUS bits to ensure that it does not overflow the eLCDIF data buffers. When eLCDIF is done transmitting H_COUNT x V_COUNT pixels, it will stop, turn off the RUN bit and assert the cur_frame_done interrupt.

37.2.7 VSYNC Interface

The VSYNC interface uses the same protocol as the MPU interface, with an additional signal VSYNC at the frame rate of the display, as shown in the figure given in MPU Interface section. It is used in the moving picture display mode where data has to be written to the internal LCD buffer at a speed higher than the display rate and displayed in synchronization with the VSYNC signal. This mode is selected by setting the

VSYNC_MODE bit in LCDIF_CTRL register. The VSYNC signal is programmable for period, polarity and direction. Many other programmable parameters are shared with the MPU interface. The VSYNC_OEB bit in LCDIF_VDCTRL0 register indicates whether the display controller will send the VSYNC signal, or whether it should be generated by eLCDIF. The timing of the VSYNC signal is based on the DISPLAY_CLK (make sure VSYNC_PULSE_WIDTH_UNIT = VSYNC_PERIOD_UNIT = 0 and VSYNC_ONLY = 1) and it is determined by the VSYNC_PERIOD, VSYNC_PULSE_WIDTH and VSYNC_POL fields in LCDIF_VDCTRL0-4 registers. The SYNC_SIGNALS_ON bit in LCDIF_VDCTRL4 register must be set if the target requires the VSYNC signal to be generated by eLCDIF. If the WAIT_FOR_VSYNC_EDGE bit in LCDIF_CTRL register is set, it indicates that the hardware should wait until it sees the leading VSYNC edge before starting the data transfer. The VERITCAL_WAIT_CNT indicates the number of DISPLAY_CLK cycles from the leading VSYNC edge after which data transfer will be started on the interface.

In the VSYNC interface mode, the LCDIF_CTRL_ BYPASS_COUNT bit must be 0. The RUN bit is cleared automatically once the eLCDIF has received/transmitted all the data as per the LCDIF_TRANSFER_COUNT register and has completed the transfer to the panel. The current transfer can be cancelled/aborted if the RUN bit is manually made 0.

37.2.7.1 Code Example to Initialize eLCDIF in VSYNC Mode

```
// Note: Common initialization steps in Initializing the eLCDIF must also be
// executed along with the following code
BF_CS1 (LCDIF_CTRL, DATA_SELECT, 1); // 0 if sending command, 1 if sending data. Note that
//the idle state for LCD_RS signal is high, regardless of the programming of the DATA_SELECT
//register.

BF_CS1 (LCDIF_CTRL, MODE86, 8080_MODE);
BF_CS1 (LCDIF_CTRL, BYPASS_COUNT, 0); //Must be 0 in MPU mode
BF_CS1 (LCDIF_CTRL1, BUSY_ENABLE, 0);
BF_CS4 (LCDIF_TIMING, CMD_HOLD, 2, CMD_SETUP, 2, DATA_HOLD, 2, DATA_SETUP, 2);  //Values
//based on DISPLAY_CLK frequency and timing requirements of controller. Note that these
//register must be non-zero for the MPU and VSYNC modes.
BF_CS2 (LCDIF_TRANSFER_COUNT, H_COUNT, 320, V_COUNT, 240);//For a 320 RGB x 240 display
//The following section indicates setting up the VSYNC signal timing when VSYNC is an output
BF_CS1 (LCDIF_VDCTRL0, VSYNC_OEB, 0); //Making VSYNC signal an output
BF_CS1 (LCDIF_VDCTRL4, VSYNC_ONLY, 1); //Only need to generate VSYNC signal
BF_CS1 (VDCTRL0, VSYNC_POL, 0); //Setting the polarity of VSYNC signal to be low during
//VSYNC_PULSE_WIDTH time
BF_CS2 (LCDIF_VDCTRL0, VSYNC_PERIOD_UNIT, 0, VSYNC_PULSE_WIDTH_UNIT, 0);
BF_CS2 (LCDIF_VDCTRL1, VSYNC_PERIOD, 400000, VSYNC_PULSE_WIDTH, 100);//Frame display rate in
//terms of number of DISPLAY_CLKs.
BF_CS2 (LCDIF_VDCTRL2, HSYNC_PULSE_WIDTH, 0, HSYNC_PERIOD, 0);
BF_CS1 (LCDIF_VDCTRL3, VERTICAL_WAIT_CNT, 50);
BF_CS1 (LCDIF_VDCTRL4, SYNC_SIGNALS_ON, 1);
BF_CS2 (LCDIF_CTRL, VSYNC_MODE, 1, WAIT_FOR_VSYNC_EDGE, 1); //set WAIT_FOR_VSYNC_EDGE if
//software wishes to transfer the next frame after the VSYNC edge occurs.
BF_CS1 (LCDIF_CTRL, RUN, 1);
```

The eLCDIF is now ready to receive data through DMA writes to the LCDIF_DATA register or fetch data directly from memory as a bus master. When eLCDIF is done transmitting H_COUNT x V_COUNT pixels, it will stop, turn off the RUN bit and assert the cur_frame_done interrupt.

37.2.8 DOTCLK Interface

The DOTCLK interface is another mode used in moving picture displays. It includes the VSYNC, HSYNC, DOTCLK and (optional) ENABLE signals. The interface is popularly called the RGB interface if the ENABLE signal is present.

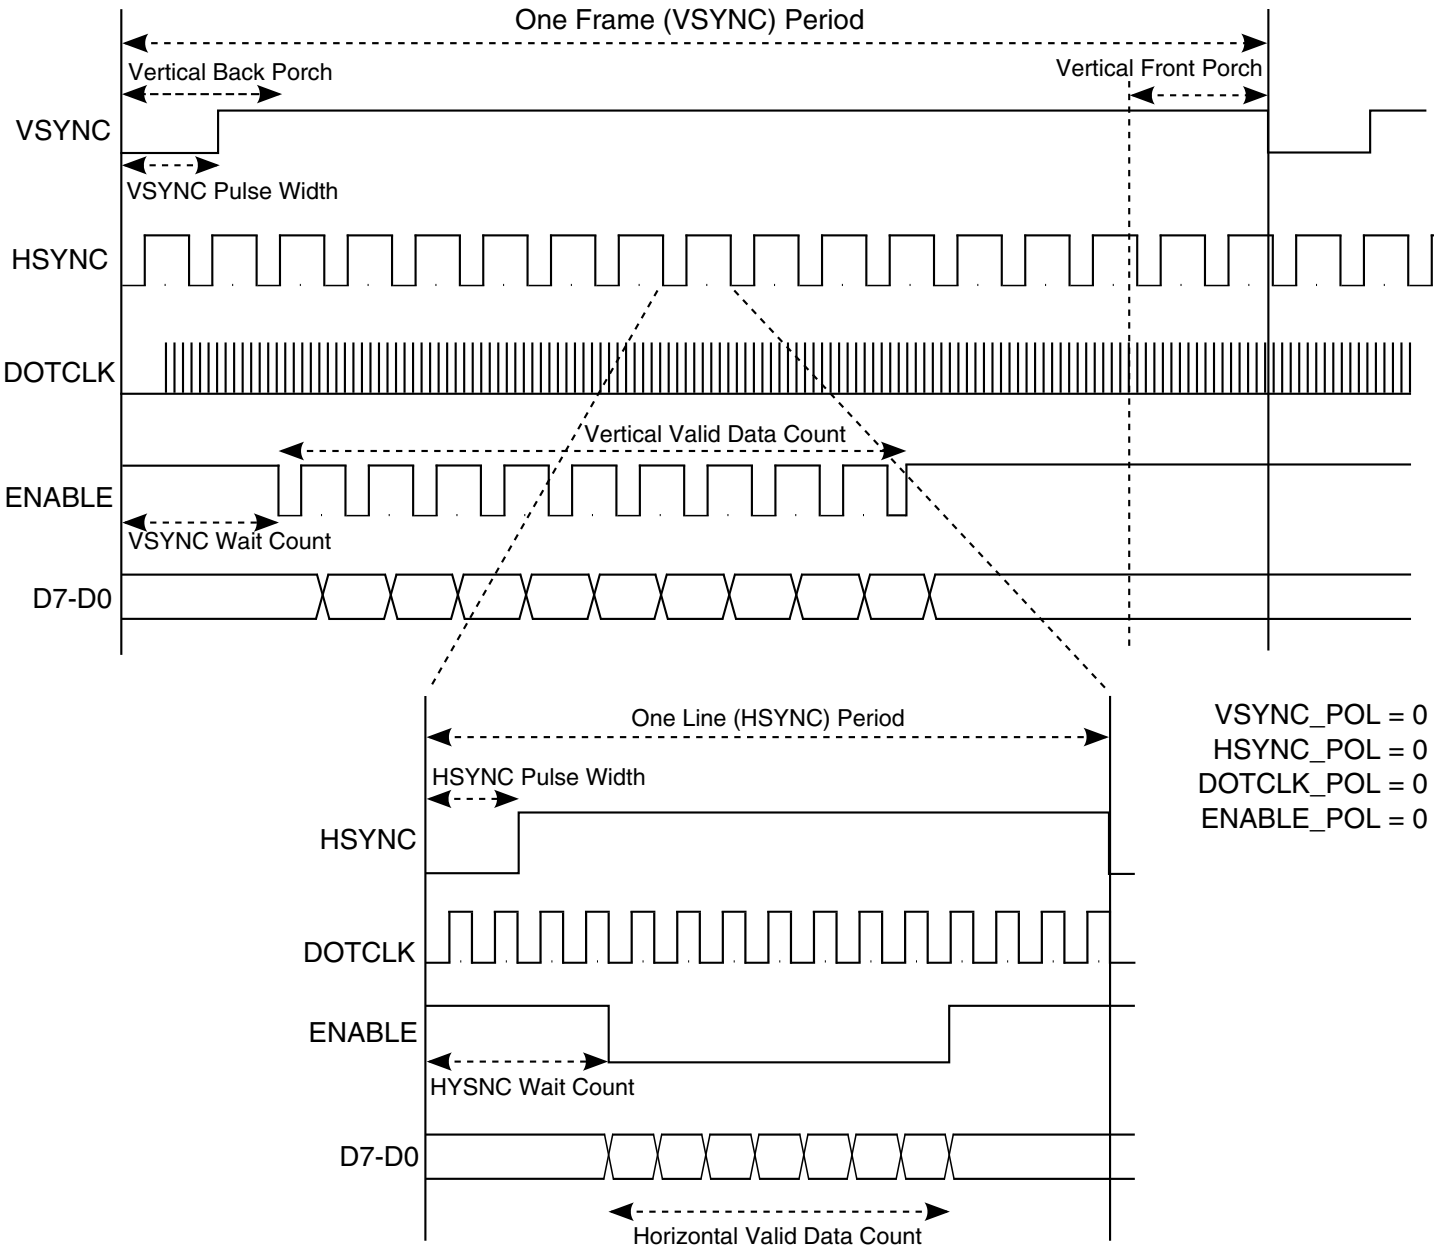

Figure 37-13. DOTCLK protocol with programmable parameters

The DOTCLK mode writes data at high speed to the LCD, and the display operation is synchronized with the VSYNC, HSYNC, ENABLE and DOTCLK signals. The polarities, periods and pulse-widths of the sync signals are programmable using the LCDIF_VDCTRL0-4 registers. The units for the VSYNC signal must be number of horizontal lines and can be selected using the VSYNC_PULSE_WIDTH_UNIT and VSYNC_PERIOD_UNIT bit fields. The VERTICAL_WAIT_CNT is by default given the same unit as the VSYNC_PERIOD. The DISPLAY_CLK frequency is managed by the CCM.

In DOTCLK mode, LCDIF_CTRL_BYPASS_COUNT bit must be set to 1. To end the current transfer, the software should make the DOTCLK_MODE bit 0, so that all data that is currently in the LCDIF LFIFO and TXFIFO is transmitted. Once that transfer is complete, the block will automatically clear the RUN bit and issue the cur_frame_done interrupt.

37.2.8.1 Code Example

The following code shows an example for programming a 320x240 display. Note that setting up the display must be done through the MPU mode or via SPI.

```
// Note: Common initialization steps in Initializing the eLCDIF must also be
// executed along with the following code
BF_CS1 (LCDIF_CTRL, DOTCLK_MODE, 1);
BF_CS1 (LCDIF_CTRL, BYPASS_COUNT, 1); //Always for DOTCLK mode
BF_CS1 (LCDIF_VDCTRL0, VSYNC_OEB, 0); //Vsync is always an output in the DOTCLK mode
BF_CS4 (LCDIF_VDCTRL0, VSYNC_POL, 0, HSYNC_POL, 0, DOTCLK_POL, 0, ENABLE_POL, 0);
BF_CS1 (LCDIF_VDCTRL0, ENABLE_PRESENT, 1);
BF_CS2 (LCDIF_VDCTRL0, VSYNC_PERIOD_UNIT, 1, VSYNC_PULSE_WIDTH_UNIT, 1);
BF_CS1 (LCDIF_VDCTRL0, VSYNC_PULSE_WIDTH, 2);
BF_CS1 (LCDIF_VDCTRL1, VSYNC_PERIOD, 280);
BF_CS2 (LCDIF_VDCTRL2, HSYNC_PULSE_WIDTH, 10, HSYNC_PERIOD, 360); //Assuming
                                                    //  LCD_DATABUS_WIDTH is 24bit
BF_CS2 (LCDIF_VDCTRL3, VSYNC_ONLY, 0);
BF_CS2 (LCDIF_VDCTRL3, HORIZONTAL_WAIT_CNT, 20, VERTICAL_WAIT_CNT, 20);
BF_CS1 (LCDIF_VDCTRL4, DOTCLK_H_VALID_DATA_CNT, 320);//Note that DOTCLK_V_VALID_DATA_CNT is
                              //implicitly assumed to be HW_LCDIF_TRANSFER_COUNT_V_COUNT
BF_CS1 (LCDIF_VDCTRL4, SYNC_SIGNALS_ON, 1);
BF_CS1 (LCDIF_CTRL, RUN, 1);
```

To stop the transfer completely, the ideal way is to make DOTCLK_MODE = 0. In that case, the block will transmit whatever it had in its FIFO, turn off the RUN bit and toggle the dma_end_cmd signal indicating to the DMA that it is done with the transfer.

37.2.9 ITU-R BT.656 Digital Video Interface (DVI)

ITU-R BT.656 Digital Video Interface shown below transmits 4:2:2 YCbCr digital component video to a digital video encoder that can translate it into 525/60 or 625/50 analog TV signal. Unique timing codes (timing reference signals) are embedded within the video stream to indicate the different timing events that would have been otherwise indicated by VSYNC, HSYNC and BLANK signals. The hardware supports 8-bit data transfers; the pins are shared with the lower 8 bits of LCD data bus. The LCD_RS pin is shared with the clock signal of the interface (called CCIRCLK here for uniqueness). CCIRCLK also can be obtained on the LCD_DOTCK pin. The mode shares the write FIFO with the LCD interface and the associated pipeline. The programmable parameters in registers LCDIF_DVICTRL0-3 allow setting the total number of horizontal lines per frame, vertical and horizontal blanking interval, odd and even field start and end

positions, and so on. In short, these parameters are provided to ensure that the hardware has enough flexibility to generate the right 525/60 or 625/50 data streams. Most of the initialization steps in Initializing the eLCDIF such as data shifting, swizzle, and so on, are applicable to DVI mode also. The register descriptions in the programmable registers section at the end of this chapter include example code for programming the DVICTRL0-3 registers.

In DVI mode, LCDIF_CTRL_BYPASS_COUNT bit must be set to 1. To end the current transfer, the software should make the DVI_MODE bit the value 0, so that all data that is currently in the LCDIF LFIFO and TXFIFO is transmitted. Once that transfer is complete, the block will automatically clear the RUN bit and assert the cur_frame_done interrupt.

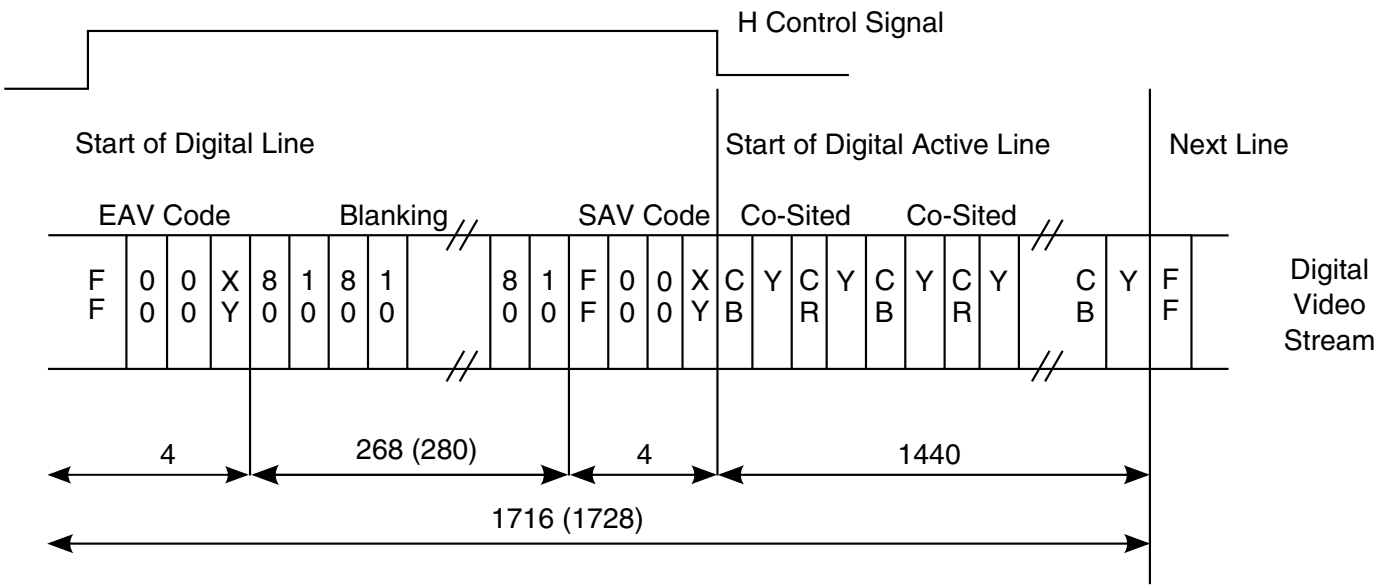

Figure 37-14. Digital Video Interface

37.2.10 eLCDIF Pin Usage by Interface Mode

Table 37-1 and Table 37-2 indicates how the eLCDIF level interface pins are used based on the desired mode of operation. The chip level I/Os should also be configured to be consistent with the desired eLCDIF operating mode.

The VSYNC signal has been mapped onto two pins, LCD_BUSY and LCD_VSYNC. The pin multiplexing can be programmed to select either of those pins to function as VSYN.

NOTE

There is an option to internally mux the HSYNC, DOTCLK and ENABLE signals in the DOTCLK mode by setting the

MUX_SYNC_SIGNALS bit in the VDCTRL0 register. There is also an option to internally mux the LCD_WR_RWn and LCD_RD_E pins in the CTRL1 register for backward compatibility.

37.3 Behavior During Reset

BUS_CLK and DISPLAY_CLK must be running before making any changes to SFTRST or CLKGATE bits. A soft reset (SFTRST) can take multiple clock periods to complete, so do not set CLKGATE when setting SFTRST. The reset process gates the clocks automatically.

37.4 Programmable Registers

eLCDIF Hardware Register Format Summary

LCDIF memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4100_A000	eLCDIF General Control Register (LCDIF_CTRL)	32	R/W	C000_0000h	37.4.1/ 2280

37.4.1 eLCDIF General Control Register (LCDIF_CTRL*n*)

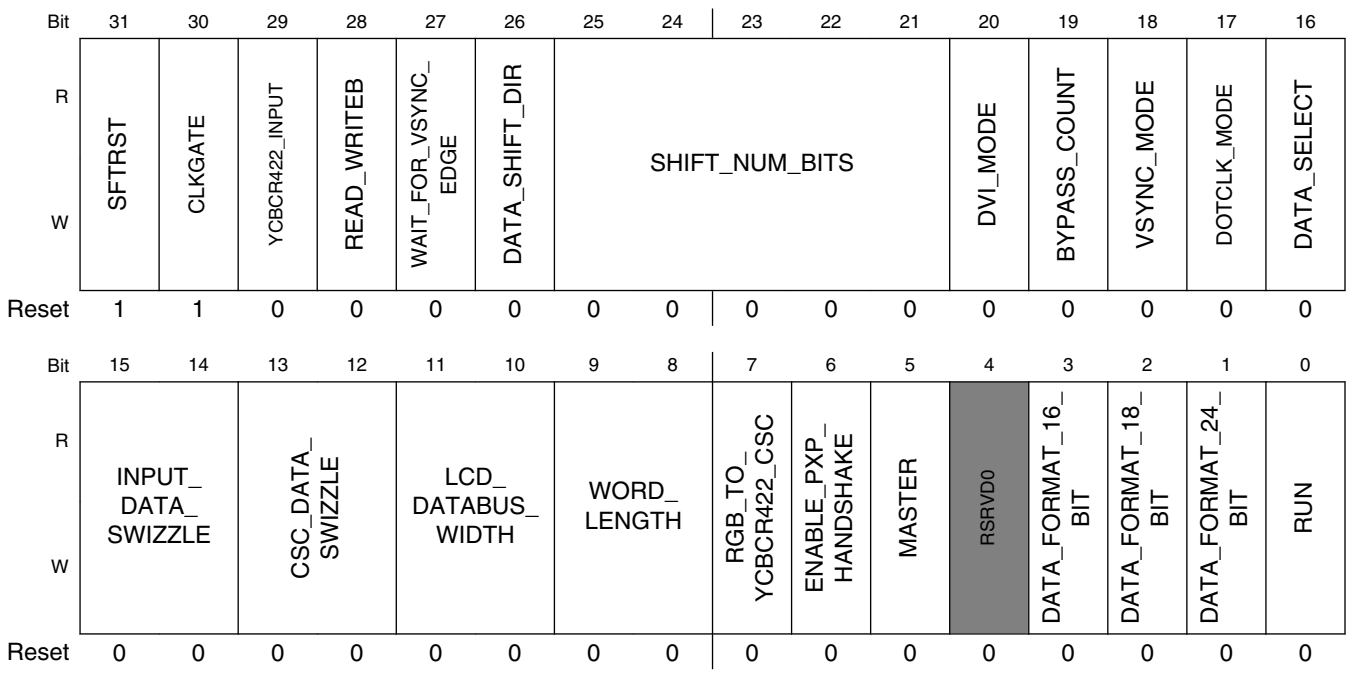
The LCD Interface Control Register provides overall control of the eLCDIF block. The eLCDIF Control Register provides a variety of control functions to the programmer. These functions allow the interface to be very flexible to work with a variety of LCD controllers, and to minimize overhead and increase performance of LCD programming. The register has been organized such that switching between the different LCD modes can be done with minimum PIO writes.

Addresses: LCDIF_CTRL is 4100_A000h base + 0h offset = 4100_A000h

LCDIF_CTRL_SET is 4100_A000h base + 4h offset = 4100_A004h

LCDIF_CTRL_CLR is 4100_A000h base + 8h offset = 4100_A008h

LCDIF_CTRL_TOG is 4100_A000h base + Ch offset = 4100_A00Ch



LCDIF_CTRL*n* field descriptions

Field	Description
31 SFTRST	This bit must be set to zero to enable normal operation of the eLCDIF. When set to one, it forces a block level reset.
30 CLKGATE	This bit must be set to zero for normal operation. When set to one it gates off the clocks to the block.
29 YCBCR422_INPUT	Zero implies input data is in RGB color space. One implies input data is in YCbCr 4:2:2 format, such that YCbYCr are packed in a 32-bit word. It also means that there are 2 pixels in 4 bytes. If this bit is set, software should program the H_COUNT field in the TRANSFER_COUNT register to the total number of pixels that will have to be fetched by the eLCDIF block per line and the BYTE_PACKING_FORMAT should be 0xF. The WORD_LENGTH does not matter in this case.

Table continues on the next page...

LCDIF_CTRL*n* field descriptions (continued)

Field	Description
28 READ_WRITEB	By default, eLCDIF is in the write mode. Setting this bit to 1 will make the hardware go into 6800/8080 MPU read mode. Make sure that DMA operation is selected (LCDIF_MASTER bit is 0) when performing read operations.
27 WAIT_FOR_ VSYNC_EDGE	Setting this bit to 1 will make the hardware wait for the triggering VSYNC edge before starting write transfers to the LCD. Used only in the VSYNC mode of operation.
26 DATA_SHIFT_ DIR	Use this bit to determine the direction of shift of transmit data. In the DVI mode, it works only on the active data, not on the timing codes and ancillary data. 0x0 **TXDATA_SHIFT_LEFT** — Data to be transmitted is shifted LEFT by SHIFT_NUM_BITS bits. 0x1 **TXDATA_SHIFT_RIGHT** — Data to be transmitted is shifted RIGHT by SHIFT_NUM_BITS bits.
25–21 SHIFT_NUM_ BITS	The data to be transmitted is shifted left or right by this number of bits.
20 DVI_MODE	Set this bit to 1 to get into theITU-R BT.656 digital video interface mode. Toggle this bit from 1 to 0 to make the hardware go out of DVI mode after completing all data transfer, deasserting the RUN bit and toggling the dma_end_cmd signal.
19 BYPASS_ COUNT	When this bit is 0, it means that eLCDIF will stop the block operation and turn off the RUN bit after the amount of data indicated by the LCDIF_TRANSFER_COUNT register has been transferred out. When this bit is set to 1, the block will continue normal operation indefinitely until it is told to stop. This bit must be 0 in MPU and VSYNC modes, and must be 1 in DOTCLK and DVI modes of operation.
18 VSYNC_MODE	Setting this bit to 1 will make the eLCDIF hardware go into VSYNC mode. WAIT_FOR_VSYNC_EDGE can be used only if this bit is set. If VSYNC signal is required to be an output from the block, SYNC_SIGNALS_ON bit in LCDIF_VDCTRL4 register must be set.
17 DOTCLK_MODE	Set this bit to 1 to make the hardware go into the DOTCLK mode, i.e. VSYNC/HSYNC/DOTCLK/ENABLE interface mode. ENABLE is optional, selected by the ENABLE_PRESENT bit. Toggle this bit from 1 to 0 to make the hardware go out of DOTCLK mode after completing all data transfer and deasserting the RUN bit.
16 DATA_SELECT	Command Mode polarity bit. This bit should only be changed when RUN is 0. 0x0 **CMD_MODE** — Command Mode. DCn signal is Low. 0x1 **DATA_MODE** — Data Mode. DCn signal is High.
15–14 INPUT_DATA_ SWIZZLE	This field specifies how to swap the bytes fetched by the bus master interface. The swizzle function is independent of the WORD_LENGTH bit. The supported swizzle configurations are: 0x0 **NO_SWAP** — No byte swapping.(Little endian) 0x0 **LITTLE_ENDIAN** — Little Endian byte ordering (same as NO_SWAP). 0x1 **BIG_ENDIAN_SWAP** — Big Endian swap (swap bytes 0,3 and 1,2). 0x1 **SWAP_ALL_BYTES** — Swizzle all bytes, swap bytes 0,3 and 1,2 (aka Big Endian). 0x2 **HWD_SWAP** — Swap half-words. 0x3 **HWD_BYTE_SWAP** — Swap bytes within each half-word.
13–12 CSC_DATA_ SWIZZLE	This field specifies how to swap the bytes after the data has been converted into an internal representation of 24 bits per pixel and before it is transmitted over the LCD interface bus. The data is always transmitted with the least significant byte/hword (half word) first after the swizzle takes place. So, INPUT_DATA_SWIZZLE takes place first on the incoming data, and then CSC_DATA_SWIZZLE is applied. The swizzle function is independent of the WORD_LENGTH or the LCD_DATABUS_WIDTH fields. If RGB_TO_YCRCB422_CSC bit is set, the swizzle occurs on the Y, Cb, Cr values. The supported swizzle configurations are:

Table continues on the next page...

LCDIF_CTRL*n* field descriptions (continued)

Field	Description
	0x0 **NO_SWAP** — No byte swapping.(Little endian) 0x0 **LITTLE_ENDIAN** — Little Endian byte ordering (same as NO_SWAP). 0x1 **BIG_ENDIAN_SWAP** — Big Endian swap (swap bytes 0,3 and 1,2). 0x1 **SWAP_ALL_BYTES** — Swizzle all bytes, swap bytes 0,3 and 1,2 (aka Big Endian). 0x2 **HWD_SWAP** — Swap half-words. 0x3 **HWD_BYTE_SWAP** — Swap bytes within each half-word.
11–10 LCD_ DATABUS_ WIDTH	LCD Data bus transfer width. 0x0 **16_BIT** — 16-bit data bus mode. 0x1 **8_BIT** — 8-bit data bus mode. 0x2 **18_BIT** — 18-bit data bus mode. 0x3 **24_BIT** — 24-bit data bus mode.
9–8 WORD_ LENGTH	Input data format. 0x0 **16_BIT** — Input data is 16 bits per pixel. 0x1 **8_BIT** — Input data is 8 bits wide. 0x2 **18_BIT** — Input data is 18 bits per pixel. 0x3 **24_BIT** — Input data is 24 bits per pixel.
7 RGB_TO_ YCBCR422_ CSC	Set this bit to 1 to enable conversion from RGB to YCbCr colorspace. See the LCDIF_CSC_ registers for further details.
6 ENABLE_PXP_ HANDSHAKE	If this bit is set and LCDIF_MASTER bit is set, the eLCDIF will act as bus master and the handshake mechanism between eLCDIF and ePXP will be turned on. If LCDIF_MASTER bit is not set, this bit becomes a don't care.
5 MASTER	Set this bit to make the eLCDIF act as a bus master. If this bit is reset, the eLCDIF will act in its traditional DMA slave mode.
4 RSRVD0	Reserved bits. Write as 0.
3 DATA_ FORMAT_16_ BIT	When this bit is 1 and WORD_LENGTH = 0, it implies that the the 16-bit data is in ARGB555 format. When this bit is 0 and WORD_LENGTH = 0, it implies that the 16-bit data is in RGB565 format. When WORD_LENGTH is not 0, this bit is a dont care.
2 DATA_ FORMAT_18_ BIT	Used only when WORD_LENGTH = 2, i.e. 18-bit. 0x0 **LOWER_18_BITS_VALID** — Data input to the block is in 18 bpp format, such that lower 18 bits contain RGB 666 and upper 14 bits do not contain any useful data. 0x1 **UPPER_18_BITS_VALID** — Data input to the block is in 18 bpp format, such that upper 18 bits contain RGB 666 and lower 14 bits do not contain any useful data.
1 DATA_ FORMAT_24_ BIT	Used only when WORD_LENGTH = 3, i.e. 24-bit. Note that this applies to both packed and unpacked 24-bit data. 0x0 **ALL_24_BITS_VALID** — Data input to the block is in 24 bpp format, such that all RGB 888 data is contained in 24 bits. 0x1 **DROP_UPPER_2_BITS_PER_BYTE** — Data input to the block is actually RGB 18 bpp, but there is 1 color per byte, hence the upper 2 bits in each byte do not contain any useful data, and should be dropped.

Table continues on the next page...

LCDIF_CTRL*n* field descriptions (continued)

Field	Description
0 RUN	When this bit is set by software, the eLCDIF will start fetching data in either the DMA mode or the bus master mode and sending it across the interface. This bit must remain set for all the time the block is in operation.

37.4.2 eLCDIF General Control1 Register (LCDIF_CTRL1*n*)

The eLCDIF Control Register provides overall control of the eLCDIF block.

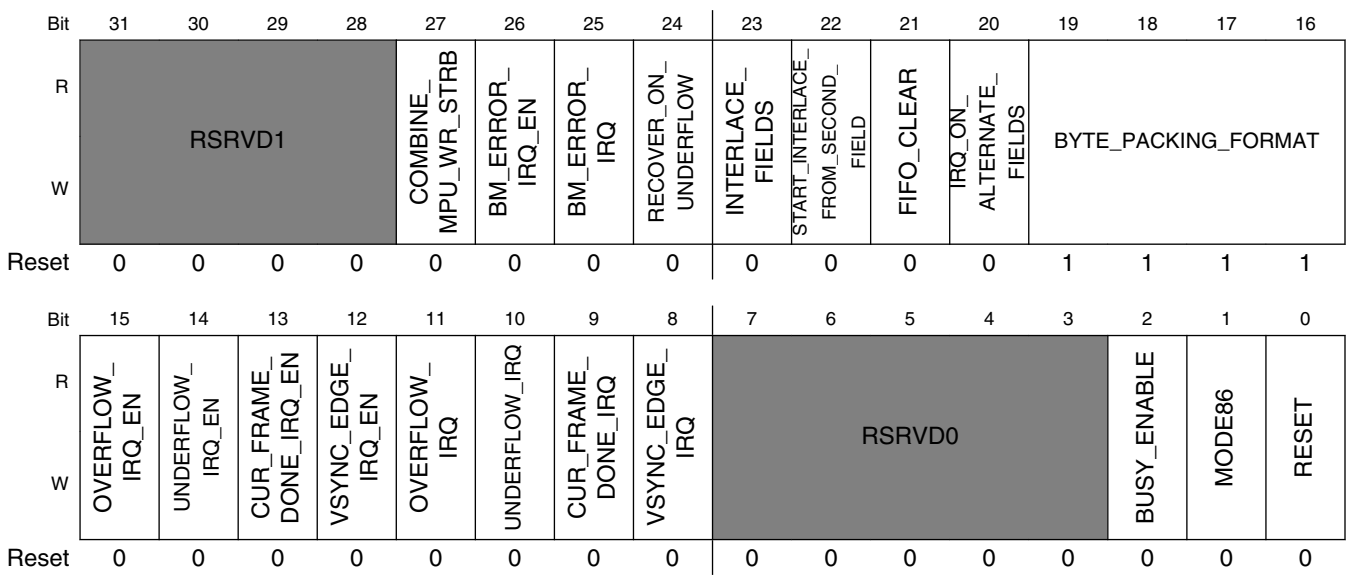
The eLCDIF Control1 Register provides additional programming to the eLCDIF. It implements some bits which are unlikely to change often in a particular application. It also carries interrupt-related bits which are common across more than one mode of operation.

Addresses: LCDIF_CTRL1 is 4100_A000h base + 10h offset = 4100_A010h

LCDIF_CTRL1_SET is 4100_A000h base + 14h offset = 4100_A014h

LCDIF_CTRL1_CLR is 4100_A000h base + 18h offset = 4100_A018h

LCDIF_CTRL1_TOG is 4100_A000h base + 1Ch offset = 4100_A01Ch



LCDIF_CTRL1*n* field descriptions

Field	Description
31–28 RSRVD1	Reserved bits. Write as 0.
27 COMBINE_ MPU_WR_STRB	If this bit is not set, the write strobe will be driven on LCD_WR_RWn pin in the 8080 mode and on the LCD_RD_E pin in the 6800 mode. If it is set, the write strobe of both the 6800 and 8080 modes will be driven only on the LCD_WR_RWn pin. Note that this does not work for read strobe.

Table continues on the next page...

LCDIF_CTRL1*n* field descriptions (continued)

Field	Description
26 BM_ERROR_ IRQ_EN	This bit is set to enable bus master error interrupt in the eLCDIF master mode.
25 BM_ERROR_ IRQ	This bit is set to indicate that an interrupt is requested by the eLCDIF block. This bit is cleared by software by writing a one to its SCT clear address. This bit will be set when the eLCDIF is in master mode and an error response was returned by the slave. 0x0 **NO_REQUEST** — No Interrupt Request Pending. 0x1 **REQUEST** — Interrupt Request Pending.
24 RECOVER_ON_ UNDERFLOW	Set this bit to enable the eLCDIF block to recover in the next field/frame if there was an underflow in the current field/frame.
23 INTERLACE_ FIELDS	Set this bit if it is required that the eLCDIF block fetches odd lines in one field and even lines in the other field. It will work only in LCDIF_MASTER is set to 1.
22 START_ INTERLACE_ FROM_ SECOND_FIELD	The default is to grab the odd lines first and then the even lines. Set this bit if it is required to grab the even lines first and then the odd lines. (Line numbers start from 1, so odd lines are 1,3,5,etc. and even lines are 2,4,6, etc.)
21 FIFO_CLEAR	Set this bit to clear all the data in the latency FIFO (LFIFO), TXFIFO and the RXFIFO.
20 IRQ_ON_ ALTERNATE_ FIELDS	If this bit is set, the eLCDIF block will assert the cur_frame_done interrupt only on alternate fields, otherwise it will issue the interrupt on both odd and even field. This bit is mostly relevant if INTERLACE_FIELDS is set. This feature is only available in DOTCLK and DVI modes.
19–16 BYTE_ PACKING_ FORMAT	This bitfield is used to show which data bytes in a 32-bit word are valid. Default value 0xf indicates that all bytes are valid. For 8-bit transfers, any combination in this bitfield will mean valid data is present in the corresponding bytes. In the 16-bit mode, a 16-bit half-word is valid only if adjacent bits [1:0] or [3:2] or both are 1. A value of 0x0 will mean that none of the bytes are valid and should not be used. For example, set the bit field value to 0x7 if the display data is arranged in the 24-bit unpacked format (A-R-G-B where A value does not have be transmitted). When input data is in YCbCr 4:2:2 format (YCBCR422_INPUT is 1), H_COUNT should be the number of pixels that should be fetched by the block and the BYTE_PACKING_FORMAT should be 0xF.(Note - YCBCR422_INPUT = 1 implies 2 pixels per 32 bits).
15 OVERFLOW_ IRQ_EN	This bit is set to enable an overflow interrupt in the TXFIFO in the write mode.
14 UNDERFLOW_ IRQ_EN	This bit is set to enable an underflow interrupt in the TXFIFO in the write mode.
13 CUR_FRAME_ DONE_IRQ_EN	This bit is set to 1 enable an interrupt every time the hardware enters in the vertical blanking state.
12 VSYNC_EDGE_ IRQ_EN	This bit is set to enable an interrupt every time the hardware encounters the leading VSYNC edge in the VSYNC and DOTCLK modes, or the beginning of every field in DVI mode.

Table continues on the next page...

LCDIF_CTRL1*n* field descriptions (continued)

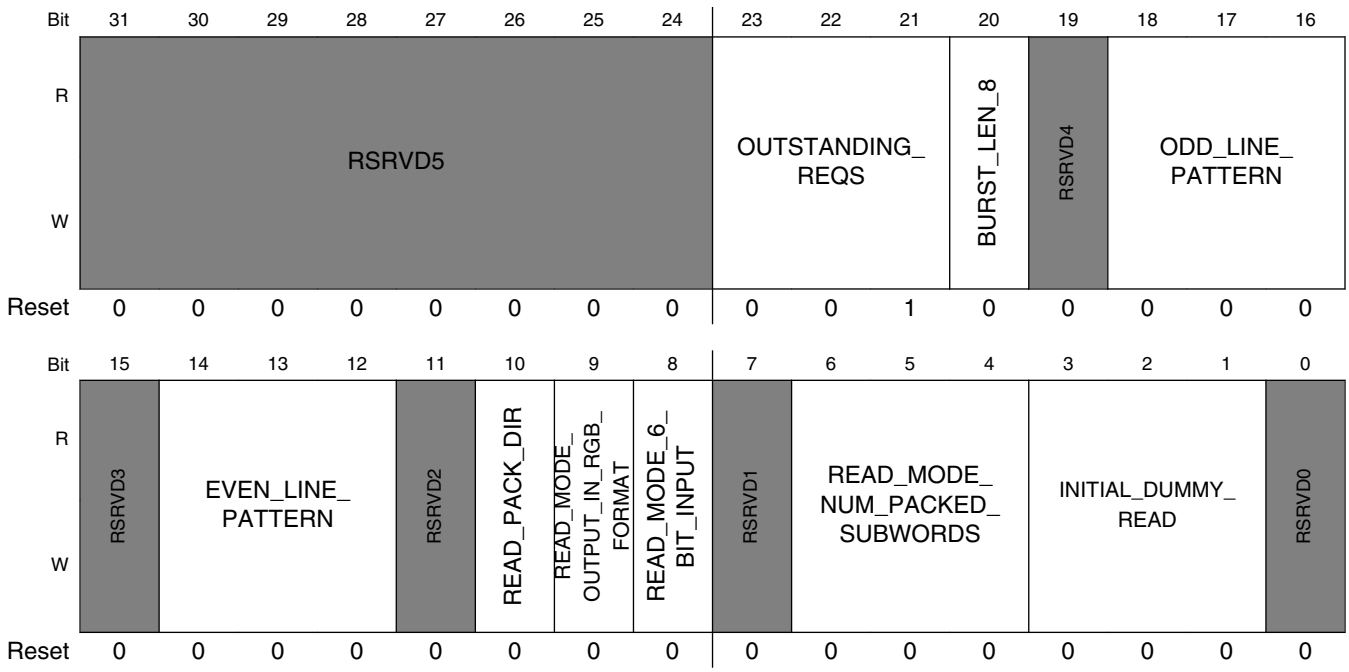
Field	Description
11 OVERFLOW_ IRQ	This bit is set to indicate that an interrupt is requested by the eLCDIF block. This bit is cleared by software by writing a one to its SCT clear address. A latency FIFO (LFIFO) overflow in the write mode (MPU/ VSYNC/DOTCLK/DVI mode) was detected, data samples have been lost. 0x0 **NO_REQUEST** — No Interrupt Request Pending. 0x1 **REQUEST** — Interrupt Request Pending.
10 UNDERFLOW_ IRQ	This bit is set to indicate that an interrupt is requested by the eLCDIF block. This bit is cleared by software by writing a one to its SCT clear address. A TXFIFO underflow in the write mode (MPU/VSYNC/DOTCLK/ DVI mode) was detected. Could produce an error in the DOTCLK / DVI modes. 0x0 **NO_REQUEST** — No Interrupt Request Pending. 0x1 **REQUEST** — Interrupt Request Pending.
9 CUR_FRAME_ DONE_IRQ	This bit is set to indicate that an interrupt is requested by the eLCDIF block. This bit is cleared by software by writing a one to its SCT clear address. It indicates that the hardware has completed transmitting the current frame and is in the vertical blanking period in the DOTCLK/DVI modes. In the MPU and VSYNC modes, this IRQ is asserted at the end of the data transfer indicated by LCDIF_TRANSFER_COUNT register. 0x0 **NO_REQUEST** — No Interrupt Request Pending. 0x1 **REQUEST** — Interrupt Request Pending.
8 VSYNC_EDGE_ IRQ	This bit is set to indicate that an interrupt is requested by the eLCDIF block. This bit is cleared by software by writing a one to its SCT clear address. It is set whenever the leading VSYNC edge is detected in the VSYNC and DOTCLK modes. In the DVI mode, it is asserted every time the block enters a new field. 0x0 **NO_REQUEST** — No Interrupt Request Pending. 0x1 **REQUEST** — Interrupt Request Pending.
7–3 RSRVD0	Reserved bits. Write as 0.
2 BUSY_ENABLE	This bit enables the use of the interface's busy signal input. This should be enabled for LCD controllers that implement a busy line (to stall the eLCDIF from sending more data until ready). Otherwise this bit should be cleared. 0x0 **BUSY_DISABLED** — The busy signal from the LCD controller will be ignored. 0x1 **BUSY_ENABLED** — Enable the use of the busy signal from the LCD controller.
1 MODE86	This bit is used to select between the 8080 and 6800 series of microprocessor modes. This bit should only be changed when RUN is 0. 0x0 **8080_MODE** — Pins LCD_WR_RWn and LCD_RD_E function as active low WR and active low RD signals respectively. 0x1 **6800_MODE** — Pins LCD_WR_RWn and LCD_RD_E function as Read/Writeb and active high Enable signals respectively.
0 RESET	Reset bit for the external LCD controller. This bit can be changed at any time. It CANNOT be reset by SFTRST. 0x0 **LCDRESET_LOW** — LCD_RESET output signal is low. 0x1 **LCDRESET_HIGH** — LCD_RESET output signal is high.

37.4.3 eLCDIF General Control2 Register (LCDIF_CTRL2*n*)

The eLCDIF Control Register provides overall control of the eLCDIF block.

The eLCDIF Control2 Register provides additional programming to the eLCDIF. It implements some bits which are unlikely to change often in a particular application.

Addresses: LCDIF_CTRL2 is 4100_A000h base + 20h offset = 4100_A020h
LCDIF_CTRL2_SET is 4100_A000h base + 24h offset = 4100_A024h
LCDIF_CTRL2_CLR is 4100_A000h base + 28h offset = 4100_A028h
LCDIF_CTRL2_TOG is 4100_A000h base + 2Ch offset = 4100_A02Ch



LCDIF_CTRL2*n* field descriptions

Field	Description
31–24 RSRVD5	Reserved bits. Write as 0.
23–21 OUTSTANDING_ REQS	This bitfield indicates the maximum number of outstanding transactions that eLCDIF should request when it is acting as a bus master. Default is 2 outstanding transactions. 0x0 **REQ_1** — 0x1 **REQ_2** — 0x2 **REQ_4** — 0x3 **REQ_8** — 0x4 **REQ_16** —
20 BURST_LEN_8	By default, when the eLCDIF is in the bus master mode, it will issue AXI bursts of length 16 (except when in packed 24 bpp mode, it will issue bursts of length 15). When this bit is set to 1, the block will

Table continues on the next page...

LCDIF_CTRL2*n* field descriptions (continued)

Field	Description
	issue bursts of length 8 (except when in packed 24 bpp mode, it will issue bursts of length 9). Note that this bitfield is only applicable when LCDIF_MASTER is set to 1.
19 RSRVD4	Reserved bits. Write as 0.
18–16 ODD_LINE_ PATTERN	This field determines the order of the RGB components of each pixel in ODD lines (line numbers 1,3,5,..). This bitfield must be 0 in DVI mode. 0x0 **RGB** — 0x1 **RBG** — 0x2 **GBR** — 0x3 **GRB** — 0x4 **BRG** — 0x5 **BGR** —
15 RSRVD3	Reserved bits. Write as 0.
14–12 EVEN_LINE_ PATTERN	This field determines the order of the RGB components of each pixel in EVEN lines (line numbers 2,4,6,..). This bitfield must be 0 in DVI mode. 0x0 **RGB** — 0x1 **RBG** — 0x2 **GBR** — 0x3 **GRB** — 0x4 **BRG** — 0x5 **BGR** —
11 RSRVD2	Reserved bits. Write as 0.
10 READ_PACK_DIR	The default value of 0 indicates data is stored in the little endian format. When LCD_DATABUS_WIDTH is 8-bit, this bit provides the option of rearranging the data byte-wise in the big endian format. For example, if READ_MODE_NUM_PACKED_SUBWORDS = 3 and the order of incoming data is 0x11, 0x22 and 0x33, then setting this bit to 1 will cause the data to be stored as 0x00112233 as opposed to the default 0x00332211. This operation occurs after the shifting operation done by SHIFT_NUM_BITS bitfield.
9 READ_MODE_ OUTPUT_IN_ RGB_FORMAT	Setting this bit will enable the eLCDIF to convert the incoming data to the RGB format given by WORD_LENGTH bitfield. This feature is not available when WORD_LENGTH is set to 8 bits. eLCDIF performs this operation of converting to RGB format after the endianness has been determined by the READ_PACK_DIR bitfield.
8 READ_MODE_6_ BIT_INPUT	Setting this bit to 1 indicates to eLCDIF that even though LCD_DATABUS_WIDTH is set to 8 bits, the input data is actually only 6 bits wide and exists on D5-D0.
7 RSRVD1	Reserved bits. Write as 0.
6–4 READ_MODE_ NUM_PACKED_ SUBWORDS	Indicates the number of valid 8/16/18/24-bit subwords that will be packed into the 32-bit word in read mode. The subword size (8,16, 18 or 24 bits) is determined by the LCD_DATABUS_WIDTH field. The swizzle operation is performed after READ_MODE_NUM_PACKED_SUBWORDS number of subwords has been received and stored in little-endian format. For example, if LCD_DATABUS_WIDTH is set to 8-bit and data to be read back has to be stored in memory in 24-bit unpacked RGB format, set READ_MODE_NUM_PACKED_SUBWORDS to 0x3 so that each 32-bit word will contain only 3 valid

Table continues on the next page...

LCDIF_CTRL2*n* field descriptions (continued)

Field	Description
	bytes (RGB). Maximum value of READ_MODE_NUM_PACKED_SUBWORDS is 4 for 8-bit databus, 2 for 16-bit databus and 1 for 18/24-bit databus.
3–1 INITIAL_DUMMY_READ	The value in this field determines the number of dummy 8/16/18/24-bit subwords that have to be read back from the LCD panel/controller. They will then not be stored in the read FIFO.
0 RSRVD0	Reserved bits. Write as 0.

37.4.4 eLCDIF Horizontal and Vertical Valid Data Count Register (LCDIF_TRANSFER_COUNT)

This register tells the eLCDIF how much data will be sent for this frame, or transaction. The total number of words is a product of the V_COUNT and H_COUNT fields. The word size is specified by the WORD_LENGTH field.

This register gives the dimensions of the input frame. For normal operation, but V_COUNT and H_COUNT should be non-zero.

Address: LCDIF_TRANSFER_COUNT is 4100_A000h base + 30h offset = 4100_A030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	V_COUNT																H_COUNT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIF_TRANSFER_COUNT field descriptions

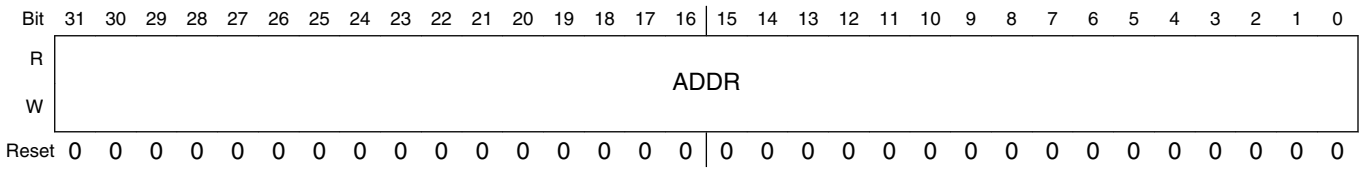
Field	Description
31–16 V_COUNT	Number of horizontal lines per frame which contain valid data. In DOTCLK mode, V_COUNT should be the same as the number of active horizontal lines in a progressive frame. In DVI mode, V_COUNT should be the number of active horizontal lines per frame, and not per field.
15–0 H_COUNT	Total valid data (pixels) in each horizontal line. The data size is given by the WORD_LENGTH. When input data is is in YCbCr 4:2:2 format (YCBCR422_INPUT is 1), H_COUNT should be the number of 32-bit words that should be fetched by the block and the BYTE_PACKING_FORMAT should be 0xF. In 24-bit packed format (WORD_LENGTH=0x3, BYTE_PACKING_FORMAT=0xF), the H_COUNT must be a multiple of 4 pixels. In 16-bit packed format (WORD_LENGTH=0x0, BYTE_PACKING_FORMAT=0xF), the H_COUNT must be a multiple of 2 pixels.

37.4.5 LCD Interface Current Buffer Address Register (LCDIF_CUR_BUF)

This register indicates the address of the current frame being transmitted by eLCDIF.

When the eLCDIF is behaving as a master, this address points to the address of the current frame of data being sent out via the LCDIF. When the current frame is done, the LCDIF block will assert the cur_frame_done interrupt for software to take action. The block will also copy the LCDIF_NEXT_BUF_ADDR into this bitfield so that the software can program the next frame address into the LCDIF_NEXT_BUF_ADDR bitfield. This address must always be double-word aligned.

Address: LCDIF_CUR_BUF is 4100_A000h base + 40h offset = 4100_A040h



LCDIF_CUR_BUF field descriptions

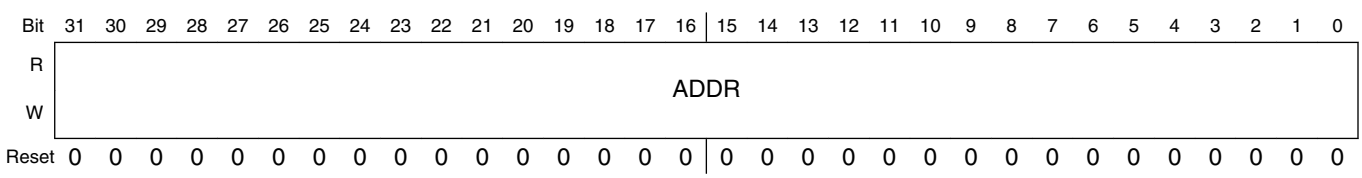
Field	Description
31–0 ADDR	-

37.4.6 LCD Interface Next Buffer Address Register (LCDIF_NEXT_BUF)

This register indicates the address of next frame that will be transmitted by eLCDIF.

When the eLCDIF is behaving as a master, this address points to the address of the next frame of data that will be sent out via the eLCDIF. It is upto the software to make sure that this register is programmed before the end of the current frame, otherwise it might result in old data going out the eLCDIF. This address must always be double-word aligned.

Address: LCDIF_NEXT_BUF is 4100_A000h base + 50h offset = 4100_A050h



LCDIF_NEXT_BUF field descriptions

Field	Description
31–0 ADDR	-

37.4.7 LCD Interface Timing Register (LCDIF_TIMING)

The LCD interface timing register controls the various setup and hold times enforced by the LCD interface in the 6800/8080 MPU and VSYNC modes of operation.

The values used in this register are dependent on the particular LCD controller used, consult the users manual for the particular controller for required timings. Each field of the register must be non-zero, therefore the minimum value is: 0x01010101. NOTE: the timings are not automatically adjusted if the CLK_DIS_LCDIFn frequency changes--it may be necessary to adjust the timings if CLK_DIS_LCDIFn changes. NOTE: Each field in this register must be non-zero for the MPU and VSYNC modes to function. The settings in this register do not affect the DOTCLK and DVI modes.

Address: LCDIF_TIMING is 4100_A000h base + 60h offset = 4100_A060h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	CMD_HOLD								CMD_SETUP								DATA_HOLD								DATA_SETUP							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIF_TIMING field descriptions

Field	Description
31–24 CMD_HOLD	Number of CLK_DIS_LCDIFn cycles that the DCn signal is active after CEn is deasserted.
23–16 CMD_SETUP	Number of CLK_DIS_LCDIFn cycles that the the DCn signal is active before CEn is asserted.
15–8 DATA_HOLD	Data bus hold time in CLK_DIS_LCDIFn cycles. Also the time that the data strobe is de-asserted in a cycle
7–0 DATA_SETUP	Data bus setup time in CLK_DIS_LCDIFn cycles. Also the time that the data strobe is asserted in a cycle.

37.4.8 eLCDIF VSYNC Mode and Dotclk Mode Control Register0 (LCDIF_VDCTRL0*n*)

This register is used to control the VSYNC and DOTCLK modes of the LCDIF so as to work with different types of LCDs like moving picture displays and delta pixel displays.

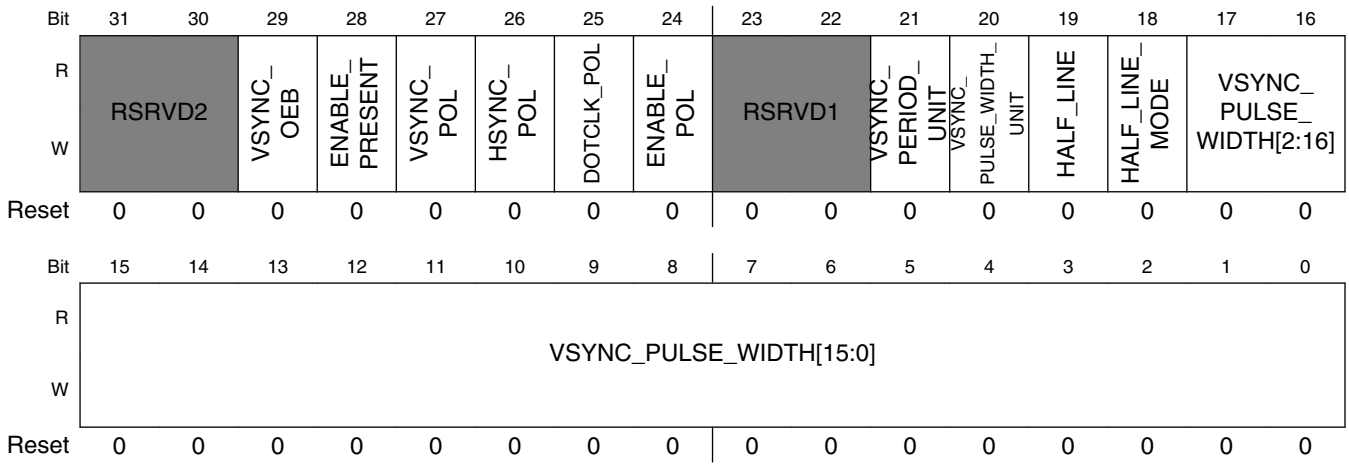
This register gives general programmability to the VSYNC signal including polarity, direction, pulse width, etc.

Addresses: LCDIF_VDCTRL0 is 4100_A000h base + 70h offset = 4100_A070h

LCDIF_VDCTRL0_SET is 4100_A000h base + 74h offset = 4100_A074h

LCDIF_VDCTRL0_CLR is 4100_A000h base + 78h offset = 4100_A078h

LCDIF_VDCTRL0_TOG is 4100_A000h base + 7Ch offset = 4100_A07Ch



LCDIF_VDCTRL0*n* field descriptions

Field	Description
31–30 RSRVD2	Reserved bits. Write as 0.
29 VSYNC_OEB	0 means the VSYNC signal is an output, 1 means it is an input. Should be set to 0 in the DOTCLK mode. 0x0 **VSYNC_OUTPUT** — The VSYNC pin is in the output mode and the VSYNC signal has to be generated by the eLCDIF block. 0x1 **VSYNC_INPUT** — The VSYNC pin is in the input mode and the LCD controller sends the VSYNC signal to the block.
28 ENABLE_ PRESENT	Setting this bit to 1 will make the hardware generate the ENABLE signal in the DOTCLK mode, thereby making it the true RGB interface along with the remaining three signals VSYNC, HSYNC and DOTCLK.
27 VSYNC_POL	Default 0 active low during VSYNC_PULSE_WIDTH time and will be high during the rest of the VSYNC period. Set it to 1 to invert the polarity.
26 HSYNC_POL	Default 0 active low during HSYNC_PULSE_WIDTH time and will be high during the rest of the HSYNC period. Set it to 1 to invert the polarity.
25 DOTCLK_POL	Default is data launched at negative edge of DOTCLK and captured at positive edge. Set it to 1 to invert the polarity. Set it to 0 in DVI mode.
24 ENABLE_POL	Default 0 active low during valid data transfer on each horizontal line.
23–22 RSRVD1	Reserved bits. Write as 0.
21 VSYNC_ PERIOD_UNIT	Default 0 for counting VSYNC_PERIOD in terms of CLK_DIS_LCDIFn cycles. Set it to 1 to count in terms of complete horizontal lines. CLK_DIS_LCDIFn cycles should be used in the VSYNC mode, while horizontal line should be used in the DOTCLK mode.

Table continues on the next page...

LCDIF_VDCTRL0*n* field descriptions (continued)

Field	Description
20 VSYNC_ PULSE_WIDTH_ UNIT	Default 0 for counting VSYNC_PULSE_WIDTH in terms of CLK_DIS_LCDIFn cycles. Set it to 1 to count in terms of complete horizontal lines.
19 HALF_LINE	Setting this bit to 1 will make the total VSYNC period equal to the VSYNC_PERIOD field plus half the HORIZONTAL_PERIOD field (i.e. VSYNC_PERIOD field plus half horizontal line), otherwise it is just VSYNC_PERIOD. Should be only used in the DOTCLK mode, not in the VSYNC interface mode.
18 HALF_LINE_ MODE	When this bit is 0, the first field (VSYNC period) will end in half a horizontal line and the second field will begin with half a horizontal line. When this bit is 1, all fields will end with half a horizontal line, and none will begin with half a horizontal line.
17–0 VSYNC_ PULSE_WIDTH	Number of units for which VSYNC signal is active. For the DOTCLK mode, the unit is determined by the VSYNC_PULSE_WIDTH_UNIT. If the VSYNC_PULSE_WIDTH_UNIT is 0 for DOTCLK mode, VSYNC_PULSE_WIDTH must be less than HSYNC_PERIOD. For the VSYNC interface mode, it should be in terms of number of CLK_DIS_LCDIFn cycles only.

37.4.9 eLCDIF VSYNC Mode and Dotclk Mode Control Register1 (LCDIF_VDCTRL1)

This register is used to control the VSYNC signal in the VSYNC and DOTCLK modes of the block.

This register determines the period and duty cycle of the VSYNC signal when it is generated in the block.

Address: LCDIF_VDCTRL1 is 4100_A000h base + 80h offset = 4100_A080h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	VSYNC_PERIOD																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIF_VDCTRL1 field descriptions

Field	Description
31–0 VSYNC_ PERIOD	Total number of units between two positive or two negative edges of the VSYNC signal. If HALF_LINE is set, it is implicitly calculated to be VSYNC_PERIOD plus half HSYNC_PERIOD.

37.4.10 LCDIF VSYNC Mode and Dotclk Mode Control Register2 (LCDIF_VDCTRL2)

This register is used to control the HSYNC signal in the DOTCLK mode of the block.

This register determines the period and duty cycle of the HSYNC signal when it is generated in the block.

Address: LCDIF_VDCTRL2 is 4100_A000h base + 90h offset = 4100_A090h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	HSYNC_PULSE_WIDTH																HSYNC_PERIOD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIF_VDCTRL2 field descriptions

Field	Description
31–18 HSYNC_ PULSE_WIDTH	Number of CLK_DIS_LCDIFn cycles for which HSYNC signal is active.
17–0 HSYNC_ PERIOD	Total number of CLK_DIS_LCDIFn cycles between two positive or two negative edges of the HSYNC signal.

37.4.11 eLCDIF VSYNC Mode and Dotclk Mode Control Register3 (LCDIF_VDCTRL3)

This register is used to determine the vertical and horizontal wait counts.

This register determines the back porches of HSYNC and VSYNC signals when they are generated by the block.

Address: LCDIF_VDCTRL3 is 4100_A000h base + A0h offset = 4100_A0A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	RSRVD0		MUX_SYNC_SIGNALS	VSYNC_ONLY	HORIZONTAL_WAIT_CNT											
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	VERTICAL_WAIT_CNT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIF_VDCTRL3 field descriptions

Field	Description
31–30 RSRVD0	Reserved bits, write as 0.
29 MUX_SYNC_ SIGNALS	When this bit is set, the eLCDIF block will internally mux HSYNC with LCD_D14, DOTCLK with LCD_D13 and ENABLE with LCD_D12, otherwise these signals will go out on separate pins. This feature can be used to maintain backward compatability with 37xx.
28 VSYNC_ONLY	This bit must be set to 1 in the VSYNC mode of operation, and 0 in the DOTCLK mode of operation.
27–16 HORIZONTAL_ WAIT_CNT	In the DOTCLK mode, wait for this number of clocks from falling edge (or rising if HSYNC_POL is 1) of HSYNC signal to account for horizontal back porch plus the number of DOTCLKs before the moving picture information begins.
15–0 VERTICAL_ WAIT_CNT	In the VSYNC interface mode, wait for this number of CLK_DIS_LCDIFn cycles from the falling VSYNC edge (or rising if VSYNC_POL is 1) before starting LCD transactions and is applicable only if WAIT_FOR_VSYNC_EDGE is set. Minimum is CMD_SETUP+5. In the DOTCLK mode, it accounts for the veritcal back porch lines plus the number of horizontal lines before the moving picture begins. The unit for this parameter is inherently the same as the VSYNC_PERIOD_UNIT.

37.4.12 eLCDIF VSYNC Mode and Dotclk Mode Control Register4 (LCDIF_VDCTRL4)

This register is used to control the DOTCLK mode of the block.

This register determines the active data in each horizontal line in the DOTCLK mode. Note that the total number of active horizontal lines in the DOTCLK mode is the same as the V_COUNT bitfield in the LCDIF_TRANSFER_COUNT register.

Address: LCDIF_VDCTRL4 is 4100_A000h base + B0h offset = 4100_A0B0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	DOTCLK_DLY_SEL			RSRVD0										SYNC_ SIGNALS_ON	DOTCLK_H_ VALID_ DATA_CNT [2:16]	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DOTCLK_H_VALID_DATA_CNT[15:0]															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIF_VDCTRL4 field descriptions

Field	Description
31–29 DOTCLK_DLY_SEL	This bitfield selects the amount of time by which the DOTCLK signal should be delayed before coming out of the LCD_DOTCK pin. 0 = 2ns; 1=4ns;2=6ns;3=8ns. Remaining values are reserved.
28–19 RSRVD0	Reserved bits, write as 0.
18 SYNC_SIGNALS_ON	Set this field to 1 if the LCD controller requires that the VSYNC or VSYNC/HSYNC/DOTCLK control signals should be active atleast one frame before the data transfers actually start and remain active atleast one frame after the data transfers end. The hardware does not count the number of frames automatically. Rather, the VSYNC edge interrupt can be monitored by software to count the number of frames that have occured after this bit is set and then the RUN bit can be set to start the data transactions. This bit must always be set in the DOTCLK mode of operation, and it must be set in the VSYNC mode of operation when VSYNC signal is an output.
17–0 DOTCLK_H_VALID_DATA_CNT	Total number of CLK_DIS_LCDIFn cycles on each horizontal line that carry valid data in DOTCLK mode.

37.4.13 Digital Video Interface Control0 Register (LCDIF_DVICTRL0)

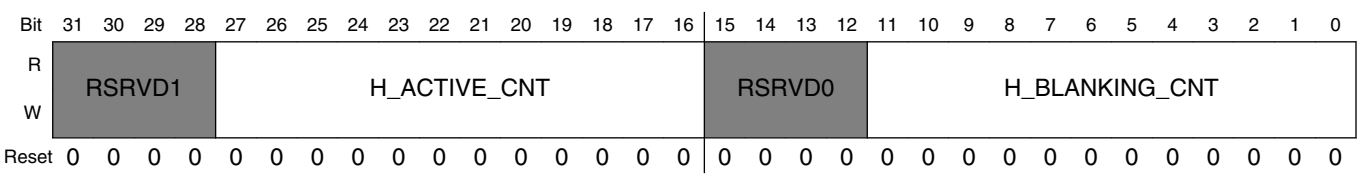
The Digital Video interface Control0 register provides the overall control of the Digital Video interface.

This register gives information about the horizontal active, horizontal blanking and total number of lines in the ITU-R BT.656 interface.

EXAMPLE

```
//525/60 video system
HW_LCDIF_DVICTRL0_H_ACTIVE_CNT_WR(0x5A0);//1440
HW_LCDIF_DVICTRL0_H_BLANKING_CNT_WR(0x106);//262
//625/50 video system
HW_LCDIF_DVICTRL0_H_ACTIVE_CNT_WR(0x5A0);//1440
HW_LCDIF_DVICTRL0_H_BLANKING_CNT_WR(0x112);//274
```

Address: LCDIF_DVICTRL0 is 4100_A000h base + C0h offset = 4100_A0C0h



LCDIF_DVICTRL0 field descriptions

Field	Description
31–28 RSRVD1	Reserved bits, write as 0.
27–16 H_ACTIVE_CNT	Number of active video samples to be transmitted. (Mostly will be 1440 for both PAL and NTSC). Must always be a multiple of 4.
15–12 RSRVD0	Reserved bits, write as 0.
11–0 H_BLANKING_ CNT	Number of blanking samples to be inserted between EAV and SAV during horizontal blanking interval.

37.4.14 Digital Video Interface Control1 Register (LCDIF_DVICTRL1)

The Digital Video interface Control1 register provides the overall control of the Digital Video interface.

This register contains information about the Field1 start and end, and the Field2 start in the ITU-R BT.656 interface.

EXAMPLE

```
//525/60 video system
HW_LCDIF_DVICTRL1_F1_START_LINE_WR(0x4);//4
HW_LCDIF_DVICTRL1_F1_END_LINE_WR(0x109);//265
HW_LCDIF_DVICTRL1_F2_START_LINE_WR(0x10A);//266
//625/50 video system
HW_LCDIF_DVICTRL1_F1_START_LINE_WR(0x1);//1
HW_LCDIF_DVICTRL1_F1_END_LINE_WR(0x138);//312
HW_LCDIF_DVICTRL1_F2_START_LINE_WR(0x139);//313
```

Address: LCDIF_DVICTRL1 is 4100_A000h base + D0h offset = 4100_A0D0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	RSRVD0		F1_START_LINE										F1_END_LINE[-6:6]			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	F1_END_LINE[5:0]								F2_START_LINE							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIF_DVICTRL1 field descriptions

Field	Description
31–30 RSRVD0	Reserved bits, write as 0.
29–20 F1_START_ LINE	Vertical line number from which Field 1 begins.
19–10 F1_END_LINE	Vertical line number at which Field1 ends.
9–0 F2_START_ LINE	Vertical line number from which Field 2 begins.

37.4.15 Digital Video Interface Control2 Register (LCDIF_DVICTRL2)

The Digital Video interface Control2 register provides the overall control of the Digital Video interface.

This register contains information about the Field2 end, and the Vertical Blanking1 interval in the ITU-R BT.656 interface.

EXAMPLE

```
//525/60 video system
HW_LCDIF_DVICTRL2_F2_END_LINE_WR(0x3);//3
HW_LCDIF_DVICTRL2_V1_BLANK_START_LINE_WR(0x108);//264
HW_LCDIF_DVICTRL2_V1_BLANK_END_LINE_WR(0x11A);//282
//625/50 video system
HW_LCDIF_DVICTRL2_F2_END_LINE_WR(0x271);//625
HW_LCDIF_DVICTRL2_V1_BLANK_START_LINE_WR(0x137);//311
HW_LCDIF_DVICTRL2_V1_BLANK_END_LINE_WR(0x14F);//335
```

Address: LCDIF_DVICTRL2 is 4100_A000h base + E0h offset = 4100_A0E0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	RSRVD0		F2_END_LINE										V1_BLANK_START_LINE [-6:6]			
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	V1_BLANK_START_LINE[5:0]								V1_BLANK_END_LINE							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIF_DVICTRL2 field descriptions

Field	Description
31–30 RSRVD0	Reserved bits, write as 0.
29–20 F2_END_LINE	Vertical line number at which Field 2 ends.
19–10 V1_BLANK_ START_LINE	Vertical line number towards the end of Field1 where first Vertical Blanking interval starts.
9–0 V1_BLANK_ END_LINE	Vertical line number in the beginning part of Field2 where first Vertical Blanking interval ends.

37.4.16 Digital Video Interface Control3 Register (LCDIF_DVICTRL3)

The Digital Video interface Control3 register provides the overall control of the Digital Video interface.

This register contains information about the Vertical Blanking2 interval in the ITU-R BT. 656 interface.

EXAMPLE

```
//525/60 video system
HW_LCDIF_DVICTRL3_V2_BLANK_START_LINE_WR(0x1);//1
HW_LCDIF_DVICTRL3_V2_BLANK_END_LINE_WR(0x13);//19
HW_LCDIF_DVICTRL0_V_LINES_CNT_WR(0x20D);//525
//625/50 video system
HW_LCDIF_DVICTRL3_V2_BLANK_START_LINE_WR(0x270);//624
HW_LCDIF_DVICTRL3_V2_BLANK_END_LINE_WR(0x16);//22
HW_LCDIF_DVICTRL0_V_LINES_CNT_WR(0x271);//625
```

Address: LCDIF_DVICTRL3 is 4100_A000h base + F0h offset = 4100_A0F0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	RSRVD0		V2_BLANK_START_LINE										V2_BLANK_END_LINE [-6:6]

R W	V2_BLANK_END_LINE[5:0]						V_LINES_CNT									
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIF_DVICTRL3 field descriptions

Field	Description
31–30 RSRVD0	Reserved bits, write as 0.
29–20 V2_BLANK_ START_LINE	Vertical line number towards the end of Field2 where second Vertical Blanking interval starts.
19–10 V2_BLANK_ END_LINE	Vertical line number in the beginning part of Field1 where second Vertical Blanking interval ends.
9–0 V_LINES_CNT	Total number of vertical lines per frame (generally 525 or 625)

37.4.17 Digital Video Interface Control4 Register (LCDIF_DVICTRL4)

The Digital Video interface Control4 register provides the overall control of the Digital Video interface.

This register is used to add side borders to the output if the input frame width is less than 720 pixels.

EXAMPLE

```
                //If input frame has only 640 pixels per line, but output is supposed to have
720 pixels per line.
                HW_LCDIF_DVICTRL4_H_FILL_CNT_WR(0x50);//80
                HW_LCDIF_DVICTRL4_Y_FILL_VALUE_WR(0x10);//16
                HW_LCDIF_DVICTRL4_CB_FILL_VALUE_WR(0x80);//128
                HW_LCDIF_DVICTRL4_CR_FILL_VALUE_WR(0x80);//128
```

Address: LCDIF_DVICTRL4 is 4100_A000h base + 100h offset = 4100_A100h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	Y_FILL_VALUE								CB_FILL_VALUE								CR_FILL_VALUE								H_FILL_CNT							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIF_DVICTRL4 field descriptions

Field	Description
31–24 Y_FILL_VALUE	Value of Y component of filler data
23–16 CB_FILL_ VALUE	Value of CB component of filler data

Table continues on the next page...

LCDIF_DVICTRL4 field descriptions (continued)

Field	Description
15–8 CR_FILL_ VALUE	Value of CR component of filler data.
7–0 H_FILL_CNT	Number of active video samples that have to be filled with the filler data in the front and back portions of the active horizontal interval. Must be a multiple of 4. This field will have to be programmed if the input frame has less than 720 pixels per line.

37.4.18 RGB to YCbCr 4:2:2 CSC Coefficient0 Register (LCDIF_CSC_COEFF0)

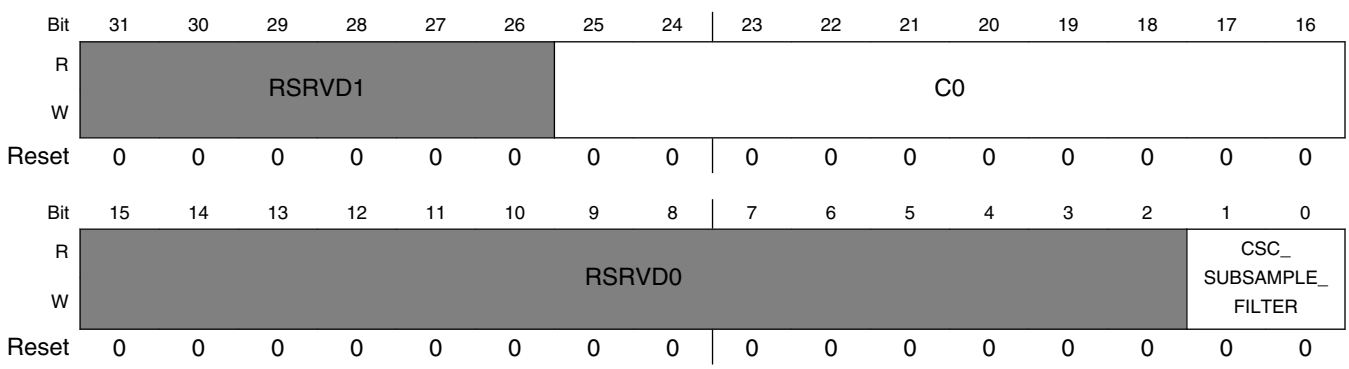
LCDIF_CSC_COEFF0 register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by: Y = C0*R + C1*G + C2*B + Y_offset Cb= C3*R + C4*G + C5*B + CbCr_offset Cr= C6*R + C7*G + C8*B + CbCr_offset

This register carries programming information about RGB to YCbCr 4:2:2 CSC.

EXAMPLE

```
HW_LCDIF_CSC_COEFF0_C0_WR(0x41);//0.257x256=65
HW_LCDIF_CSC_COEFF0_CSC_SUBSAMPLE_FILTER_WR(0x3);
```

Address: LCDIF_CSC_COEFF0 is 4100_A000h base + 110h offset = 4100_A110h



LCDIF_CSC_COEFF0 field descriptions

Field	Description
31–26 RSRVD1	Reserved bits, write as 0.
25–16 C0	Two's complement red multiplier coefficient for Y

Table continues on the next page...

LCDIF_CSC_COEFF0 field descriptions (continued)

Field	Description
15–2 RSRVD0	Reserved bits, write as 0.
1–0 CSC_ SUBSAMPLE_ FILTER	This register describes the filtering and subsampling scheme to be performed on the chroma components in order to convert from YCbCr 4:4:4 to YCbCr 4:2:2 space. Note that the following descriptions apply individually to Cb and Cr. 0x0 **SAMPLE_AND_HOLD** — No filtering, simply keep every chroma value for samples numbered 2n and discard chroma values associated with all samples numbered 2n+1. 0x1 **RSRVD** — Reserved 0x2 **INTERSTITIAL** — Chroma samples numbered 2n and 2n+1 are averaged (weights 1/2, 1/2) and that chroma value replaces the two chroma values at 2n and 2n+1. This chroma now exists horizontally halfway between the two luma samples. 0x3 **COSITED** — Chroma samples numbered 2n-1, 2n, and 2n+1 are averaged (weights 1/4,1/2,1/4) and that chroma value exists at the same site as the luma sample numbered 2n and the chroma samples at 2n+1 are discarded.

37.4.19 RGB to YCbCr 4:2:2 CSC Coefficient1 Register (LCDIF_CSC_COEFF1)

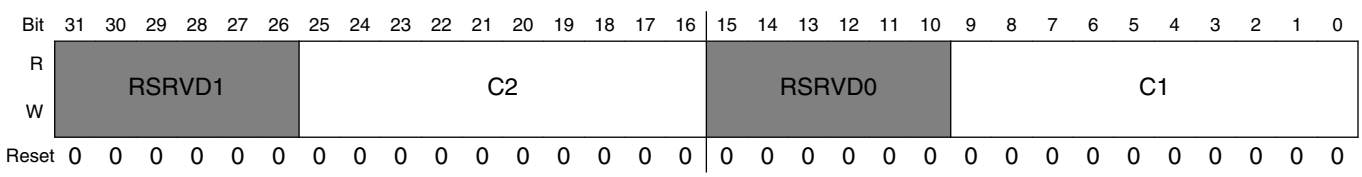
LCDIF_CSC_COEFF1 register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by: Y = C0*R + C1*G + C2*B + Y_offset Cb= C3*R + C4*G + C5*B + CbCr_offset Cr= C6*R + C7*G + C8*B + CbCr_offset

This register carries programming information about RGB to YCbCr 4:2:2 CSC.

EXAMPLE

```
HW_LCDIF_CSC_COEFF1_C1_WR(0x81);//0.504x256=129
HW_LCDIF_CSC_COEFF1_C2_WR(0x19);//0.098x256=25
```

Address: LCDIF_CSC_COEFF1 is 4100_A000h base + 120h offset = 4100_A120h



LCDIF_CSC_COEFF1 field descriptions

Field	Description
31–26 RSRVD1	Reserved bits, write as 0.

Table continues on the next page...

LCDIF_CSC_COEFF1 field descriptions (continued)

Field	Description
25–16 C2	Two's complement blue multiplier coefficient for Y
15–10 RSRVD0	Reserved bits, write as 0.
9–0 C1	Two's complement green multiplier coefficient for Y

37.4.20 RGB to YCbCr 4:2:2 CSC Coefficent2 Register (LCDIF_CSC_COEFF2)

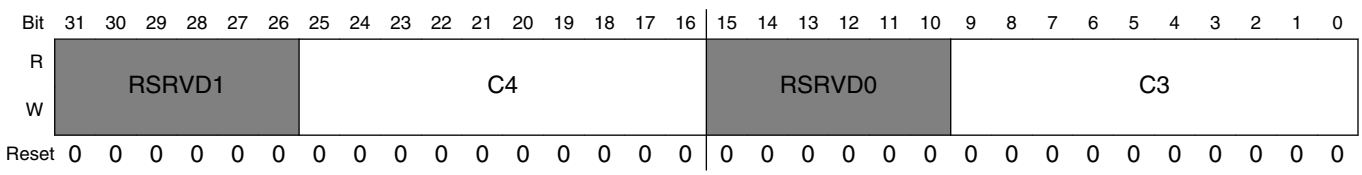
LCDIF_CSC_COEFF2 register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by: Y = C0*R + C1*G + C2*B + Y_offset Cb= C3*R + C4*G + C5*B + CbCr_offset Cr= C6*R + C7*G + C8*B + CbCr_offset

This register carries programming information about RGB to YCbCr 4:2:2 CSC.

EXAMPLE

```
HW_LCDIF_CSC_COEFF2_C3_WR(0x3DB);//-0.148x256=-37
HW_LCDIF_CSC_COEFF2_C4_WR(0x3B6);//-0.291x256=-74
```

Address: LCDIF_CSC_COEFF2 is 4100_A000h base + 130h offset = 4100_A130h



LCDIF_CSC_COEFF2 field descriptions

Field	Description
31–26 RSRVD1	Reserved bits, write as 0.
25–16 C4	Two's complement green multiplier coefficient for Cb
15–10 RSRVD0	Reserved bits, write as 0.
9–0 C3	Two's complement red multiplier coefficient for Cb

37.4.21 RGB to YCbCr 4:2:2 CSC Coefficient3 Register (LCDIF_CSC_COEFF3)

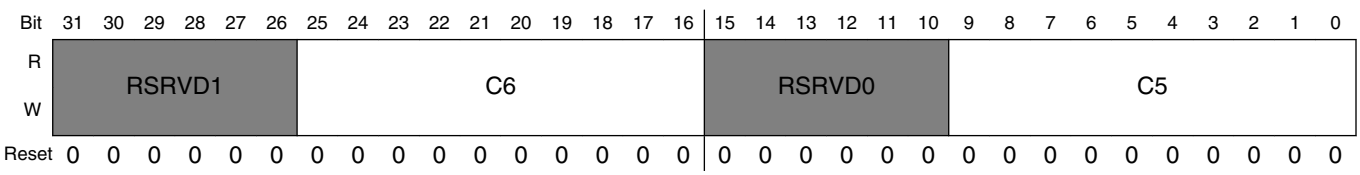
LCDIF_CSC_COEFF3 register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by: Y = C0*R + C1*G + C2*B + Y_offset Cb= C3*R + C4*G + C5*B + CbCr_offset Cr= C6*R + C7*G + C8*B + CbCr_offset

This register carries programming information about RGB to YCbCr 4:2:2 CSC.

EXAMPLE

```
HW_LCDIF_CSC_COEFF3_C5_WR(0x70);//0.439x256=112
HW_LCDIF_CSC_COEFF3_C6_WR(0x70);//0.439x256=112
```

Address: LCDIF_CSC_COEFF3 is 4100_A000h base + 140h offset = 4100_A140h



LCDIF_CSC_COEFF3 field descriptions

Field	Description
31–26 RSRVD1	Reserved bits, write as 0.
25–16 C6	Two's complement red multiplier coefficient for Cr
15–10 RSRVD0	Reserved bits, write as 0.
9–0 C5	Two's complement blue multiplier coefficient for Cb

37.4.22 RGB to YCbCr 4:2:2 CSC Coefficient4 Register (LCDIF_CSC_COEFF4)

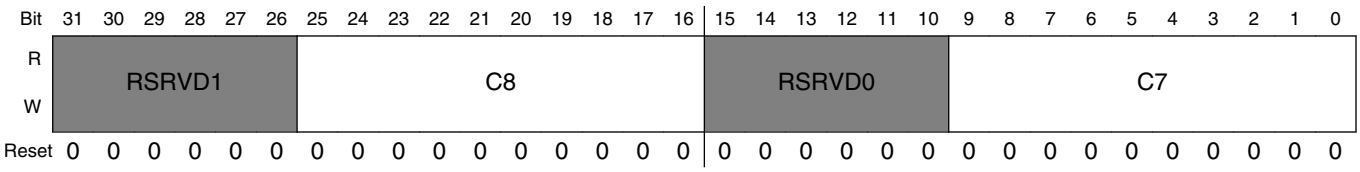
LCDIF_CSC_COEFF4 register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by: Y = C0*R + C1*G + C2*B + Y_offset Cb= C3*R + C4*G + C5*B + CbCr_offset Cr= C6*R + C7*G + C8*B + CbCr_offset

This register carries programming information about RGB to YCbCr 4:2:2 CSC.

EXAMPLE

```
HW_LCDIF_CSC_COEFF4_C7_WR(0x3A2);//-0.368x256=-94
HW_LCDIF_CSC_COEFF4_C8_WR(0x3EE);//-0.071x256=-18
```

Address: LCDIF_CSC_COEFF4 is 4100_A000h base + 150h offset = 4100_A150h



LCDIF_CSC_COEFF4 field descriptions

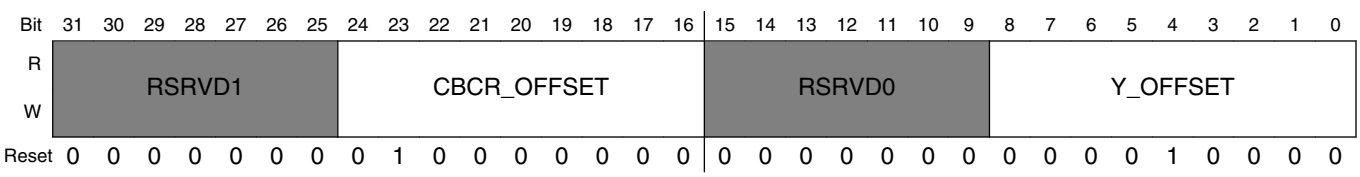
Field	Description
31–26 RSRVD1	Reserved bits, write as 0.
25–16 C8	Two's complement blue multiplier coefficient for Cr
15–10 RSRVD0	Reserved bits, write as 0.
9–0 C7	Two's complement green multiplier coefficient for Cr

37.4.23 RGB to YCbCr 4:2:2 CSC Offset Register (LCDIF_CSC_OFFSET)

LCDIF_CSC_ register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by: Y = C0*R + C1*G + C2*B + Y_offset Cb= C3*R + C4*G + C5*B + CbCr_offset Cr= C6*R + C7*G + C8*B + CbCr_offset

This register carries programming information about RGB to YCbCr 4:2:2 CSC.

Address: LCDIF_CSC_OFFSET is 4100_A000h base + 160h offset = 4100_A160h



LCDIF_CSC_OFFSET field descriptions

Field	Description
31–25 RSRVD1	Reserved bits, write as 0.
24–16 CBCR_OFFSET	Two's complement offset for the Cb and Cr components
15–9 RSRVD0	Reserved bits, write as 0.
8–0 Y_OFFSET	Two's complement offset for the Y component

37.4.24 RGB to YCbCr 4:2:2 CSC Limit Register (LCDIF_CSC_LIMIT)

LCDIF_CSC_CTRL0 register provides overall control over color space conversion from RGB to 4:2:2 YCbCr. The equations for the conversion are given by: Y = C0*R + C1*G + C2*B + Y_offset Cb= C3*R + C4*G + C5*B + CbCr_offset Cr= C6*R + C7*G + C8*B + CbCr_offset

This register carries programming information about RGB to YCbCr 4:2:2 CSC. Note that the values in this register are unsigned.

EXAMPLE

```
HW_LCDIF_CSC_LIMIT_CBCR_MIN_WR(0x10);//16
HW_LCDIF_CSC_LIMIT_CBCR_MAX_WR(0xF0);//240
HW_LCDIF_CSC_LIMIT_Y_MIN_WR(0x10);//16
HW_LCDIF_CSC_LIMIT_Y_MAX_WR(0xEB);//235
```

Address: LCDIF_CSC_LIMIT is 4100_A000h base + 170h offset = 4100_A170h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	CBCR_MIN								CBCR_MAX								Y_MIN								Y_MAX							
Reset	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1	0	0	0	0	0	0	0	0	1	1	1	1	1	1	1	1

LCDIF_CSC_LIMIT field descriptions

Field	Description
31–24 CBCR_MIN	Lower limit of Cb and Cr after RGB to 4:2:2 YCbCr conversion
23–16 CBCR_MAX	Upper limit of Cb and Cr after RGB to 4:2:2 YCbCr conversion
15–8 Y_MIN	Lower limit of Y after RGB to 4:2:2 YCbCr conversion

Table continues on the next page...

LCDIF_CSC_LIMIT field descriptions (continued)

Field	Description
7–0 Y_MAX	Upper limit of Y after RGB to 4:2:2 YCbCr conversion

37.4.25 LCD Interface Data Register (LCDIF_DATA)

NOTE: this is now an unsupported feature of the eLCDIF and this should be removed from the design. The data sent to an external LCD controller is written to this register. Data can be written to this register (from the processor\'s perspective) as bytes half-words (16 bits) or words (32 bits) as appropriate.

This register holds the 32-bit word written by either the ARM platform or the DMA into LCDIF. This data then gets sent out by the block across the interface. When the block is in bus master mode, this register gets the value of the lower 32 bits of the 64-bit data bus whenever it is received.

Address: LCDIF_DATA is 4100_A000h base + 180h offset = 4100_A180h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DATA_THREE								DATA_TWO								DATA_ONE								DATA_ZERO							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIF_DATA field descriptions

Field	Description
31–24 DATA_THREE	Byte 3 (most significant byte) of data written to LCDIF by the DMA or the ARM platform.
23–16 DATA_TWO	Byte 2 of data written to eLCDIF by the DMA or the ARM platform.
15–8 DATA_ONE	Byte 1 of data written to eLCDIF by the DMA or the ARM platform.
7–0 DATA_ZERO	Byte 0 (least significant byte) of data written to eLCDIF by the DMA or the ARM platform.

37.4.26 Bus Master Error Status Register (LCDIF_BM_ERROR_STAT)

This register reflects the virtual address at which the AXI master received an error response from the slave.

When the BM_ERROR_IRQ is asserted, the address of the bus error is updated in the register.

Address: LCDIF_BM_ERROR_STAT is 4100_A000h base + 190h offset = 4100_A190h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	ADDR																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIF_BM_ERROR_STAT field descriptions

Field	Description
31–0 ADDR	Virtual address at which bus master error occurred.

37.4.27 CRC Status Register (LCDIF_CRC_STAT)

This register reflects the CRC value of each frame sent out by eLCDIF. The CRC is done on the final output bus, so the value will be dependent on the LCD_DATABUS_WIDTH bitfield even if the input data is the same.

This register will be updated when the CUR_FRAME_DONE_IRQ is asserted. In the case of DVI mode, the CRC is calculated for the entire frame, not separately for each field in the frame.

Address: LCDIF_CRC_STAT is 4100_A000h base + 1A0h offset = 4100_A1A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LCDIF_CRC_STAT field descriptions

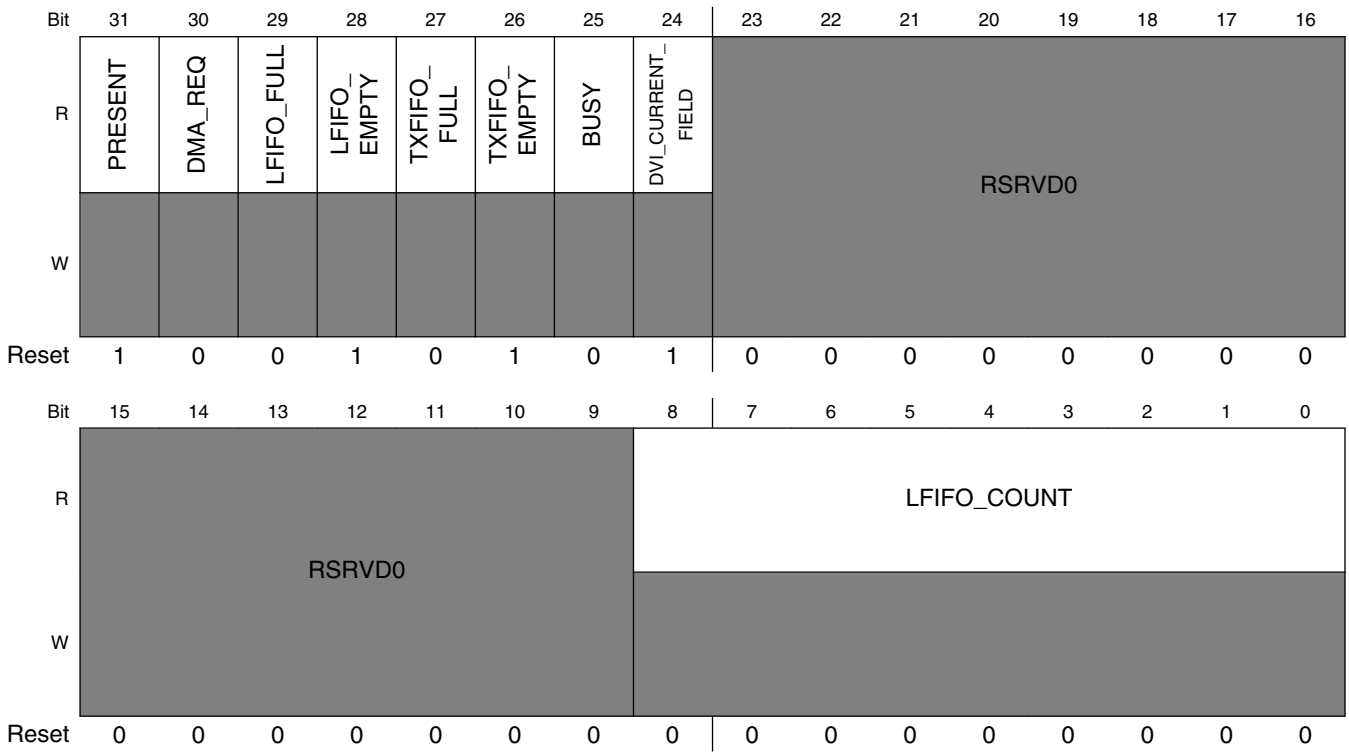
Field	Description
31–0 CRC_VALUE	Calculated CRC value.

37.4.28 LCD Interface Status Register (LCDIF_STAT)

The LCD interface status register can be used to check the current status of the eLCDIF block.

The LCD interface status register that contains read only views of some parameters or current state of the block.

Address: LCDIF_STAT is 4100_A000h base + 1B0h offset = 4100_A1B0h



LCDIF_STAT field descriptions

Field	Description
31 PRESENT	0: eLCDIF not present on this product 1: eLCDIF is present.
30 DMA_REQ	Reflects the current state of the DMA Request line for the eLCDIF. The DMA Request line toggles for each new request.
29 LFIFO_FULL	Read only view of the signal that indicates that LCD read datapath FIFO is full, will be generally used in the write mode of the LCD interface.
28 LFIFO_EMPTY	Read only view of the signal that indicates that LCD read dapatath FIFO is empty, will be generally used in the read mode of the LCD interface.
27 TXFIFO_FULL	Read only view of the signal that indicates that LCD write datapath FIFO is full, will be generally used in the write mode of the LCD interface.
26 TXFIFO_EMPTY	Read only view of the signal that indicates that LCD write dapatath FIFO is empty, will be generally used in the read mode of the LCD interface.
25 BUSY	Read only view of the input busy signal from the external LCD controller.
24 DVI_CURRENT_ FIELD	Read only view of the current field being transmitted. DVI_CURRENT_FIELD = 0 means field 1. DVI_CURRENT_FIELD = 1 means field 2.
23–9 RSRVD0	Reserved bits. Write as 0.
8–0 LFIFO_COUNT	Read only view of the current count in Latency buffer (LFIFO).

37.4.29 LCD Interface Version Register (LCDIF_VERSION)

The LCD interface version register can be used to read the version of the eLCDIF IP being used in this SoC.

The LCD interface debug register is for diagnostic use only.

Address: LCDIF_VERSION is 4100_A000h base + 1C0h offset = 4100_A1C0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LCDIF_VERSION field descriptions

Field	Description
31–24 MAJOR	Fixed read-only value reflecting the MAJOR field of RTL version.
23–16 MINOR	Fixed read-only value reflecting the MINOR field of RTL version.
15–0 STEP	Fixed read-only value reflecting the stepping of RTL version.

37.4.30 LCD Interface Debug0 Register (LCDIF_DEBUG0)

The LCD interface debug0 register provides a diagnostic view of the state machine and other useful internal signals.

The LCD interface debug register is for diagnostic use only.

Address: LCDIF_DEBUG0 is 4100_A000h base + 1D0h offset = 4100_A1D0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

LCDIF_DEBUG0 field descriptions

Field	Description
31 STREAMING_END_DETECTED	Read only view of the DOTCLK_MODE or DVI_MODE bit going from 1 to 0.
30 WAIT_FOR_VSYNC_EDGE_OUT	Read only view of WAIT_FOR_VSYNC_EDGE bit in the VSYNC mode after it comes out of the TXFIFO.
29 SYNC_SIGNALS_ON_REG	Read only view of internal sync_signals_on_reg signal.
28 DMACMDKICK	Read only view of the DMA command kick signal.
27 ENABLE	Read only view of ENABLE signal.
26 HSYNC	Read only view of HSYNC signal.

Table continues on the next page...

LCDIF_DEBUG0 field descriptions (continued)

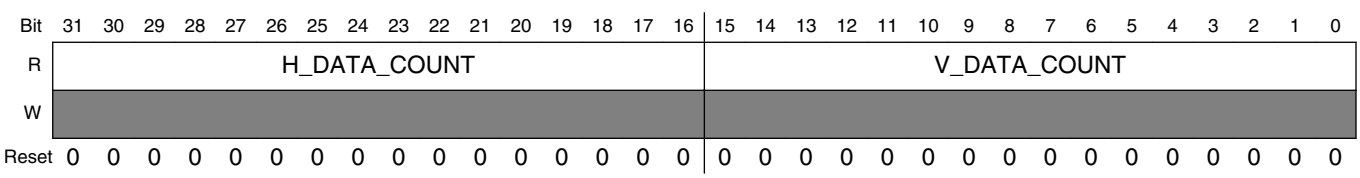
Field	Description
25 VSYNC	Read only view of VSYNC signal.
24 CUR_FRAME_TX	This bit is 1 for the time the current frame is being transmitted in the VSYNC mode. Useful for VSYNC mode debug.
23 EMPTY_WORD	Indicates that the current word is empty.
22–16 CUR_STATE	Read only view of the current state machine state in the current mode of operation.
15 PXP_LCDIF_B0_READY	Buffer0 ready signal issued by ePXP.
14 PXP_B0_DONE	Buffer0 done signal issued by eLCDIF.
13 PXP_LCDIF_B1_READY	Buffer1 ready signal issued by ePXP.
12 PXP_B1_DONE	Buffer1 done signal issued by eLCDIF.
11–10 CUR_REQ_STATE	Read only view of the request state machine.
9 MST_AVALID	Read only view of the mst_avalid signal issued by the AXI bus master.
8–4 MST_OUTSTANDING_REQS	Read only view of the current outstanding requests issued by the AXI bus master.
3–0 MST_WORDS	Read only view of the current bursts issued by the AXI bus master.

37.4.31 LCD Interface Debug1 Register (LCDIF_DEBUG1)

The LCD interface debug1 register provides a diagnostic view of the state machine and other useful internal signals.

The LCD interface debug register is for diagnostic use only.

Address: LCDIF_DEBUG1 is 4100_A000h base + 1E0h offset = 4100_A1E0h



LCDIF_DEBUG1 field descriptions

Field	Description
31–16 H_DATA_ COUNT	Read only view of the current state of the horizontal data counter.
15–0 V_DATA_ COUNT	Read only view of the current state of the vertical data counter.

37.4.32 LCD Interface Debug2 Register (LCDIF_DEBUG2)

The LCD interface debug2 register provides a diagnostic view of the state machine and other useful internal signals.

The LCD interface debug register is for diagnostic use only.

Address: LCDIF_DEBUG2 is 4100_A000h base + 1F0h offset = 4100_A1F0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LCDIF_DEBUG2 field descriptions

Field	Description
31–0 MST_ADDRESS	Read only view of the current address issued by the AXI bus master.

37.4.33 eLCDIF Threshold Register (LCDIF_THRES)

This register is used to activate control signals when the number of pixels reaches the programmed threshold. These control signals, in turn, can be used to manipulate access priority or dynamically change the input clock frequency to meet the required pixel throughput.

Memory request priority threshold register.

Address: LCDIF_THRES is 4100_A000h base + 200h offset = 4100_A200h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

LCDIF_THRES field descriptions

Field	Description
31–25 RSRVD2	Reserved bits. Write as 0.
24–16 FASTCLOCK	This value should be set to a value of pixels, from 0 to 511. When the number of pixels in the input pixel FIFO is LESS than this value, the fast clock control output will be raised. This signal can be used to reduce the system bus clock frequency to save power during horizontal/vertical blanking intervals. This value should also be programmed to a value that is greater than the "PANIC" threshold value. This will allow a faster clock to recover the number of pixels in the FIFO before a "panic" level is encountered.
15–9 RSRVD1	Reserved bits. Write as 0.
8–0 PANIC	This value should be set to a value of pixels, from 0 to 511. When the number of pixels in the input pixel FIFO is LESS than this value, the panic control output will be raised. This signal can be used to raise the access eLCDIF's access priority.

Chapter 38
On-Chip OTP (OCOTP) Controller

38.1 Introduction

This chapter describes the requirements for the on-chip TSMC eFuse OTP controller. It describes the block functionality and implementation in detail. In this document, the words “eFuse” and “OTP” are interchangeable. OCOTP refers to the hardware block itself. For more information on eFuse, refer to the latest version of TSMC’s 256-bit serial interface electrical fuse specification.

38.2 Overview of On-Chip OTP APB Slave (OCOTP)

The OCOTP provides the following features :

- 32-bit word restricted access to 1.25 Kbyte of TSMC eFuse OTP ROM through APB.
- Memory mapped access for reading eFuse contents.
- Data-register access for programming eFuse contents.
- Generation of hwv_fuse (hardware visible fuse bus) and the hwv_reg bus which is made up of volatile PIO register based “fuses”. The hwv_reg bits come from the SCS (Software Controllable Signals) register.
- Sending of crypto keys and read enable via parallel connections. The 128-bit AES crypto key is sent 32-bits at a time over 4 apb_clk cycles. This key is comprised of OCOTP_SCC0 through OCOTP_SCC3. The second key (the “unique” key used for content key encryption) is 64-bits sent 32-bits at a time over 2 apb_clk cycles. This key is comprised of OCOTP_CFG0 and OCOTP_CFG1.
- Chip-level pin access to unrestricted portions of OTP.
- Loading and housing of fuse and LOCK shadow registers.

38.3 Top-Level Symbol and Functional Overview

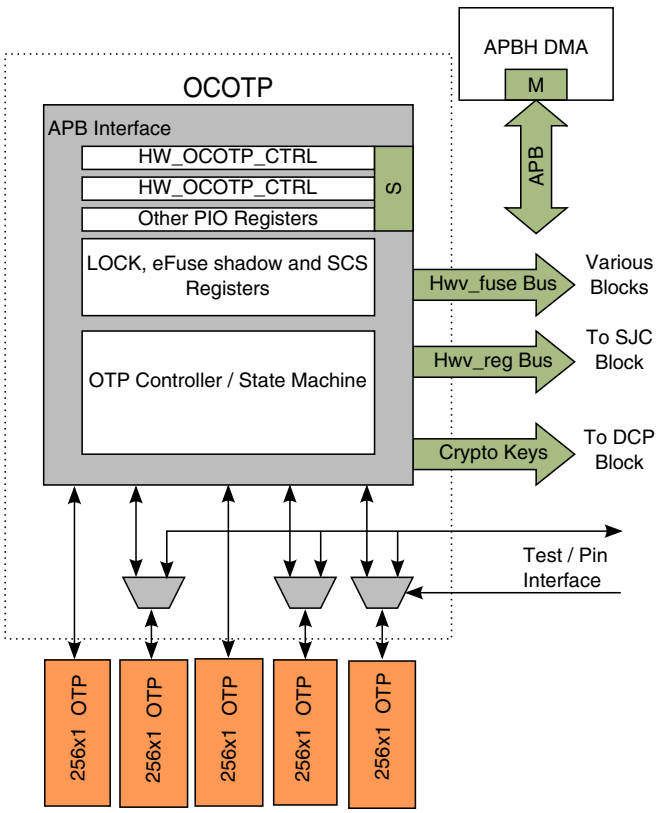

Figure 38-1. OCOTP System Level Diagram

38.3.1 Operation

The APB interface of the OCOTP provides two functions:

- Programmers model access to registers (see OCOTP Memory Map/Register Definition for details).
- Restricted 32-bit word access to the 1.25 Kbyte OTP

OTP reads and writes can only be performed on 32-bit words. For writes, the 32-bit word reflects the “write-mask.” Bit fields with 0 will not be programmed and bit fields with 1 will be programmed.

For OTP random access, the programming interface consists of:

- OCOTP_DATA[31:0] : data register (32- bit) for eFuse programming (writes).

- OCOTP_CTRL[ADDR] : address register (5-bit) for eFuse programming (writes).
- OCOTP_CTRL[BUSY] : Read/Write request/status handshake bit.
- OCOTP_CTRL[RD_BANK_OPEN] : This bit is obsolete in i.MX50 and should not be set.
- OCOTP_CTRL[ERROR] : Read/Write access error status.

38.3.1.1 Fuse and Shadow Register Reads

In past implementations of the OCOTP block the functionality existed to read unshadowed fuse values directly from fuse banks. This was accomplished through the use of the OCOTP_CTRL[RD_BANK_OPEN] bit. This functionality is now obsolete in i.MX50 and should not be used because all fuse bits are shadowed in this implementation.

NOTE

Do not program OCOTP_CTRL[RD_BANK_OPEN] to 1.

Therefore, fuse information is only available through memory mapped shadow registers. If fuses are subsequently programmed, the shadow registers should be reloaded to keep them coherent with the fuse bank arrays.

All shadow registers are always readable through the APB bus except in the SCC and SJC regions. When their corresponding fuse lock bits are set (OCOTP_LOCK[SCC] and OCOTP_LOCK[SJC]), the shadow registers also become read locked. After read locking, reading from these registers will return 0xBADABADA. In addition OCOTP_CTRL[ERROR] will be set. It must be cleared by software before any new write or reload access can be issued. Subsequent reads to unlocked shadow locations will still work successfully however.

The “reload shadows” feature allows the user to force a reload of the shadow registers (including OCOTP_LOCK) without having to reset the device. To force a reload, complete the following steps:

1. Set the OCOTP_TIMING[RD_BUSY] field value appropriately (as explained in a later section).
2. set the OCOTP_CTRL[RELOAD_SHADOWS] bit.
3. Wait for OCOTP_CTRL[BUSY] and OCOTP_CTRL[RELOAD_SHADOWS] to be cleared by the controller. BUSY will take on the order of 280ns to clear depending on the values programmed into the OCOTP_TIMING register.

The OCOTP_CTRL[RELOAD_SHADOWS] bit can be set at any time. There is no need to wait for OCOTP_CTRL[BUSY] or OCOTP_CTRL[ERROR] to be clear. In the case of OCOTP_CTRL[BUSY] being set due to an active write, the controller will perform

the bank opening and shadow reloading immediately after the completion of the write. The controller will automatically clear the OCOTP_CTRL[RELOAD_SHADOWS] bit after the successful completion of the operation.

38.3.1.2 Fuse and Shadow Register Writes

In order to avoid “rogue” code performing erroneous writes to OTP, a special unlocking sequence is required for writes to the fuse banks. To write to the fuse banks correctly complete the following steps:

1. Program OCOTP_TIMING[SCLK_COUNT] and OCOTP_TIMING[RELAX] fields with timing values to match the current frequency of the apb_clk. OTP writes will work at maximum bus frequencies as long as the OCOTP_TIMING parameters are set correctly.
2. Set the VDDIO voltage to 2.8 V. The VDDIO voltage is used to program OTP. Incorrect voltage and timing parameter settings will result in the OTP being programmed with incorrect values.
3. Check that OCOTP_CTRL[BUSY] and OCOTP_CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write or reload must be completed before a write access can be requested.
4. Write the requested address to OCOTP_CTRL[ADDR] and program the unlock code into OCOTP_CTRL[WR_UNLOCK]. This must be programmed for each write access. The lock code is documented in the register description. Both the unlock code and address can be written in the same operation.
5. Write the data to the OCOTP_DATA register. This will automatically set OCOTP_CTRL[BUSY] and clear OCOTP_CTRL[WR_UNLOCK]. In this case, the data is a programming mask. Bit fields with 1’s will result in that OTP bit being set. Only the controller can clear OCOTP_CTRL[BUSY]. The controller will use the mask to program a 32-bit word in the OTP per the address in OCOTP_CTRL[ADDR]. At the same time that the write is accepted, the controller makes an internal copy of OCOTP_CTRL[ADDR] which cannot be updated until the next write sequence is initiated. This copy guarantees that erroneous writes to OCOTP_CTRL[ADDR] will not affect an active write operation. It should also be noted that during the programming OCOTP_DATA will shift right (with zero fill). This shifting is required to program the OTP serially. During the write operation, OCOTP_DATA cannot be modified.
6. Once complete, the controller will clear BUSY. A write request to a protected or locked region will result in no OTP access and no setting of OCOTP_CTRL[BUSY]. In addition OCOTP_CTRL[ERROR] will be set. It must be cleared by software before any new write access can be issued.

It should be noted that write latencies to OTP are in the order of 100's of micro-seconds per word (with max latency up to 1.2ms). Write latencies will vary based on the location of the word within the OTP bank. Each OTP bank has 8 words, so given n-th word location (where 0 n 7), and 32-bits per word the approximate write latency for a given word is:

$5us \times 32 \times (n + 1)$

Shadow register bits can be overridden by software until the corresponding OCOTP_LOCK[*n*_SHADOW] bit for the region is set. When the lock shadow bit is set, the shadow registers for that lock region become write locked. The exceptions to this are registers CFG5, CFG6, MEM5 and LOCK. The first three registers (CFG5, CFG6, MEM5) are always unlocked and they have no corresponding shadow or fuse lock bits. The latter register, LOCK, also has no shadow or fuse lock bits but it is always read only.

OCOTP_CTRL[ERROR] will be set under the following conditions:

- A write is performed to a shadow register during a shadow reload (essentially, while OCOTP_CTRL[RELOAD_SHADOWS] is set. In addition, the contents of the shadow register shall not be updated.
- A write is performed to a shadow register which has been locked.
- A read is performed from a shadow register which has been read locked.

38.3.1.3 Write Postamble

Due to internal electrical characteristics of the OTP during writes, all OTP operations following a write must be separated by 2 ms after the clearing of OCOTP_CTRL_BUSY following the write. This guarantees programming voltages on-chip to reach a steady state when exiting a write sequence. This includes reads, shadow reloads, or other writes. A recommended software sequence to meet the postamble requirements is as follows:

- Issue the write and poll for BUSY (as per Fuse Shadow Memory Footprint).
- Once BUSY is clear, use EPIT to wait 2 ms.
- Perform the next OTP operation.

38.3.2 Fuse Shadow Memory Footprint

The OTP memory footprint is shown in Figure 38-2. The registers are grouped by lock region. Their names correspond to the PIO register and fusemap names.

NOTE

Only some banks are pin accessible.

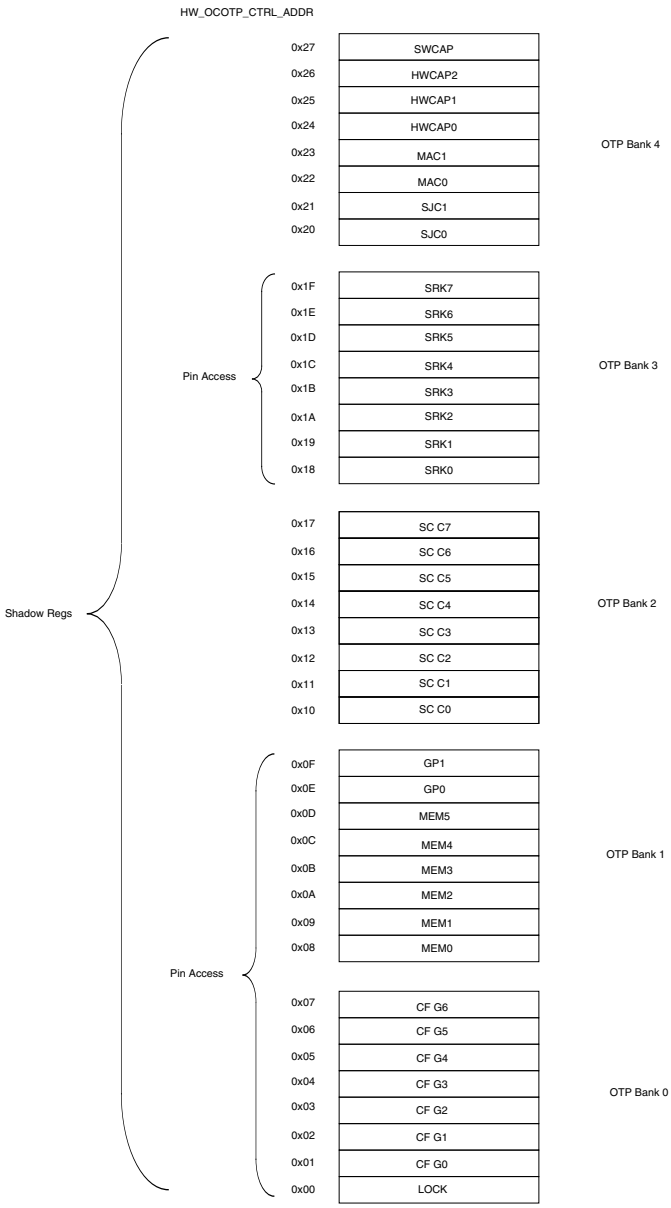

Figure 38-2. OTP Memory Footprint

38.3.3 OTP Read/Write Timing Parameters

There are 3 timing fields contained in the OCOTP_TIMING register that specify counter limit values that are used to time how long the state machine remains in the various states and also specify the SCLK signal timing. They are all specified in apb_clk cycles. Since the apb_clk frequency can be set to a range of values these parameters must be adjusted with the clock to yield the appropriate delay.

The OCOTP_TIMING[RELAX] field specifies how long to remain in the WR_SETUP1, WR_SETUP2, WR_SETUP3, WR_END2, RD_SETUP1 and RD_CLOSE states. It also specifies the SCLK low time (tCKLP) during fuse writes. This parameter should be set by the equation:

tRELAX = tCKLP = (OCOTP_TIMING[RELAX]/apb_frequency) > 10.5 ns

Even though the eFuse specification [eFUSE] specifies that tCKLP can be as short as 5ns it must be programmed to a minimum 10.5ns because the OCOTP_TIMING[RELAX] field is used to create other timing delays in addition to tCLKP. For all timing to be met, this is the minimum delay that must be programmed.

The OCOTP_TIMING[SCLK_COUNT field specifies the period of the SCK signal for fuse writes (during state WR) and is given in units of apb_clk cycles. This value should be specified so that the requirement for the time when the SCLK is asserted high is met: 4000ns < tCKHP < 6000ns is met. Even though a range is given for tCKHP, it is advised in [eFUSE] to program for a value of 5000ns. Therefore, this field should be set according to the equation:

tCKHP = ((OCOTP_TIMING[SCLK_COUNT]/apb_frequency) – tRELAX) = 5000ns.

Figure 38-3 illustrates the relationship between the SCLK signal in programming mode and the timing PIO register fields that affect it. The implementation uses one counter to generate the SCLK waveform within one period and a second counter counts the number of cycles to create for programming the designated word.

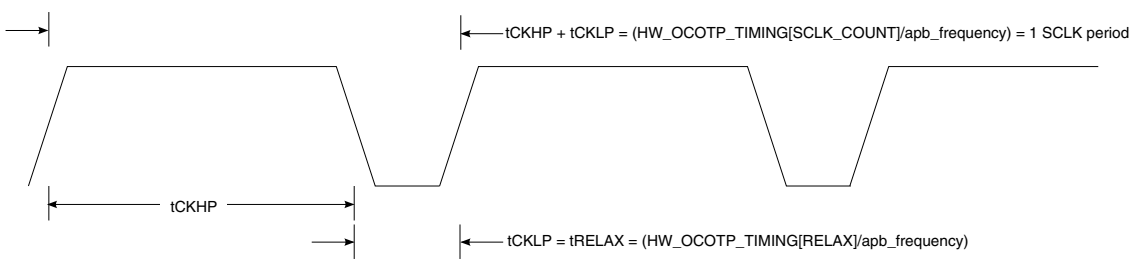

Figure 38-3. SCLK Signal Creation and Timing

The OCOTP_TIMING[RD_BUSY] value gives the time to wait in the RD_BUSY state (wait for banks to be opened for reading) according to the equation:

tRD_BUSY = (OCOTP_TIMING[RD_BUSY]/apb_frequency) > 250ns

38.3.4 Hardware Visible Fuses

The hwv_fuse bus emanates from the OCOTP block and goes to various other blocks inside the chip. This bus is made up of the shadow register bits for banks 0, 1, 2 and 4. Only a subset of these fuse bits are currently used by the hardware. The fuse bits are initially copied from the eFuse banks after reset is deasserted. When all fuse bits are loaded into their shadow registers, the OCOTP asserts the fuse_latched output signal.

The hwv_reg bus also comes from the OCOTP. Its source is the OCOTP_SCS register. For i.MX50 this register has 1 defined bit, the HAB_JDE bit, that is connected to the SJC block. The SCS bits are intended to be used as volatile fuse bits under software control. Additional bits will be defined as needed in future implementations.

The system-wide reset sequence must be coordinated by the system reset controller so that the hwv_fuse and hwv_reg busses are stable and reflect the values of the fuses before they are used by the rest of the system.

The Crypto key which comprises registers SCC0-SCC3 and the Unique key which comprises registers CFG0 and CFG1, can be read by other blocks in the design through two different interfaces.

1. This information can be sent 32 bits at a time using the ocotp_crypto_key_data, ocotp_crpyto_key_smpl, ocotp_unique_key_data and ocotp_unique_key_smpl signals. When the OCOTP first comes out of reset and loads the fuse bits it asserts the “key_smpl” signals for 4 cycles of the apb_clk for the Crypto key and 2 cycles for the Unique key, and synchronizes the data on the “key_data” signals so that the receiving logic can latch the key data 32 bits at a time on the rising edge of apb_clk. The data is sent beginning with the least significant word.
2. After fuse_latched is asserted, the key information is always present in the hwv_fuse bus. The Crypto key makes up bits hwv_fuse[639:512] and and the Unique key is in bits hwv_fuse[95:32].

38.3.5 Behavior During Reset

The OCOTP is always active. The shadow registers automatically load the appropriate OTP contents after reset is deasserted. During this load-time OCOTP_CTRL_BUSY is set. The load time is similar to that of a “reload shadow” operation.

38.4 OCOTP Memory Map/Register Definition

OCOTP Hardware Register Format Summary

OCOTP memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

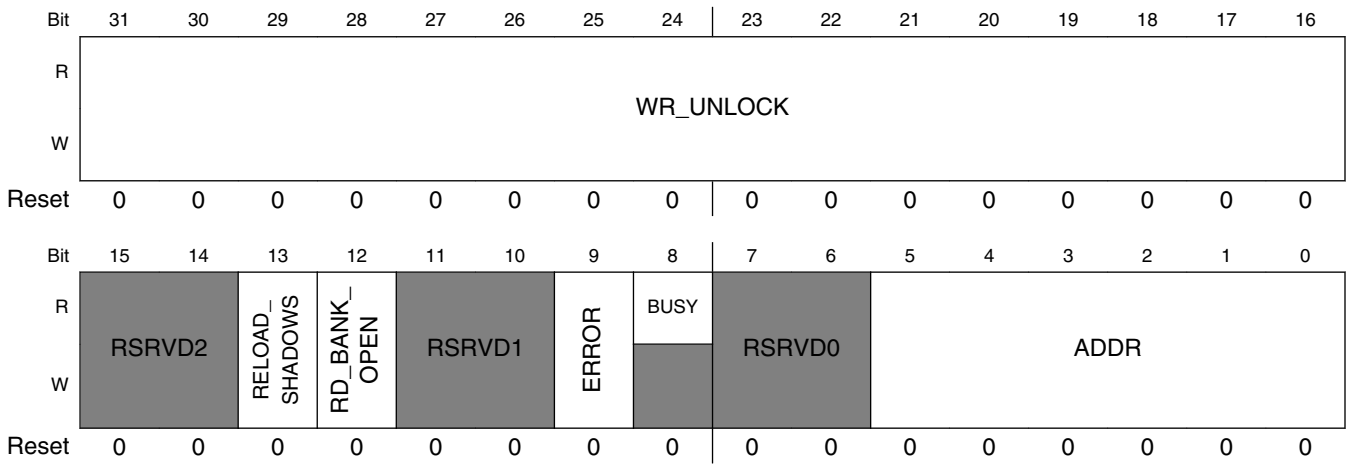
38.4.1 OTP Controller Control Register (OCOTP_CTRL*n*)

The OCOTP Control and Status Register specifies the copy state, as well as the control required for random access of the OTP memory

The OCOTP Control and Status Register provides the necessary software interface for performing read and write operations to the On-Chip OTP (One-Time Programmable ROM). The control fields such as WR_UNLOCK, ADDR and BUSY/ERROR may be used in conjuction with the OCOTP_DATA register to perform write operations. Read operations are performed via the direct memory mapped registers. In the cases where OTP values are shadowed into local memory storage, the memory mapped location can

be read directly. In the cases where the OTP values are not shadowed into local memory, the read-preparation sequence involving RD_BANK_OPEN and BUSY/ERROR fields must be used before performing the read.

Addresses: OCOTP_CTRL is 4100_2000h base + 0h offset = 4100_2000h
OCOTP_CTRL_SET is 4100_2000h base + 4h offset = 4100_2004h
OCOTP_CTRL_CLR is 4100_2000h base + 8h offset = 4100_2008h
OCOTP_CTRL_TOG is 4100_2000h base + Ch offset = 4100_200Ch



OCOTP_CTRL*n* field descriptions

Field	Description
31–16 WR_UNLOCK	Write 0x3E77 to enable OTP write accesses. NOTE: This register must be unlocked on a write-by-write basis (a write is initiated when OCOTP_DATA is written), so the UNLOCK bitfield must contain the correct key value during all writes to OCOTP_DATA, otherwise a write shall not be initiated. This field is automatically cleared after a successful write completion (clearing of BUSY). 0x3E77 **KEY** — Key needed to unlock OCOTP_DATA register.
15–14 RSRVD2	These bits always read back zero.
13 RELOAD_ SHADOWS	Set to force re-loading the shadow registers (HW/SW capability and LOCK). This operation will automatically open banks (but will not set RD_BANK_OPEN) and set BUSY. Once the shadow registers have been re-loaded, BUSY and RELOAD_SHADOWS are automatically cleared by the controller. There is no need to set RD_BANK_OPEN to force the reload. If RD_BANK_OPEN is already set, its still possible to set RELOAD_SHADOWS. In this case, the shadow registers will only be updated upon the clearing of RD_BANK_OPEN.
12 RD_BANK_ OPEN	Set to open the all the OTP banks for reading. When set, the controller sets BUSY to allow time for the banks to become available (approximatly 32 HCLK cycles later at which time the controller will clear BUSY). Once BUSY is clear, the various OTP words are accessible via their memory mapped address. Note that OTP words which are shadowed, can be read at anytime and will not be affected by RD_BANK_OPEN. This bit must be cleared after reading is complete. Keeping the OTP banks open causes additional current draw. BUSY must be clear before this setting will take affect. If there is a write transaction pending (holding BUSY), then the bank opening sequence will begin automatically upon the previous transaction clears BUSY. Note that if a read is performed from non-shadowed locations without RD_BANK_OPEN, ERROR will be set
11–10 RSRVD1	These bits always read back zero.

Table continues on the next page...

OCOTP_CTRL*n* field descriptions (continued)

Field	Description
9 ERROR	Set by the controller when either an access to a locked region is requested or a read is requested from non-shadowed efuse locations without the banks being open. Must be cleared before any further write access can be performed. This bit can only be set by the controller. This bit is also set if the Pin interface is active and software requests an access to the OTP. In this instance, the ERROR bit cannot be cleared until the Pin interface access has completed. Reset this bit by writing a one to the SCT clear address space and not by a general write.
8 BUSY	OTP controller status bit. When active, no new write access or bank open operations (including RELOAD_SHADOWS) can be performed. Cleared by controller when access complete (for writes), or the banks are open (for reads). After reset (or after setting RELOAD_SHADOWS), this bit is set by the controller until the HW/SW and LOCK registers are successfully copied, after which time it is automatically cleared by the controller.
7–6 RSRVD0	These bits always read back zero.
5–0 ADDR	OTP write access address register. Specifies one of 40 word address locations (0x00 - 0x27). If a valid write is accepted by the controller (see OCOTP_DATA for details on what constitutes a valid write), the controller makes an internal copy of this value (to avoid the OTP programming being corrupted). This internal copy will not update until the write access is complete.

38.4.2 OTP Controller Timing Register (OCOTP_TIMING)

The OCOTP Data Register is used for OTP Programming

This register specifies timing parameters for programming and reading the OCOTP fuse array.

Address: OCOTP_TIMING is 4100_2000h base + 10h offset = 4100_2010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	RSRVD0										RD_BUSY						RELAX				SCLK_COUNT											
Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	0	1	0	0	0	0	0	1	1	1	1	0	0	1

OCOTP_TIMING field descriptions

Field	Description
31–22 RSRVD0	These bits always read back zero.
21–16 RD_BUSY	This count value specifies the time to wait while the banks are busy after requesting a read.
15–12 RELAX	This count value specifies the time to add to all default timing parameters other than the Tckhp. It is given in number of apb_clk periods.
11–0 SCLK_COUNT	This count value specifies the sclk high time. It is given in number of apb_clk periods. Valid field values are greater 15.

38.4.3 OTP Controller Write Data Register (OCOTP_DATA)

The OCOTP Data Register is used for OTP Programming

This register is used in conjuction with OCOTP_CTRL to perform one-time writes to the OTP. Please see the "Software Write Sequence" section for operating details.

Address: OCOTP_DATA is 4100_2000h base + 20h offset = 4100_2020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DATA

OCOTP_DATA field descriptions

Field	Description
31–0 DATA	Used to initiate a write to OTP. Please see the "Software Write Sequence" section for operating details.

38.4.4 Value of OTP Bank0 Word0 (Lock controls) (OCOTP_LOCK)

Shadowed memory mapped access to OTP Bank 0, word 0 (ADDR = 0x00).

Address: OCOTP_LOCK is 4100_2000h base + 30h offset = 4100_2030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

OCOTP_LOCK field descriptions

Field	Description
31–26 UNALLOCATED	Value of un-used portion of LOCK word
25 PIN	Status of Pin access lock bit. When set, pin access is disabled.
24 DCPKEY_ALT	Status of alternate bit for DCPKEY lock
23 SCC_ALT	Status of alternate bit for SCC lock
22 DCPKEY	Status of read lock bit for DCP APB crypto key access. When set, the DCP will disallow reads of its crypto keys via its APB interface.
21 SWCAP_ SHADOW	Status of shadow register lock for the region contained in the SWCAP registers. When set, the over-riding (writing) of this region's shadow bits is blocked.
20 SWCAP	Status of register lock for the fuse region contained in the SWCAP registers. When set, these fuse bits are write blocked.
19 HWCAP_ SHADOW	Status of shadow register lock for the region contained in the HWCAP registers. When set, the over-riding (writing) of this region's shadow bits is blocked.
18 HWCAP	Status of register lock for the fuse region contained in the CRYPTO registers. When set, these fuse bits are write blocked.
17 MAC_SHADOW	Status of shadow register lock for the region contained in the MAC registers. When set, the over-riding (writing) of this region's shadow bits is blocked. These shadow registers are always readable.
16 MAC	Status of register lock for the fuse region contained in the MAC registers. When set, these fuse bits are write blocked.
15 SJC_SHADOW	Status of shadow register lock for the fuse region contained in the SJC (sjc_response) registers. When set, the over-riding (writing) of this region's shadow bits is blocked. These shadow registers are readable as long as the LOCK_SJC bit is not set.
14 SJC	Status of register lock for the region contained in the SJC (sjc_response) registers. When set, these fuse bits are write blocked. Also, their shadow registers are read blocked.
13 SRK_SHADOW	Status of shadow register lock for the region contained in the SRK registers. When set, the over-riding (writing) of this region's shadow bits is blocked. These shadow registers are always readable.
12 SRK	Status of register lock for the fuse region contained in the SRK registers. When set, these fuse bits are write blocked.
11 SCC_SHADOW	Status of shadow register lock for the region contained in the SCC registers. When set, the over-riding (writing) of this region's shadow bits is blocked. These shadow registers are readable as long as the LOCK_SCC bit is not set.
10 SCC	Status of register lock for the fuse region contained in the SCC registers. When set, these fuse bits are write blocked. Also, their shadow registers are read blocked.
9 GP_SHADOW	Status of shadow register lock for the region contained in the GP (General Purpose) registers. When set, the over-riding (writing) of this region's shadow bits is blocked. These shadow registers are always readable.
8 GP	Status of register lock for the fuse region contained in the GP (General Purpose). When set, these fuse bits are write blocked.

Table continues on the next page...

OCOTP_LOCK field descriptions (continued)

Field	Description
7 MEM_MISC_ SHADOW	Status of shadow register lock for the region contained in the MEM registers 5-6. When set, the over-riding (writing) of this region's shadow bits is blocked. These shadow registers are always readable.
6 MEM_TRIM_ SHADOW	Status of shadow register lock for the region contained in the MEM registers 0-4. When set, the over-riding (writing) of this region's shadow bits is blocked. These shadow registers are always readable.
5 MEM_TRIM	Status of register lock for the fuse region contained in the MEM registers 0-4. When set, these fuse bits are write blocked.
4 CFG_MISC_ SHADOW	Status of shadow register lock for the region contained in the CFG registers 5-6. When set, the over-riding (writing) of this region's shadow bits is blocked. These shadow registers are always readable.
3 CFG_BOOT_ SHADOW	Status of shadow register lock for the region contained in the CFG registers 3-4. When set, the over-riding (writing) of this region's shadow bits is blocked. These shadow registers are always readable.
2 CFG_BOOT	Status of register lock for the fuse region contained in the CFG registers 3-4. When set, these fuse bits are write blocked.
1 CFG_TESTER_ SHADOW	Status of shadow register lock for the region contained in the CFG registers 0-2. When set, the over-riding (writing) of this region's shadow bits is blocked. These shadow registers are always readable.
0 CFG_TESTER	Status of register lock for the fuse region contained in the CFG registers 0-2. When set, these fuse bits are write blocked.

38.4.5 Value of OTP Bank0 Word1 (Configuration and Manufacturing Info.) (OCOTP_CFG0)

Copied from the OTP automatically after reset. Can be re-loaded by setting OCOTP_CTRL[RELOAD_SHADOWS]

Shadowed memory mapped access to OTP Bank 0, word 1 (ADDR = 0x01).

Address: OCOTP_CFG0 is 4100_2000h base + 40h offset = 4100_2040h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

OCOTP_CFG0 field descriptions

Field	Description
31–0 BITS	This register contains 32 bits of the Unique ID and SJC_CHALLENGE field. Reflects value of OTP Bank 0, word 1 (ADDR = 0x01). These bits become read-only after the OCOTP_LOCK[CFG_SHADOW] bit is set.

38.4.6 Value of OTP Bank0 Word2 (Configuration and Manufacturing Info.) (OCOTP_CFG1)

Copied from the OTP automatically after reset. Can be re-loaded by setting OCOTP_CTRL[RELOAD_SHADOWS]

shadowed memory mapped access to OTP Bank 0, word 2 (ADDR = 0x02).

Address: OCOTP_CFG1 is 4100_2000h base + 50h offset = 4100_2050h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

OCOTP_SCC1 field descriptions

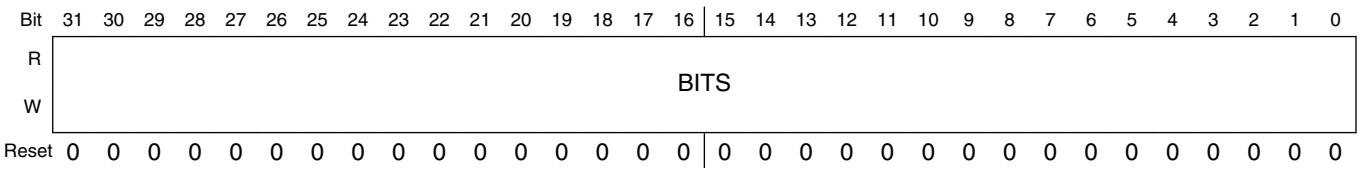
Field	Description
31–0 BITS	Shadow register for the SCC and CRYPTO Key word1 (Copy of OTP Bank 2, word 1 (ADDR = 0x15)). These bits become read-only after the OCOTP_LOCK[SCC_SHADOW] bit is set. If OCOTP_LOCK[SCC] is set, returns 0xBADA_BADA and sets OCOTP_CTRL[ERROR].

38.4.22 Shadow Register for OTP Bank2 Word2 (SCC and CRYPTO Key) (OCOTP_SCC2)

Copied from the OTP automatically after reset. Can be re-loaded by setting OCOTP_CTRL[RELOAD_SHADOWS].

Shadowed memory mapped access to OTP Bank 2, word 2 (ADDR = 0x12).

Address: OCOTP_SCC2 is 4100_2000h base + 150h offset = 4100_2150h



OCOTP_SCC2 field descriptions

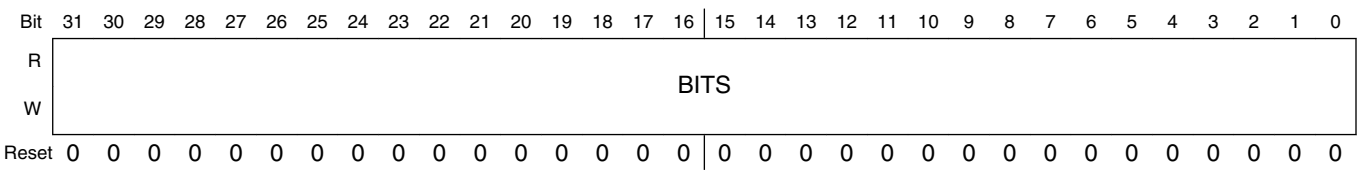
Field	Description
31–0 BITS	Shadow register for the SCC and CRYPTO Key word2 (Copy of OTP Bank 2, word 2 (ADDR = 0x16)). These bits become read-only after the OCOTP_LOCK[SCC_SHADOW] bit is set. If OCOTP_LOCK[SCC] is set, returns 0xBADA_BADA and sets OCOTP_CTRL[ERROR].

38.4.23 Shadow Register for OTP Bank2 Word3 (SCC and CRYPTO Key) (OCOTP_SCC3)

Copied from the OTP automatically after reset. Can be re-loaded by setting OCOTP_CTRL[RELOAD_SHADOWS].

Shadowed memory mapped access to OTP Bank 2, word 3 (ADDR = 0x13).

Address: OCOTP_SCC3 is 4100_2000h base + 160h offset = 4100_2160h



OCOTP_SCC3 field descriptions

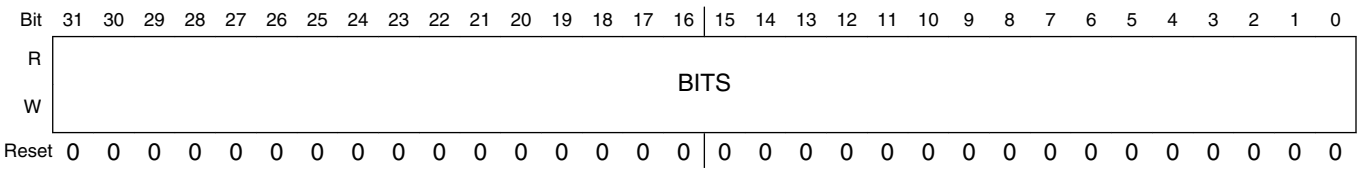
Field	Description
31–0 BITS	Shadow register for the SCC and CRYPTO Key word3 (Copy of OTP Bank 2, word 3 (ADDR = 0x17)). These bits become read-only after the OCOTP_LOCK[SCC_SHADOW] bit is set. If OCOTP_LOCK[SCC] is set, returns 0xBADA_BADA and sets OCOTP_CTRL[ERROR].

38.4.24 Shadow Register for OTP Bank2 Word4 (SCC Key) (OCOTP_SCC4)

Copied from the OTP automatically after reset. Can be re-loaded by setting OCOTP_CTRL[RELOAD_SHADOWS].

Shadowed memory mapped access to OTP Bank 2, word 4 (ADDR = 0x14).

Address: OCOTP_SCC4 is 4100_2000h base + 170h offset = 4100_2170h



OCOTP_SCC4 field descriptions

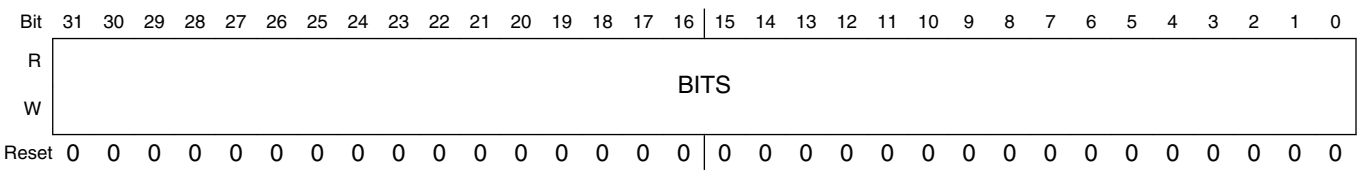
Field	Description
31–0 BITS	Shadow register for the SCC Key word4 (Copy of OTP Bank 2, word 4 (ADDR = 0x18)). These bits become read-only after the OCOTP_LOCK[SCC_SHADOW] bit is set. If OCOTP_LOCK[SCC] is set, returns 0xBADA_BADA and sets OCOTP_CTRL[ERROR].

38.4.25 Shadow Register for OTP Bank2 Word5 (SCC Key) (OCOTP_SCC5)

Copied from the OTP automatically after reset. Can be re-loaded by setting OCOTP_CTRL[RELOAD_SHADOWS].

Shadowed memory mapped access to OTP Bank 2, word 5 (ADDR = 0x15).

Address: OCOTP_SCC5 is 4100_2000h base + 180h offset = 4100_2180h



OCOTP_SCC5 field descriptions

Field	Description
31–0 BITS	Shadow register for the SCC Key word5 (Copy of OTP Bank 2, word 5 (ADDR = 0x19)). These bits become read-only after the OCOTP_LOCK[SCC_SHADOW] bit is set. If OCOTP_LOCK[SCC] is set, returns 0xBADA_BADA and sets OCOTP_CTRL[ERROR].

38.4.26 Shadow Register for OTP Bank2 Word6 (SCC Key) (OCOTP_SCC6)

Copied from the OTP automatically after reset. Can be re-loaded by setting OCOTP_CTRL[RELOAD_SHADOWS].

Shadowed memory mapped access to OTP Bank 2, word 6 (ADDR = 0x16).

Address: OCOTP_SCC6 is 4100_2000h base + 190h offset = 4100_2190h

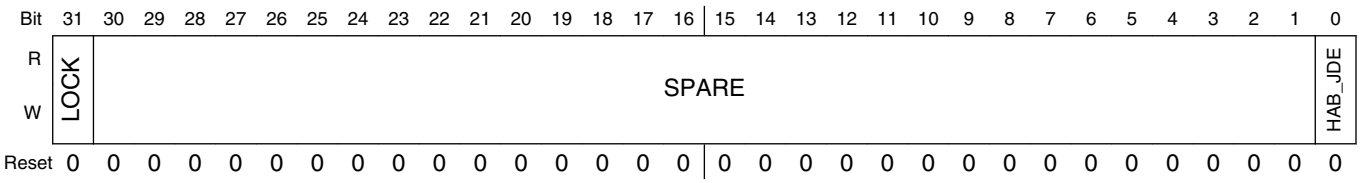
OCOTP_SWCAP field descriptions

Field	Description
31–0 BITS	Reflects value of OTP Bank 4, word 7 (ADDR = 0x27).

38.4.44 Software Controllable Signals Register (OCOTP_SCS*n*)

This register holds volatile configuration values that can be set and locked by software. All values are returned to their defualt values after POR.

Addresses: OCOTP_SCS is 4100_2000h base + 2B0h offset = 4100_22B0h
OCOTP_SCS_SET is 4100_2000h base + 2B4h offset = 4100_22B4h
OCOTP_SCS_CLR is 4100_2000h base + 2B8h offset = 4100_22B8h
OCOTP_SCS_TOG is 4100_2000h base + 2BCh offset = 4100_22BCh



OCOTP_SCS*n* field descriptions

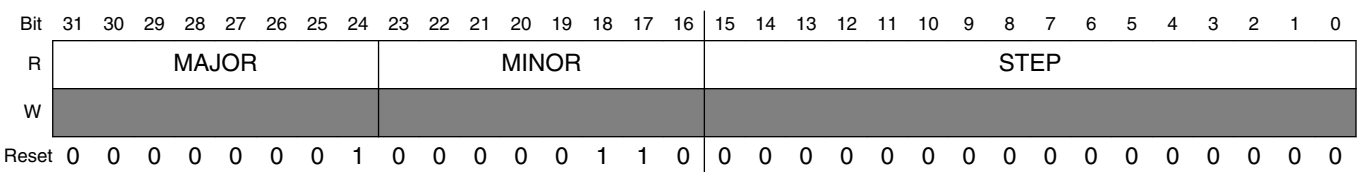
Field	Description
31 LOCK	When set, all of the bits in this register are locked and can not be changed through SW programming. This bit is only reset after a POR is issued.
30–1 SPARE	Unallocated read/write bits for implementation specific software use.
0 HAB_JDE	HAB JTAG Debug Enable. This bit is used by the HAB to enable JTAG debugging, assuming that a properlay signed command to do so is found and validated by the HAB. The HAB must lock the register before passing control to the OS whether or not JTAG debugging has been enabled. Once JTAG is enabled by this bit, it can not be disabled unless the system is reset by POR. 0: JTAG debugging is not enabled by the HAB (it may still be enabled by other mechanisms). 1: JTAG debugging is enabled by the HAB (though this signal may be gated off).

38.4.45 OTP Controller Version Register (OCOTP_VERSION)

This register always returns a known read value for debug purposes it indicates the version of the block.

This register indicates the RTL version in use.

Address: OCOTP_VERSION is 4100_2000h base + 2C0h offset = 4100_22C0h



OCOTP_VERSION field descriptions

Field	Description
31–24 MAJOR	Fixed read-only value reflecting the MAJOR field of the RTL version.
23–16 MINOR	Fixed read-only value reflecting the MINOR field of the RTL version.
15–0 STEP	Fixed read-only value reflecting the stepping of the RTL version.

Chapter 39
On-Chip RAM (OCRAM)

39.1 Overview

The on-chip RAM block is implementd as an slave module on the 64-bit system AXI bus. Designed as a simple on-chip memory block, it has only one bank of single port SRAM and supports only one AXI port. For the AXI port, the read and write transactions are handled by two independent modules. As it is possible to have simultaneous read and write request from the AXI bus, an arbiter with round-robin scheme is implemented to handle this. After arbitration, the granted read or write access command can then be issued to the memory cell through a read/write MUX.

A couple of options are provided to adding pipeline or wait-state in read/write access, in order to ensures flexible timing control at high/low frequency working conditions.

The internal block are shown in Figure 39-1.

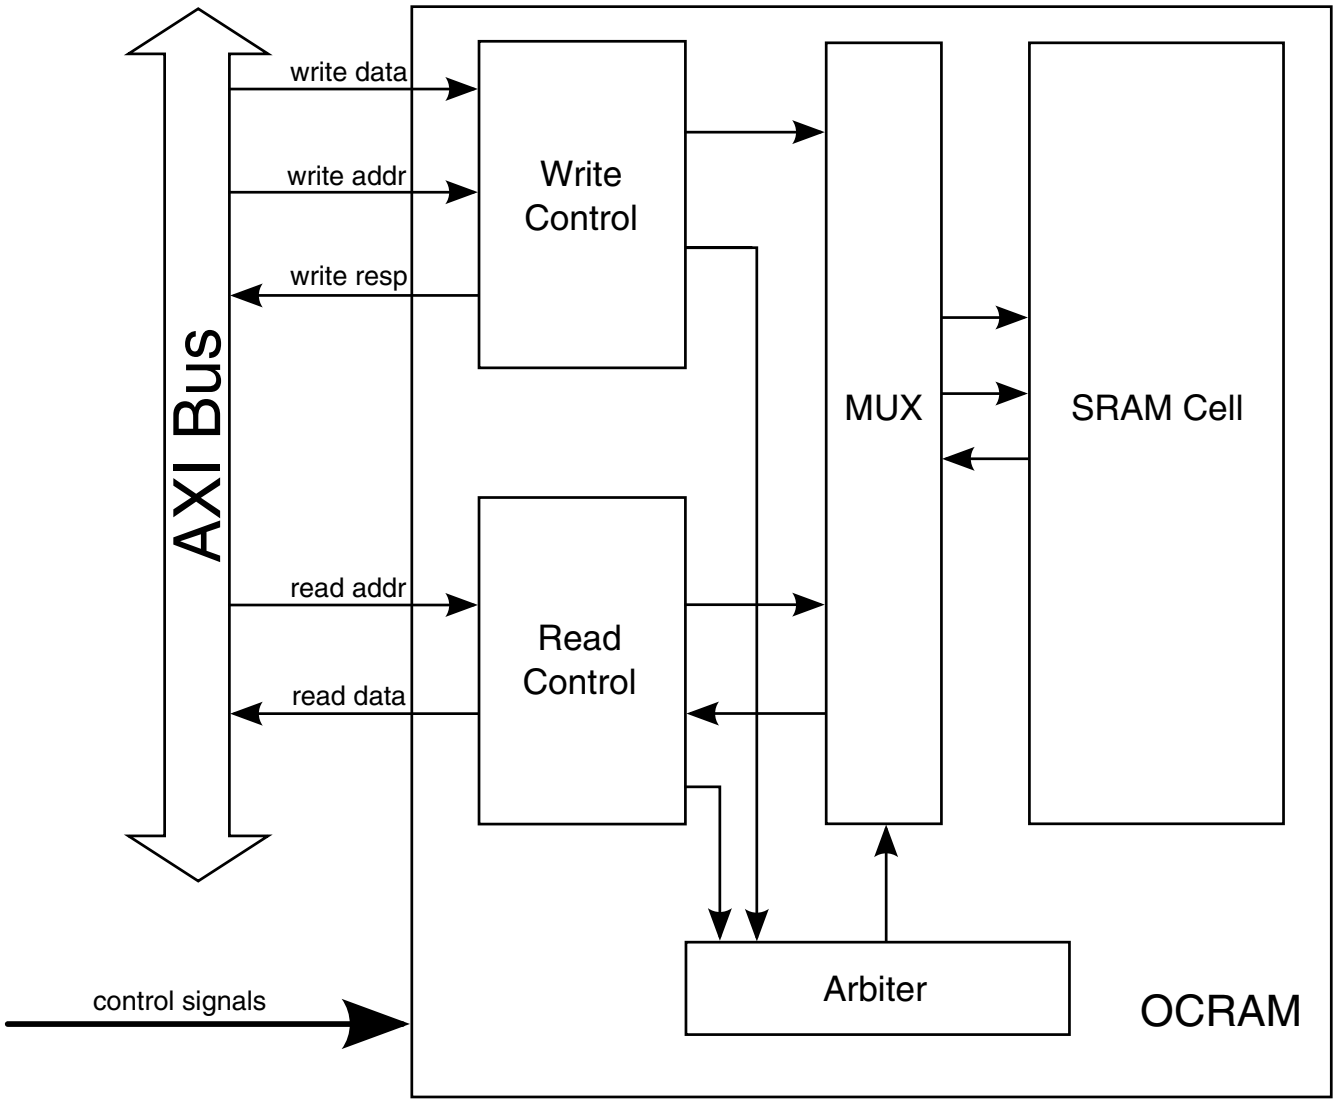


Figure 39-1. On-chip RAM Block Diagram

39.1.1 Memory Map

The on-chip RAM size for i.MX50 is 128 Kbytes, organized as 16K x 64 bits, mapped from 0 x 0000_0000 to 0x0001_FFFF.

Memory Alias is also supported for on-chip RAM. Address from 0 x 0002_0000 to 0 x 3FFF_FFFF are alias addresses for it, any read/write operation to this area will be mapped back to the 128 Kbyte area.

The 32-bit AXI address are arranged as below:

Table 39-1. On-Chip RAM Address Bits

AHB ADDR Bits	USAGE	DESCRIPTION
29:3	Address	Selects one of the 16K words in the memory (64-bit a word).
2:0	Byte Address	Selects/masks out specific bytes within a word.

39.1.2 Read/Write Arbitration

Generally, the arbitration is using the round-robin method. The detailed rules used in arbitration can be described as follows:

- If there is no granted read or write in the last cycle, and there is only read request or write request, the request will be granted.
- If there is no granted read or write in the last cycle, and there are both read or write requests coming at the same time, the read request will be granted first.
- If a granted read/write transaction has just finished, the write/read request will have the higher priority in next cycle.
- If the first read/write access request in a transaction is granted, all the data transfer in this burst will be finished before next arbitration begins, i.e., the round-robin arbitration mechanism is based on AXI transaction, not based on data access.

39.2 Advanced Features

Below are some advanced features designed to avoid timing issues when the on-chip RAM is working at high frequency. All of them can be disabled/enabled by set/clear the corresponding fields of the control register for on-chip RAM. These control registers are implemented in the DIGCTL block withing the SoC. Refer to the chapter entitled "Digital Control (DIGCTL) and On-Chip RAM" for detailed bit definitions.

39.2.1 Read Data Wait State

When the wait state is enabled, it will cost 2 cycles for each read access, (each beat of a read burst). This can avoid the potential timing problem caused by the relatively longer memory access time at higher frequency.

When this feature is disabled, it only costs 1 clock cycle to finish a read transaction, i.e., get read data back in the next cycle of read request becomes valid on the bus.

39.2.2 Read Address Pipeline

When this feature is enabled, the read address from the AXI master would be delayed 1 cycle before it can be accepted by the on-chip RAM. This can avoid setup time issue for the read access on the memory cell at high frequency. Enable this feature would cost at most 1 more clock cycle for each AXI read transaction, that is, at most 1 more clock cycle for each read burst with multiple beats of data.

When this feature is disabled, the read address from the AXI master can be accepted by the on-chip RAM without delay, and data can become ready for master at next clock cycle (if no other access and no read data wait).

39.2.3 Write Data Pipeline

When this feature is enabled, the write data from the AXI master would be delayed 1 cycle before it can be accepted by the on-chip RAM. This can avoid setup time issue for the write access on the memory cell at high frequency. Enable this feature would cost at most 1 more clock cycle for each AXI write transaction, that is, at most 1 more clock cycle for each write burst with multiple beats of data.

When this feature is disabled, the write data from the AXI master can be accepted by the on-chip RAM without delay, and data can be written to memory at this cycle (if no other access and write address is also ready at this cycle).

39.2.4 Write Address Pipeline

When this feature is enabled, the write address from the AXI master would be delayed 1 cycle before it can be accepted by the on-chip RAM. This can avoid setup time issue for the write access on the memory cell at high frequency. Enable this feature would cost at most 1 more clock cycle for each AXI write transaction, that is, at most 1 more clock cycle for each write burst with multiple beats of data.

When this feature is disabled, the write address from the AXI master can be accepted by the on-chip RAM without delay, and data can be written to memory at this cycle (if no other access and write data is also ready at this cycle).

39.3 Programmable Registers

There are no programmable registers in this block.

Chapter 40
1-Wire Block (OWIRE)

40.1 Overview

The OWIRE provides the communication link to a generic 1-Kbit add-only memory. The block sends or receives one bit at a time with an option for software to manage the data using bytes. The required protocol for accessing the generic OWIRE device is defined by Maxim-Dallas. The generic OWIRE device holds battery characteristics information.

The following figure shows a block diagram of the OWIRE.

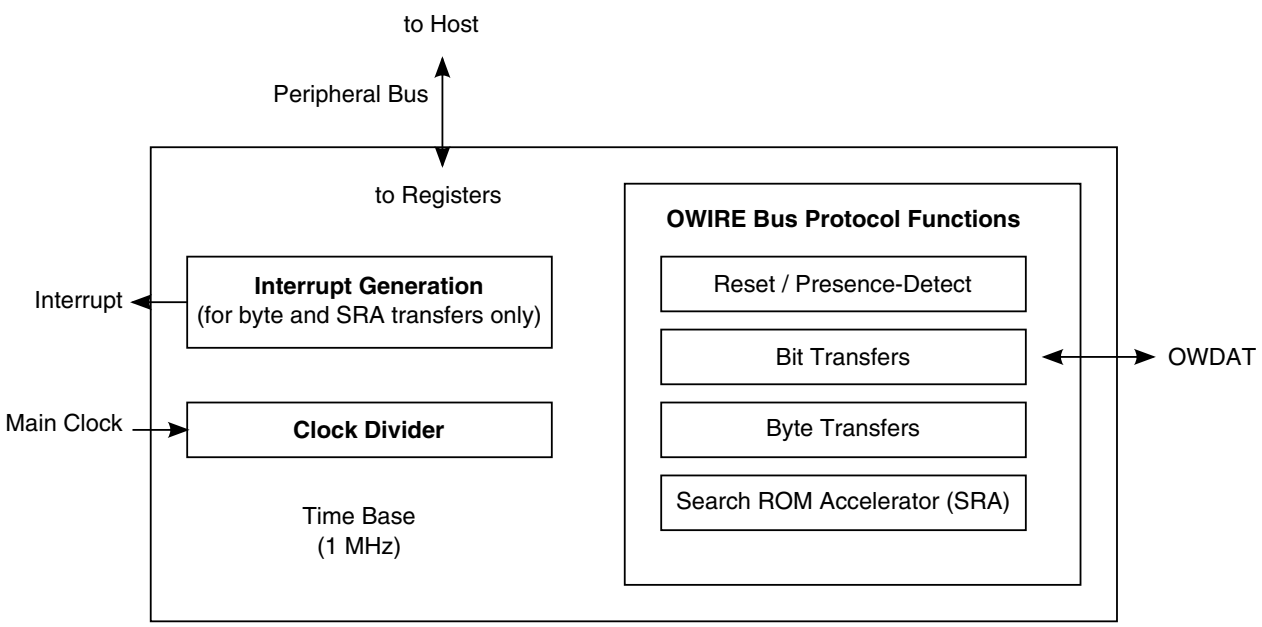

Figure 40-1. OWIRE Block Diagram

40.1.1 Features

The OWIRE includes the following features:

- Performs the OWIRE bus protocol to communicate with an external OWIRE device.
- Provides a clock divider to a generate a OWIRE bus reference clock (derived from the main clock provided internally to the block).
- Supports byte transfers with optional interrupts for more efficient programming.
- Provides a search ROM accelerator mode to speed the search ROM protocol.

40.1.2 Modes of Operation

The OWIRE supports the following operations:

- Normal Operating Modes (See Normal Operating Modes.)
  - Bit or Byte Transfers
  - Reset/Presence-detect Pulse
  - Search ROM Accelerator Mode
- Low Power Mode (See Low Power Mode.)

40.2 External Signals

Table 40-1 shows the signal that interfaces with a generic OWIRE device.

Table 40-1. OWIRE Block Signal

Signal	I/O	Function
OWDAT	I/O	One-Wire bus Requires an external pull-up resistor. The recommended resistor value is specified by the generic OWIRE device used in a given system.

40.3 Functional Description

The OWIRE interfaces with a generic 1-Kbit add-only memory, through a simple 1-bit bus. Software uses the OWIRE bus to program and read the 1-Kbyte memory.

The protocol involves first issuing one of four ROM function commands before the EPROM is accessible:

- Read ROM
- Match ROM
- Search ROM
- Skip ROM

Through the OWIRE bus, the host software interfaces with the generic OWIRE device and allows the required commands to be issued to control the EPROM of a generic OWIRE device. The host (through the OWIRE interface) is the bus master, and the generic OWIRE device(s) are the slave(s)

40.3.1 Normal Operating Modes

The OWIRE supports the following bus protocol functions:

- Reset/Presence-detect Pulse using the Control register (See Reset/Presence-detect Pulse.)
- Bit Transfers using the Control register (See Bit Transfers .)
- Byte Transfers using the TX/RX register (See Byte Transfers.)
- Search ROM Accelerator Mode using the Command register and the TX/RX register (See Search ROM Accelerator Mode.)

40.3.1.1 Reset/Presence-detect Pulse

The OWIRE provides for an automated initialization sequence for the OWIRE bus. Software initiates the initialization sequence by setting OWIRE_CONTROL[RPP]. The automated initialization sequence is as follows:

1. Generate a reset pulse.
2. Listen for a response from an external device by sampling for the OWIRE device presence bit.
3. After an amount of time determined by the OWIRE standard, latch the presence bit (true or false) in OWIRE_CONTROL[PST].

If an external device is detected (PST = 1), software can begin communications on the OWIRE bus.

The presence pulse is used by the OWIRE to determine if at least one generic OWIRE device is connected. Software determines if more than one generic OWIRE device exists.

40.3.1.2 Bit Transfers

After the initialization sequence (see Reset/Presence-detect Pulse), software can write and read one bit at a time using the Control register.

40.3.1.2.1 Write-0 Sequence

The Write-0 sequence writes a zero bit to the generic OWIRE device. Setting the OWIRE_CONTROL[WR0] bit initiates the Write-0 pulse sequence. Once the write is complete, the WR0 bit is automatically cleared.

40.3.1.2.2 Write-1 / Read Sequence

The Write-1 sequence writes a one bit to the generic OWIRE device. Setting the OWIRE_CONTROL[WR1] bit initiates the Write-1 pulse sequence. Once the write is complete, the WR1 bit is automatically cleared.

Because the Write-1 and Read timings are identical, this sequence also reads a bit from the bus. The sampled value is stored in the read status bit OWIRE_CONTROL[RDST] and is valid after the WR1 bit is self-cleared.

40.3.1.3 Byte Transfers

After the initialization sequence (see Reset/Presence-detect Pulse), software can transfer a byte at a time using the TX/RX register. Writing to the register connects to the Transmit buffer; reading to the register connects to the Receive buffer. See Figure 40-2.

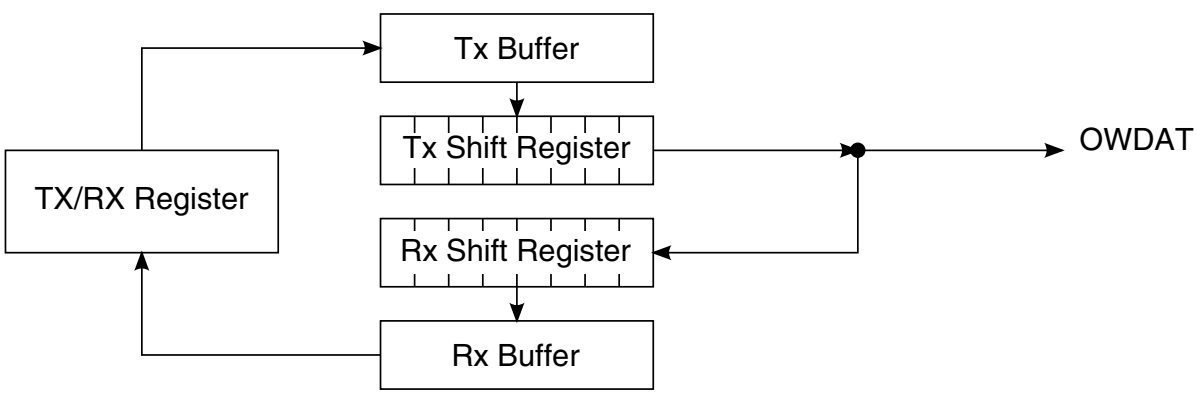

Figure 40-2. Byte Transfers

The Transmit buffer connects to an internal Transmit Shift Register where data is shifted serially onto the bus LSB first. Similarly, the Receive buffer connects to an internal Receive Shift Register where data is sampled serially from the bus.

Software can read a byte from the generic OWIRE device as follows:

1. Write 0xFF to the Transmit/Receive register location (connected to the Transmit buffer).

2. Wait for the receive-buffer-full (OWIRE_INTERRUPT[RBF]) interrupt (or poll the flag bit directly if the interrupt is disabled). During this time, the hardware is writing ones on the bus while sampling the wired-AND of the data from the device. The read data is shifted into the Receive Shift Register. When a byte is collected in the Receive Shift Register, the data is transferred to the Receive buffer, and the RBF flag is set.
3. Read from the Transmit/Receive register location (connected to the Receive buffer) upon receiving the RBF interrupt.

If the Receive buffer is full, new data is not shifted from the Receive Shift Register until the current data is read. To prevent the loss of data, software must read the TX/RX register to clear the receive-buffer-full flag (OWIRE_INTERRUPT[RBF]). This allows the Receive Shift Register to shift new data into the Receive buffer.

40.3.1.4 Search ROM Accelerator Mode

In *search ROM accelerator* mode the OWIRE relieves software from having to perform single-bit operations on the bus and helps determine if more than one generic OWIRE device exists.

The OWIRE enters search ROM accelerator mode when OWIRE_COMMAND[SRA] is set. This protocol specifies that the bus master read two bits (a bit and its complement), then writes a bit to specify which devices should remain on the bus for further processing.

Note that this mode requires that a reset followed by the search ROM command (0xF0) has already been issued on the OWIRE bus.

The OWIRE automatically exits search ROM accelerator mode if the OWIRE bus is re-initialized; see Reset/Presence-detect Pulse.

40.3.2 Low Power Mode

The OWIRE. automatically goes into low power mode whenever it is not communicating with a generic OWIRE device. The main clock is gated off in low power mode.

As soon as software writes to any register, the OWIRE exits low power mode.

40.3.3 Clocks

The OWIRE takes a main clock as a block input and passes it through a clock divider. (See the block diagram in Figure 40-1.) Software must program the divider factor to generate a 1-MHz clock that is used as an internal time base for the block, as given by the following equation:

time_base = main_clock ÷ (TIME_DIVIDER[DVDR] + 1)

For example, if the main clock frequency is 30 MHz, the value to write to the divider register is 29. If the main clock input frequency is not an integer, the programmer must ensure the time base frequency is within the range given by the following equation:

0.98 MHz ≤ time_base ≤ 1.02 MHz

NOTE

A main clock frequency below 10 MHz causes improper function of the block.

40.3.4 Reset

The OWIRE supports two levels of reset: hardware and software.

40.3.4.1 Hardware Reset

Whenever a device reset occurs, a hard reset is performed on the OWIRE, clearing all values written to all registers.

40.3.4.2 Software Reset

Software initiates a software reset by setting the reset bit OWIRE_RESET[RST]. A software reset clears all data written to the registers except for the Command and Interrupt registers (OWIRE_COMMAND, OWIRE_INTERRUPT).

NOTE

The reset register (OWIRE_RESET) itself is not cleared during a software reset. Software must clear the RST bit to release the software reset.

40.3.5 Interrupts

The OWIRE generates interrupts through the programming of the Interrupt Enable register; see Interrupt Enable Register (OWIRE_INTERRUPT_EN). The OWIRE can generate interrupts under the following conditions:

- Receive shift register or buffer full
- Transmit shift register or buffer empty
- Presence detect

Once any of these conditions are met, the Interrupt register (see Interrupt Register (OWIRE_INTERRUPT)) sets the corresponding bit and generates an interrupt if enabled in the Interrupt Enable register. The IAS bit within the Interrupt Enable register determines if the interrupt generated is active low, or active high. By default all interrupts are active high, and software should not modify IAS.

40.4 Programmable Registers

This section provides the block memory map and detailed descriptions of all registers.

OWIRE memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
63FA_4000	Control register (OWIRE_CONTROL)	16	R/W	0000h	40.4.1/ 2364
63FA_4002	Time Divider register (OWIRE_TIME_DIVIDER)	16	R/W	0000h	40.4.2/ 2365
63FA_4004	Reset register (OWIRE_RESET)	16	R/W	0000h	40.4.3/ 2365
63FA_4006	Command Register (OWIRE_COMMAND)	16	R/W	0000h	40.4.4/ 2366
63FA_4008	Transmit/Receive Register (OWIRE_TX/RX)	16	R/W	0000h	40.4.5/ 2367
63FA_400A	Interrupt Register (OWIRE_INTERRUPT)	16	R	000Eh	40.4.6/ 2367
63FA_400C	Interrupt Enable Register (OWIRE_INTERRUPT_EN)	16	R/W	0000h	40.4.7/ 2369

40.4.1 Control register (OWIRE_CONTROL)

The control register is used to initiate the reset/presence-detect sequence and bit transfers. The register also provides the presence-detect status and bit-read status.

Address: OWIRE_CONTROL is 63FA_4000h base + 0h offset = 63FA_4000h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0								RPP	PST	WR0	WR1	RDST	0		
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

OWIRE_CONTROL field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7 RPP	Reset/Presence-detect Pulse. This bit is self-clearing and is cleared after the presence is determined. See Reset/Presence-detect Pulse. When writing: 0 Do nothing. 1 Generate Reset Pulse and sample the bus for the presence pulse from the external device. When reading: 0 Reset pulse complete. 1 Sequence not complete.
6 PST	Presence Status. This bit is valid after the RPP bit is self-cleared. 0 Device is not present. 1 Device is present.
5 WR0	Write 0. This bit is self-clearing and is cleared when the write of the bit is complete. See Write-0 Sequence. When writing: 0 Do nothing. 1 Write a 0 bit to the interface. When reading: 0 Write sequence complete. 1 Sequence not complete.
4 WR1	Write-1 / Read. This bit is self-clearing and is cleared when the write sequence is complete. See Write-1 / Read Sequence. When writing: 0 Do nothing 1 Write a 1 bit to the interface and sample the bus. When reading:

Table continues on the next page...

OWIRE_CONTROL field descriptions (continued)

Field	Description
	0 Sequence complete. 1 Sequence not complete.
3 RDST	Read Status. This bit is valid after the WR1 bit is self cleared. 0 A 0 has been sampled. 1 A 1 has been sampled.
2–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

40.4.2 Time Divider register (OWIRE_TIME_DIVIDER)

The time divider register is used for dividing the main clock input down to 1 MHz.

Address: OWIRE_TIME_DIVIDER is 63FA_4000h base + 2h offset = 63FA_4002h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0								DVDR							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

OWIRE_TIME_DIVIDER field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7–0 DVDR	**Divider Factor.** The internal clock divider uses this field to generate the required time base for the block. See Clocks. 0x00 1 (default) 0x01 2 0xFF 256

40.4.3 Reset register (OWIRE_RESET)

The reset register is used to perform a software reset of the OWIRE.

Address: OWIRE_RESET is 63FA_4000h base + 4h offset = 63FA_4004h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0															RST
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

OWIRE_RESET field descriptions

Field	Description
15–1 Reserved	This read-only field is reserved and always has the value zero. Reserved
0 RST	Software Reset. See Software Reset. 0 Do not perform a software reset. 1 Initiate a software reset and hold the block in the software-reset state.

40.4.4 Command Register (OWIRE_COMMAND)

The OWIRE can be configured to run in Search ROM Accelerator mode using the command register. See Search ROM Accelerator Mode.

Address: OWIRE_COMMAND is 63FA_4000h base + 6h offset = 63FA_4006h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0														SRA	0
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

OWIRE_COMMAND field descriptions

Field	Description
15–2 Reserved	This read-only field is reserved and always has the value zero. Reserved
1 SRA	**Search ROM Accelerator. This bit is cleared when the reset-presence-pulse bit CONTROL[RPP] is set.** 0 Deactivate the search ROM accelerator. 1 Switch to search ROM accelerator mode.
0 Reserved	This read-only field is reserved and always has the value zero. Reserved

40.4.5 Transmit/Receive Register (OWIRE_TX/RX)

Data sent and received from the OWIRE passes through the Transmit/Receive (TX/RX) register location. The OWIRE is double-buffered with separate transmit and receive buffers connected to the TX/RX register. See Byte Transfers.

Address: OWIRE_TX/RX is 63FA_4000h base + 8h offset = 63FA_4008h

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0								DATA							
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

OWIRE_TX/RX field descriptions

Field	Description
15–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7–0 DATA	Data byte. When writing: The data byte is written to the Transmit buffer. When reading: A data byte is read from the Receive buffer. The data is valid only when INTERRUPT[RBF] is set.

40.4.6 Interrupt Register (OWIRE_INTERRUPT)

Flags for the reset/presence-detect sequence and byte transfer operations are located in the Interrupt Register. These flags can generate an interrupt if the corresponding enable bit is set in the Interrupt Enable Register.

If interrupts are enabled, reading the Interrupt Register deactivates the interrupt even if all current flags are not cleared; therefore, the interrupt service routine should clear all pending flags during each routine call.

NOTE

When a byte is written to the Transmit/Receive Register, software then waits for a Transmit Shift Register Empty (TSRE) interrupt to occur. When the TSRE flag is set, the Receive Buffer Full (RBF) flag is also set. The RBF flag does not trigger an interrupt, assuming it is disabled. However, software should read the Transmit/Receive Register to clear the

RBF flag in order to give a proper status of the pending interrupts.

Address: OWIRE_INTERRUPT is 63FA_4000h base + Ah offset = 63FA_400Ah

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0										RSRF	RBF	TSRE	TBE	PDR	PD
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	0

OWIRE_INTERRUPT field descriptions

Field	Description
15–6 Reserved	This read-only field is reserved and always has the value zero. Reserved
5 RSRF	Receive Shift Register Full. Hardware automatically clears this flag when data in the Receive Shift Register is transferred to the Receive buffer. 0 The Receive Shift Register is empty or currently receiving data. 1 A byte is waiting in the Receive Shift Register to be transferred to the Receive buffer.
4 RBF	Receive Buffer Full. This flag is cleared when software reads the byte from the TX/RX register. This flag prevents new data from being shifted into the Receive buffer from the Receive Shift Register. 0 No new data 1 A byte is waiting to be read from the TX/RX register.
3 TSRE	Transmit Shift Register Empty. Hardware automatically clears this flag when data in the Transmit buffer is transferred to the Transmit Shift Register. 0 Sending data 1 The Transmit Shift Register is empty and is ready to receive the next byte from the Transmit buffer.
2 TBE	Transmit Buffer Empty. This flag is cleared when software writes a byte to the TX/RX register. 0 The Transmit buffer is currently sending data to the Transmit Shift Register. 1 Nothing to transmit
1 PDR	Presence Detect Result. When a presence-detect (PD) interrupt occurs, this bit reflects the result of the presence-detect sequence. Note that this bit does not generate an interrupt. 0 Device found 1 Device not found
0 PD	Presence Detect. After an OWIRE reset has been issued, this flag is set after the appropriate amount of time for a presence detect pulse to have occurred. This flag is cleared when software reads the Interrupt Register. 0 A reset/presence-detect sequence has not been issued. 1 Reset/presence-detect sequence has completed. The result is provided in the PDR bit.

40.4.7 Interrupt Enable Register (OWIRE_INTERRUPT_EN)

The Interrupt Enable Register allows the system programmer to specify the source of interrupts. During a reset (hardware or software), all bits in this register are cleared, disabling all interrupt sources.

Address: OWIRE_INTERRUPT_EN is 63FA_4000h base + Ch offset = 63FA_400Ch

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Read	0										ERSF	ERBF	ETSE	ETBE	IAS	EPD
Write																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

OWIRE_INTERRUPT_EN field descriptions

Field	Description
15–6 Reserved	This read-only field is reserved and always has the value zero. Reserved
5 ERSF	Enable Receive Shift Register Full Interrupt. 0 Disable interrupt. 1 Enable interrupt.
4 ERBF	Enable Receive Buffer Full Interrupt. 0 Disable interrupt. 1 Enable interrupt.
3 ETSE	Enable Transmit Shift Register Empty Interrupt. 0 Disable interrupt. 1 Enable interrupt.
2 ETBE	Enable Transmit Buffer Empty Interrupt. 0 Disable interrupt. 1 Enable interrupt.
1 IAS	Interrupt Trigger Active State. This bit determines the polarity for all interrupts. Note that this bit is not an interrupt-enable bit. 0 Active high 1 Active low
0 EPD	Enable Presence Detect. 0 Disable interrupt. 1 Enable interrupt.

Chapter 41
Performance Monitor (PerfMon)

41.1 Introduction

This chapter describes the Performance Monitor (PerfMon) function included on the i.MX50.

41.2 Overview

The i.MX50 implements a real time systerm performance monitor, it provides the following functions:

- Real-time performance statistics collection on AXI buses
- Single or Multiple master transactions monitoring
- Various interrupts support: address trap, latency threshold and so on.
- AXI protocol and out-of-order sequence support

The performance monitor is illustrated in Figure 41-1.

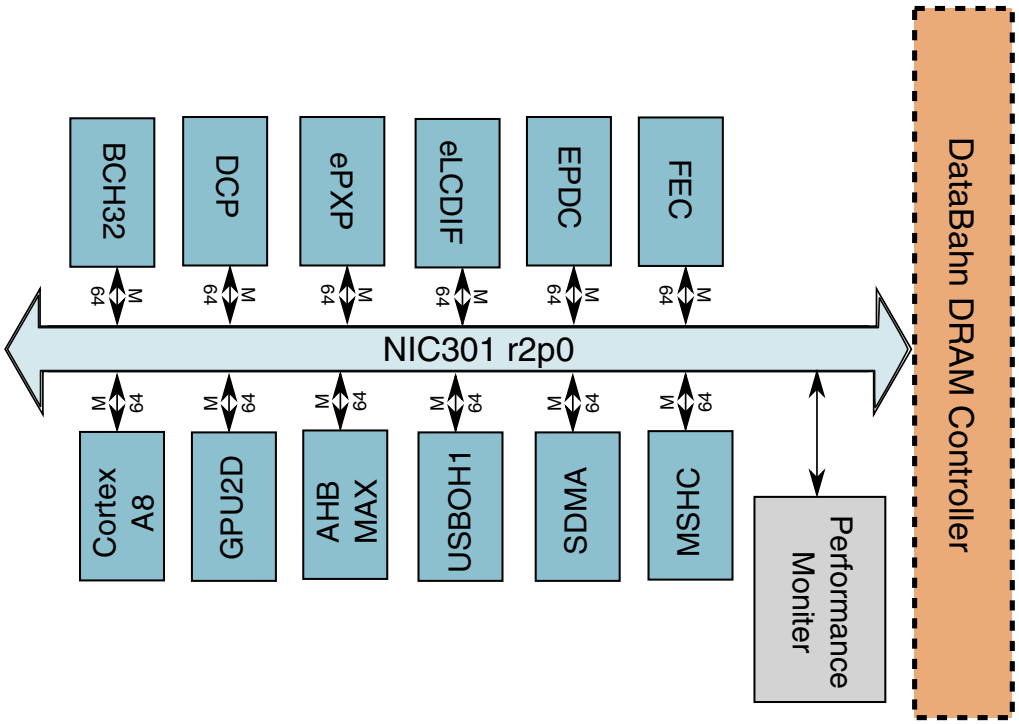

Figure 41-1. Block diagram of PerfMon

41.3 Operation

The role of the performance monitor in an AXI system is to collect real time bus transaction statistics, including transaction average and maximum latency, total data bandwidth, total active cycles. The statistics collection can be configured for single master or multiple masters on the same AXI bus, and can be enable for either read or write transactions.

Table 41-1. Masters and IDs Supported in i.MX50 Perfmon

Master	ARM	DCP	ePXP	USB	GPU2D	BCH32	AHBMAX	EPDC	eLCDIF	SDMA	FEC	MSHC
MID	0	1	2	3	4	5	6	7	8	10	10	11

AXI protocol supports out-of-order transaction completion. In i.MX50, out-of-order transaction is programmable in Databahn DRAM controller. Tag ID is used to trace each transaction and match the data phase with the correct address phase. Performance Monitor supports out-of-order transactions. AXI protocol separates the address/control phase and data phase, and has the ability to issue multiple outstanding addresses. It gives

an ID tag to every transaction across the interface , which consists 4bit master ID and 4 bit subID. Every master has its own unique master ID, and each master could have up to 16 sub IDs, which means up to 16 outstanding address phases.

PerfMon collects the accumulated latency on cycle counts and number of transfers, the average latency can be calculated by dividing the total latency over number of transfers. Since the AXI protocol separates the address and data phases, the address and data phases could be overlapped, and individual data phase could overlap with multiple address phase. Statistics on total cycles, total data transfer in bytes will be collected as well. All statistics are collected for either read or write transactions, which could be switched by the enable bit in the control register.

To calculate the maximum latency and support out-of-order transaction, PerfMon needs to cache the tag ID for all the outstanding requests. The potential number of outstanding requests depends on how deep the command queue in the memory controller (Databahn) which includes two level of command queues. A scoreboard will be implemented to match the tag ID of the ongoing data phase with the ID from the outstanding requests. PerfMon snapshots the master ID (8 bits), burst length (4 bits), burst type (2 bits), burst size(3 bits) for the content register of maximum latency, but no transfer address (32 bits).

Registers in PerfMon are accessible through APBH bridge, and PerfMon registers sits on APBH clock domain. Shade registers are added for the coherence among statistics/status registers, and the snapshot bit in PerfMon control register will trigger the shade register being filled at the same cycle for these registers: total transfers, total latency, maximum latency, content register for max_latency, total data bytes, total active cycles, and total cycles.

Various interrupts supported in this module are as follows:

- Address trap IRQ-IRQ will be asserted if any transaction address hit within the pre-configured address range.
- Address range inversion IRQ-IRQ will be asserted if any transaction address hit outside the pre-configured address range.
- Max latency threshold IRQ-IRQ will be asserted if maximum latency is above the value defined in the threshold register.
- Bus error IRQ-IRQ will be asserted if any AXI transaction triggers an error response.

41.4 Programmable Registers

PERFMON Hardware Register Format Summary

PERFMON memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4101_4000	PerfMon Control Register (PERFMON_CTRL)	32	R/W	C000_0000h	41.4.1/ 2374
4101_4004	PerfMon Control Register (PERFMON_CTRL_SET)	32	R/W	C000_0000h	41.4.1/ 2374
4101_4008	PerfMon Control Register (PERFMON_CTRL_CLR)	32	R/W	C000_0000h	41.4.1/ 2374
4101_400C	PerfMon Control Register (PERFMON_CTRL_TOG)	32	R/W	C000_0000h	41.4.1/ 2374
4101_4010	PerfMon Master Enable Register (PERFMON_MASTER_EN)	32	R/W	0000_0000h	41.4.2/ 2376
4101_4020	PerfMon Trap Range Low Address Register (PERFMON_TRAP_ADDR_LOW)	32	R/W	0000_0000h	41.4.3/ 2377
4101_4030	PerfMon Trap Range High Address Register (PERFMON_TRAP_ADDR_HIGH)	32	R/W	0000_0000h	41.4.4/ 2378
4101_4040	PerfMon Latency Threshold Register (PERFMON_LAT_THRESHOLD)	32	R/W	0000_0000h	41.4.5/ 2379
4101_4050	PerfMon AXI Active Cycle Count Register (PERFMON_ACTIVE_CYCLE)	32	R	0000_0000h	41.4.6/ 2379
4101_4060	PerfMon Transfer Count Register (PERFMON_TRANSFER_COUNT)	32	R	0000_0000h	41.4.7/ 2380
4101_4070	PerfMon Total Latency Count Register (PERFMON_TOTAL_LATENCY)	32	R	0000_0000h	41.4.8/ 2380
4101_4080	PerfMon Total Data Count Register (PERFMON_DATA_COUNT)	32	R	0000_0000h	41.4.9/ 2381
4101_4090	PerfMon Maximum Latency Register (PERFMON_MAX_LATENCY)	32	R	0000_0000h	41.4.10/ 2381
4101_40A0	PerfMon Debug Register (PERFMON_DEBUG)	32	R/W	0000_0001h	41.4.11/ 2382
4101_40B0	PerfMon Version Register (PERFMON_VERSION)	32	R	0101_0000h	41.4.12/ 2383

41.4.1 PerfMon Control Register (PERFMON_CTRL*n*)

The PerfMon Control Register specifies the reset state and the interrupt controls for the Performance Monitor.

This register controls various functions of the system performance monitor.

EXAMPLE

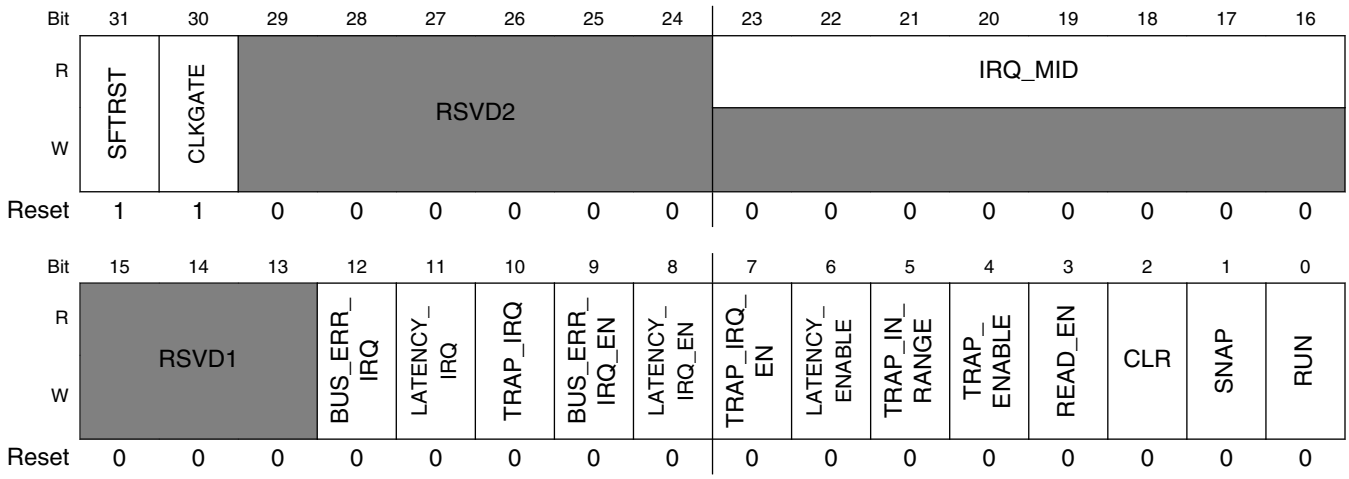
```
// turn off soft reset and clock gating
PERFMON_CTRL_CLR(BM_PERFMON_CTRL_SFTRST| BM_PERFMON_CTRL_CLKGATE);
```

Addresses: PERFMON_CTRL is 4101_4000h base + 0h offset = 4101_4000h

PERFMON_CTRL_SET is 4101_4000h base + 4h offset = 4101_4004h

PERFMON_CTRL_CLR is 4101_4000h base + 8h offset = 4101_4008h

PERFMON_CTRL_TOG is 4101_4000h base + Ch offset = 4101_400Ch



PERFMON_CTRL*n* field descriptions

Field	Description
31 SFTRST	Set to zero for normal operation. When this bit is set to one (default), then the entire block is held in its reset state. 0x0 **RUN** — Allow PerfMon to operate normally. 0x1 **RESET** — Hold PerfMon in reset.
30 CLKGATE	This bit must be set to zero for normal operation. When set to one it gates off the clocks to the block. 0x0 **RUN** — Allow PerfMon to operate normally. 0x1 **NO_CLKS** — Do not clock PerfMon gates in order to minimize power consumption.
29–24 RSVD2	Always set this bit field to zero.
23–16 IRQ_MID	This field contains the master ID and sub ID associated with the interrupt. If multiple IRQs, it is the ID associated the first IRQ transaction, and will not update until the IRQ being cleared.
15–13 RSVD1	Always set this bit field to zero.
12 BUS_ERR_IRQ	This bit is set if there is error on any AXI transaction and the BUS_ERR_IRQ_EN bit is set.
11 LATENCY_IRQ	This status bit is set if maximum latency is above the value defined in the latency threshold register and the LATENCY_ENABLE bit is set. Writing a one to its SCT clear address to clear it.
10 TRAP_IRQ	This status bit is set to indicate that an address trap occurs. This bit is cleared by software by writing a one to its SCT clear address. This bit is set if axi address is within the pre-configured address range and the trap function is enabled with TRAP_ENABLE bit.
9 BUS_ERR_IRQ_EN	Enables the PerfMon AXI BUS ERROR IRQ. When an error occurs and this bit is set, an interrupt is sent to the ARM core.

Table continues on the next page...

PERFMON_CTRL*n* field descriptions (continued)

Field	Description
8 LATENCY_IRQ_EN	Enables the PerfMon Latency threshold IRQ. When an error occurs and this bit is set, an interrupt is sent to the ARM core.
7 TRAP_IRQ_EN	Enables the PerfMon Address Trap IRQ. When an trap occurs and this bit is set, an interrupt is sent to the ARM core.
6 LATENCY_ENABLE	Enables the PerfMon AXI latency threshold functions. When a transfer latency larger than the threshold and this bit is set, the LATENCY_IRQ status bit will be set.
5 TRAP_IN_RANGE	Determines whether the debug trap function causes a match when the master address is inside (low-address <= current-address <= high-address) the specified range. 0 = The trap occurs when the master address falls outside of the range. 1 = The check is inside the range.
4 TRAP_ENABLE	Enables the PerfMon AXI address trap functions. When a trap occurs and this bit is set, the TRAP_IRQ status bit will be set.
3 READ_EN	Set this bit to One to monitor all Read transactions, set to zero to monitor all Write transactions. 0 = performance monitoring on all WRITE activities. 1 = performance monitoring on all READ activities.
2 CLR	Set this bit to clear all the PerfMon's statistics registers. This bit will be reset to 0 once the clear process is done.
1 SNAP	Set this bit to snap shot PerfMon's statistics registers into the shadow registers for reads. PerfMon will continue collecting and updating statistics registers. This bit will be reset to 0 once the snapshot processing is done.
0 RUN	Set this bit to one to enable the PerfMon operation. 0x0 **HALT** — No PerfMon command in progress. 0x1 **RUN** — Process Performance monitoring.

41.4.2 PerfMon Master Enable Register (PERFMON_MASTER_EN)

The Master Enable Register defines single or multiple MasterIDs to be monitored by Perfmon.

This register configs the MasterID mask to be monitored. The master ID of Core is 0, DCP is 1, ePXP is 2, USBOH1 is 3, GPU2D is 4, BCH32 is 5 , AHB MAX is 6, EPDC is 7, eLCDIF is 8, SDMA is 9, FEC is 10, and MSHC is 11.

Address: PERFMON_MASTER_EN is 4101_4000h base + 10h offset = 4101_4010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	RSVD0																MID15	MID14	MID13	MID12	MID11	MID10	MID9	MID8	MID7	MID6	MID5	MID4	MID3	MID2	MID1	MID0
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PERFMON_MASTER_EN field descriptions

Field	Description
31–16 RSVD0	Always set this bit field to zero.
15 MID15	Set to 1 to enable performance monitoring and statistics collection on MasterID 15.
14 MID14	Set to 1 to enable performance monitoring and statistics collection on MasterID 14.
13 MID13	Set to 1 to enable performance monitoring and statistics collection on MasterID 13.
12 MID12	Set to 1 to enable performance monitoring and statistics collection on MasterID 12.
11 MID11	Set to 1 to enable performance monitoring and statistics collection on MasterID 11.
10 MID10	Set to 1 to enable performance monitoring and statistics collection on MasterID 10.
9 MID9	Set to 1 to enable performance monitoring and statistics collection on MasterID 9.
8 MID8	Set to 1 to enable performance monitoring and statistics collection on MasterID 8.
7 MID7	Set to 1 to enable performance monitoring and statistics collection on MasterID 7.
6 MID6	Set to 1 to enable performance monitoring and statistics collection on MasterID 6.
5 MID5	Set to 1 to enable performance monitoring and statistics collection on MasterID 5.
4 MID4	Set to 1 to enable performance monitoring and statistics collection on MasterID 4.
3 MID3	Set to 1 to enable performance monitoring and statistics collection on MasterID 3.
2 MID2	Set to 1 to enable performance monitoring and statistics collection on MasterID 2.
1 MID1	Set to 1 to enable performance monitoring and statistics collection on MasterID 1.
0 MID0	Set to 1 to enable performance monitoring and statistics collection on MasterID 0.

41.4.3 PerfMon Trap Range Low Address Register (PERFMON_TRAP_ADDR_LOW)

The Debug Trap Range Low Address Register defines the lower bound for an address range that can be enabled to trigger an interrupt to the ARM core when an AXI cycle occurs within this range.

This register sets the lower address that defines the debug trap function. When this function is enabled, any active AXI cycle which accesses this range will trigger an interrupt to the ARM core.

Address: PERFMON_TRAP_ADDR_LOW is 4101_4000h base + 20h offset = 4101_4020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PERFMON_TRAP_ADDR_LOW field descriptions

Field	Description
31–0 ADDR	This field contains the 32-bit lower address for the debug trap range.

41.4.4 PerfMon Trap Range High Address Register (PERFMON_TRAP_ADDR_HIGH)

The Trap Range High Address Register defines the upper bound for an address range that can be enabled to trigger an interrupt to the ARM core when an AXI cycle occurs within this range.

This register sets the upper address that defines the debug trap function. When this function is enabled, any active AXI cycle which accesses this range will trigger an interrupt to the ARM core.

Address: PERFMON_TRAP_ADDR_HIGH is 4101_4000h base + 30h offset = 4101_4030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PERFMON_TRAP_ADDR_HIGH field descriptions

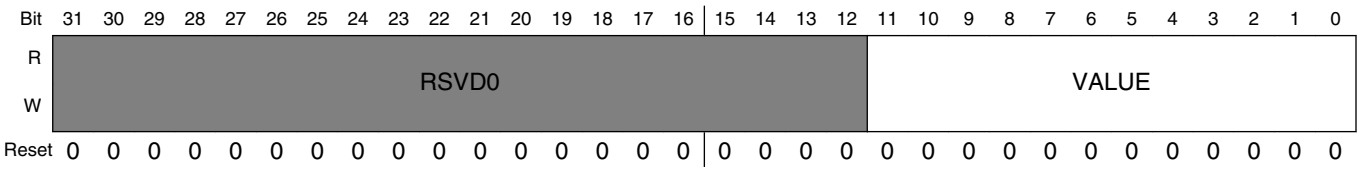
Field	Description
31–0 ADDR	This field contains the 32-bit upper address for the debug trap range.

41.4.5 PerfMon Latency Threshold Register (PERFMON_LAT_THRESHOLD)

The Latency Threshold Register defines the threshold for AXI transaction latency that can be enabled to trigger an interrupt to the ARM core when an AXI transaction latency is above this value.

This register sets the threshold value of AXI transaction. When this function is enabled, any active AXI cycle which has a latency above this value will trigger an interrupt to the ARM core.

Address: PERFMON_LAT_THRESHOLD is 4101_4000h base + 40h offset = 4101_4040h



PERFMON_LAT_THRESHOLD field descriptions

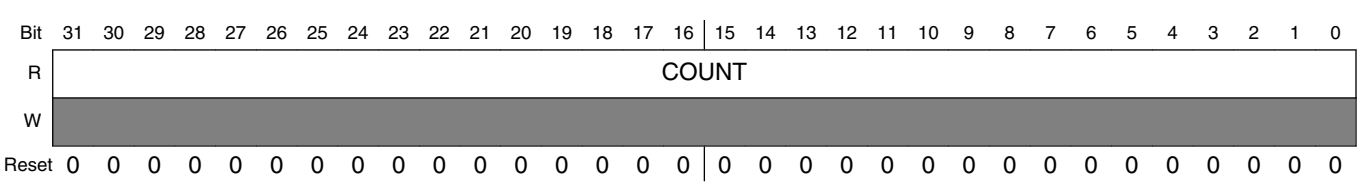
Field	Description
31–12 RSVD0	Always set this bit field to zero.
11–0 VALUE	This field contains the 12-bit transaction latency threshold.

41.4.6 PerfMon AXI Active Cycle Count Register (PERFMON_ACTIVE_CYCLE)

The Active Cycle Count Register counts the number of AXI cycles during which a transaction is active on AXI bus.

This register counts the number of AXI cycles in which a master was requesting a transfer, and the slave had not responded. This is including cycles in which it was requesting transfers but was not accepted by slave yet. The Master Enable Register PERFMON_MASTER_EN are used to mask which master(s) cycles are actually recorded here.

Address: PERFMON_ACTIVE_CYCLE is 4101_4000h base + 50h offset = 4101_4050h



PERFMON_ACTIVE_CYCLE field descriptions

Field	Description
31–0 COUNT	This field contains the total active AXI cycle counts. If overflow, the value will be 0xFFFFFFFF.

41.4.7 PerfMon Transfer Count Register (PERFMON_TRANSFER_COUNT)

The Transfer Count Register defines the total number of transfers has been completed during the whole monitoring period.

Divide the register PERFMON_LATENCY_CYCLE value over this value of this register will give the average latency for each transfer.

Address: PERFMON_TRANSFER_COUNT is 4101_4000h base + 60h offset = 4101_4060h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	VALUE																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PERFMON_TRANSFER_COUNT field descriptions

Field	Description
31–0 VALUE	This field contains the total amount transfers. If overflow, the value will be 0xFFFFFFFF.

41.4.8 PerfMon Total Latency Count Register (PERFMON_TOTAL_LATENCY)

The Total Latency Count Register defines the total number of latency in cycles during the monitoring period.

Divide the register value over value of register PERFMON_TRANSFER_COUNT will give the average latency for each transfer.

Address: PERFMON_TOTAL_LATENCY is 4101_4000h base + 70h offset = 4101_4070h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	COUNT																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PERFMON_TOTAL_LATENCY field descriptions

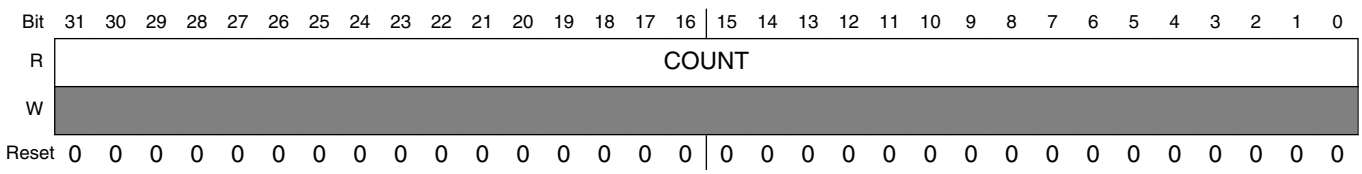
Field	Description
31–0 COUNT	This field contains the total latency in cycle counts. If overflow, the value will be 0xFFFFFFFF.

41.4.9 PerfMon Total Data Count Register (PERFMON_DATA_COUNT)

The Data Count Register defines the total number of data transferred in bytes during the monitoring period.

Total transfer data count in bytes.

Address: PERFMON_DATA_COUNT is 4101_4000h base + 80h offset = 4101_4080h



PERFMON_DATA_COUNT field descriptions

Field	Description
31–0 COUNT	This field contains the total bytes of data transferred. If overflow, the value will be 0xFFFFFFFF.

41.4.10 PerfMon Maximum Latency Register (PERFMON_MAX_LATENCY)

The Maximum Latency Register contains the maximum latency in cycles during the monitoring period.

This register contains the maximum latency counts in cycle and control signals for this transaction.

Address: PERFMON_MAX_LATENCY is 4101_4000h base + 90h offset = 4101_4090h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	ABURST		ALEN				ASIZE			TAGID[-8:1]						
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	TAGID[bit 0]	RSVD0			COUNT											
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

PERFMON_MAX_LATENCY field descriptions

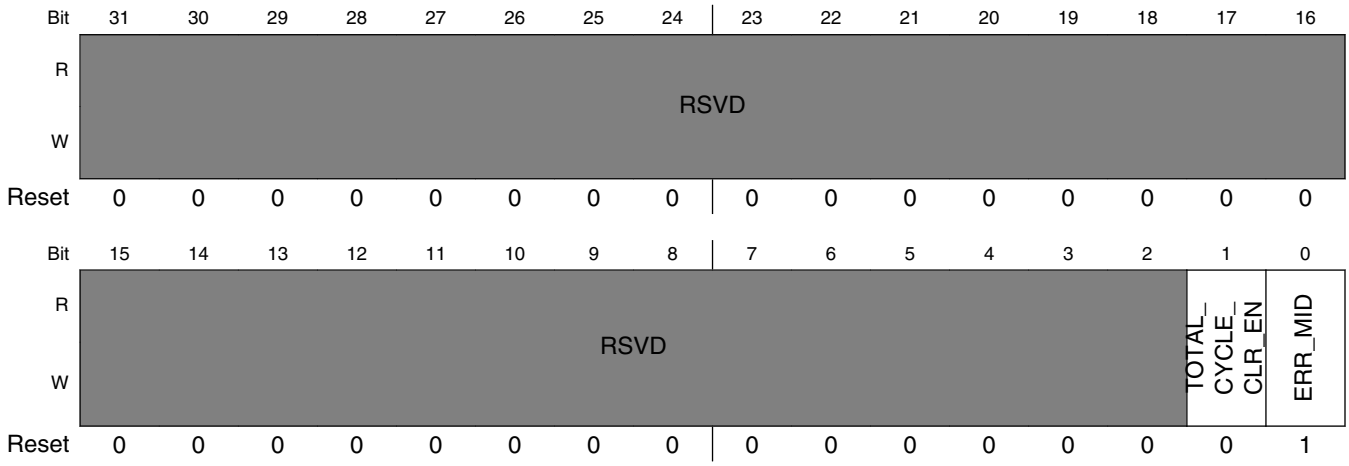
Field	Description
31–30 ABURST	This field contains axi_aburst signal associated with the worst latency transaction.
29–26 ALEN	This field contains axi_alen signal associated with the worst latency transaction.
25–23 ASIZE	This field contains axi_asize signal associated with the worst latency transaction.
22–15 TAGID	This field contains the master id and sub id associated with the worst latency transaction.
14–12 RSVD0	Always set this bit field to zero.
11–0 COUNT	This field contains the worst transfer latency. If overflow, the value will be 0xFFF.

41.4.11 PerfMon Debug Register (PERFMON_DEBUG)

The Debug Register is for internal use only.

Divide the register PERFMON_LATENCY_CYCLE value over this value of this register will give the average latency for each transfer.

Address: PERFMON_DEBUG is 4101_4000h base + A0h offset = 4101_40A0h



PERFMON_DEBUG field descriptions

Field	Description
31–2 RSVD	Always set this bit field to zero.
1 TOTAL_CYCLE_CLR_EN	This field is for debug purpose. Set to 1 to clear the internal total cycle register no matter there is pending request or not when the clear bit in control register is set.
0 ERR_MID	This field is for debug purpose. Set to 0 will not record the MID for bus error irq.

41.4.12 PerfMon Version Register (PERFMON_VERSION)

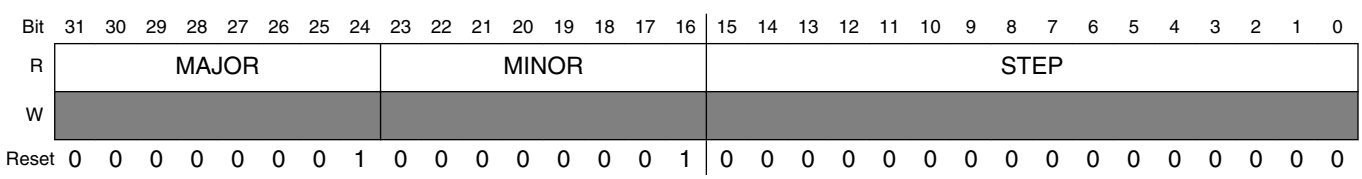
The Version Register always returns a known read value for debug purposes it indicates the version of the block.

This register indicates the RTL version in use.

EXAMPLE

```
if (PERFMON_VERSION.B.MAJOR != 1) Error();
```

Address: PERFMON_VERSION is 4101_4000h base + B0h offset = 4101_40B0h



PERFMON_VERSION field descriptions

Field	Description
31–24 MAJOR	Fixed read-only value reflecting the MAJOR field of the RTL version.
23–16 MINOR	Fixed read-only value reflecting the MINOR field of the RTL version.
15–0 STEP	Fixed read-only value reflecting the stepping of the RTL version.

Chapter 42
Pulse Width Modulation (PWM)

42.1 Overview

The Pulse Width Modulation (PWM) has a 16-bit counter, and is optimized to generate sound from stored sample audio images and it can also generate tones. It uses 16-bit resolution and a 4 x 16 data FIFO.

This section presents an overview of the PWM. The figure below illustrates the PWM diagram.

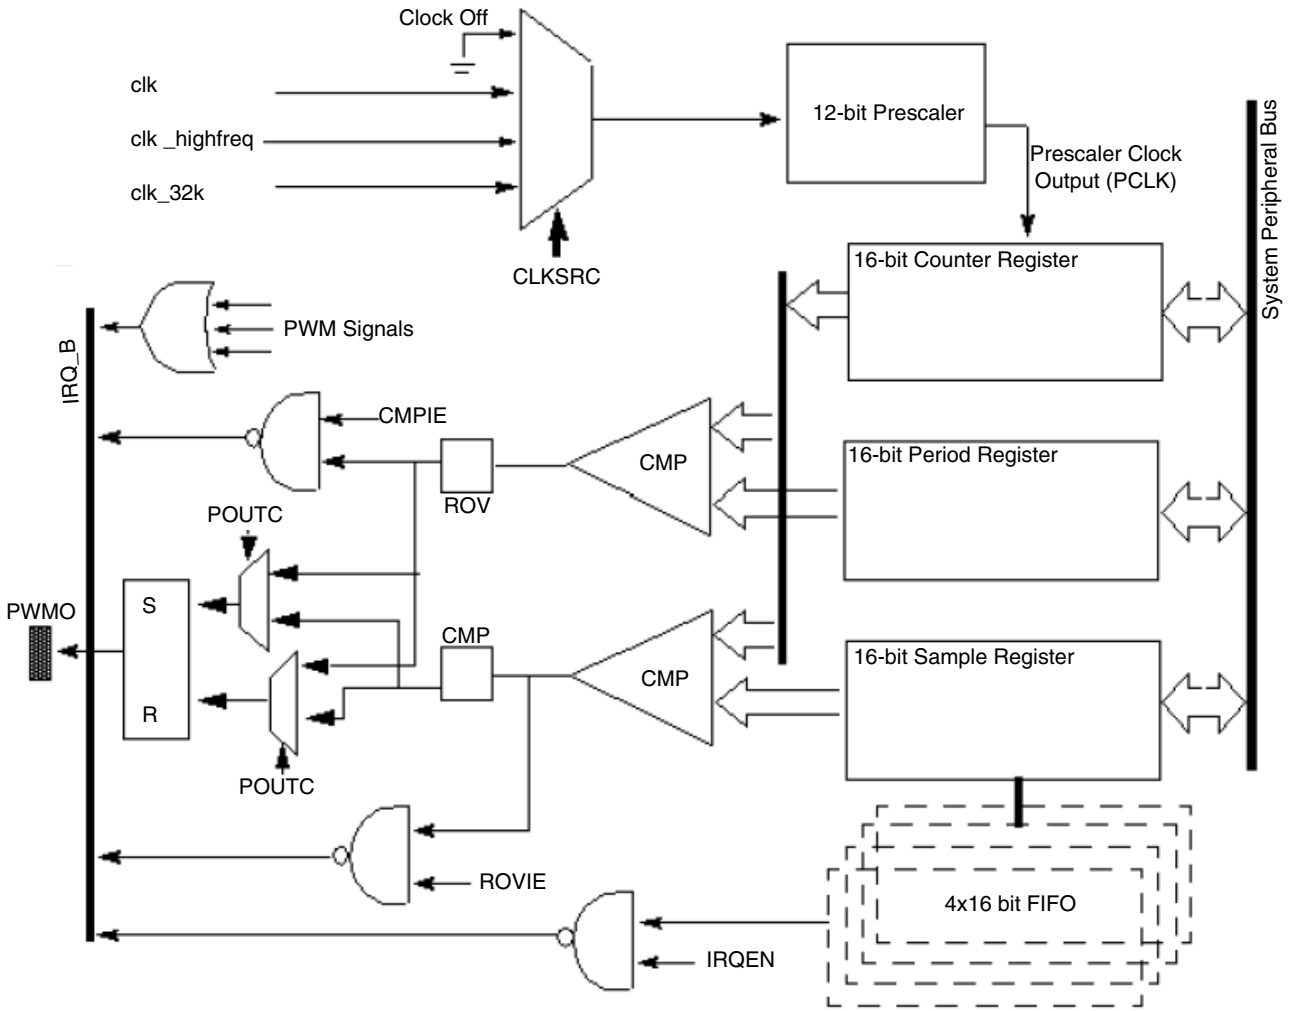


Figure 42-1. Pulse-Width Modulator Block Diagram

The following features characterize the PWM:

- 16-bit up-counter with clock source selection
- 4 x 16 FIFO to minimize interrupt overhead
- 12-bit prescaler for division of clock
- Sound and melody generation
- Active high or active low configured output
- Can be programmed to be active in low-power mode
- Can be programmed to be active in debug mode
- Interrupts at compare and rollover

42.2 Signal Description

The PWM follows IP Bus protocol when interfacing with the processor core. It does not have any interface signals with any other block inside the chip except for clock and reset inputs from the Clock Control Module (CCM), System Reset Controller (SRC), and interrupt signals to the processor interrupt handler. There is a single output signal going outside the chip boundary.

42.2.1 External Signals

PWM has a single output signal to the chip boundary named ipp_do_pwmo.

The following table outlines the external signals.

Table 42-1. External Signals

Name	Direction	Function	Reset State	Pull up
PWMxO	Output	This is the functional output of the PWM. The modulated signal of the block is observed at this pin. It can be viewed as a clock signal whose period and duty cycle can be varied with different settings of the PWM. The smallest period can be two ipg_clk clock periods with duty cycle of 50%.	0	-

42.3 Functional Description

The following sections detail the PWM operation and function.

42.3.1 Operation

The output of the PWM is a toggling signal whose frequency and duty cycle can be modulated by programming the appropriate registers. It has a 16-bit up counter which counts from 0x0000 until the counter value equals the [Value in Period register] + 1. After this match occurs the Counter is reset to 0x0000.

At the beginning of a count period cycle, the PWMO pin is set to one (default) and the counter begins counting up from 0x0000. The sample value in the sample FIFO is compared on each count of prescaler clock. When the sample and count values match, the PWMO signal is cleared to zero (default). The counter continues counting until the period match occurs and subsequently another period cycle begins.

When the PWM is enabled the counter starts running and generates an output with the reset values in the period and sample registers. It is recommended that the programming of these registers be done before PWM is enabled.

A hardware reset results in all the PWM count and sample registers begin cleared and the FIFO being flushed. The control register shows that FIFO is empty and it can be written into, and the PWM is disabled. A software reset has the same results, however the state of the STOPEN, DOZEN, WAITEN, and DBGEN bits in the control register are not affected. Software reset can be asserted even when the PWM is in disabled state.

42.3.1.1 Clocks

The clock that feeds the prescaler can be selected from:

- High frequency Clock (ipg_clk_highfreq) pat_ref or CKIH

  This is a high frequency clock, provided by the Clock Control Module (CCM). This clock should be in the low power mode when the ipg_clk is turned off. Thus, the PWM can be run on this clock in the low power mode.

- Low Reference Clock (ipg_clk_32k) CKIL

  This is the 32 KHz low reference clock which is provided by the CCM. This clock should be on in the low power mode when ipg_clk is turned off. Thus, PWM can be run on this clock in the low power mode.

- Global Functional Clock (ipg_clk)

  This clock should be on in normal operations. In low power modes it can be switched off.

The clock input source is determined by the CLKSRC field of the PWM control register. The CLKSRC value should only be changed when the PWM is disabled.

A change in the value of the PRESCALER field of the control register is immediately reflected on its output clock frequency.

42.3.1.2 FIFO

Digital sample values can be loaded into the pulse-width modulator as 16-bit words. The endianess can be changed using the BCTR and HCTR bits of the control register. A 4-word (16-bit) FIFO minimizes interrupt overhead. A maskable interrupt is generated when the number of data words fall below the water level set by the FWM field in the control register.

A write in the sample register results in the value being stored into the FIFO if it is not full. A write when the FIFO is full sets FWE (FIFO write error) bit in the status register and the FIFO contents remain unchanged. The FIFO can be written into when the PWM is disabled. The FIFOAV field shows how many data words are currently contained in the FIFO and whether or not it can be written into.

A read on the sample register yields the current FIFO value that is being used, or will be used, by the PWM for generation on the output signal. Therefore, a write and a subsequent read on the sample register may result in different values being obtained.

42.3.1.3 Rollover and Compare Event

The counter is reset to 0x0000 after its value equals the PERIOD + 1 and resumes counting thereafter. This event is referred to as a rollover. When PERIOD = 0x0000, the counter is reset after count reaches 0x0001. Therefore PERIOD = 0xffff or 0xfffe results in the counter value being reset after count till 0xffff. During a rollover event the output is either set (default), reset or has no effect according to the programming of the POUTC field in the control register. This event can also generate an interrupt if the respective interrupt enable bit is set in the control register.

When the counter value reaches the sample value, the output of the PWM is reset (default), set or has no effect according to the programming of the POUTC field of control register. This event is referred to as a compare event. This event can also generate an interrupt if the respective interrupt enable bit is set in the control register.

If the rollover event sets the PWM output signal, the compare event will reset it and vice versa for a particular programming configuration of POUTC field.

42.3.1.4 Low Power Mode Behavior

In low power modes, if the clock from the selected clock source is available, the PWM counter continues to run and an output is produced, depending on whether the control bit for that mode is set or not. In the absence of the clock itself, or if the corresponding low power bit in the control register is 0, the counter is reset and resumes counting when it exits the low power mode.

42.3.1.5 Debug Mode Behavior

In debug mode, PWM has the option of continuing to run or be halted. If the DBGEN bit is not set in the PWM_PWMCR, the PWM is halted. If the DBGEN bit is set, then the PWM will continue to run in the debug mode.

42.4 Programmable Registers

The PWM includes six user-accessible 32-bit registers.

PWM memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
53FB_4000	PWM Control Register (PWM-1_PWMCR)	32	R/W	0000_0000h	42.4.1/ 2391
53FB_4004	PWM Status Register (PWM-1_PWMSR)	32	w1c	0000_0008h	42.4.2/ 2393
53FB_4008	PWM Interrupt Register (PWM-1_PWMIR)	32	R/W	0000_0000h	42.4.3/ 2394
53FB_400C	PWM Sample Register (PWM-1_PWMSAR)	32	R/W	0000_0000h	42.4.4/ 2395
53FB_4010	PWM Period Register (PWM-1_PWMPR)	32	R/W	0000_FFFEh	42.4.5/ 2396

42.4.1 PWM Control Register (PWMx_PWMCR)

The PWM control register (PWM_PWMCR) is used to configure the operating settings of the PWM. It contains the prescaler for the clock division.

Addresses: PWM-1_PWMCR is 53FB_4000h base + 0h offset = 53FB_4000h

PWM-2_PWMCR is 53FB_8000h base + 0h offset = 53FB_8000h

PWMx_PWMCR field descriptions

Field	Description
31–28 Reserved	This read-only field is reserved and always has the value zero. Reserved. These reserved bits are always read as zero.
27–26 FWM	FIFO Water Mark. These bits are used to set the data level at which the FIFO empty flag will be set and the corresponding interrupt generated 00 FIFO empty flag is set when there are more than or equal to 1 empty slots in FIFO 01 FIFO empty flag is set when there are more than or equal to 2 empty slots in FIFO 10 FIFO empty flag is set when there are more than or equal to 3 empty slots in FIFO 11 FIFO empty flag is set when there are more than or equal to 4 empty slots in FIFO
25 STOPEN	Stop Mode Enable. This bit keeps the PWM functional while in stop mode. When this bit is cleared, the input clock is gated off in stop mode. This bit is not affected by software reset. It is cleared by hardware reset.

Table continues on the next page...

PWMx_PWMCR field descriptions (continued)

Field	Description
	0 Inactive in stop mode 1 Active in stop mode
24 DOZEN	Doze Mode Enable. This bit keeps the PWM functional in doze mode. When this bit is cleared, the input clock is gated off in doze mode. This bit is not affected by software reset. It is cleared by hardware reset. 0 Inactive in doze mode 1 Active in doze mode
23 WAITEN	Wait Mode Enable. This bit keeps the PWM functional in wait mode. When this bit is cleared, the input clock is gated off in wait mode. This bit is not affected by software reset. It is cleared by hardware reset. 0 Inactive in wait mode 1 Active in wait mode
22 DBGEN	Debug Mode Enable. This bit keeps the PWM functional in debug mode. When this bit is cleared, the input clock is gated off in debug mode. This bit is not affected by software reset. It is cleared by hardware reset. 0 Inactive in debug mode 1 Active in debug mode
21 BCTR	Byte Data Swap Control. This bit determines the byte ordering of the 16-bit data when it goes into the FIFO from the sample register. 0 byte ordering remains the same 1 byte ordering is reversed
20 HCTR	Half-word Data Swap Control. This bit determines which half word data from the 32-bit IP Bus interface is written into the lower 16 bits of the sample register. 0 Half word swapping does not take place 1 Half words from write data bus are swapped
19–18 POUTC	PWM Output Configuration. This bit field determines the mode of PWM output on the output pin. 00 Output pin is set at rollover and cleared at comparison 01 Output pin is cleared at rollover and set at comparison 10 PWM output is disconnected 11 PWM output is disconnected
17–16 CLKSRC	Select Clock Source. These bits determine which clock input will be selected for running the counter. After reset the system functional clock is selected. The input clock can also be turned off if these bits are set to 00. This field value should only be changed when the PWM is disabled 00 Clock is off 01 ipg_clk 10 ipg_clk_highfreq 11 ipg_clk_32k
15–4 PRESCALER	Counter Clock Prescaler Value. This bit field determines the value by which the clock will be divided before it goes to the counter. 0x000 Divide by 1 0x001 Divide by 2 0xfff Divide by 4096

Table continues on the next page...

PWMx_PWMCR field descriptions (continued)

Field	Description
3 SWR	Software Reset. PWM is reset when this bit is set to 1. It is a self clearing bit. A write 1 to this bit is a single wait state write cycle. When the block is in reset state this bit is set and is cleared when the reset procedure is over. Setting this bit resets all the registers to their reset values except for the STOPEN, DOZEN, WAITEN, and DBGEN bits in this control register. 0 PWM is out of reset 1 PWM is undergoing reset
2–1 REPEAT	Sample Repeat. This bit field determines the number of times each sample from the FIFO is to be used. 00 Use each sample once 01 Use each sample twice 10 Use each sample four times 11 Use each sample eight times
0 EN	PWM Enable. This bit enables the PWM. If this bit is not enabled, the clock prescaler and the counter is reset. When the PWM is enabled, it begins a new period, the output pin is set to start a new period while the prescaler and counter are released and counting begins. 0 PWM disabled 1 PWM enabled

42.4.2 PWM Status Register (PWMx_PWMSR)

The PWM status register (PWM_PWMSR) contains seven bits which display the state of the FIFO and the occurrence of rollover and compare events. The FIFOAV bit is read-only but the other four bits can be cleared by writing 1 to them. The FE, ROV, and CMP bits are associated with FIFO-Empty, Roll-over, and Compare interrupts, respectively.

Addresses: PWM-1_PWMSR is 53FB_4000h base + 4h offset = 53FB_4004h

PWM-2_PWMSR is 53FB_8000h base + 4h offset = 53FB_8004h

PWMx_PWMSR field descriptions

Field	Description
31–7 Reserved	This read-only field is reserved and always has the value zero. Reserved. These reserved bits are always read as zero.

Table continues on the next page...

PWMx_PWMSR field descriptions (continued)

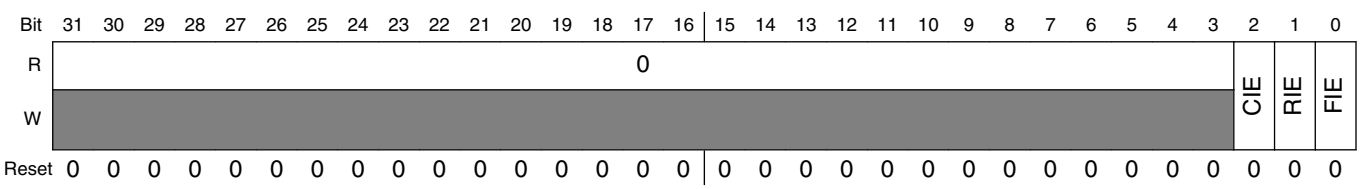
Field	Description
6 FWE	FIFO Write Error Status. This bit shows that an attempt has been made to write FIFO when it is full. 0 FIFO write error not occurred 1 FIFO write error occurred
5 CMP	Compare Status. This bit shows that a compare event has occurred. 0 Compare event not occurred 1 Compare event occurred
4 ROV	Roll-over Status. This bit shows that a roll-over event has occurred. 0 Roll-over event not occurred 1 Roll-over event occurred
3 FE	FIFO Empty Status Bit. This bit indicates the FIFO data level in comparison to the water level set by FWM field in the control register. 0 Data level is above water mark 1 When the data level falls below the mark set by FWM field
2–0 FIFOAV	FIFO Available. These read-only bits indicate the data level remaining in the FIFO. An attempted write to these bits will not affect their value and no transfer error is generated. 000 No data available 001 1 word of data in FIFO 010 2 words of data in FIFO 011 3 words of data in FIFO 100 4 words of data in FIFO 101 unused 110 unused 111 unused

42.4.3 PWM Interrupt Register (PWMx_PWMIR)

The PWM Interrupt register (PWM_PWMIR) contains three bits which control the generation of the compare, rollover and FIFO empty interrupts.

Addresses: PWM-1_PWMIR is 53FB_4000h base + 8h offset = 53FB_4008h

PWM-2_PWMIR is 53FB_8000h base + 8h offset = 53FB_8008h



PWMx_PWMIR field descriptions

Field	Description
31–3 Reserved	This read-only field is reserved and always has the value zero. Reserved. These reserved bits are always read as zero.
2 CIE	Compare Interrupt Enable. This bit controls the generation of the Compare interrupt. 0 Compare Interrupt not enabled 1 Compare Interrupt enabled
1 RIE	Roll-over Interrupt Enable. This bit controls the generation of the Rollover interrupt. 0 Roll-over interrupt not enabled 1 Roll-over Interrupt enabled
0 FIE	FIFO Empty Interrupt Enable. This bit controls the generation of the FIFO Empty interrupt. 0 FIFO Empty interrupt disabled 1 FIFO Empty interrupt enabled

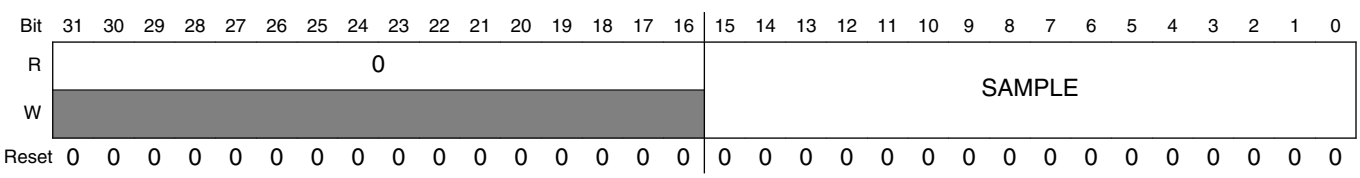
42.4.4 PWM Sample Register (PWMx_PWMSAR)

The PWM sample register (PWM_PWMSAR) is the input to the FIFO. 16-bit words are loaded into the FIFO. The FIFO can be written and read when the PWM is disabled. The PWM will run at the last set duty-cycle setting if all the values of the FIFO has been utilized, until the FIFO is reloaded or the PWM is disabled. When a new value is written, the duty cycle changes after the current period is over.

A value of zero in the sample register will result in the ipp_pwm_pwmo output signal always being low/high (POUTC = 00 it will be low and POUTC = 01 it will be high), and no output waveform will be produced. If the value in this register is higher than the PERIOD + 1, the output will never be set/reset depending on POUTC value.

Addresses: PWM-1_PWMSAR is 53FB_4000h base + Ch offset = 53FB_400Ch

PWM-2_PWMSAR is 53FB_8000h base + Ch offset = 53FB_800Ch



PWMx_PWMSAR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. These are reserved bits and writing a value will not affect the functionality of PWM and are always read as zero.
15–0 SAMPLE	Sample Value. This is the input to the 4x16 FIFO. The value in this register denotes the value of the sample being currently used.

42.4.5 PWM Period Register (PWMx_PWMPR)

The PWM period register (PWM_PWMPR) determines the period of the PWM output signal. After the counter value matches PERIOD + 1, the counter is reset to start another period.

PWMO (Hz) = PCLK(Hz) / (period +2)

A value of zero in the PWM_PWMPR will result in a period of two clock cycles for the output signal. Writing 0xFFFF to this register will achieve the same result as writing 0xFFFE.

A change in the period value due to a write in PWM_PWMPR results in the counter being reset to zero and the start of a new count period.

Addresses: PWM-1_PWMPR is 53FB_4000h base + 10h offset = 53FB_4010h

PWM-2_PWMPR is 53FB_8000h base + 10h offset = 53FB_8010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PWMx_PWMPR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. These are reserved bits and writing a value will not affect the functionality of PWM and are always read as zero.
15–0 PERIOD	Period Value. These bits determine the Period of the count cycle. The counter counts up to [Period Value] +1 and is then reset to 0x0000.

42.4.6 PWM Counter Register (PWMx_PWMCNR)

The read-only pulse-width modulator counter register (PWM_PWMCNR) contains the current count value and can be read at any time without disturbing the counter.

Addresses: PWM-1_PWMCNR is 53FB_4000h base + 14h offset = 53FB_4014h

PWM-2_PWMCNR is 53FB_8000h base + 14h offset = 53FB_8014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

PWMx_PWMCNR field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. These are reserved bits and writing a value will not affect the functionality of PWM and are always read as zero.
15–0 COUNT	Counter Value. These bits are the counter register value and denotes the current count state the counter register is in.

Chapter 43
Enhanced Pixel Pipeline (ePXP)

43.1 Overview

The enhanced pixel pipeline is used to perform alpha blending of graphic or video buffers with graphics data before sending to an LCD display or TV encoder. The ePXP also supports image rotation for hand-held devices that require both portrait and landscape image support.

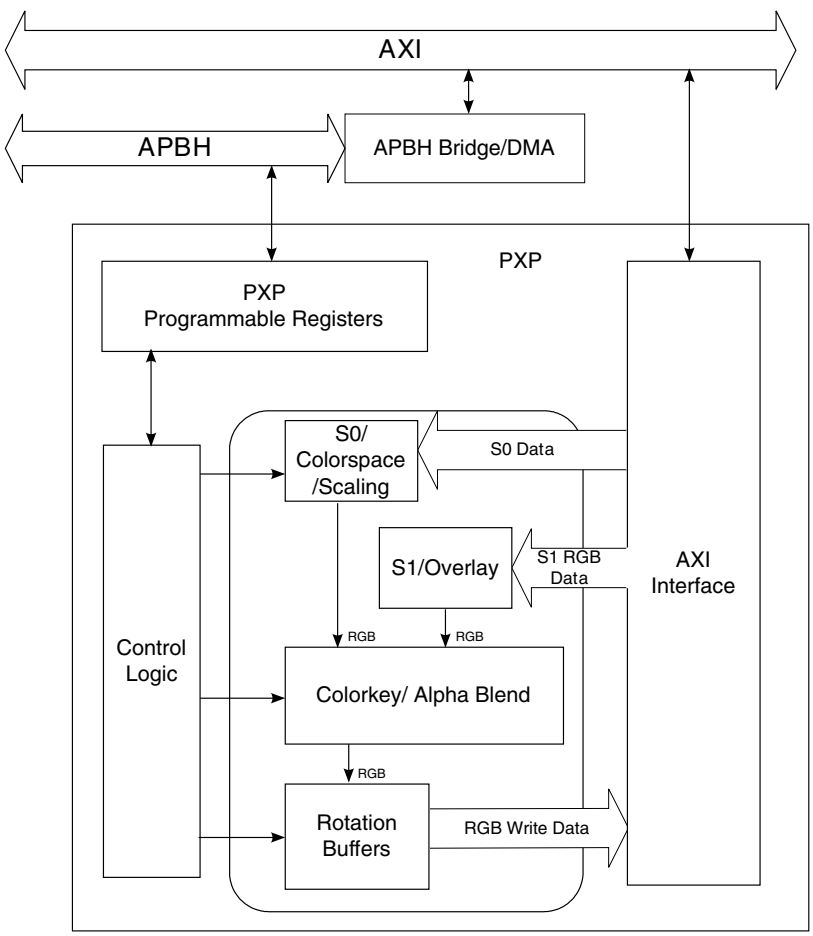

Figure 43-1. ePXP Block Diagram

The ePXP is organized as having a background image (S0) and one or more overlay images that can be blended with the background. Each overlay image must be a multiple of the block size in pixels in both height and width and the offset of the overlay into the background image must also be a multiple of the block size in pixels. As the ePXP processes data, it reads each NxN block from the background image and finds the highest priority (lowest numbered) overlay that is co-located at that block coordinate. The ePXP then fetches the overlay and performs the alpha blending and color key operations on the two blocks. The resulting pixel block is then written to the corresponding block in the output buffer.

For the S0 plane, the ePXP supports RGB images (unscaled) or color space conversion (YUV->RGB) and scaling of YUV images. The S1 plane consists of up to eight overlay regions consisting of 16- or 32-bit RGB data. The S0 and S1 planes may then be combined by alpha blending, color key substitution, or raster operations (ROPs) to form the output image. Finally, the resulting image may be clockwise rotated in 90 degree increments and/or flipped horizontally and/or vertically. The ePXP also supports letterboxing and interlacing of progressive content (by writing alternate lines to different frame buffers).

The flow of data through the ePXP is shown below.

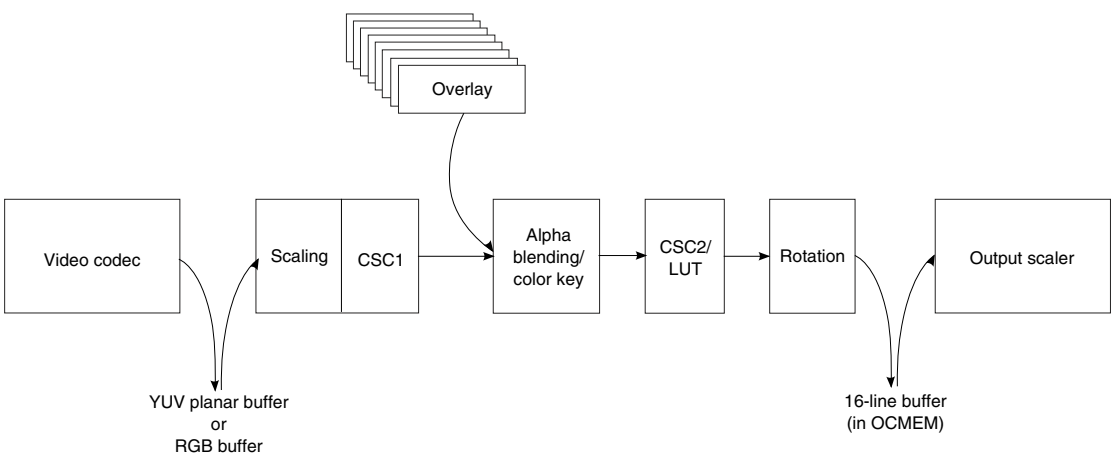

Figure 43-2. ePXP Data flow

43.1.1 Image Support

The ePXP's S0 buffer supports the following image formats:

- 24-bit unpacked RGB (32bpp)
- 24-bit packed RGB (24bpp)

- 16-bit RGB in either 555 or 565 format
- YUV/YCbCr 4:2:2 1/2/3 plane format
- YUV/YCbCr 4:2:0 2/3 plane format

The ePXP's S1 buffer supports the following image formats:

- 32-bit RGB (with or without alpha)
- 16-bit RGB in either 555, 565, or 1555 (alpha)

The ePXP's output buffer supports:

- 32-bit RGB (with alpha)
- 24-bit packed RGB (24bpp)
- 16-bit RGB in either 565, 555, or 1555 format
- YUV 4:4:4/4:2:2 1-plane
- YUV 4:2:2/4:2:0 2-plane
- Y8/4 1-plane monochrome
- Interlaced output processing

Internally, all image data is handled as 32bpp data (either RGB or YUV, depending on output mode selection) for all steps after the color space conversion. Input RGB images are always converted to the equivalent 32bpp format before processing.

43.1.2 Block Size Selection

The ePXP can be configured to process blocks that are either 8 x 8 pixels or 16 x 16 pixels. The granularity of image size and location of video or overlay buffers within the final destination frame buffer has twice the precision when selecting 8 x 8 pixel block sizes. When selecting a 16 x 16 pixel block size, the accesses to fetch S0 and S1 images and write the final frame buffer are more efficient since twice as much data is requested and processed per memory request. When optimizing the system for memory bandwidth and image processing time, configure the ePXP to process 16x16 pixel blocks.

The control registers that are in block size units need to be programmed consistently with the ePXP_CTRL[BLOCK_SIZE] control bit setting. If the source image is 32 x 32 pixels, then the width and height setting will be 4 when selecting 8x8 pixel block size and 2 when selecting 16 x 16 block size.

43.1.3 ePXP Limitations/Issues

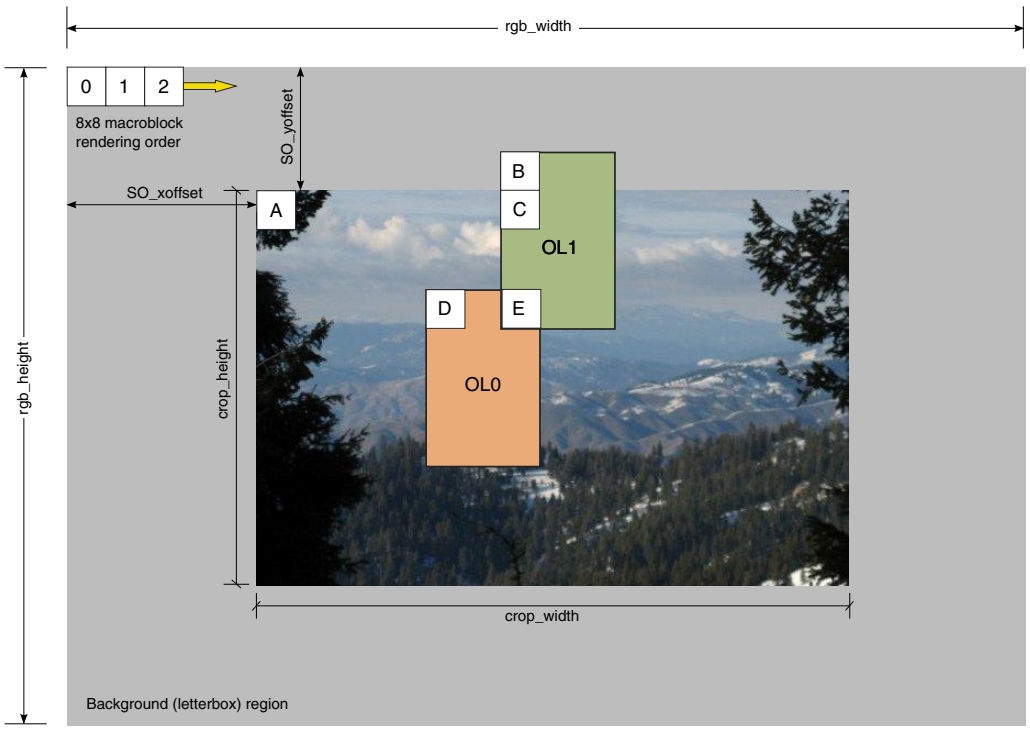
- The ePXP's scalar uses a bilinear scaling algorithm and can scale YUV images from 1/4x to 4096x in 12-bit fractional steps.

- When using the NEXT register, the interrupt enable setting should remain the same for all frames. If not, the ePXP will change the interrupt enable register value and possibly cause the loss of an interrupt.
- The ePXP cannot rotate/flip video in the interlaced modes.
- When performing input interlacing, the input image and overlays must be multiples of 8 x 16 (in 8x8 block size mode) or 16 x 32 (16 x 16 pixel blocks) pixels. Overlays must also reside on the same boundaries.
- Rotations of 180/270 are not supported when performing LCD handshakes.

43.2 Operation

The ePXP operates by rendering the output frame buffer in 8x8 or 16x16 pixel macroblocks in display order (left to right, then top to bottom). At each output macroblock location, the ePXP determines whether the S0 buffer is visible based on the cropping register and S0 offset parameters. If the S0 plane is visible, the ePXP will fetch and process the required data from the S0 image, otherwise, the S0's contribution to the output macroblock will be the ePXP_S0BACKGROUND register value. This value is effectively the color of the letterboxed region or background color.

The ePXP will also determine if an overlay is present for that macroblock location, and if so, instruct the S1 buffer to fetch the required data. If multiple overlays cover the macroblock, the ePXP will select only the lowest numbered overlay and direct the S1 buffer to load the data for this overlay. For areas with no overlays, the S1 buffer contributes nothing to the rendered image. The following figure shows the order in which the output blocks are generated (blocks 0, 1, 2) and indicates how various blocks are rendered (blocks A-E).



0,1,2: Pixel blocks rendered with the background color. The numbering and arrow indicate the order of macroblock rendering.
A: SO Image rendered.
B: Overlay 1 blended with background.
C: Overlay 1 blended with SO image.
D: Overlay 0 blended with SO image.
E: Overlay 0 blended with SO image (OL0 takes precedence over OL1).

Figure 43-3. Output Blocks

It is important to understand how the ePXP renders each output macroblock to properly understand how it accomplishes cropping, letterboxing, and overlay blending. The following sections will provide more details on these operations.

The ePXP also has the ability to rotate/flip images for cases when the pixel scan order is not in the traditional left-to-right/top-to-bottom raster scan (landscape raster). This can occur when a handheld device with a traditional landscape scan is rotated into a portrait orientation (in which the scan order is now bottom-to-top/left-to-right or vice versa) or when a cell phone oriented display (portrait raster) is rotated into a landscape orientation for viewing videos. In these cases, the ePXP still renders the image in scan-order format (as sent to the device), but it will traverse the input images based on the transformations required.

The following sections detail each of the ePXP's functional capabilities.

43.2.1 Pixel Handling

All pixels are internally represented as 24-bit RGB or YUV/YCbCr values with an 8-bit alpha value at all stages in the ePXP after the color space converter (CSC). The output format selected determines the colorspace representation of pixels after the CSC stage of the pixel pipeline. It should be noted that pixels in the YUV/YCbCr color space cannot be blended with S1 overlay pixels since this channel only processes RGB pixel formats.

Input pixels are converted into the RGB format using the following rules:

- 32-bit ARGB8888 pixels are read directly with no conversion for both the S0 and overlay images.
- 32-bit RGB888 pixels are assumed to have an alpha value of 0xFF (full opaque).
- 16-bit RGB565 and RGB555 values are expanded into the corresponding 24-bit color space and assigned an alpha value of 0xFF (opaque). The expansion process replicates the upper pixel bits into the lower pixel bits (for instance a 16-bit RGB565 triplet of 0x1F/0x20/0x07 would be expanded to 0xFF/0x82/0x39).
- 16-bit RGB1555 values are expanded into the corresponding 24-bit color space and assigned an alpha value of either 0x00 or 0xFF, based on the 1-bit alpha value in the pixel. The ALPHA_MULTIPLY function is useful in this scenario to allow scaling of the opaque pixels to a semi-transparent value.

Input pixels are processed in the YUV/YCbCr format using the following rules:

- All pixels are processed through the scaling engine for conversion to the YUV/YCbCr 4:4:4 24-bit format.
- When not resizing the input image, the input pixels are still processed through the scaling engine to convert 4:2:2 or 4:2:0 formats to 4:4:4 formats. Essentially, the chroma values are resized to contain a unique chroma sample for each pixel site.
- S1, or overlays cannot be supported in this case since S1 RGB pixels cannot be converted to YUV/YCbCr.

Output pixels will retain the effective alpha value of the overlay or can be set to a programmed alpha value using the ALPHA field of the ePXP_OUTSIZE register. 16-bit pixels values are formed from the most significant bits of the 24-bit pixel values.

43.2.2 S0 Cropping/Masking

The ePXP's cropping operation should be viewed as a mask on the output image through which the background S0 plane can be viewed. Using this definition clarifies a subtlety on the usage of cropping an image when the image is scaled. When scaling is not used, the input and output image sizes are the same, therefore, the operation is analogous to cropping the input source image.

The background output image can be cropped to a width and height independent of the image size at a given offset into the image (all sizes are in terms of block size pixel units) using the values in the ePXP_S0CROP register. The XBASE and YBASE provide the coordinates of the first block to be displayed from the source image and the WIDTH and HEIGHT parameters specify an effective size of the resulting image in the output buffer.

Cropping must be enabled by setting the CROP bit in the ePXP_CTRL register to a 1. When not set, the visible portions of the S0 image will be rendered based on the WIDTH and HEIGHT specified in the S0SIZE field. The following figure indicates how the various cropping parameters relate to the source and RGB images (non-scaled case).

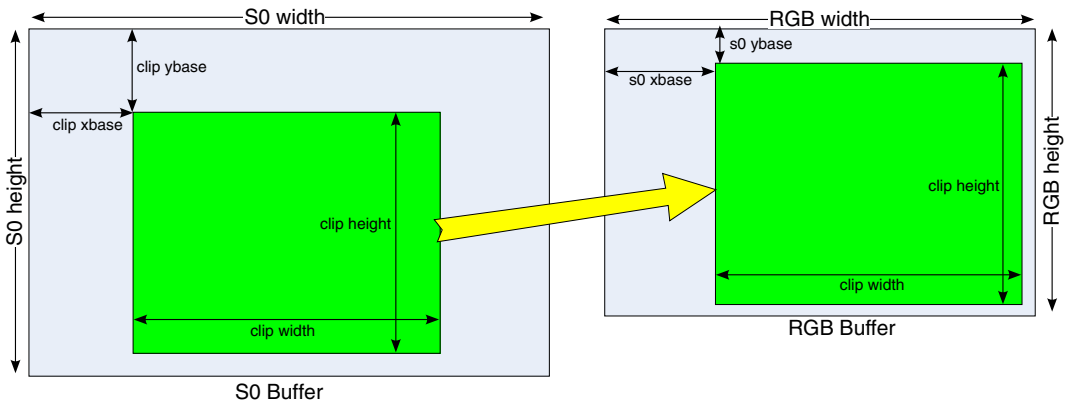


Figure 43-4. Cropping Parameters

It is important to note that when scaling an image, software must specify a valid cropping region since the ePXP will default to using the source image size. When downscaling, this is not an issue, but with upscaling the resulting image will be a scaled up version of the source, but cropped to the same size as the source image as shown below.

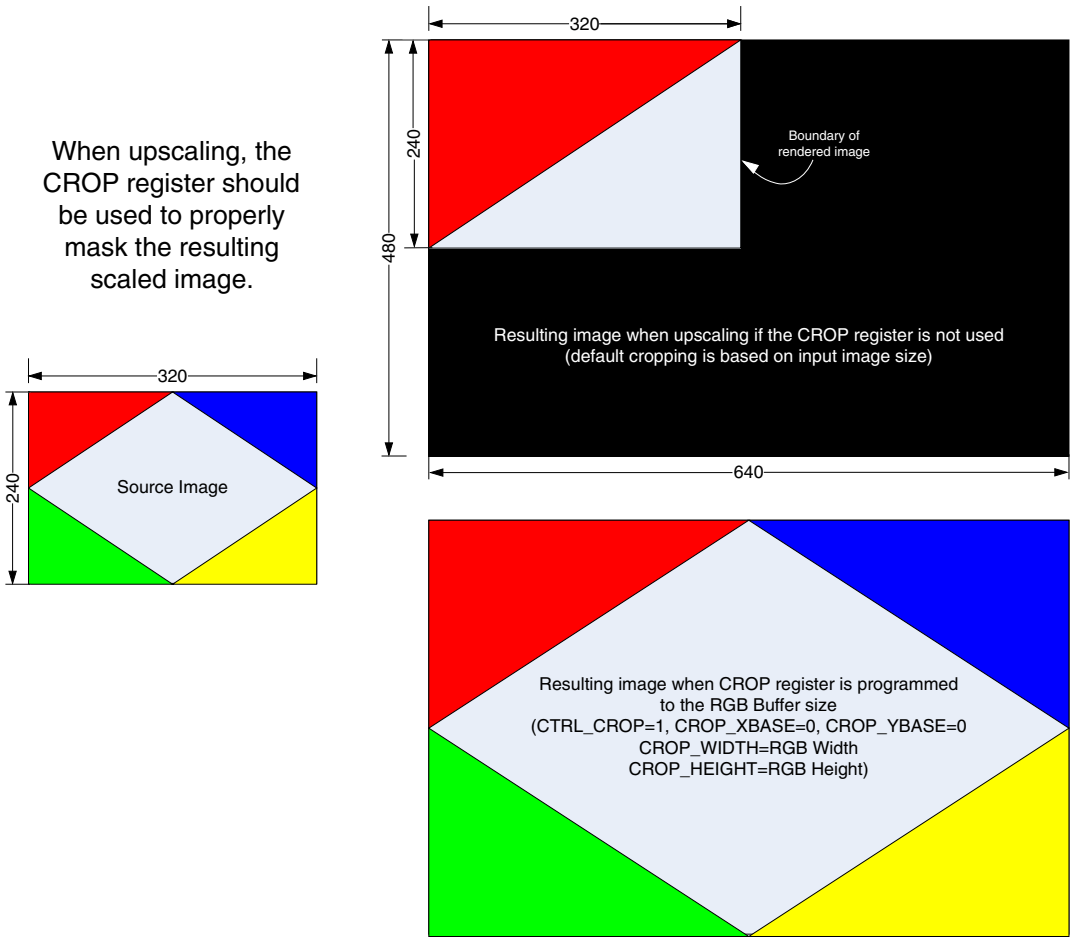

Figure 43-5. Upscaling

The cropping extents should fall completely within the S0 buffer to avoid displaying incorrect data. The ePXP hardware does not check for these conditions and will render the image as shown in the following two diagrams. (Note that the cropping width and height can be viewed as applying to the input buffer only because it is not scaled. In actuality, it is applied to the output buffer).

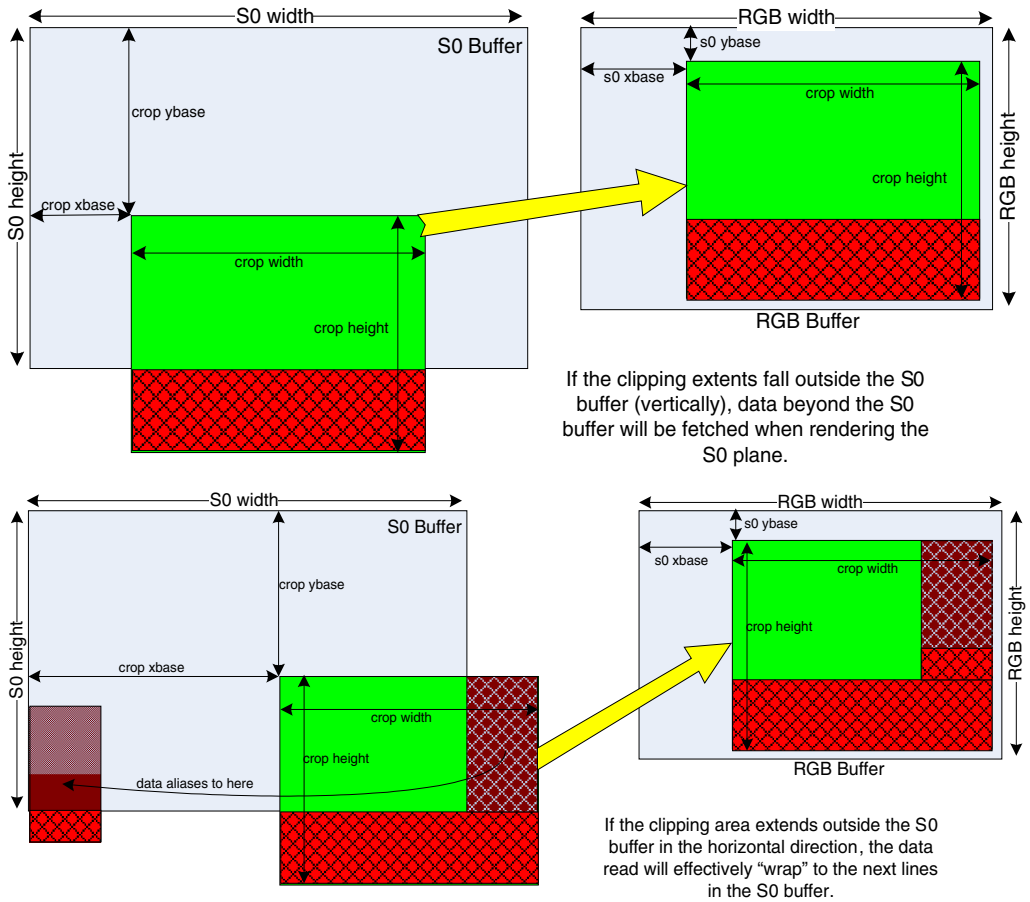

Figure 43-6. Rendering with Extents Ouside of S0 Buffer

43.2.3 Scaling

The ePXP can scale YUV images from 1/4x to about 4096x using a bilinear scaling algorithm. The hardware is capable of scaling with 12-bit fractional resolution, or in 1/4096th pixel increments with independent scaling ratios for the X and Y direction. The scaler also implements an initial offset, which can be useful when scaling by powers of 2 in order to ensure that the resulting pixels are averages (select ½ pixel offset) of the source pixels instead of producing a decimated or replicated image. Also, the offset can be used to achieve per pixel addressing on the input source image.

The scaling parameter is specified to the hardware in terms of the inverse of the scaling ratio desired. This can also be viewed as the step size between computed sample values. For instance, when scaling by 2x the inverse is 1/2, therefore the scaler will increment by 1/2 pixel steps across the input image and compute the bilinear average for each sample point.

The scaling values are represented by 12-bit fractional values in the scaling register and hardware. The scaling ratios are computed as the input size divided by the output size. The resulting decimal value must then be converted into a 12-bit fixed point value by multiplying by 212 or 4096 to produce the value programmed into the scaling registers.

To scale an image from 400 x 300 to 320 x 200, the horizontal XSCALE factor is computed as:

XSCALE = (Input Size / Output Size) x 4K = 400/320 x 4K = 5120 = 0x1400

The vertical YSCALE can be similarly computed as:

YSCALE = (Input Size/Output Size) x 4 K = 300/200 x 4K = 6144= 0x1800

The scaler will use the CROP_XBASE and CROP_YBASE values as an offset into the source S0 image for the origin of the input image to be scaled. The CROP_WIDTH and CROP_HEIGHT parameters will be used to determine the extent of the scaled image in the output buffer. It is tempting to view the cropping width and height as being applied to the input buffer, but this is incorrect -- the ePXP uses these values as a mask on the output buffer to determine which regions of the output buffer require data from the scaled input image.

To enable scaling, the ePXP_CTRL[SCALE] bit must be set and the desired scaling ratios written into the ePXP_S0SCALE registers. Initial offsets should be programmed into the ePXP_S0OFFSET register.

43.2.3.1 Bilinear Image Scaling Filter

The ePXP implements a bilinear scaling filter to resize an input image to a different resolution for display output. The bilinear filter is a weighted average of the four nearest pixels that can be sourced to approximate the pixel in the output frame buffer. It should be noted that when scaling from a large image to a smaller image by a factor of at least 2, then some lines will be decimated. In the extreme case of a 4:1 reduction in image size, half the lines will be decimated unless a two pass scaling technique is employed. This decimation results in a bilinear filtering algorithm that uses 2 pixels while stepping 4 pixels for each scaling increment.

When scaling YUV data, the UV values are offset by 0x80 (top bit inverted) to shift the signed UV bits into an unsigned equivalent with a range of 0 to 255. YCbCr data does not have to be shifted since it is defined as an unsigned byte. The YCBCR_MODE bit of the COEFF0 register controls whether this operation is applied to the input UV bytes.

After scaling, the offset is removed so that the range for UV data is signed from -128 to 127.

The reason for this adjustment is based on the implementation of an unsigned scaling engine, and therefore, is to ensure that the scaled values are handled properly. Consider the following table:

Format	Pixel0	Pixel1	Average	Result
decimal	-2	+2	0	Correct
CbCr	0x7E	0x82	0x80	Correct (0x80 is 0 in CbCr)
UV	0xFE	0x02	0x80	Incorrect (0x80 is -128 in UV)
decimal	-32	+16	-8	Correct
CbCr	0x60	0x90	0x78	Correct (0x78 is -8 in CbCr)
UV	0xE0	0x10	0x78	Incorrect (0x78 is +120 in UV)

To compute the output pixel value at position as indicated by P, consider the diagram below.

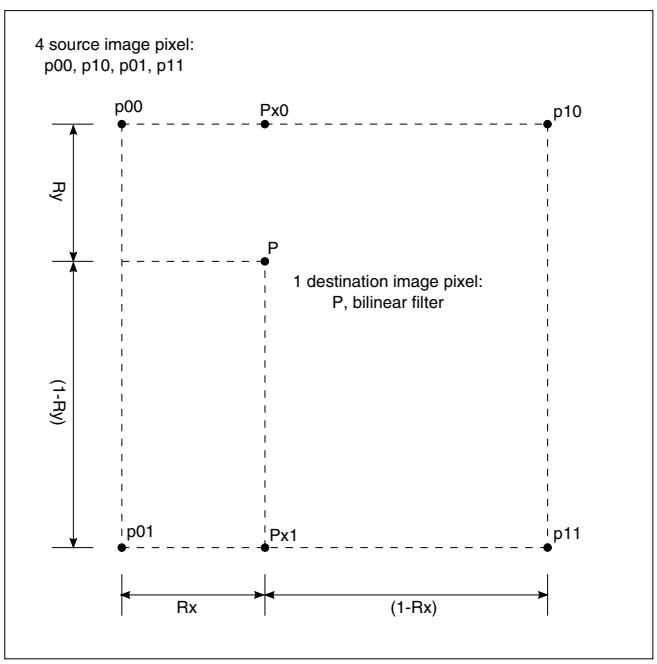

Figure 43-7. Output Pixel Computation

A step function is used to indicate the position of the pixel "P" in the output frame. This position may not coincide with a single pixel position in the input frame buffer. In this case, the four closest pixels in the input frame are used to approximate the value of the pixel in the output frame.

The ePXP scaler first computes a linear filter in the X axis to create the two intermediate pixel values Px0 and Px1. The step function's X fractional component is used to provide the weighting factor for blending p00 with p10 to provide Px0. Likewise, Px1 is also derived from a linear filter using p01 and p11.

The equations for Px0 and Px1 are as follows:

Px0 = p00 x (1 - Rx) + p10 x Rx

Px1 = p01 x (1 - Rx) + p11 x Rx

The ePXP scaler uses the intermediate X pixels Px0 and Px1 and implements a bilinear filter on these two pixel values to produce the final pixel value at position P. The remainder of the step function for the Y axis is used to compute the weighted average pixel result. The equation for final filtered pixel is:

P = Px0 x (1 - Ry) + Px1 x Ry

43.2.3.2 YUV 4:2:2 Image Scaling

The following figure illustrates the positioning of YUV samples for the 4:2:2 formats. There are twice as many Y luma samples then U and V chroma samples horizontally.

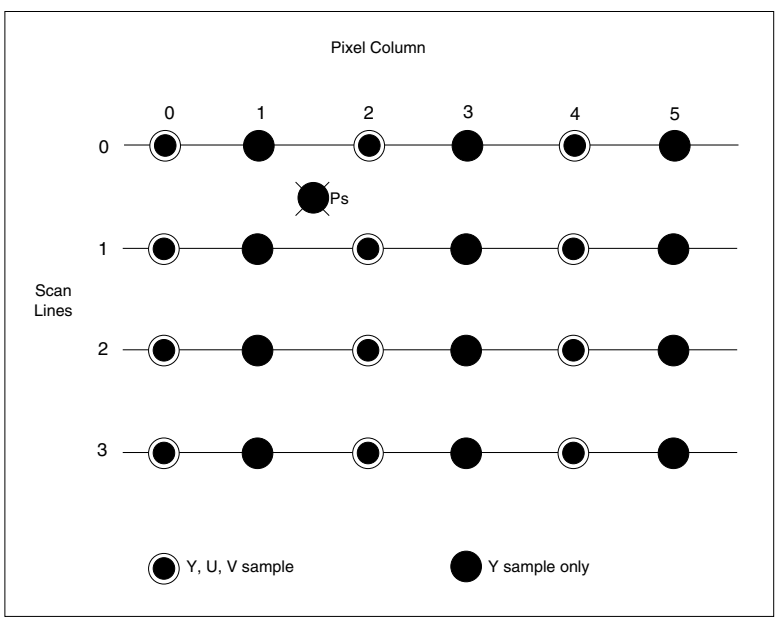

Figure 43-8. YUV Samples, 4:2:2

Consider the scaled output pixel Ps (pixel scaled) which has an accumulated step function of X=1.5 and Y=0.5. The remainder for the step function is Rx = 0.5 and Ry = 0.5. Or, the sub pixel position of output pixel Ps is half way between line 0 and 1 and half way between column 1 and 2.

The Y output component of Ps is simply the bilinear function of the four nearest Y samples from the input image. Specifically, the Y values at [1,0], [2,0], [1,1], and [2,1] are used to compute the Y for Ps.

For the U and V components of Ps, there are no samples present in the column position 1. The bilinear filter uses chroma components located at [0,0], [2,0], [0,1] and [2,1]. Since the chroma components are not sub sampled vertically, the remainder used to combine pixels vertically is Ry=0.5 (the same as for Y). However, horizontally, the scaling engine shifts the remainder by a factor of 2. So an X axis step function value of X=1.5 has a remainder Rx=0.75. Source chroma values are not replicated, they are completely interpolated using the four nearest chroma samples to approximate U and V at Ps.

43.2.3.3 YUV 4:2:0 Image Scaling

The following figure illustrates the positioning of YUV samples for the 4:2:0 formats. Chroma is sub sampled both horizontally and vertically. In this format, the chroma frame buffers contain ¼ the data that the luma frame buffers store.

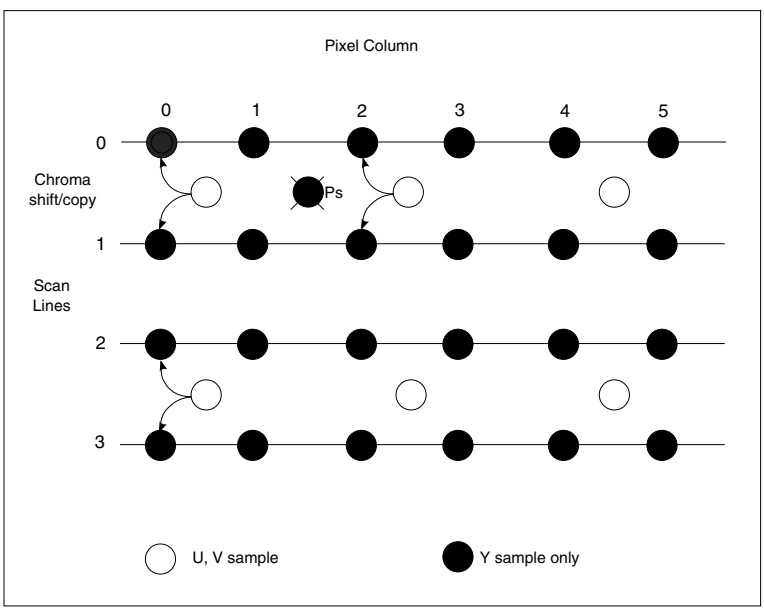

Figure 43-9. YUV Samples, 4:2:0

43.2.4 Color Space Conversion (CSC)

There are two modules in the ePXP to convert pixels between color spaces. They are referred to as CSC1 and CSC2 (for lack of a better naming convention). CSC1 exists after the scaling unit and is dedicated to converting from YUV to RGB. CSC2 is a full duplex color space converter in that is can convert into either RGB or YUV (or YCbCr) color

spaces depending on the desired output pixel format. All coefficients are programmed as two's complement numbers and both CSC units can be bypassed if CSC is not desired at either position of these CSC units in the pixel data path.

43.2.4.1 CSC1 Operation

The CSC1 module receives scaled YUV/YCbCr444 pixels from the scale engine and converts the pixels to the RGB888 color space only if CSC1 is enabled. The CSC1 module will convert only to the RGB color space and it can be bypassed to allow YUV pixels through the data path. These pixels are loaded into the pixel FIFO for processing by subsequent modules in the pixel data path.

The following equations are used to perform YUV/YCbCr -> RGB conversion. The constants will be stored in the ePXP control registers as two's complement values to allow flexibility in the implementation and to allow for differences in the video encode and decode operations. In addition, this provides a software mechanism to manipulate brightness or contrast.

R = C0(Y + Yoffset) + C1(V + UVoffset)

G = C0(Y + Yoffset) + C3(U + UVoffset) + C2(V + UVoffset)

B = C0(Y + Yoffset) + C4(U + UVoffset)

Note: In the equations above, U and V are synonymous with Cb and Cr in regards to the color space format of the source frame buffer.

Saturation of each color channel is checked and corrected for excursions outside the nominal YUV/YCbCr color spaces. Overflow for the three channels are saturated at 0x255 and underflow is saturated at 0x00.

The table below indicates the expected coefficients for YUV and YCbCr modes of operation:

Table 43-2. Coefficients for YUV and YCbCr Operation

Coefficient	YUV	YCbCr
Yoffset	0x000	0x1F0 (-16)
UVoffset	0x000	0x180 (-128)
C0	0x100 (1.00)	0x12A (1.164)
C1	0x123 (1.140)	0x198 (1.596)
C2	0x76B (-0.581)	0x730 (-0.813)
C3	0x79B (-0.394)	0x79C (-0.392)
C4	0x208 (2.032)	0x204 (2.017)

43.2.4.2 YUV versus YCbCr Support

By default, the ePXP color space coefficients are set to support the conversion of YUV data to RGB data. If YCbCr input is present, software must change the coefficient registers appropriately (see the register definitions for values). Software must also set the YCBCR_MODE bit in the ePXP_COEFF0 register to ensure proper conversion of YUV versus YCBCR data.

43.2.4.3 CSC2 Operation

The CSC2 module receives pixels in any color space and can convert the pixels into any of RGB, YUV, or YCbCr color spaces. All coefficients are programmable and in the two's complement notation. The output pixels are passed onto the LUT and rotation engine for further processing.

The following equations indicate the CSC2 modules ALU architecture.

Selecting RGB output in ePXP_CSC2CTRL[CSC_MODE] configures the ALU in the following manner:

R = A1(Y - D1) + A2(U - D2) + A3(V - D3)

G = B1(Y - D1) + B2(U - D2) + B3(V - D3)

B = C1(Y - D1) + C2(U - D2) + C3(V - D3)

Selecting YUV output configures the ALU in the alternate manner:

Y = A1 x R + A2 x G + A3 x B + D1

U = B1 x R + B2 x G + B3 x B + D2

V = C1 x R + C2 x G + C3 x B + D3

Saturation of each color channel is checked and corrected for excursions outside the nominal color space. Overflow for the three channels is saturated at 0x255 and underflow is saturated at 0x00.

The table below indicates the coefficients used to convert from RGB to YCbCr or YUV. These decimal values should be converted to their two's complement representation.

Table 43-3. Coefficients for RGB to YUV/YCbCr Conversion

Coefficient	RGB -> YUV	RGB -> YCbCr
A1, A2, A3	0.299, 0.587, 0.114	0.257, 0.504, 0.098

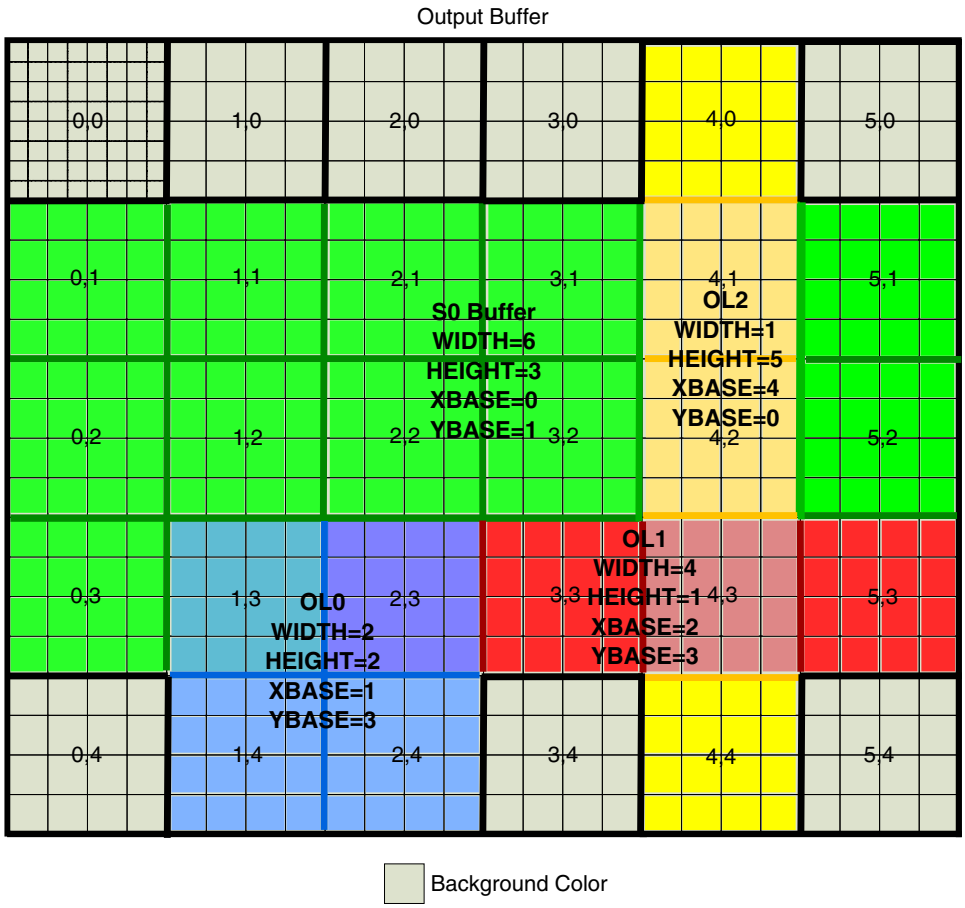
Table continues on the next page...

Table 43-3. Coefficients for RGB to YUV/YCbCr Conversion (continued)

Coefficient	RGB -> YUV	RGB -> YCbCr
B1, B2, B3	-0.147, -0.289, 0.436	-0.148, -0.291, 0.439
C1, C2, C3	0.615, -0.515, -0.100	0.439, -0.368, -0.071
D1, D2, D3	0, 0, 0	16, 128, 128

43.2.5 Overlays

The ePXP supports up to eight overlays that can be used to merge graphic data with video (or other graphic data). Each overlay consists of a rectangular area that is a multiple of Ôn' (where n is the block size) pixels in both the vertical and horizontal directions. Overlays must also be located on NxN boundaries within the output image. As the ePXP processes each NxN macroblock, it determines if any of the enabled overlays cover the block and then merges the overlay data with the background image as specified in the overlay's control registers. If multiple overlays overlap for a given NxN block, the ePXP will select the lowest numbered one for the blending operation. If the desired affect is to blend the overlays together, this can be accomplished as a multi-step process using the IN_PLACE functionality. (See In-place Rendering.)



The S0 buffer and each overlay can be placed within the output buffer using their XBASE and YBASE registers and the dimensions of each region are set using their WIDTH and HEIGHT parameters. Overlay 0 has the highest priority (effectively it is the highest in the stacking order) and the S0 buffer and background color have the lowest priority.

Overlays can be blended with the background or S0 planes, but not with each other. Effectively only a single overlay is active for each 8x8 pixel block.

Figure 43-10. Overlays

Each overlay can perform one of three classes of operations between the overlay and the underlying background (S0) image: alpha blending, color keying, or raster operations.

An overlay can be enabled by writing the address of the overlay image to the OLn register, the overlay's size and location information into the ePXP_OLnSIZE register, and then setting the OLnPARAM_ENABLE bit. The ePXP_OL_n_PARAM registers also contain further controls to select the modes of operation.

43.2.6 Alpha Blending

The alpha value for an individual pixel represents a mathematical weighting factor applied to the S1 pixel. An alpha value of 0x00 corresponds to a transparent pixel and a value of 0xFF corresponds to an opaque pixel.

The effective alpha value for an overlay pixel is determined by the ALPHA bit-field and the two ALPHA control bits in the ePXP_OLnPARAM register. If the ALPHA_CTRL field is set to ALPHA_OVERRIDE, the alpha value for the pixel is taken from the ALPHA bit-field. This can be useful for applying a constant alpha to an entire image or for image formats that do not include an alpha value. If ALPHA_MULTIPLY is selected, the pixel's alpha value will be multiplied by the ALPHA value in order to allow scaling of the pixel's alpha or to provide better control for pixel formats such as RGB1555, which only contains a single bit of alpha.

For each color channel, the equation used to blend two source pixels is defined below:

$E\alpha$ = Embedded alpha associated with S1 pixel

$\alpha = G\alpha \times E\alpha + 0x80$

$G\alpha$ = PIO programmed global alpha (8-bit value)

The result for the red channel as an example is as follows:

$Yr[7:0] = (\alpha \times S1.r) + ((1 - \alpha) \times S0.r)$

When alpha is 0xFF, the S1 pixel will not be blended with S0, but S1 will be passed as the output pixel and will not be blended with S0. In this case, S0 will be discarded. Likewise, if alpha is 0x00 for a given pixel, S0 will be loaded as the output pixel.

Alpha values in the overlays are loaded from the source image for all pixel formats. For formats that do not support an alpha value, the pixel is assigned an alpha value of 0xFF (opaque). This can be modified by the overlay processing by setting either the ALPHA_MULTIPLY or ALPHA_OVERRIDE bit in the associated ePXP_OLnPARAM register.

43.2.7 Color Key

Pixels may be made transparent to the corresponding overlay by using the S0 color key registers. If an S0 pixel matches the range specified by the ePXP_S0COLORKEYLOW and ePXP_S0COLORKEYHIGH registers, the pixel from the associated overlay will be displayed. If no overlay is present for that block, a black pixel will be generated since the default overlay pixel is 0x00000000 (transparent black pixel).

The most common use for this is when a bitmap does not support an alpha-field or for applications such as "green screen" where an image is substituted for a solid background color as shown below.

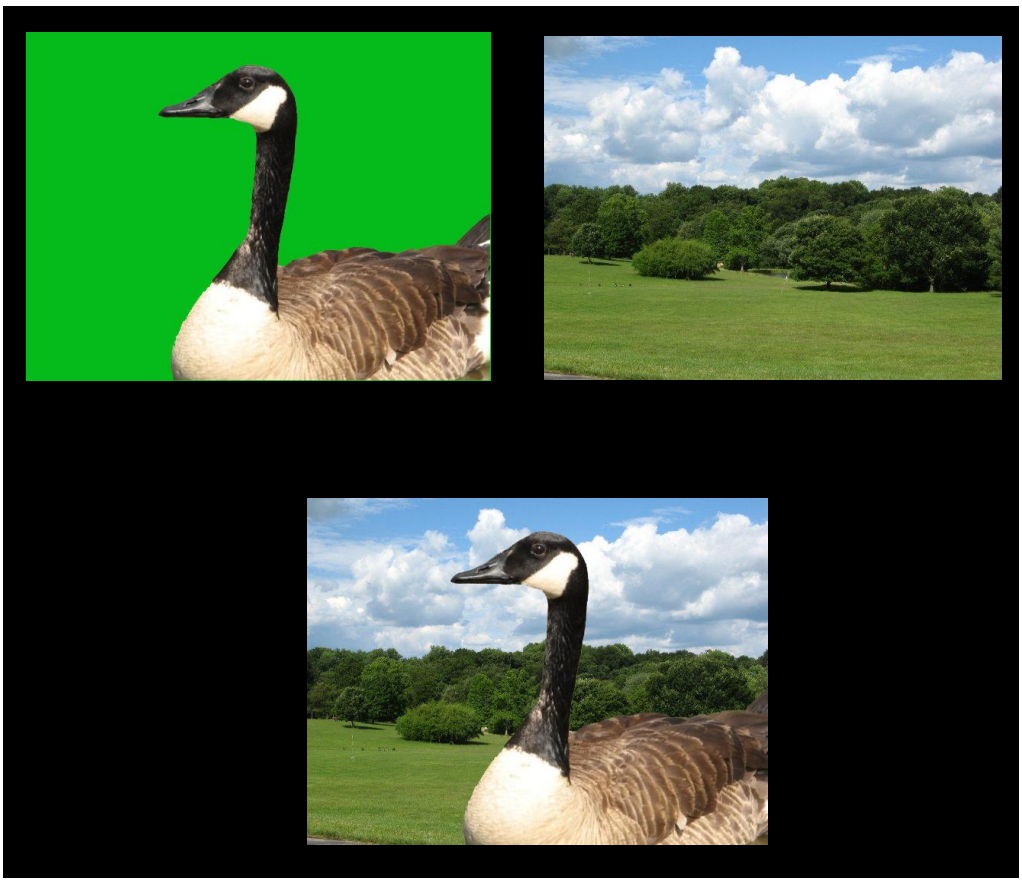


Figure 43-11. Background Image Substitution

The green portion of the overlay image can be color keyed to display the contents of the S0 buffer for locations that match the color range. For this example, the color range is

OL Colorkey: 00<R<80 70<G<ff 00<B<80

Conversely, background color keying could also have been used if the images had been swapped.

If color keying is enabled for an overlay, any pixels matching the color key parameters will be handled as color keyed pixels. Non-matching pixels will be alpha blended or handled by ROP operations as normal.

43.2.8 Raster Operations (ROPs)

In addition to alpha blending and color keying, the ePXP's alpha blender also supports a set of raster operations that may be performed between the active overlay and the background image. The operations are done on a per-pixel basis and are performed using the 24-bit overlay and background image values. The following table lists the supported ROP operations

Table 43-4. Supported ROP Operations

Mnemonic	Value	Operation
MASKOL	0x0	OL & S0
MASKNOTOL	0x1	~OL & S0
MASKOLNOT	0x2	OLL & ~S0
MERGEOL	0x3	OL | S0
MERGEOLNET	0x4	~OL | S0
MERGEOLNOT	0x5	OL | ~S0
NOTCOPYOL	0x6	~OL
NOT	0x7	~S0
NOTMASKOL	0x8	~(OL & S0) (nand)
NOTMERGEOL	0x9	~(OL | S0) (nor)
XOROL	0xA	OL ^ S0 (xor)
NOTXOROL	0xB	~(OL ^ S0) (xnor)

These operations are specified in the overlay's ePXP_PARAM register and must be enabled by setting the ALPHA_CTRL field to ROPs.

43.2.9 Lookup Table (LUT) Memory

The gamma correction lookup table is used to modify pixels in a manor that is not linear and that cannot be achieved by the color space conversion modules. Nonlinear response to input pixels can be achieved based on how the lookup table is programmed. Only the third byte is process by the lookup table. The third byte is represented by the Y value or the R value in the data path since pixel data is either YUV[23:0] or RGB[23:0] where the Y or R byte encompass bits [23:16] respectfully. So, bits 16:0 are always bypassed. Currently, the LUT is intended to process Y data when either of the monochrome output pixel formats are selected. However, this resource can be enabled and used for any conceivable purpose.

Some applications for the LUT are:

- Gamma Correction

- Pixel inversion, Converting black text on a white page to white on black.
- Pixel rounding and conversion to alternate pixel formats, like Y8 to 5-bit monochrome format.

43.2.10 Histogram

The histogram feature provides statistics about pixel values for a complete ePXP operation. The histogram logic compares the Y channel pixels at the output of the LUT resource against the values programmed in the histogram parameter registers. If the LUT is bypassed, the high order byte, or Y byte, is still processed by the histogram logic, so the histogram comparison is not dependent on using the LUT resource. Generally, this resource is used to produce statistics when the output mode is monochrome. It can be used to determine if the output pixels are limited to a specific set of values for a given ePXP process.

43.2.11 Rotation

Rotation is an inherently inefficient operation, especially for a graphics device operating in a raster-scan fashion since the resulting memory fetches would be non-contiguous. The ePXP solves this problem by operating on NxN pixel blocks. This allows the ePXP to rotate a subportion of the image, where it can fetch N lines of pixels, process them, and then write N lines of pixels regardless of the rotation orientation.

Rotation is mainly useful for reorganizing the frame buffer for handheld LCD displays for cases when the user rotates the device from a portrait to landscape orientation. Consider the following scenario:

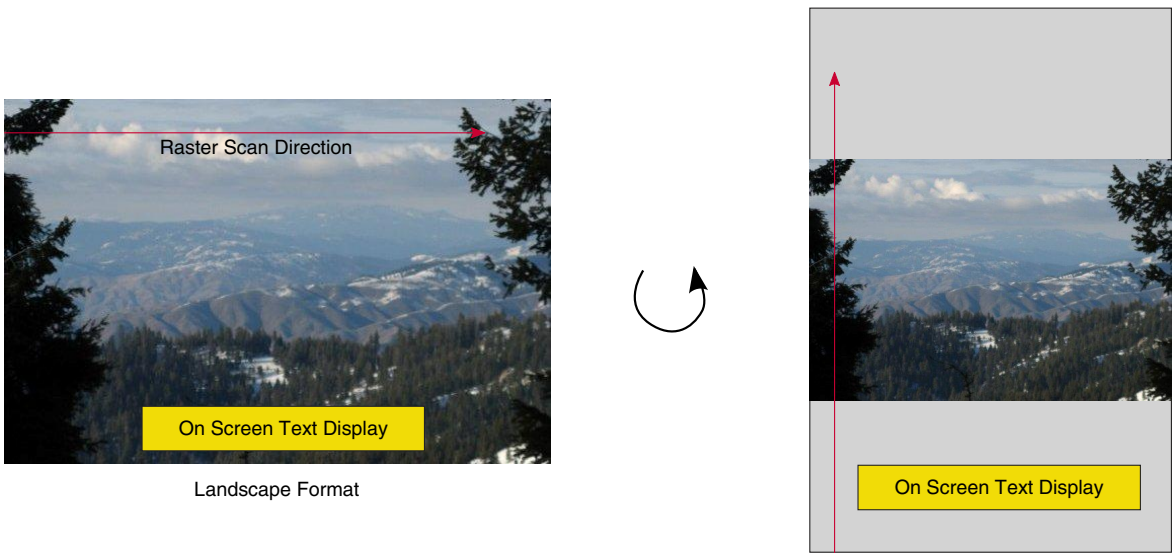

Figure 43-12. Portrait to Landscape

While this looks like a trivial operation, consider what the frame buffer must look like in memory before being sent to the LCD in raster-scan format

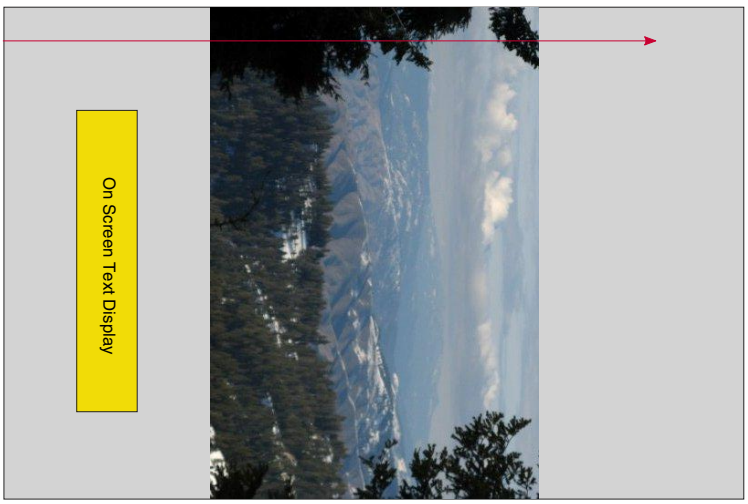

Figure 43-13. Frame Buffer in Portrait

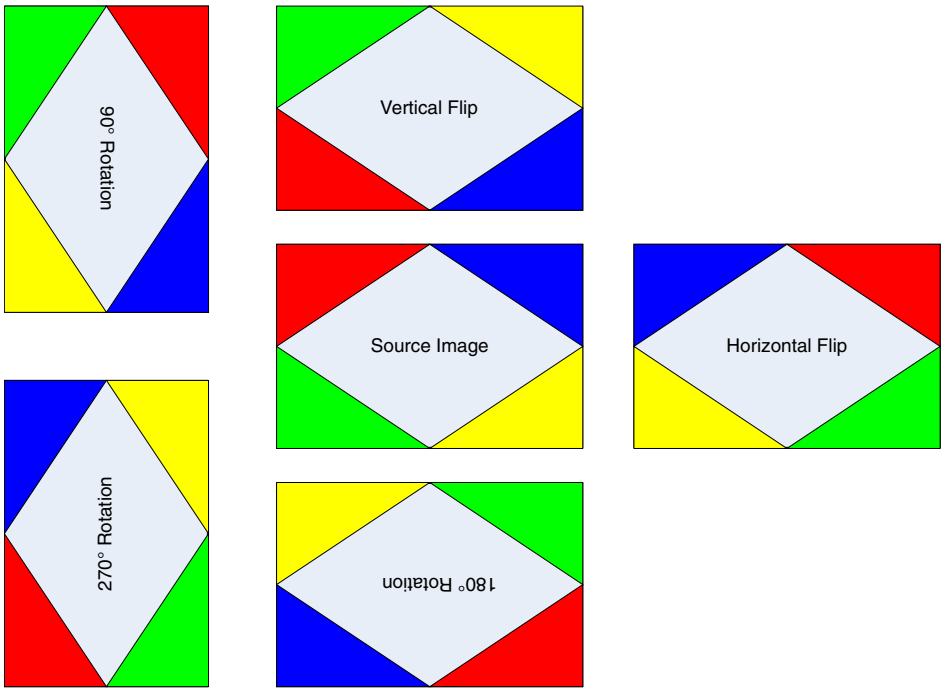
Not only must the image be rotated, but any on-screen graphics must also be rendered in a different orientation. By building rotation into the rendering process, the ePXP allows software to construct the image in the traditional portrait format and simply rotate the image/overlays for the LCD interface during composition.

The rotation operations are defined as rotations in a clockwise direction and the flip operations will flip the pixels in the specified direction.

Figure 43-14. Rotation and Flip Operations



The ePXP supports rotation in 90 degree increments as well as horizontal and vertical flip operations. These can be done in any combination (for example, 90 degree rotation with both vertical and horizontal flip). When a flip operation is specified in combination with a rotation operation, the ePXP will render the output such that the effect of the flip operation(s) occur BEFORE the rotation operation.

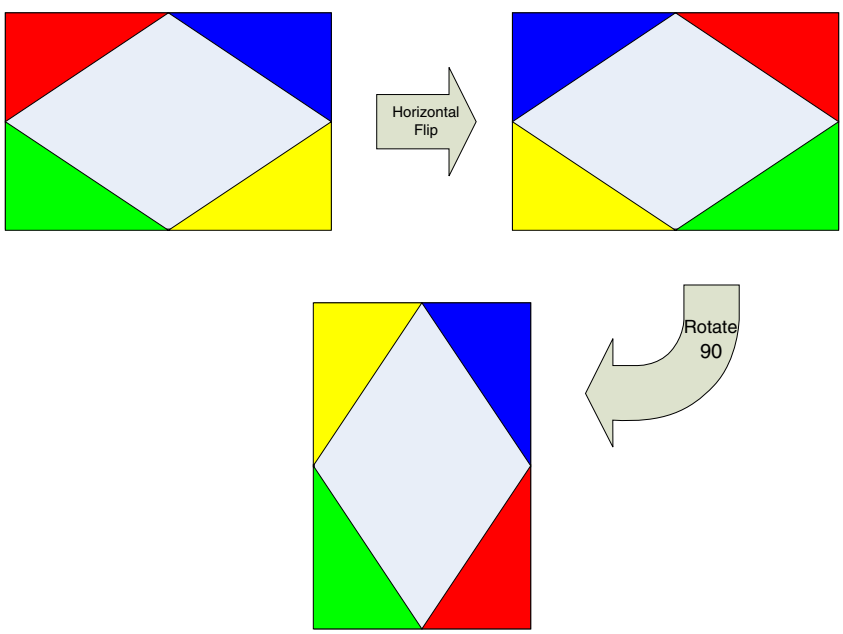


Figure 43-15. Flip with Rotation

Rotations and flip operations are enabled by setting the VFLIP, HFLIP, and ROTATE fields of the ePXP_CTRL register.

43.2.12 In-place Rendering

The ePXP also has the ability to process an image and write the resulting buffer back to the original S0 buffer. This is referred to as in place rendering. This scenario may be useful when software wishes to alpha blend multiple images where the overlays effectively overlap each other.

When the IN_PLACE control bit is set to 1, the control logic will optimize the ePXP's operations to only process the blocks that match an overlay region since all other pixels will be unmodified. This considerably reduces the processing time as well as the memory bandwidth used.

In place rendering is enabled by setting the IN_PLACE bit in the ePXP_CTRL registers. Note the following restrictions when rendering in place:

- The source buffer is used as the destination buffer (RGBBUF is not used)
- Only RGB S0 images are supported (not YUV)
- The output RGB format must be programmed to the same value as the input RGB format

43.2.13 Interlaced Video Support

The ePXP has some minimal ability to generate interlaced video content from a progressive source. There two available options, based on the bandwidth requirements and how software is managing video frames. The ePXP can either interlace on the input side (by reading every other line of input data) or on the output side (by writing the individual lines of video into two separate fields). Generally, output interleaving should be used since it is the most flexible mode (it allows scaling and full overlay support) and it only requires a single pass of the ePXP to generate two separate output fields. Input interleaving can be beneficial in cases where the ePXP is running at 60 fps, since it requires fewer fetches to produce the output data.

The ePXP will perform input interlacing when the INTERLACED_INPUT field is programmed to either FIELD0 or FIELD1 (to select the desired field). When performing output interlacing, the ePXP will write field0 data to the OUTBUF pointer and the field1 data to the OUTBUF2 pointer. The OUTPUT_INTERLACING field of the ePXP_CTRL register controls which of these fields (or both) are generated.

Output interlacing AND 2-plane output modes are not supported concurrently.

43.2.14 eLCDIF Interlock

The ePXP and eLCDIF support a mode where the internal SRAM can be used for the frame buffer to minimize external memory bandwidth required. This is accomplished by creating two buffers in SRAM that each correspond to n-lines of the frame buffer. The buffers must be consecutive and allocated as a single block of data.

When this mode is enabled, the ePXP will process one row of NxN pixel blocks and write the results to the first SRAM buffer (buffer 0). The ePXP will then alternate between writing subsequent rows to buffer 0 and buffer 1. After the ePXP generates the data for one buffer, the eLCDIF will begin reading that buffer and send the contents to the display device. Once the eLCDIF finishes reading a buffer, it will start displaying from the other buffer while the ePXP continues filling the now-empty buffer.

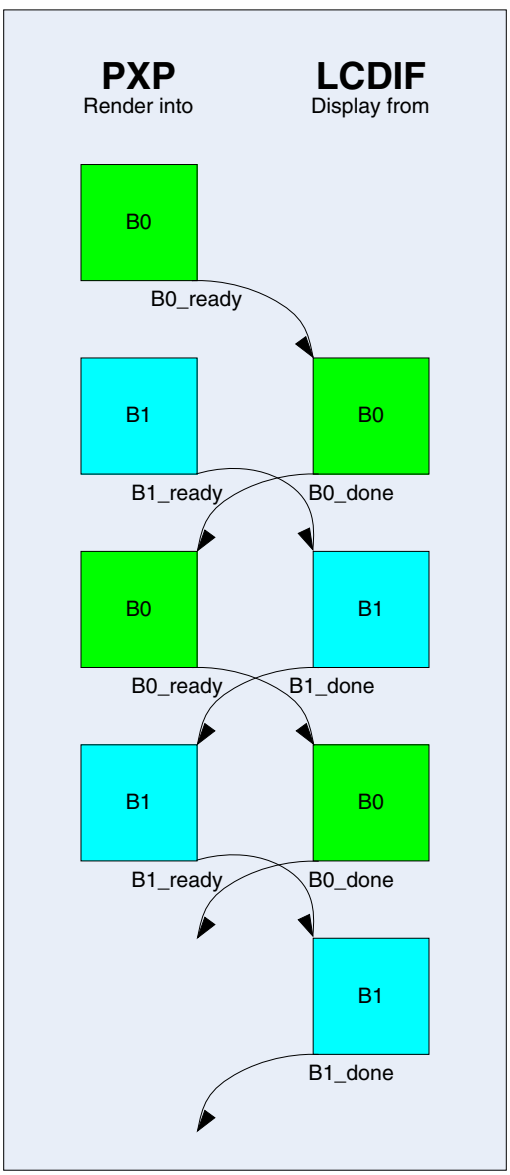

Figure 43-16. ePXP and eLCDIF Buffer Sharing

When the memory subsystem is not loaded, the ePXP should be able to render the buffers faster than the eLCDIF can drain the buffers. It is possible under some scenarios (high eLCDIF output rates with high memory latency) that the ePXP may not be able to keep up with the eLCDIF, even in the SRAM mode of operation. When this happens, the eLCDIF will signal that it has completed one of the buffers before the other has been rendered by the ePXP. This condition will be detected by the ePXP's control logic as an eLCDIF Abort, that causes the ePXP to abort processing in the current row and proceed to the following row. While an abort will create artifacts in the video display, it does minimize the artifacts by limiting them to the remaining pixels blocks in the current row versus ruining the entire frame buffer.

The memory requirements in SRAM to accommodate the partial frame buffer depends on the pixel resolution (16bpp, 24bpp, or 32bpp), the horizontal line size of the output image, and the block size (16 pixels or 8 pixels square).

Table 43-5. SRAM Memory Requirements

Image Size	Buffer Size (16bpp)	Buffer Size (24bpp)	Buffer Size (32bpp)
320x240 (QVGA) 0/180 rotation	10 Kbyte	15 Kbyte	2 0 Kbyte
320x240 (QVGA) 90/270 rotation	7.5 Kbyte	11.5 Kbyte	15 Kbyte
640x480 (VGA) 0/180 rotation	20 Kbyte	30 Kbyte	40 Kbyte
640x480 (VGA) 90/270 rotation	15 Kbyte	22.5 Kbyte	30 Kbyte

To enable the ePXP/eLCDIF Interlock mode, software must set the PXP_CTRL_ENABLE_LCD_HANDSHAKE bit in the ePXP and the LCDIF_ENABLE_PXP_HANDSHAKE bit in the eLCDIF. Using this mode requires the ePXP to begin processing the next frame immediately in order to have data ready for the eLCDIF at the beginning of the next frame. See Queueing Frame Operations to see how this can be accomplished.

43.2.15 Queueing Frame Operations

The ePXP supports a primitive ability to queue up one operation while the current operation is running. This is enabled through the use of the ePXP_NEXT register. When this register is written, it enables the ePXP to reload its current register contents with the data found at the location pointed to by this address (when it completes processing of the current frame (note that if virtual memory is used, this will be a virtual memory address).

This feature may be useful in helping to reduce the interrupt latency in servicing the ePXP, especially in cases where the ePXP and eLCDIF are using the on-chip SRAM buffer handshake (since the ePXP must begin generating next frame data immediately).

If the ePXP is idle when the ePXP_NEXT register is written, the ePXP treats this as an indication that it should immediately load the values at the pointer and begin processing the frame. This ability should allow software to use the same routines when programming the ePXP (so that the first frame does not differ from subsequent frames).

When loading values from the ePXP_NEXT register, nearly all registers in the ePXP are reloaded, including the interrupt enable bit in the control register. It is recommended that the interrupt enable value not be changed when using queued operations to ensure that interrupts are not spuriously lost or generated. The following table indicates the registers that are affected and the offset into the block address in memory.

Table 43-6. Registers and Offsets

Offset	Register	Offset	Register
0x00	CTRL	0x60	OL2
0x04	RGBBUF	0x64	OL2SIZE
0x08	RGBBUF2	0x68	OL2PARAM
0x0C	RGBSIZE	0x6C	OL2PARAM2

43.3 Examples

This section includes several examples of programming the ePXP to render an output image. The image could be either a still image or one frame of a sequence of video images. For each case, the input and output images will be shown along with a table of ePXP register settings. In all examples, pointers to the data structures with image data will be referred to in the following notation: *imagename_type, where imagename indicates which image is being used and type indicates either luma (y), chroma (u, v) or RGB data (rgb). All register names are assumed to have the ePXP_ register prefix. The registers can be written in any order except the ePXP_CTRL register, which must be written last since it enables the ePXP's operation.

43.3.1 Basic QVGA Example

This example shows how to perform basic color space conversion of a 3-plane YUV image into an RGB image suitable for an LCD device.

Table 43-7. Register Use for Conversion

Register	Value	Description
RGBBUF	*example1_rgb	Pointer to the output buffer.
RGBSIZE	0xFF1400F0	ALPHA=0xFF WIDTH=0x140=320 HEIGHT=0x0F0=240
S0BUF	*morraine_y	Pointer to input Y buffer
S0UBUF	*morraine_u	Pointer to input U buffer
SOVBUF	*morraine_v	Pointer to input V buffer
S0PARAM	0x0000281E	WIDTH=0x28=40 (40*8=320 pixels) HEIGHT=0x1E=30 (30*8=240 pixels)
S0BACKGROUND	0x00000000	Black background region
S0CROP	0x00000000	No Cropping

Table continues on the next page...

Table 43-7. Register Use for Conversion (continued)

Register	Value	Description
S0CSCCOEFF0 S0CSCCOEFF1 S0CSCCOEFF2	0x04030000 0x01230208 0x076b079b	YUV->RGB Coefficient Values
OL0PARAM	0x00000000	Overlay 0 disabled
OL1PARAM	0x00000000	Overlay 1 disabled
OL2PARAM	0x00000000	Overlay 2 disabled
OL3PARAM	0x00000000	Overlay 3 disabled
OL4PARAM	0x00000000	Overlay 4 disabled
OL5PARAM	0x00000000	Overlay 5 disabled
OL6PARAM	0x00000000	Overlay 6 disabled
OL7PARAM	0x00000000	Overlay 7 disabled
CTRL	0x00009003	S0_FORMAT=9 (YUV420) IRQ_ENABLE=1 ENABLE=1

The resulting image is simply the RGB equivalent of the YUV image:

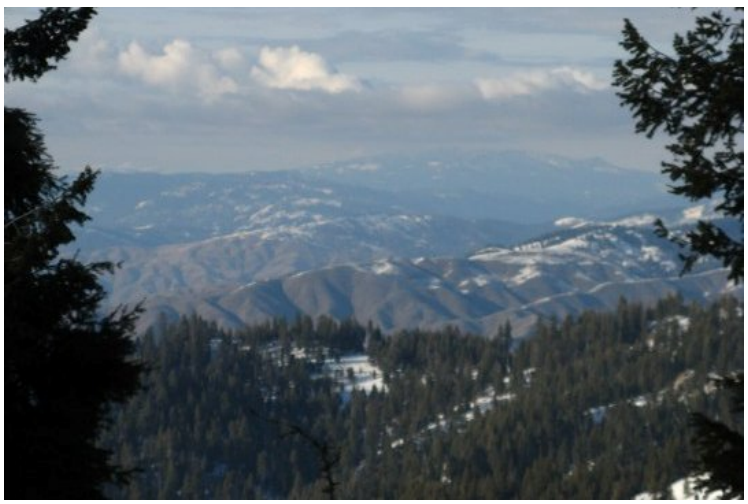

Figure 43-17. 3-Plane YUV to RGB Image

43.3.2 Basic QVGA with Overlays

This example is similar to the last, but adds two overlay images, one for a logo and the other as a time counter/control bar. The two overlay images are shown below. (Note that the black background is actually transparent in the real image).

Figure 43-18. Overlay Images

Table 43-8. Register Use for Conversion

Register	Value	Description
RGBBUF	*example1_rgb	Pointer to the output buffer.

CTRL	0x00009003	S0_FORMAT=9 (YUV420) IRQ_ENABLE=1 ENABLE=1

The resulting image is shown below. Note the presence of the overlays in the upper left and lower right corners of the image.

Figure 43-19. Resulting Image

43.3.3 Cropped QVGA Example

This example displays the same image as the first example, but does so on a portrait-oriented display (240x320) without the overlays. Changes from the first example are shown in bold.

Table 43-9. Register Use for Conversion

Register	Value	Description
RGBBUF	*example1_rgb	Pointer to the output buffer.
RGBSIZE	0xFF0F0140	ALPHA=0xFF WIDTH=0x0F0=240 pixels HEIGHT=0x140=320 pixels
S0BUF	*morraine_y	Pointer to input Y buffer
S0UBUF	*morraine_u	Pointer to input U buffer
SOVBUF	*morraine_v	Pointer to input V buffer

Table continues on the next page...

Table 43-9. Register Use for Conversion (continued)

OL7PARAM	0x00000000	Overlay 7 disabled
CTRL	0x00089003	CROP=1 S0_FORMAT=9 (YUV420) IRQ_ENABLE=1 ENABLE=1

In this case, we have now changed the RGB size to reflect the portrait nature of the display. The S0PARAM_YBASE has been changed to 0x05 (40 pixels) to place the S0 plane down 40 pixels from the top of the screen. The cropping register is now also used to control the cropping extents. The CROP_XBASE is set to 0x05 (40 pixels) to move the origin of the S0 buffer to the (40,0) location within the buffer. The CROP_WIDTH/ CROP_HEIGHT are also programmed to ensure that the resulting image in the output buffer is cropped to 240x240 pixels. Since the image no longer covers the entire output buffer, the S0BACKGROUND register is used to letterbox the image in black. The resulting image is shown below.

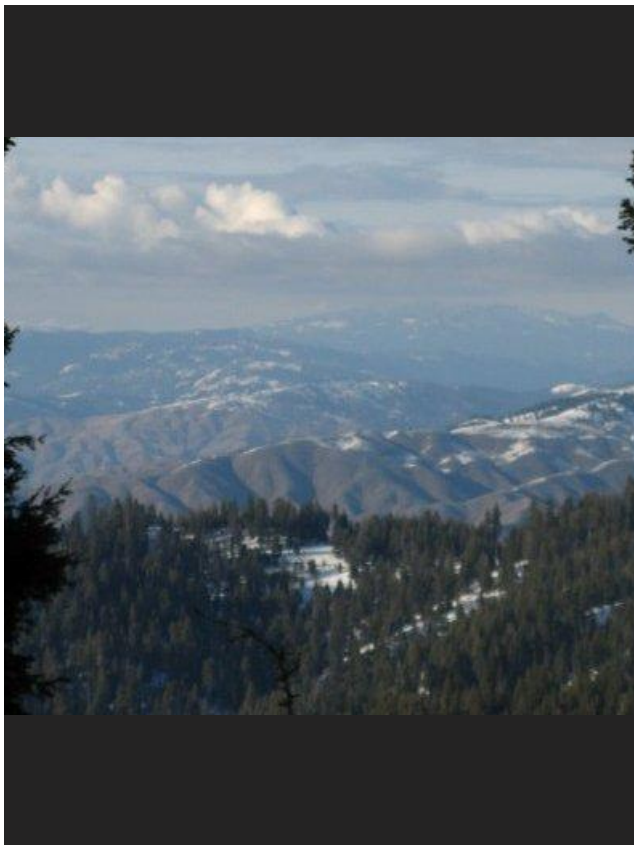

Figure 43-20. Cropped QVGA Example

43.3.4 Upscale QVGA to VGA with Overlays

In this example, the image will be upscaled from QVGA to VGA resolution and displayed with the two overlays from the second example. Changes from the second example are shown in bold.

Table 43-10. Register Use for Conversion (continued)

Register	Value	Description
CTRL	0x000c9003	SCALE=1 CROP=1 S0_FORMAT=9 (YUV420) IRQ_ENABLE=1 ENABLE=1

The resulting image is shown in the figure below. The overlays have moved in this image and that the overall image size is now larger than before.

Figure 43-21. Upscale QVGA to VGA with Overlays

43.3.5 Downscale VGA to WQVGA (480x272) to fill screen

In this example, a VGA image will be downscaled to fix the extents of a 480x272 WQVGA display. This means that the aspect ratio of the resulting image will not match that of the source image, therefore the scaling factors in the horizontal and vertical directions will differ from each other.

Table 43-11. Register Use for Conversion

Register	Value	Description
RGBBUF	*example_rgb	Pointer to the output buffer.
RGBSIZE	0xFFf1E0110	ALPHA=0xFF WIDTH=0x1E0=480 HEIGHT=0x110=272
S0BUF	*garden_y	Pointer to input Y buffer
S0UBUF	*garden_u	Pointer to input U buffer
SOVBUF	*garden_v	Pointer to input V buffer
S0PARAM	0x0000503C	WIDTH=0x50=80=640 pixels HEIGHT=0x3C=60=480 pixels
S0BACKGROUND	0x00000000	Black background region
S0CROP	0x00003C22	WIDTH=0x3C=480 pixels HEIGHT=0x22=272 pixels
S0SCALE	0x1C3C1555	YSCALE=0x1C3C=1/1.765x XSCALE=0x1555=1/1.333x
S0CSCCOEFF0 S0CSCCOEFF1 S0CSCCOEFF2	0x04030000 0x01230208 0x076b079b	YUV->RGB Coefficient Values
OL0PARAM	0x00000000	Overlay 0 disabled
OL1PARAM	0x00000000	Overlay 1 disabled
OL2PARAM	0x00000000	Overlay 2 disabled
OL3PARAM	0x00000000	Overlay 3 disabled
OL4PARAM	0x00000000	Overlay 4 disabled
OL5PARAM	0x00000000	Overlay 5 disabled
OL6PARAM	0x00000000	Overlay 6 disabled
OL7PARAM	0x00000000	Overlay 7 disabled
CTRL	0x000C9003	SCALE=1 CROP=1 S0_FORMAT=9 (YUV420) IRQ_ENABLE=1 ENABLE=1

Note that the scaling factors are computed as (source/dest)*4096, thus in the horizontal direction 640/480 x 4096 = 5461 = 0 x 1555. In the vertical direction, the scaling factor is computed as 480/272 x 4096=7228 = 0x1C3C. The original source image and resulting scaled images are shown below:

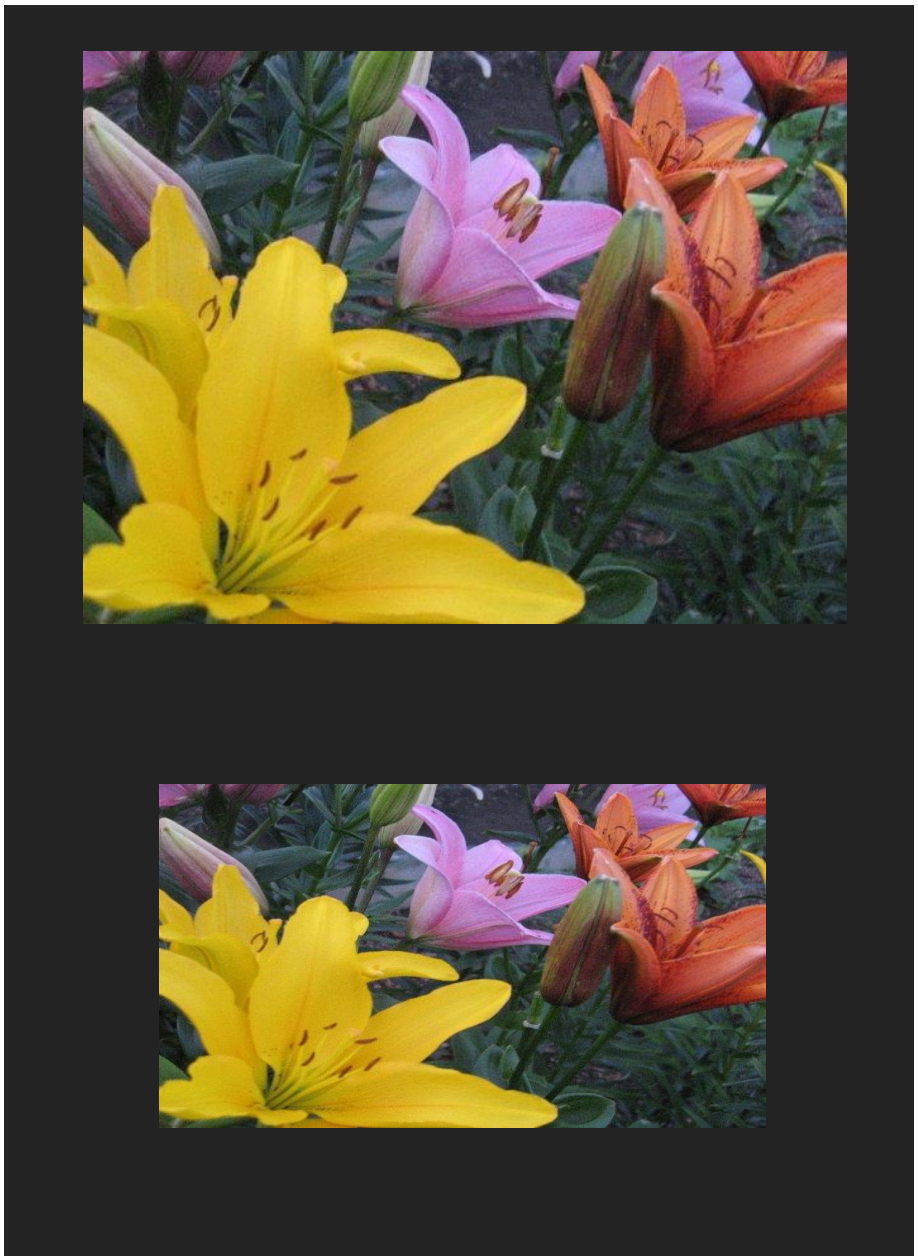

Figure 43-22. Downscale VGA to WQVGA (480x272)

43.3.6 Downscale VGA to QVGA with Overlapping Overlays

The final example will perform a 1/2x scaling of a VGA image to QVGA to maintain the aspect ratio. It will also add four overlays to present the image as if it were a photo album application.

Table 43-12. Register Use for Conversion

CTRL	0x000C9003	SCALE=1 CROP=1 S0_FORMAT=9 (YUV420) IRQ_ENABLE=1 ENABLE=1

The resulting image is shown below. The text is rendered in a transparent overlay (overlay #2) on the right side of the screen. The background color (#000040) is dark blue and shows through the overlay as the background color. Overlay #3 applies a thin white alpha-blended border around the image to frame it. Overlays #0 and #1 generate the

Next> and <Prev images alpha blended onto the image. Because these overlays are higher priority (lower numbered) than the border, they are used at these locations instead of overlay #3.

43.4.1 ePXP Control Register 0 (ePXP_CTRL*n*)

The Control register contains the primary controls for the ePXP block. The present bits indicate which of the sub-features of the block are present in the hardware.

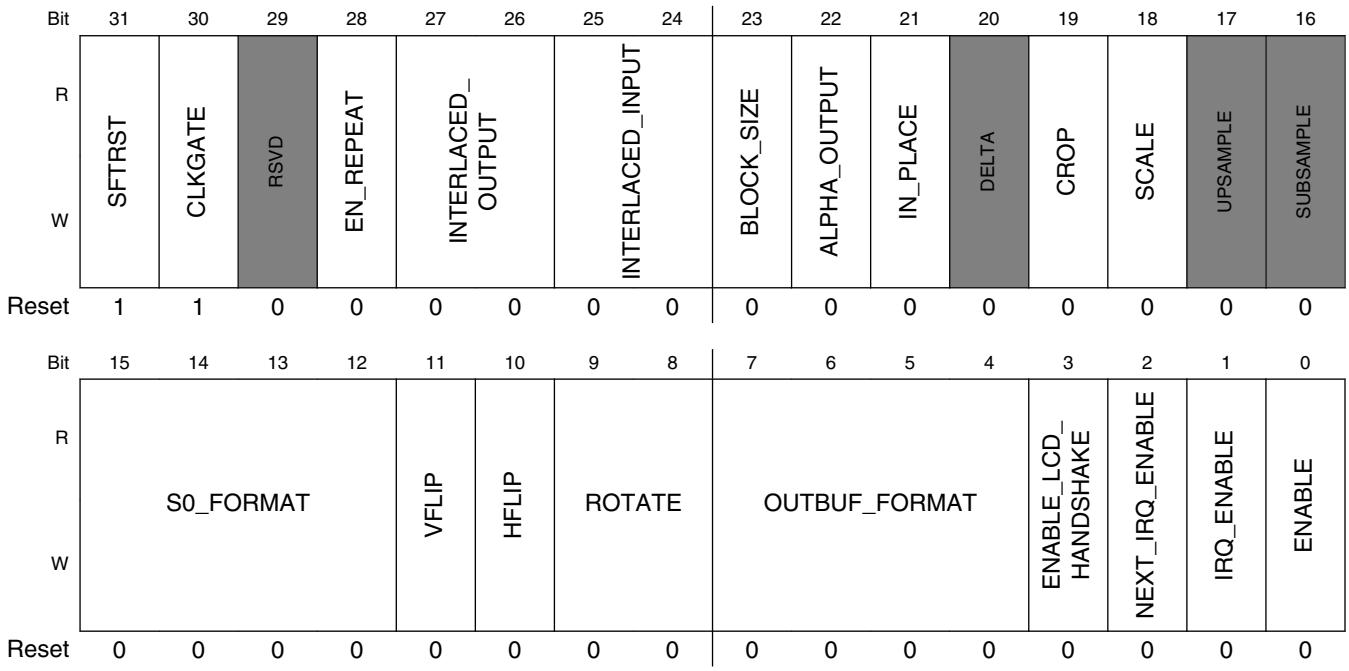
```
ePXP_CTRL_SET(BM_PXP_CTRL_SFTRST);
    ePXP_CTRL_CLR(BM_PXP_CTRL_SFTRST | BM_PXP_CTRL_CLKGATE);
```

Addresses: ePXP_CTRL is 4100_C000h base + 0h offset = 4100_C000h

ePXP_CTRL_SET is 4100_C000h base + 4h offset = 4100_C004h

ePXP_CTRL_CLR is 4100_C000h base + 8h offset = 4100_C008h

ePXP_CTRL_TOG is 4100_C000h base + Ch offset = 4100_C00Ch



ePXP_CTRL*n* field descriptions

Field	Description
31 SFTRST	Set this bit to zero to enable normal ePXP operation. Set this bit to one (default) to disable clocking with the ePXP and hold it in its reset (lowest power) state. This bit can be turned on and then off to reset the ePXP block to its default state.
30 CLKGATE	This bit must be set to zero for normal operation. When set to one it gates off the clocks to the block.
29 RSVD	Reserved, always set to zero.
28 EN_REPEAT	Enables the ePXP to run continuously. When this bit is set, the ePXP will repeat based on the current configuration register settings. If this bit is not set, the ePXP will complete the process and enter the idle state ready to accept the next frame to be processed. This bit should be set when the LCDIF handshake mode is enabled so that the next frame is automatically generated for the next screen refresh cycle. If it not set and the handshake mode is enabled, the CPU will have to initiate the ePXP for the next refresh cycle. When the ePXP NEXT feature is used, it has priority over the REPEAT mode, in that the new register settings are fetched first, and then the next ePXP operation will continue.
27–26 INTERLACED_OUTPUT	Determines how the ePXP writes its output data. Output interlacing should not be used in conjunction with input interlacing. Splitting frames into fields is most efficient using output interlacing. two-plane output formats AND interlaced output is not supported. 0x0 **PROGRESSIVE** — All data written in progressive format to the OUTBUF Pointer. 0x1 **FIELD0** — Interlaced output: only data for field 0 is written to the OUTBUF Pointer. 0x2 **FIELD1** — Interlaced output: only data for field 1 is written to the OUTBUF2 Pointer. 0x3 **INTERLACED** — Interlaced output: data for field 0 is written to OUTBUF and data for field 1 is written to OUTBUF2.

Table continues on the next page...

ePXP_CTRL*n* field descriptions (continued)

Field	Description
25–24 INTERLACED_ INPUT	When set, causes the fetch side of the ePXP to fetch every other line from the source buffers. This effectively produces one field of interlaced output data. Scaling should NOT be enabled for interlaced operation and only overlays with boundaries on 8x16 multiples are supported. 0x0 **PROGRESSIVE** — All data will be read and processed in progressive format. 0x2 **FIELD0** — Interlaced, Field 0: only data for field 0 (even lines) is read/processed. 0x3 **FIELD1** — Interlaced, Field 1: only data for field 1 (odd lines) is read/processed.
23 BLOCK_SIZE	Select the block size to process. 0x0 **8X8** — Process 8x8 pixel blocks. 0x1 **16X16** — Process 16x16 pixel blocks.
22 ALPHA_ OUTPUT	Indicates that alpha component in output buffer pixels should be overridden by PXP_OUTSIZE[ALPHA] register. If 0, retain their alpha value from the computed alpha for that pixel.
21 IN_PLACE	When set, this enables the ePXP to perform an alpha blend operation on an existing buffer (output buffer is set to S0 buffer). In this case, the ePXP will perform the alpha blending of the overlays into the source buffer. Since only pixels containing an overlay are processed, the ePXP does this very efficiently.
20 DELTA	Reserved for future use.
19 CROP	Indicates that the S0 plane should use the cropping register to provide the extents for the output S0 buffer cropping. If not set, the input video cropping extents will be inferred from the S0 WIDTH and HEIGHT fields. When scaling, the CROP bit and controls should be used to specify the scaled image size in the output buffer.
18 SCALE	This bit indicates that the output image should be scaled (only YUV/YCbCr images may be scaled -- RGB scaling is not supported). The XSCALE and YSCALE registers should be programmed accordingly. In addition, the CROP bit and the S0CROP registers should be programmed to ensure that the scaled image is properly cropped in the output buffer. When this bit is zero, the contents of the scaling registers are ignored.
17 UPSAMPLE	Reserved for future use.
16 SUBSAMPLE	Reserved for future use.
15–12 S0_FORMAT	Source 0 buffer format. To select between YUV and YCbCr formats, see bit 31 of the CSCCOEF0 register. 0x1 **RGB888** — 32-bit pixels (unpacked 24-bit format) 0x4 **RGB565** — 16-bit pixels 0x5 **RGB555** — 16-bit pixels 0x8 **YUV422** — 16-bit pixels (3-plane format) 0x9 **YUV420** — 16-bit pixels (3-plane format) 0xA **UYVY1P422** — 16-bit pixels (1-plane U0,Y0,V0,Y1 interleaved bytes) 0xB **VYUY1P422** — 16-bit pixels (1-plane V0,Y0,U0,Y1 interleaved bytes) 0xC **YUV2P422** — 16-bit pixels (2-plane UV interleaved bytes) 0xD **YUV2P420** — 16-bit pixels 0xE **YVU2P422** — 16-bit pixels (2-plane VU interleaved bytes) 0xF **YVU2P420** — 16-bit pixels

Table continues on the next page...

ePXP_CTRL*n* field descriptions (continued)

Field	Description
11 VFLIP	Indicates that the output buffer should be flipped vertically (effect applied before rotation).
10 HFLIP	Indicates that the output buffer should be flipped horizontally (effect applied before rotation).
9–8 ROTATE	Indicates the clockwise rotation to be applied at the output buffer. The rotation effect is defined as occurring after the FLIP_X and FLIP_Y permutation. 0x0 **ROT_0** — 0x1 **ROT_90** — 0x2 **ROT_180** — 0x3 **ROT_270** —
7–4 OUTBUF_ FORMAT	Output framebuffer format. The UV byte lanes are synonymous with CbCr byte lanes for YUV output pixel formats. For example, the YUV2P420 format should be selected when the output is YCbCr 2-plane 420 output format. 0x0 **ARGB8888** — 32-bit pixels 0x1 **RGB888** — 32-bit pixels (unpacked 24-bit pixel in 32 bit DWORD.) 0x2 **RGB888P** — 24-bit pixels (packed 24-bit format) 0x3 **ARGB1555** — 16-bit pixels 0x4 **RGB565** — 16-bit pixels 0x5 **RGB555** — 16-bit pixels 0x7 **YUV444** — 32-bit pixels (1-plane XYUV unpacked) 0x8 **MONOC8** — 8-bit monochrome pixels (1-plane Y luma output) 0x9 **MONOC4** — 4-bit monochrome pixels (1-plane Y luma, 4 bit truncation) 0xA **UYVY1P422** — 16-bit pixels (1-plane U0,Y0,V0,Y1 interleaved bytes) 0xB **VYUY1P422** — 16-bit pixels (1-plane V0,Y0,U0,Y1 interleaved bytes) 0xC **YUV2P422** — 16-bit pixels (2-plane UV interleaved bytes) 0xD **YUV2P420** — 16-bit pixels (2-plane UV) 0xE **YVU2P422** — 16-bit pixels (2-plane VU interleaved bytes) 0xF **YVU2P420** — 16-bit pixels (2-plane VU)
3 ENABLE_LCD_ HANDSHAKE	Enable handshake with LCD controller. When this is set, the ePXP will not process an entire framebuffer, but will instead process rows of NxN blocks in a double-buffer handshake with the LCDIF. This enables the use of the onboard SRAM for a partial frame buffer.
2 NEXT_IRQ_ ENABLE	Next command interrupt enable. When set, the ePXP will issue an interrupt when a queued command initiated by a write to the PXP_NEXT register has been loaded into the ePXP's registers. This interrupt also indicates that a new command may now be queued.
1 IRQ_ENABLE	Interrupt enable. When set, the ePXP will issue an interrupt when PXP processing is complete. Note: When using the PXP_NEXT functionality to reprogram the ePXP, the new value of this bit will be used and may therefore enable or disable an interrupt unintentionally.
0 ENABLE	Enables ePXP operation with specified parameters. The ENABLE bit will remain set while the ePXP is active and will be cleared once the current operation completes. Software should use the IRQ bit in the PXP_STAT when polling for ePXP completion.

43.4.2 ePXP Status Register (ePXP_STAT*n*)

The ePXP Interrupt Status register provides ePXP interrupt status and the current X/Y block coordinate that is being processed.

EXAMPLE

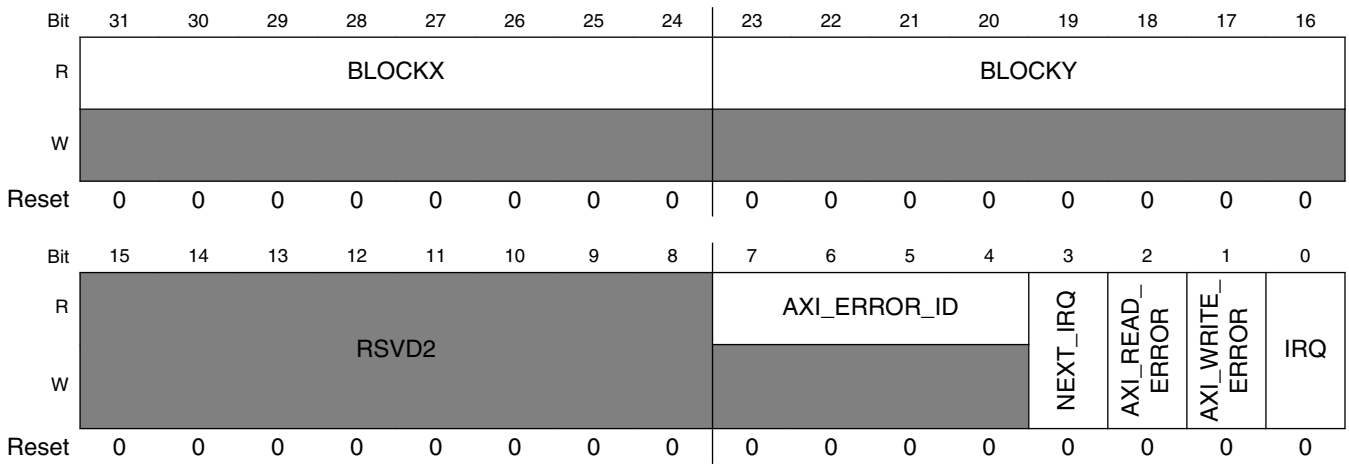
```
ePXP_STAT_CLR(BM_PXP_STAT_IRQ);  // clear CSC interrupt
```

Addresses: ePXP_STAT is 4100_C000h base + 10h offset = 4100_C010h

ePXP_STAT_SET is 4100_C000h base + 14h offset = 4100_C014h

ePXP_STAT_CLR is 4100_C000h base + 18h offset = 4100_C018h

ePXP_STAT_TOG is 4100_C000h base + 1Ch offset = 4100_C01Ch



ePXP_STAT*n* field descriptions

Field	Description
31–24 BLOCKX	Indicates the X coordinate of the block currently being rendered.
23–16 BLOCKY	Indicates the X coordinate of the block currently being rendered.
15–8 RSVD2	Reserved, always set to zero.
7–4 AXI_ERROR_ID	Indicates the AXI ID of the failing bus operation.
3 NEXT_IRQ	Indicates that a command issued with the "Next Command" functionality has been issued and that a new command may be initiated with a write to the PXP_NEXT register.
2 AXI_READ_ ERROR	Indicates PXP encountered an AXI read error and processing has been terminated.
1 AXI_WRITE_ ERROR	Indicates ePXP encountered an AXI write error and processing has been terminated.

Table continues on the next page...

ePXP_STAT*n* field descriptions (continued)

Field	Description
0 IRQ	Indicates current ePXP interrupt status.

43.4.3 Output Frame Buffer Pointer (ePXP_OUTBUF)

Output Framebuffer Pointer. This register points to the beginning of the output frame buffer. This pointer is used for progressive format and field 0 when generating interlaced output.

This register is used by the logic to point to the current output location for the output frame buffer.

EXAMPLE

```
PXP_OUTBUF_WR( buffer );
```

Address: ePXP_OUTBUF is 4100_C000h base + 20h offset = 4100_C020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ePXP_OUTBUF field descriptions

Field	Description
31–0 ADDR	Current address pointer for the output frame buffer. The address must be word-aligned for proper ePXP operation.

43.4.4 Output Frame Buffer Pointer #2 (ePXP_OUTBUF2)

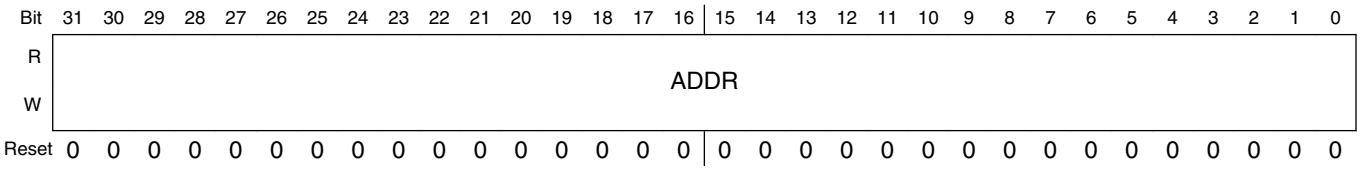
Output Framebuffer Pointer #2. This register points to the beginning of the output frame buffer for eitherfield 1 when generating interlaced output or for the UV buffer when in YUV 2-plane output modes. Both interlaced output AND 2-plane output modes are not supported. This register is NOT used as the pointer to the 2nd buffer when in LCDIF_HANDSHAKE mode.

This register is used by the logic to point to the current output location for the field 1 or UV output frame buffer.

EXAMPLE

```
PXP_OUTBUF_WR( field0 );  // buffer for interlaced field 0
PXP_OUTBUF2_WR( field1 ); // buffer for interlaced field 1
```

Address: ePXP_OUTBUF2 is 4100_C000h base + 30h offset = 4100_C030h



ePXP_OUTBUF2 field descriptions

Field	Description
31–0 ADDR	Current address pointer for the output frame buffer. The address must be word-aligned for proper ePXP operation.

43.4.5 ePXP Output Buffer Size (ePXP_OUTSIZE)

This register contains framebuffer size information for the output buffer (independent of the rotation). When rotating the framebuffer, the ePXP will automatically modify the output WIDTH/HEIGHT to accomodate the rotated size.

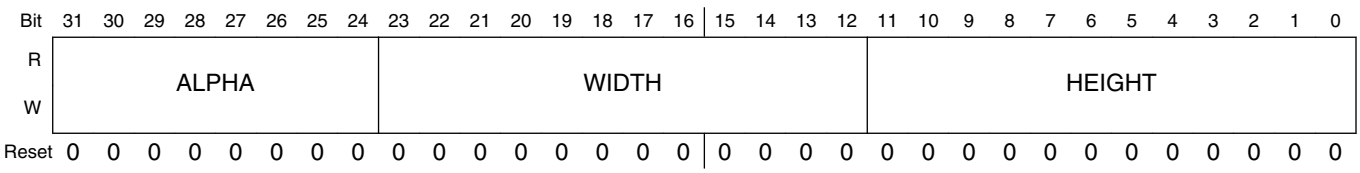
This register sets the size of the output frame buffer in pixels, not blocks. The frame buffer need not be a multiple of NxN pixels. Partial blocks will be written for output frame buffer sizes that are not divisable by N pixels in either dimension.

EXAMPLE

```
PXP_OUTSIZE.U.WIDTH=320;   // set width
PXP_OUTSIZE.U.HEIGHT=240;  // set height

PX_OUTSIZE_WR( BF_PXP_OUTSIZE_WIDTH(320) |  BF_PXP_OUTSIZE_HEIGHT(240) );
```

Address: ePXP_OUTSIZE is 4100_C000h base + 40h offset = 4100_C040h



ePXP_OUTSIZE field descriptions

Field	Description
31–24 ALPHA	When generating an output buffer with an alpha component, the value in this field will be used.
23–12 WIDTH	Indicates number of horizontal PIXELS in the image (non-rotated). The image size is not required to be a multiple of 8 pixels. The ePXP will handle clipping the pixel output at this boundary.
11–0 HEIGHT	Indicates the number of vertical PIXELS in the image (non-rotated). The image size is not required to be a multiple of 8 pixels. The ePXP will handle clipping the pixel output at this boundary.

43.4.6 ePXP Source 0 (video) Input Buffer Pointer (ePXP_S0BUF)

S0 Input Buffer Pointer. This should be programmed to the starting address of the RGB data or Y (luma) data for the S0 plane.

This register contains the pointer to the Luma/RGB buffer.

EXAMPLE

```
PXP_S0BUF_WR(image_rgb); // RGB image

PXP_S0BUF_WR(image_y);   // Y (luma) image data
PXP_S0UBUF_WR(image_u);  // U (Cb) image data
PXP_S0VBUF_WR(image_v);  // V (Cr) image data
```

Address: ePXP_S0BUF is 4100_C000h base + 50h offset = 4100_C050h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ePXP_S0BUF field descriptions

Field	Description
31–0 ADDR	Address pointer for the S0 RGB or Y (luma) input buffer. The address must be word-aligned for proper ePXP operation.

43.4.7 Source 0 U/Cb or 2 Plane UV Input Buffer Pointer (ePXP_S0UBUF)

S0 Chroma (U/Cb/UV) Input Buffer Pointer. This register points to the beginning of the Source 0 U/Cb input buffer. In two plane operation, this register points to the beginning of the Source 0 UV chroma input buffer.

This register contains the pointer to the Chroma U/Cb or 2 plane UV buffer when performing colorspace conversion. This register is unused when processing RGB data.

EXAMPLE

```
PXP_S0BUF_WR(image_y);   // Y (luma) image data
PXP_S0UBUF_WR(image_u);  // U (Cb) image data
PXP_S0VBUF_WR(image_v);  // V (Cr) image data
```

Address: ePXP_S0UBUF is 4100_C000h base + 60h offset = 4100_C060h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ePXP_S0UBUF field descriptions

Field	Description
31–0 ADDR	Address pointer for the S0 (video) U/Cb or two-plane UV Chroma input buffer. The address must be word-aligned for proper ePXP operation.

43.4.8 Source 0 V/Cr Input Buffer Pointer (ePXP_S0VBUF)

S0 Chroma (V/Cr) Input Buffer Pointer. This register points to the beginning of the Source 0 V/Cr input buffer. In two-plane operation, this register is not used.

This register contains the pointer to the Chroma V/Cr buffer when performing colorspace conversion. This register is unused when processing RGB data.

EXAMPLE

```
PXP_S0BUF_WR(image_y);   // Y (luma) image data
PXP_S0UBUF_WR(image_u);  // U (Cb) image data
PXP_S0VBUF_WR(image_v);  // V (Cr) image data
```

Address: ePXP_S0VBUF is 4100_C000h base + 70h offset = 4100_C070h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	ADDR																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ePXP_S0VBUF field descriptions

Field	Description
31–0 ADDR	Address pointer for the S0 (video) V/Cr Chroma input buffer. The address MUST be word-aligned for proper ePXP operation.

43.4.9 ePXP Source 0 (video) Buffer Parameters (ePXP_S0PARAM)

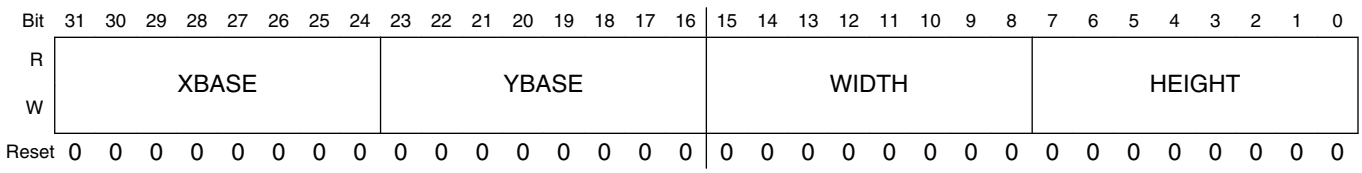
This register contains buffer information for the S0 input RGB/YUV buffer.

The S0 Parameter register contains the size of the S0 input buffer (WIDTH, HEIGHT) as well as provides an offset for the display of this buffer within the output frame buffer (XBASE,YBASE). All four values are in terms of NxN pixel blocks. In 16 pixel block size mode, only the low 7 bits of each field can be used and the most significant bit must be set to 0.

EXAMPLE

```
PXP_S0PARAM_WR(0x0101281E); // S0 buffer will appear at offset (8,8) in the output buffer.
                            // the size is 0x28 (40*8=320 pixels) by 0x1E (30*8=240
pixels)
```

Address: ePXP_S0PARAM is 4100_C000h base + 80h offset = 4100_C080h



ePXP_S0PARAM field descriptions

Field	Description
31–24 XBASE	This field indicates the horizontal offset location (in NxN block) of the S0 buffer within the output frame buffer.
23–16 YBASE	This field indicates the vertical offset location (in NxN block) of the S0 buffer within the output frame buffer.
15–8 WIDTH	Indicates number of horizontal NxN blocks in the image (non-rotated).
7–0 HEIGHT	Indicates the number of vertical NxN blocks in the image (non-rotated).

43.4.10 Source 0 Background Color (ePXP_S0BACKGROUND)

S0 Background Pixel Color. This register provides a pixel value used when processing blocks outside of the region specified by the S0SIZE register. This value can effectively be used to set the color of the letterboxing region around a video image.

This register contains a pixel value to be used for any S0 blocks that fall outside the S0 extents. This is effectively a background or letterbox color.

EXAMPLE

```
PXP_S0BACKGROUND_WR(0x00000000);  // letterbox is black
PXP_S0BACKGROUND_WR(0x00800000);  // letterbox is dark red
PXP_S0BACKGROUND_WR(0x00008000);  // letterbox is dark green
PXP_S0BACKGROUND_WR(0x00000080);  // letterbox is dark blue
```

Address: ePXP_S0BACKGROUND is 4100_C000h base + 90h offset = 4100_C090h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	COLOR																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ePXP_S0BACKGROUND field descriptions

Field	Description
31–0 COLOR	Background color (in 32bpp format) for any pixels not in the S0 buffer range specified in the S0SIZE register.

43.4.11 Source 0 Cropping Register (ePXP_S0CROP)

This register contains controls for image/video cropping. XBASE and YBASE select the origin of the S0 buffer for ePXP operations. The WIDTH and HEIGHT determine the visible size of the selected region in the output frame buffer. Software should program the input framebuffer cropped width/height values into these fields. Cropping is applied in the output buffer, therefore after any scaling operations. Scaled regions may need to be cropped to avoid artifacts at the edge of a scaled region.

The cropping register can be used to specify cropping extents for S0 plane in the output buffer. It is only used if the CROP bit is set in the ePXP_CTRL register is set. When this bit is not set, no cropping of the input image will be performed and the ePXP will default to using the S0 WIDTH and HEIGHT parameters. Cropping should always be used when scaling images since the PXP cannot determine the scaled image size. In 16 pixel block size mode, only the low 7 bits of each field can be used and the most significant bit must be set to 0.

EXAMPLE

```
PXP_S0CROP_WR(0x02021810);  // S0 origin is at (16,16) -- 0x0202
                               // output width is 192 (0x18->24*8=192 pixels)
                               // output height is 128 (0x10->16*8=128 pixels)
```

Address: ePXP_S0CROP is 4100_C000h base + A0h offset = 4100_C0A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	XBASE								YBASE								WIDTH								HEIGHT							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ePXP_S0CROP field descriptions

Field	Description
31–24 XBASE	This field indicates the horizontal offset (in terms of N-pixel blocks) into the S0 buffer which is considered the origin of the image. This allows selection of a subset of a source image for processing.
23–16 YBASE	This field indicates the vertical offset (in terms of N-pixel blocks) into the S0 buffer which is considered the origin of the image. This allows selection of a subset of a source image for processing.
15–8 WIDTH	Output buffer cropped video width (in terms of N pixel blocks). This field should be programmed to the desired cropped width of the S0 plane in the output buffer. When scaling is not used, this value is effectively the width of the input buffer that should appear in the output buffer. For scaling operations, it's important that this field be programmed to the width of the scaled size of the S0 output image.
7–0 HEIGHT	Input buffer cropped video height (in terms of N pixel blocks). This field should be programmed to the desired cropped height of the S0 plan in the output buffer. When scaling is not used, this value is effectively the height of the input buffer that should appear in the output buffer. For scaling operations, it's important that this field be programmed to the height of the scaled size of the S0 output image.

43.4.12 Source 0 Scale Factor Register (ePXP_S0SCALE)

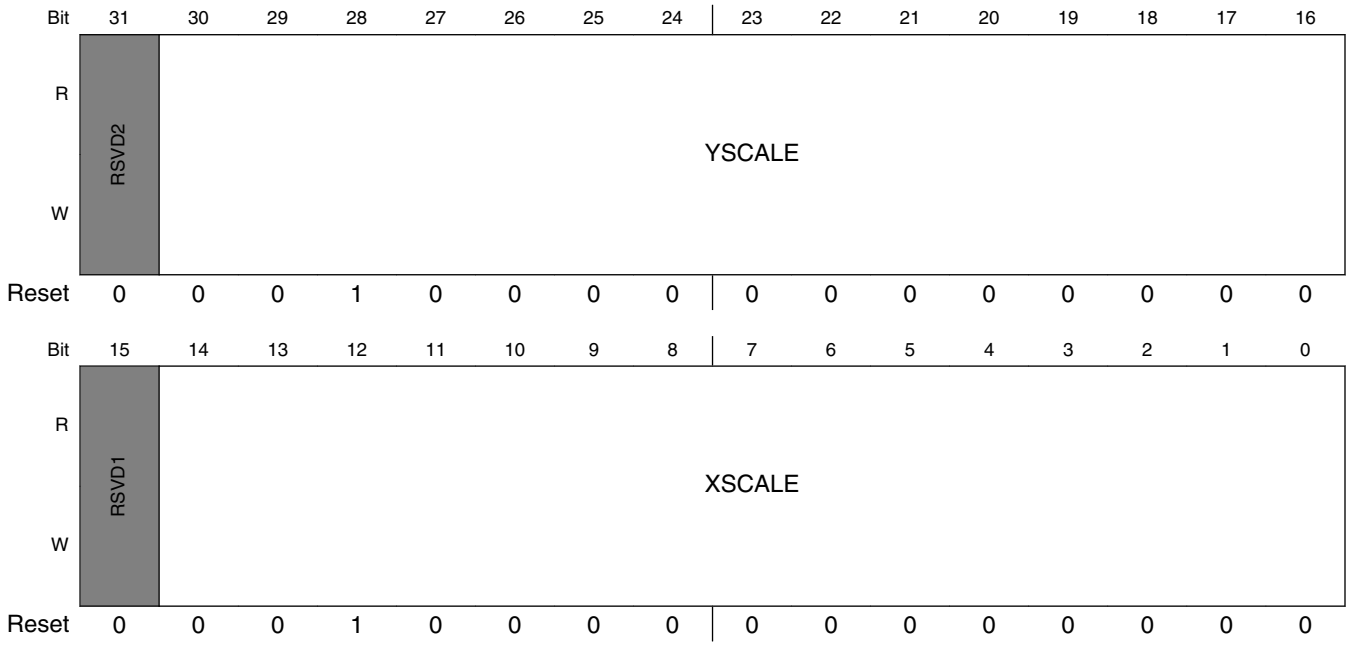
S0 Scale Factor. This register provides the scale factor for the S0 (video) buffer.

The maximum down scaling factor is 1/4 such that the output image in either axis is 1/4th the size of the source. The maximum up scaling factor is 2^12 for either axis. The reciprocal of the scale factor should be loaded into this register. To reduce the S0 buffer by a factor of two in the output frame buffer, a value of 10.0000_0000_0000 should be loaded into this register. The scale up by a factor of 4, the value of 1/4, or 00.0100_0000_0000, should be loaded into this register. To scale up by 8/5, the value of 00.1010_0000_0000 should be loaded.

EXAMPLE

```
PXP_S0SCALE_WR(0x10001000);  // 1:1  scaling (0x1.000)
PXP_S0SCALE_WR(0x08000800);  // 2x   scaling (0x0.800)
PXP_S0SCALE_WR(0x20002000);  // 1/2x scaling (0x2.000)
```

Address: ePXP_S0SCALE is 4100_C000h base + B0h offset = 4100_C0B0h



ePXP_S0SCALE field descriptions

Field	Description
31 RSVD2	Reserved, always set to zero.
30–16 YSCALE	This is a three bit integer and 12 bit fractional representation (###.####_####_####) of the Y scaling factor for the S0 source buffer. The maximum value programmed should be 4 since scaling down by a factor greater than 4 is not supported.
15 RSVD1	Reserved, always set to zero.
14–0 XSCALE	This is a three bit integer and 12 bit fractional representation (###.####_####_####) of the X scaling factor for the S0 source buffer. The maximum value programmed should be 4 since scaling down by a factor greater than 4 is not supported.

43.4.13 Source 0 Scale Offset Register (ePXP_S0OFFSET)

S0 Scale Offset. This register provides the initial scale offset for the S0 (video) buffer.

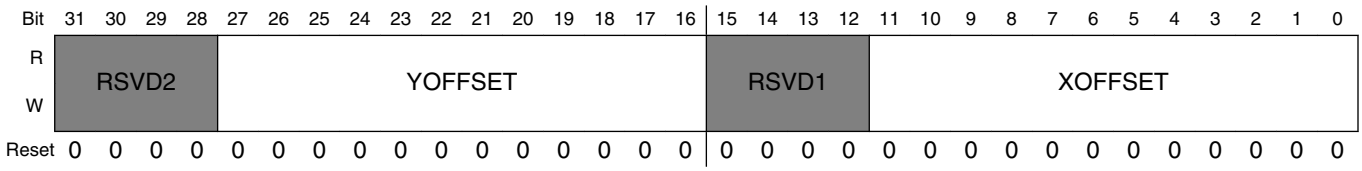
The X and Y offset provides the ability to access the source image with a per pixel or per sub-pixel granularity. To shift the source input image by a single pixel, for example, a value of 0x200 (for 8x8 block size) would be loaded into this offset field. For a 8x8 block size, 0x200 (or 1/8), will provide a fixed offset of 1 pixel for the entire ePXP operation. With this setting for 16x16 block size, the value of 0x200 will provide a fixed offset of 2 pixels since 1/8 of a 16 pixel block is 2. The fixed offset values can also be used for sub-pixel adjustments in the bilinear scaling filter. For example, when scaling an image down

by a factor of 2, an initial offset of 0x0 would result in sub-sampling every other pixel. If a fixed offset of 0x100 (1/16) with 8x8 block size selected is programmed, all pixels are used in scaling the final output pixel value.

EXAMPLE

```
Empty Example.
PXP_S0SCALE_WR(0x20002000);   // 1/2x scaling (0x2.000)
PXP_S0OFFSET_WR(0x01000100);  // half-pixel offset for 8x8 block size in both X and Y to
ensure averaging versus pixel replication
```

Address: ePXP_S0OFFSET is 4100_C000h base + C0h offset = 4100_C0C0h



ePXP_S0OFFSET field descriptions

Field	Description
31–28 RSVD2	Reserved, always set to zero.
27–16 YOFFSET	This is a 12 bit fractional representation (0.####_####_####) of the Y scaling offset. This represents a fixed block offset which gets added to the scaled block address to determine source data for the scaling engine.
15–12 RSVD1	Reserved, always set to zero.
11–0 XOFFSET	This is a 12 bit fractional representation (0.####_####_####) of the X scaling offset. This represents a fixed block offset which gets added to the scaled block address to determine source data for the scaling engine.

43.4.14 Color Space Conversion Coefficient Register 0 (ePXP_CSCCOEF0)

This register contains color space conversion coefficients in two's complement notation.

The Coefficient 0 register contains coefficients used in the color space conversion algorithm. The Y and UV offsets are added to the source buffer to normalize them before the conversion. C0 is the coefficient that is used to multiply the luma component of the data for all three RGB components.

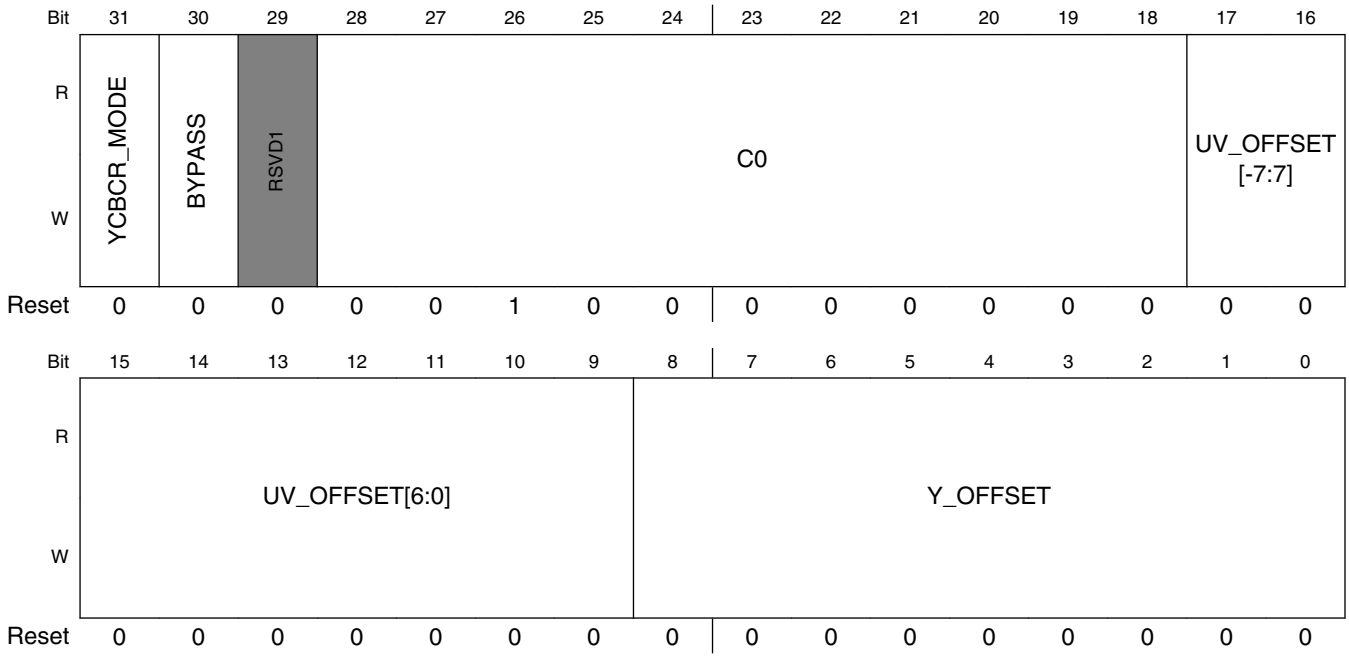
EXAMPLE

```
//  The equations used for Colorspace conversion are:
//     R = C0*(Y+YOFFSET)                    + C1(V+UV_OFFSET)
//     G = C0*(Y+YOFFSET) + C3(U+UV_OFFSET) + C2(V+UV_OFFSET)
//     R = C0*(Y+YOFFSET) + C4(U+UV_OFFSET)

   PXP_CSCCOEF0_WR(0x04030000); // YUV coefficients: C0, Yoffset, UVoffset
```

```
PXP_CSCCOEF1_WR(0x01230208); // YUV coefficients: C1, C4
PXP_CSCCOEF2_WR(0x076B079b); // YUV coefficients: C2, C3
```

Address: ePXP_CSCCOEF0 is 4100_C000h base + D0h offset = 4100_C0D0h



ePXP_CSCCOEF0 field descriptions

Field	Description
31 YCBCR_MODE	Set to 1 when performing YCbCr conversion to RGB. Set to 0 when converting YUV to RGB data. This bit changes the behavior of the scaler when performing U/V scaling.
30 BYPASS	Bypass the CSC unit in the scaling engine. When set to logic 1, bypass is enabled and the output pixels will be in the YUV/YCbCr color space. When set to logic 0, the CSC unit is enabled and the pixels will be converted based on the programmed coefficients.
29 RSVD1	Reserved, always set to zero.
28–18 C0	Two's complement Y multiplier coefficient. YUV=0x100 (1.000) YCbCr=0x12A (1.164)
17–9 UV_OFFSET	Two's complement phase offset implicit for CbCr data. Generally used for YCbCr to RGB conversion. YCbCr=0x180, YUV=0x000 (typically -128 or 0x180 to indicate normalized -0.5 to 0.5 range)
8–0 Y_OFFSET	Two's complement amplitude offset implicit in the Y data. For YUV, this is typically 0 and for YCbCr, this is typically -16 (0x1F0)

43.4.15 Color Space Conversion Coefficient Register 1 (ePXP_CSCCOEF1)

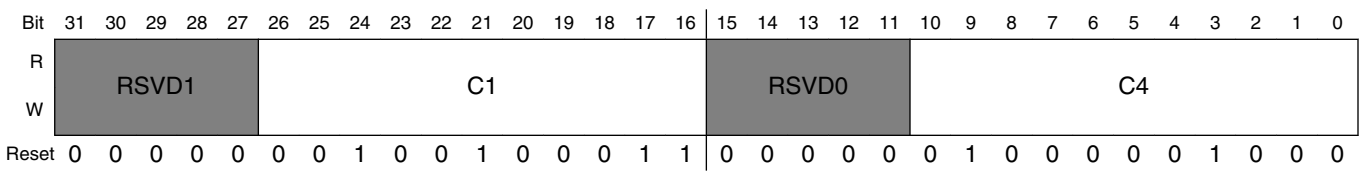
This register contains color space conversion coefficients in two's complement notation.

The Coefficient 1 register contains coefficients used in the color space conversion algorithm. C1 is the coefficient that is used to multiply the chroma (Cr/V) component of the data for the red component. C4 is the coefficient that is used to multiply the chroma (Cb/U) component of the data for the blue component. Both values should be coded as a two's complement fixed point number with 8 bits right of the decimal.

EXAMPLE

```
PXP_CSCCOEF0_WR(0x04030000); // YUV coefficients: C0, Yoffset, UVoffset
   PXP_CSCCOEF1_WR(0x01230208); // YUV coefficients: C1, C4
   PXP_CSCCOEF2_WR(0x076B079b); // YUV coefficients: C2, C3
```

Address: ePXP_CSCCOEF1 is 4100_C000h base + E0h offset = 4100_C0E0h



ePXP_CSCCOEF1 field descriptions

Field	Description
31–27 RSVD1	Reserved, always set to zero.
26–16 C1	Two's complement Red V/Cr multiplier coefficient. YUV=0x123 (1.140) YCbCr=0x198 (1.596)
15–11 RSVD0	Reserved, always set to zero.
10–0 C4	Two's complement Blue U/Cb multiplier coefficient. YUV=0x208 (2.032) YCbCr=0x204 (2.017)

43.4.16 Color Space Conversion Coefficient Register 2 (ePXP_CSCCOEF2)

This register contains color space conversion coefficients in two's complement notation.

The Coefficient 2 register contains coefficients used in the color space conversion algorithm. C2 is the coefficient that is used to multiply the chroma (Cr/V) component of the data for the green component. C3 is the coefficient that is used to multiply the chroma (Cb/U) component of the data for the green component. Both values should be coded as a two's complement fixed point number with 8 bits right of the decimal.

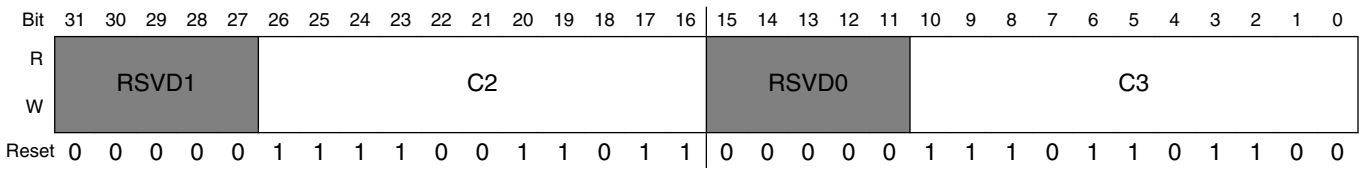
EXAMPLE

```
// NOTE: The default values for the CSCCOEF2 register are incorrect.  C2 should be 0x76B and
C3 should be 0x79C for proper operation.

   PXP_CSCCOEF0_WR(0x04030000); // YUV coefficients: C0, Yoffset, UVoffset
```

```
PXP_CSCCOEF1_WR(0x01230208); // YUV coefficients: C1, C4
PXP_CSCCOEF2_WR(0x076B079b); // YUV coefficients: C2, C3
```

Address: ePXP_CSCCOEF2 is 4100_C000h base + F0h offset = 4100_C0F0h



ePXP_CSCCOEF2 field descriptions

Field	Description
31–27 RSVD1	Reserved, always set to zero.
26–16 C2	Two's complement Green V/Cr multiplier coefficient. YUV=0x76B (-0.581) YCbCr=0x730 (-0.813)
15–11 RSVD0	Reserved, always set to zero.
10–0 C3	Two's complement Green U/Cb multiplier coefficient. YUV=0x79C (-0.394) YCbCr=0x79C (-0.392)

43.4.17 ePXP Next Frame Pointer (ePXP_NEXT*n*)

This register contains a pointer to a data structure used to reload the ePXP registers at the end of the current frame.

To enable this functionality, software must write this register while the ePXP is processing the current data frame (if the ePXP is currently idle, this will also initiate an immediate load of registers from the pointer). The process of writing this register (WRITE operation) will set a semaphore in hardware to notify the control logic that a register reload operation must be performed when the current frame processing is complete. At the end of a frame, the ePXP will fetch the register settings from this location, signal an interrupt to software, then proceed with rendering the next frame of data. Software may cancel the reload operation by issuing a CLEAR operation to this register. SET and TOGGLE operations should not be used when addressing this register. All registers will be reloaded with the exception of the following: STAT, CSCCOEFn, NEXT, VERSION. All other registers will be loaded in the order they appear in the register map. Once the pointer's contents have been loaded into the ePXP's registers, the NEXT_IRQ interrupt will be issued (see the ePXP_STATUS register).

EXAMPLE

```
// create register command structure in memory
  u32* pxp_commands0[48], pxp_commands1;
  u32  rc;
```

```
// initialize control structure for frame 0
  pxp_commands0[0] = ...; // CTRL
  pxp_commands0[1] = ...; // OUT Buffer
  ...
  pxp_commands0[47] = ..; // Overlay7 param2

// initialize control structure for frame 1
  pxp_commands1[0] = ...; // CTRL
  pxp_commands1[1] = ...; // OUT Buffer
  ...
  pxp_commands1[47] = ..; // Overlay7 param2

// poll until a command isn't queued
  while (rc=PXP_NEXT_RD() & BM_PXP_NEXT_ENABLED );
  PXP_NEXT_WR(pxp_commands0);  // enable PXP operation 0 via command pointer

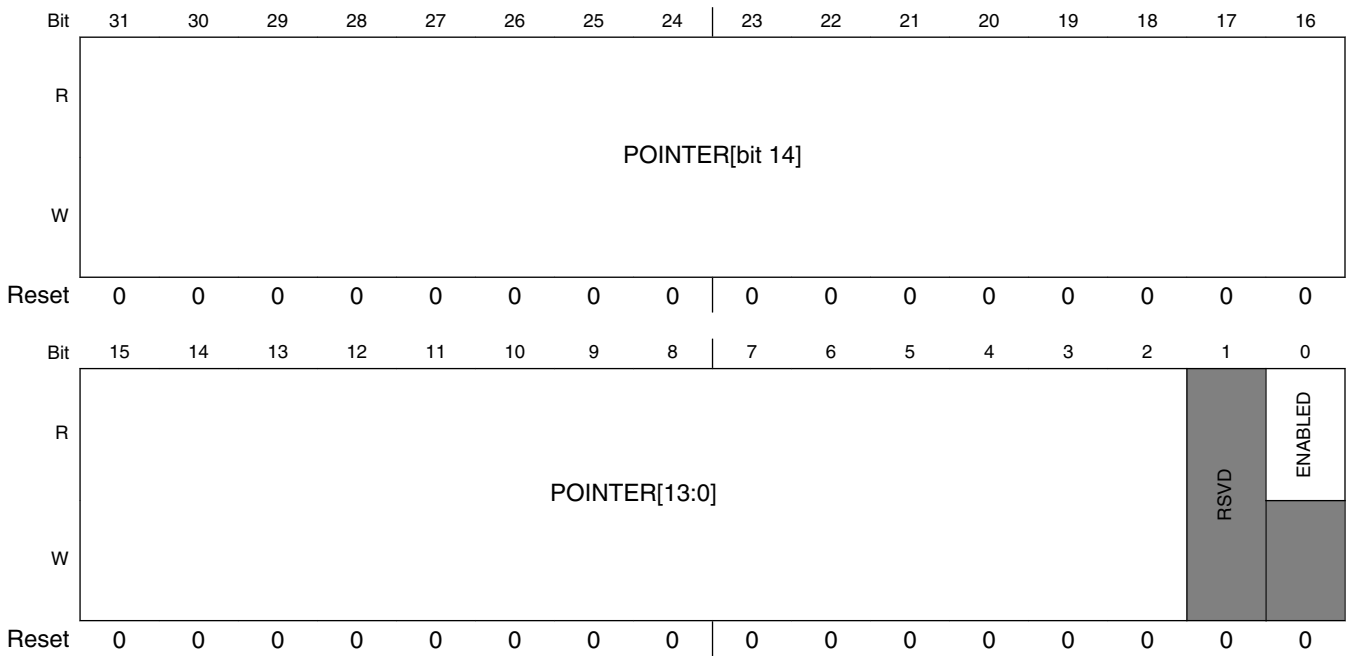
// poll until first command clears
  while (rc=PXP_NEXT_RD() & BM_PXP_NEXT_ENABLED );
  PXP_NEXT_WR(pxp_commands1);  // enable PXP operation 1 via command pointer
```

Addresses: ePXP_NEXT is 4100_C000h base + 100h offset = 4100_C100h

ePXP_NEXT_SET is 4100_C000h base + 104h offset = 4100_C104h

ePXP_NEXT_CLR is 4100_C000h base + 108h offset = 4100_C108h

ePXP_NEXT_TOG is 4100_C000h base + 10Ch offset = 4100_C10Ch



ePXP_NEXT*n* field descriptions

Field	Description
31–2 POINTER	A pointer to a data structure containing register values to be used when processing the next frame. The pointer must be 32-bit aligned and should reside in on-chip or off-chip memory.
1 RSVD	Reserved, always set to zero.
0 ENABLED	Indicates that the "next frame" functionality has been enabled. This bit reflects the status of the hardware semaphore indicating that a reload operation is pending at the end of the current frame.

43.4.18 ePXP S0 Color Key Low (ePXP_S0COLORKEYLOW)

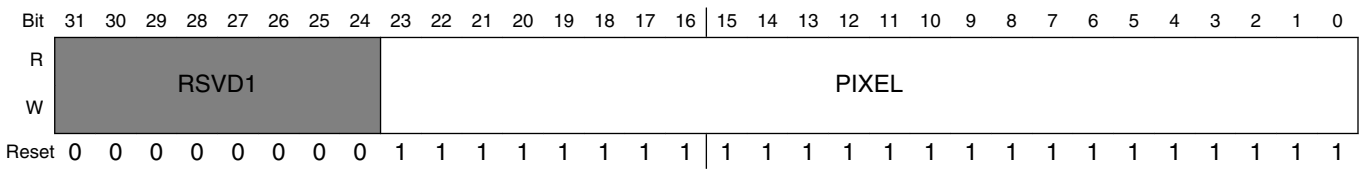
This register contains the color key low value for the S0 buffer.

When processing an image, the if the ePXP finds a pixel in the background image with a color that falls in the range from the S0COLORKEYLOW to S0COLORKEYHIGH range, it will substitute the color found in the matching overlay. If no overlay is present or if the overlay also matches its colorkey range, the s0background color is used.

EXAMPLE

```
// colorkey values between
PXP_S0COLORKEYLOW_WR (0x008000); // medium green and
PXP_S0COLORKEYHIGH_WR(0x00FF00); // light green
```

Address: ePXP_S0COLORKEYLOW is 4100_C000h base + 180h offset = 4100_C180h



ePXP_S0COLORKEYLOW field descriptions

Field	Description
31–24 RSVD1	Reserved, always set to zero.
23–0 PIXEL	Low range of RGB color key applied to S0 buffer. To disable S0 colorkeying, set the low colorkey to 0xFFFFFF and the high colorkey to 0x000000.

43.4.19 ePXP S0 Color Key High (ePXP_S0COLORKEYHIGH)

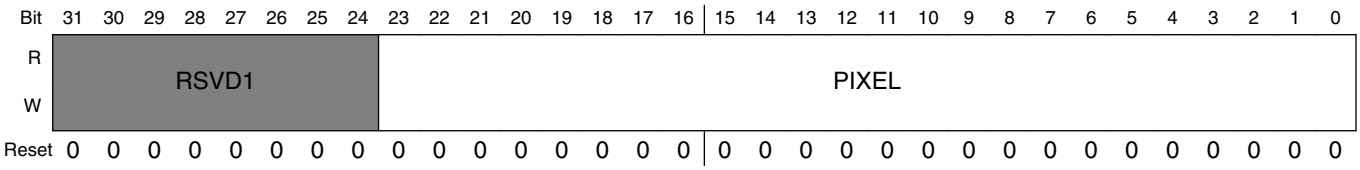
This register contains the color key high value for the S0 buffer.

When processing an image, if the ePXP finds a pixel in the background image with a color that falls in the range from the S0COLORKEYLOW to S0COLORKEYHIGH range, it will substitute the color found in the matching overlay. If no overlay is present or if the overlay also matches its colorkey range, the s0background color is used.

EXAMPLE

```
// colorkey values between
PXP_S0COLORKEYLOW_WR (0x008000); // medium green and
PXP_S0COLORKEYHIGH_WR(0x00FF00); // light green
```

Address: ePXP_S0COLORKEYHIGH is 4100_C000h base + 190h offset = 4100_C190h



ePXP_S0COLORKEYHIGH field descriptions

Field	Description
31–24 RSVD1	Reserved, always set to zero.
23–0 PIXEL	High range of RGB color key applied to S0 buffer. To disable S0 colorkeying, set the low colorkey to 0xFFFFFF and the high colorkey to 0x000000.

43.4.20 ePXP Overlay Color Key Low (ePXP_OLCOLORKEYLOW)

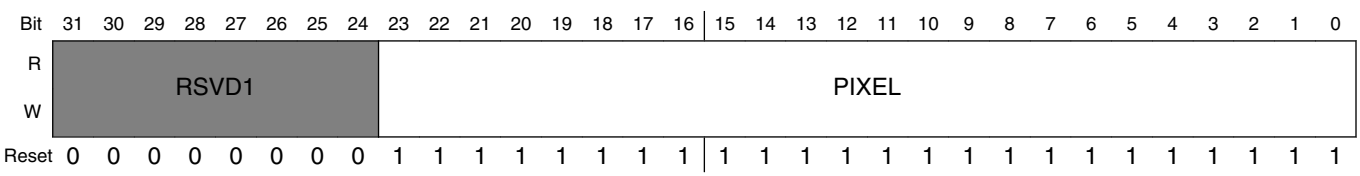
This register contains the color key low value for the OL buffer.

When processing an image, the if the ePXP finds a pixel in the current overlay image with a color that falls in the range from the OLCOLORKEYLOW to OLCOLORKEYHIGH range, it will use the S0 pixel value for that location. If no S0 image is present or if the S0 image also matches its colorkey range, the s0background color is used. Colorkey operations are higher priority than alpha or ROP operations.

EXAMPLE

```
// colorkey values between
PXP_OLCOLORKEYLOW_WR (0x000000); // black and
PXP_OLCOLORKEYHIGH_WR(0x800000); // medium red
```

Address: ePXP_OLCOLORKEYLOW is 4100_C000h base + 1A0h offset = 4100_C1A0h



ePXP_OLCOLORKEYLOW field descriptions

Field	Description
31–24 RSVD1	Reserved, always set to zero.
23–0 PIXEL	Low range of RGB color key applied to OL buffer. Each overlay has an independent colorkey enable.

43.4.21 ePXP Overlay Color Key High (ePXP_OLCOLORKEYHIGH)

This register contains the color key high value for the OL buffer.

When processing an image, the if the ePXP finds a pixel in the current overlay image with a color that falls in the range from the OLCOLORKEYLOW to OLCOLORKEYHIGH range, it will use the S0 pixel value for that location. If no S0 image is present or if the S0 image also matches its colorkey range, the s0background color is used. Colorkey operations are higher priority than alpha or ROP operations.

EXAMPLE

```
// colorkey values between
PXP_OLCOLORKEYLOW_WR (0x000000); // black and
PXP_OLCOLORKEYHIGH_WR(0x800000); // medium red
```

Address: ePXP_OLCOLORKEYHIGH is 4100_C000h base + 1B0h offset = 4100_C1B0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ePXP_OLCOLORKEYHIGH field descriptions

Field	Description
31–24 RSVD1	Reserved, always set to zero.
23–0 PIXEL	High range of RGB color key applied to OL buffer. Each overlay has an independent colorkey enable.

43.4.22 ePXP Debug Register (ePXP_DEBUG)

This register returns selected debug register values.

Debug register. Select the appropriate register in debug control and the values are returned here.

EXAMPLE

Address: ePXP_DEBUG is 4100_C000h base + 1E0h offset = 4100_C1E0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ePXP_DEBUG field descriptions

Field	Description
31–0 DATA	Debug data

43.4.23 ePXP Overlay n Buffer Pointer (ePXP_OL*n*)

Overlay n Buffer Address Pointer. This register points to the beginning of the RGB Overlay n input buffer.

This register is used by the logic to point to the current output location for the RGB frame buffer.

EXAMPLE

```
u32* overlay_ptr;
PXP_OLn_WR(n,overlay_ptr);
```

Addresses: ePXP_OL0 is 4100_C000h base + 200h offset = 4100_C200h
ePXP_OL1 is 4100_C000h base + 240h offset = 4100_C240h
ePXP_OL2 is 4100_C000h base + 280h offset = 4100_C280h
ePXP_OL3 is 4100_C000h base + 2C0h offset = 4100_C2C0h
ePXP_OL4 is 4100_C000h base + 300h offset = 4100_C300h
ePXP_OL5 is 4100_C000h base + 340h offset = 4100_C340h
ePXP_OL6 is 4100_C000h base + 380h offset = 4100_C380h
ePXP_OL7 is 4100_C000h base + 3C0h offset = 4100_C3C0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ePXP_OL*n* field descriptions

Field	Description
31–0 ADDR	Address pointer for the overlay n buffer. The address MUST be word-aligned for proper ePXP operation.

43.4.24 ePXP Overlay n Size (ePXP_OL__SIZE)

This register contains buffer size/location information for the Overlay n input buffer.

This register contains information about Overlay n indicating the size of the overlay (in NxN blocks) and the overlay's location within the output frame buffer (in NxN blocks). In 16 pixel block size mode, only the low 7 bits of each field can be used and the most significant bit must be set to 0.

EXAMPLE

```
PXP_OLnSIZE_WR(n,0x10000401); // 32x8 overlay at offset +128+0
```

Addresses: ePXP_OL__SIZE0 is 4100_C000h base + 210h offset = 4100_C210h
ePXP_OL__SIZE1 is 4100_C000h base + 250h offset = 4100_C250h
ePXP_OL__SIZE2 is 4100_C000h base + 290h offset = 4100_C290h
ePXP_OL__SIZE3 is 4100_C000h base + 2D0h offset = 4100_C2D0h
ePXP_OL__SIZE4 is 4100_C000h base + 310h offset = 4100_C310h
ePXP_OL__SIZE5 is 4100_C000h base + 350h offset = 4100_C350h
ePXP_OL__SIZE6 is 4100_C000h base + 390h offset = 4100_C390h
ePXP_OL__SIZE7 is 4100_C000h base + 3D0h offset = 4100_C3D0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	XBASE								YBASE								WIDTH								HEIGHT							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ePXP_OL__SIZE*n* field descriptions

Field	Description
31–24 XBASE	This field indicates the X-coordinate (in blocks) of the top-left NxN block in the overlay within the output frame buffer.
23–16 YBASE	This field indicates the Y-coordinate (in blocks) of the top-left NxN block in the overlay within the output frame buffer.
15–8 WIDTH	Indicates number of horizontal NxN blocks in the image (non-rotated).
7–0 HEIGHT	Indicates the number of vertical NxN blocks in the image (non-rotated).

43.4.25 ePXP Overlay n Parameters (ePXP_OL__PARAM)

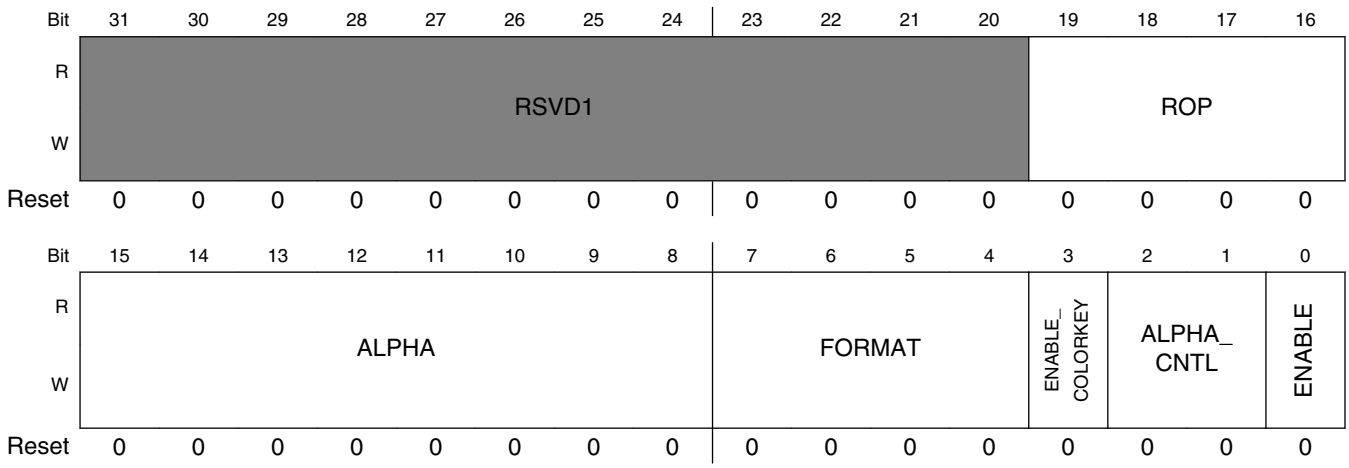
This register contains buffer parameters for the Overlay n input buffer.

The S1 Overlay n Parameter register provides additional controls for Overlay n.

EXAMPLE

```
u32 olparam;
      olparam  = BF_PXP_OLnPARAM_ENABLE    (1);
      olparam |= BF_PXP_OLnPARAM_ALPHA_CNTL(BV_PXP_OLnPARAM_ALPHA_CNTL__ROPs);
      olparam |= BF_PXP_OLnPARAM_FORMAT    (BV_PXP_OLnPARAM_FORMAT__ARGB8888);
      olparam |= BF_PXP_OLnPARAM_ROP       (BV_PXP_OLnPARAM_ROP__XOROL);
PXP_OLnPARAM_WR(n,olparam);  // enable overlay to perform XOR ROP using RGB8888 overlay
```

Addresses: ePXP_OL__PARAM0 is 4100_C000h base + 220h offset = 4100_C220h
ePXP_OL__PARAM1 is 4100_C000h base + 260h offset = 4100_C260h
ePXP_OL__PARAM2 is 4100_C000h base + 2A0h offset = 4100_C2A0h
ePXP_OL__PARAM3 is 4100_C000h base + 2E0h offset = 4100_C2E0h
ePXP_OL__PARAM4 is 4100_C000h base + 320h offset = 4100_C320h
ePXP_OL__PARAM5 is 4100_C000h base + 360h offset = 4100_C360h
ePXP_OL__PARAM6 is 4100_C000h base + 3A0h offset = 4100_C3A0h
ePXP_OL__PARAM7 is 4100_C000h base + 3E0h offset = 4100_C3E0h



ePXP_OL__PARAM*n* field descriptions

Field	Description
31–20 RSVD1	Reserved, always set to zero.
19–16 ROP	Indicates a raster operation to perform when enabled. Raster operations are enabled through the ALPHA_CNTL field. 0x0 **MASKOL** — OL AND S0 0x1 **MASKNOTOL** — nOL AND S0 0x2 **MASKOLNOT** — OL AND nS0 0x3 **MERGEOL** — OL OR S0 0x4 **MERGENOTOL** — nOL OR S0 0x5 **MERGEOLNOT** — OL OR nS0 0x6 **NOTCOPYOL** — nOL 0x7 **NOT** — nS0 0x8 **NOTMASKOL** — OL NAND S0 0x9 **NOTMERGEOL** — OL NOR S0 0xA **XOROL** — OL XOR S0 0xB **NOTXOROL** — OL XNOR S0
15–8 ALPHA	Alpha modifier used when the ALPHA_MULTIPLY or ALPHA_OVERRIDE bits are set. The output alpha value will either be replaced (ALPHA_OVERRIDE) or scaled (ALPHA_MULTIPLY) when enabled in the ALPHA_CNTL field.
7–4 FORMAT	Indicates the input buffer format for overlay n. 0x0 **ARGB8888** — 32-bit pixels with alpha

Table continues on the next page...

ePXP_OL__PARAM*n* field descriptions (continued)

Field	Description
	0x1 **RGB888** — 32-bit pixels without alpha (unpacked 24-bit format) 0x3 **ARGB1555** — 16-bit pixels with alpha 0x4 **RGB565** — 16-bit pixels without alpha 0x5 **RGB555** — 16-bit pixels without alpha
3 ENABLE_ COLORKEY	Indicates that colorkey functionality is enabled for this overlay. Pixels found in the overlay colorkey range will be displayed as transparent (the S0 pixel will be used).
2–1 ALPHA_CNTL	Determines how the alpha value is constructed for this overlay. Indicates that the value in the ALPHA field should be used instead of the alpha values present in the input pixels. 0x0 **Embedded** — Indicates that the OL pixel alpha value will be used to blend the OL with S0. The ALPHA field is ignored. 0x1 **Override** — Indicates that the value in the ALPHA field should be used instead of the alpha values present in the input pixels. 0x2 **Multiply** — Indicates that the value in the ALPHA field should be used to scale all pixel alpha values. Each pixel alpha is multiplied by the value in the ALPHA field. 0x3 **ROPs** — Enable ROPs. The ROP field indicates an operation to be performed on the overlay and S0 pixels.
0 ENABLE	Indicates that the overlay is active for this operation.

43.4.26 Color Space Conversion Control Register. (ePXP_CSC2CTRL)

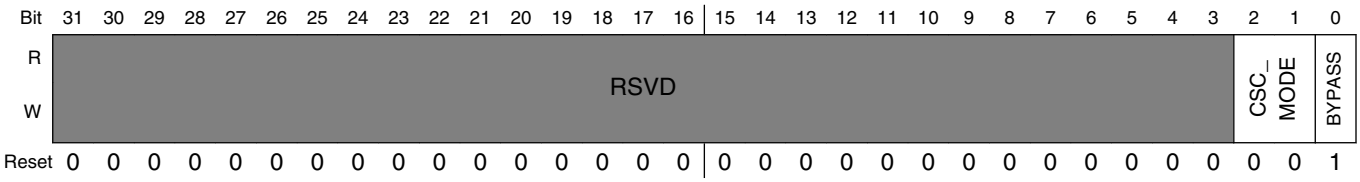
This register contains the control registers to configure the CSC module.

The CSC control register will configure the CSC module to perform color space conversion between the RGB/YUV/YCbCr color spaces.

EXAMPLE

```
//Converting from YUV/YCbCr color spaces to the RGB color space uses the
   //following equation structure:
   //
   // R = A1(Y-D1) + A2(U-D2) + A3(V-D3)
   // G = B1(Y-D1) + B2(U-D2) + B3(V-D3)
   // B = C1(Y-D1) + C2(U-D2) + C3(V-D3)
   //
   //Converting from the RGB color space to YUV/YCbCr color spaces uses the
   //following equation structure:
   //
   // Y = A1*R + A2*G + A3*B + D1
   // U = B1*R + B2*G + B3*B + D2
   // V = C1*R + C2*G + C3*B + D3
   //
   //All math is signed, so all coefficients come in as two's comp numbers
   //
```

Address: ePXP_CSC2CTRL is 4100_C000h base + 400h offset = 4100_C400h



ePXP_CSC2CTRL field descriptions

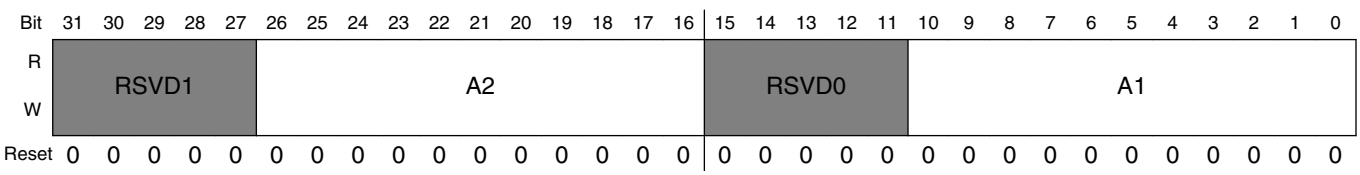
Field	Description
31–3 RSVD	Reserved, always set to zero.
2–1 CSC_MODE	This field controls how the CSC unit operates on pixels when the CSC is not bypassed. 0x0 **YUV2RGB** — Convert from YUV to RGB. 0x1 **YCbCr2RGB** — Convert from YCbCr to RGB. 0x2 **RGB2YUV** — Convert from RGB to YUV. 0x3 **RGB2YCbCr** — Convert from RGB to YCbCr.
0 BYPASS	This bit controls whether the pixels entering the CSC2 unit get converted or not. When BYPASS is set, no operations occur on the pixels. When BYPASS is cleared, the selected CSC operation takes place.

43.4.27 Color Space Conversion Coefficient Register 0 (ePXP_CSC2COEF0)

This register contains color space conversion coefficients in two's complement notation.

EXAMPLE

Address: ePXP_CSC2COEF0 is 4100_C000h base + 410h offset = 4100_C410h



ePXP_CSC2COEF0 field descriptions

Field	Description
31–27 RSVD1	Reserved, always set to zero.
26–16 A2	Two's complement coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.
15–11 RSVD0	Reserved, always set to zero.
10–0 A1	Two's complement coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.

43.4.28 Color Space Conversion Coefficient Register 1 (ePXP_CSC2COEF1)

This register contains color space conversion coefficients in two's complement notation.

EXAMPLE

Address: ePXP_CSC2COEF1 is 4100_C000h base + 420h offset = 4100_C420h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	RSVD1					B1											RSVD0					A3											
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ePXP_CSC2COEF1 field descriptions

Field	Description
31–27 RSVD1	Reserved, always set to zero.
26–16 B1	Two's complement coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.
15–11 RSVD0	Reserved, always set to zero.
10–0 A3	Two's complement coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.

43.4.29 Color Space Conversion Coefficient Register 2 (ePXP_CSC2COEF2)

This register contains color space conversion coefficients in two's complement notation.

EXAMPLE

Address: ePXP_CSC2COEF2 is 4100_C000h base + 430h offset = 4100_C430h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	RSVD1					B3											RSVD0					B2											
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ePXP_CSC2COEF2 field descriptions

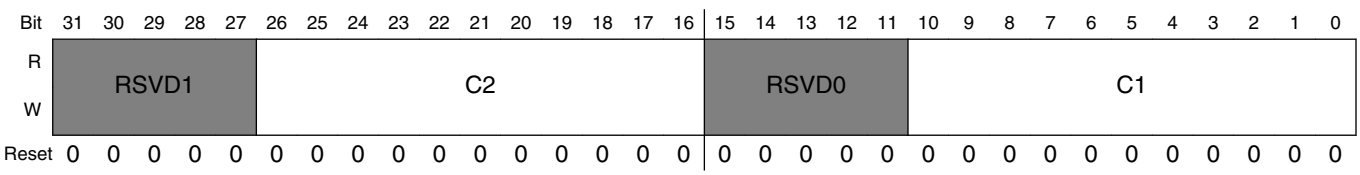
Field	Description
31–27 RSVD1	Reserved, always set to zero.
26–16 B3	Two's complement coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.
15–11 RSVD0	Reserved, always set to zero.
10–0 B2	Two's complement coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.

43.4.30 Color Space Conversion Coefficient Register 3 (ePXP_CSC2COEF3)

This register contains color space conversion coefficients in two's complement notation.

EXAMPLE

Address: ePXP_CSC2COEF3 is 4100_C000h base + 440h offset = 4100_C440h



ePXP_CSC2COEF3 field descriptions

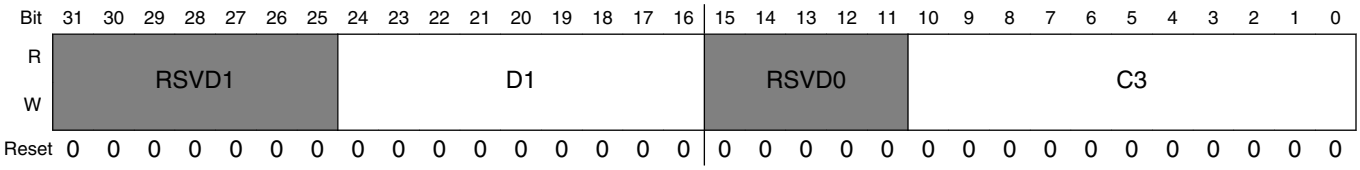
Field	Description
31–27 RSVD1	Reserved, always set to zero.
26–16 C2	Two's complement coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.
15–11 RSVD0	Reserved, always set to zero.
10–0 C1	Two's complement coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.

43.4.31 Color Space Conversion Coefficient Register 4 (ePXP_CSC2COEF4)

This register contains color space conversion coefficients in two's complement notation.

EXAMPLE

Address: ePXP_CSC2COEF4 is 4100_C000h base + 450h offset = 4100_C450h



ePXP_CSC2COEF4 field descriptions

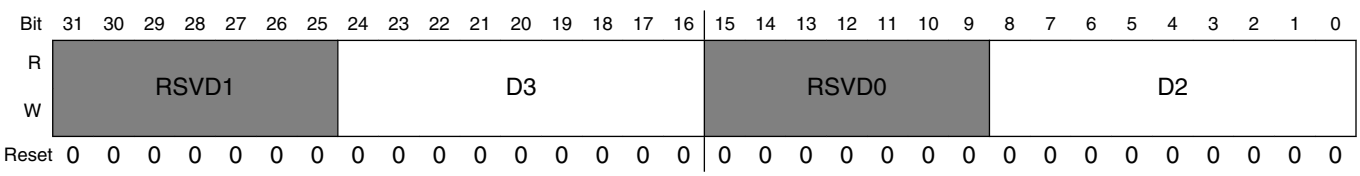
Field	Description
31–25 RSVD1	Reserved, always set to zero.
24–16 D1	Two's complement coefficient integer offset to be added.
15–11 RSVD0	Reserved, always set to zero.
10–0 C3	Two's complement coefficient offset. This coefficient has a sign bit, 2 bits integer, and 8 bits of fraction as ###.####_####.

43.4.32 Color Space Conversion Coefficient Register 5 (ePXP_CSC2COEF5)

This register contains color space conversion coefficients in two's complement notation.

EXAMPLE

Address: ePXP_CSC2COEF5 is 4100_C000h base + 460h offset = 4100_C460h



ePXP_CSC2COEF5 field descriptions

Field	Description
31–25 RSVD1	Reserved, always set to zero.
24–16 D3	Two's complement coefficient integer offset to be added.
15–9 RSVD0	Reserved, always set to zero.

Table continues on the next page...

ePXP_CSC2COEF5 field descriptions (continued)

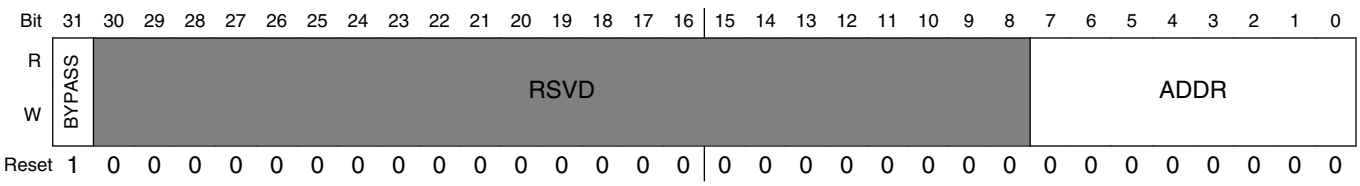
Field	Description
8–0 D2	Two's complement coefficient integer offset to be added.

43.4.33 Lookup Table Control Register. (ePXP_LUT_CTRL)

This register is used to access/control the Monochrome Lookup table.

EXAMPLE

Address: ePXP_LUT_CTRL is 4100_C000h base + 470h offset = 4100_C470h



ePXP_LUT_CTRL field descriptions

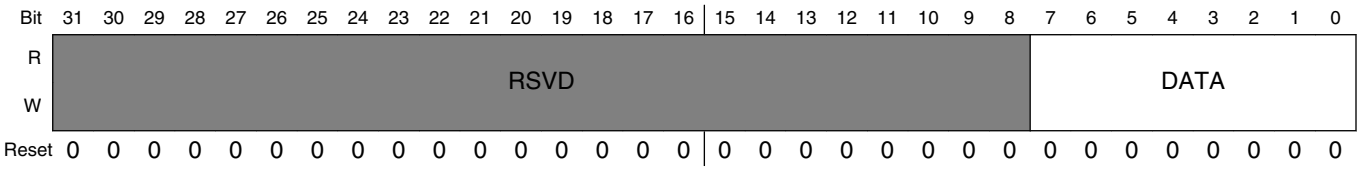
Field	Description
31 BYPASS	Set this bit to bypass the Y (Luma) lookup table. If Gamma correction is required, as for monochrome output, then clear this bit, program the LUT with valid data, and clear the bypass bit to enable the LUT resources.
30–8 RSVD	Reserved, always set to zero.
7–0 ADDR	LUT indexed address pointer. When the LUT data register is written, the contents of the LUT at the address specified by this address filed will be loaded. This address pointer will be incremented after the LUT data is written. This will provide recursive writes to the LUT data regeister to initialize the entire LUT array.

43.4.34 Lookup Table Data Register. (ePXP_LUT)

This register is used to load data into the lookup table.

EXAMPLE

Address: ePXP_LUT is 4100_C000h base + 480h offset = 4100_C480h



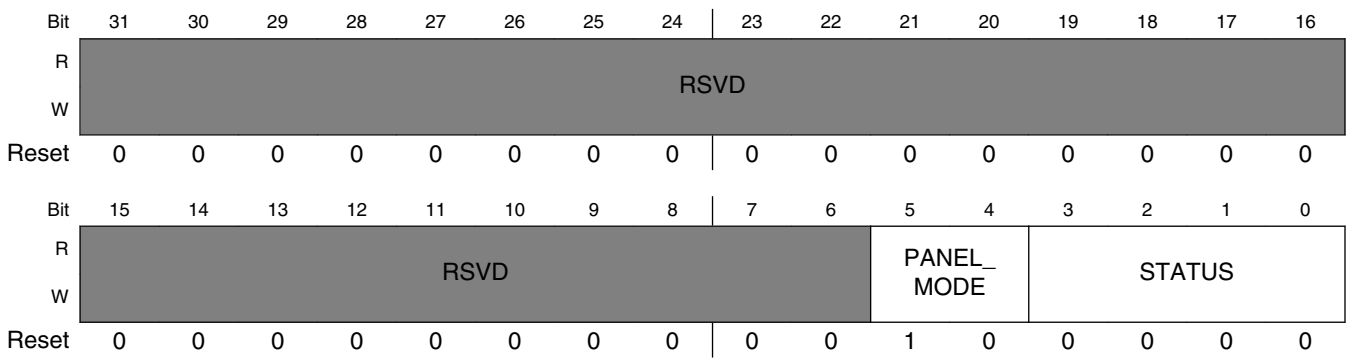
ePXP_LUT field descriptions

Field	Description
31–8 RSVD	Reserved, always set to zero.
7–0 DATA	Writting this field will write the data indexed by the ADDR field of the ePXP_LUT_CTRL register.

43.4.35 Histogram Control Register. (ePXP_HIST_CTRL)

Provides control and status registers for the ePXP's histogram classification algorithm.

Address: ePXP_HIST_CTRL is 4100_C000h base + 490h offset = 4100_C490h



ePXP_HIST_CTRL field descriptions

Field	Description
31–6 RSVD	Reserved, always set to zero.
5–4 PANEL_MODE	Specifies the EPDC panel grayscale depth. This value is used to specify the number of bits used in comparisons when matching pixels to histogram bins. All comparator values MUST be programmed such that their bit width is consistent with the value of this register field. For instance, if GRAY16 is selected, comparator values must be in the range of 0x0-0xF. 0x0 **GRAY4** — 4-bit grayscale 0x1 **GRAY8** — 8-bit grayscale 0x2 **GRAY16** — 16-bit grayscale 0x3 **GRAY32** — 32-bit grayscale

Table continues on the next page...

ePXP_HIST_CTRL field descriptions (continued)

Field	Description
3–0 STATUS	Indicates which histogram matched the processed bitmap. Bit[0] indicates that the bitmap pixels were fully contained within the HIST2 (black / white) histogram. Bit[1] indicates that the bitmap pixels were fully contained within the HIST4 (2-bit grayscale) histogram. Bit[2] indicates that the bitmap pixels were fully contained within the HIST8 (3-bit grayscale) histogram. Bit[3] indicates that the bitmap pixels were fully contained within the HIST16 (4-bit grayscale) histogram.

43.4.36 2-level Histogram Parameter Register. (ePXP_HIST2_PARAM)

This register specifies the valid values for a 2-level histogram. If all pixels in a bitmap match these two values, ePXP_HIST_CTRL[STATUS[0]] will be set at the end of frame processing. All comparator values should be programmed such that they are consistent with ePXP_HIST_CTRL[PANEL_MODE].

EXAMPLE

Address: ePXP_HIST2_PARAM is 4100_C000h base + 4A0h offset = 4100_C4A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	RSVD																RSVD1			VALUE1					RSVD0			VALUE0					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	1	0	0	0	0	0	0	0	0

ePXP_HIST2_PARAM field descriptions

Field	Description
31–16 RSVD	Reserved, always set to zero.
15–13 RSVD1	Reserved, always set to zero.
12–8 VALUE1	White value for 2-level histogram
7–5 RSVD0	Reserved, always set to zero.
4–0 VALUE0	Black value for 2-level histogram

43.4.37 4-level Histogram Parameter Register. (ePXP_HIST4_PARAM)

This register specifies the valid values for a 4-level histogram. If all pixels in a bitmap match these two values, ePXP_HIST_CTRL[STATUS[1]] will be set at the end of frame processing. All comparator values should be programmed such that they are consistent with ePXP_HIST_CTRL[PANEL_MODE].

EXAMPLE

Address: ePXP_HIST4_PARAM is 4100_C000h base + 4B0h offset = 4100_C4B0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	RSVD3			VALUE3					RSVD2			VALUE2					RSVD1			VALUE1					RSVD0			VALUE0				
Reset	0	0	0	0	1	1	1	1	0	0	0	0	1	0	1	0	0	0	0	0	0	1	0	1	0	0	0	0	0	0	0	0

ePXP_HIST4_PARAM field descriptions

Field	Description
31–29 RSVD3	Reserved, always set to zero.
28–24 VALUE3	GRAY3 (White) value for 4-level histogram
23–21 RSVD2	Reserved, always set to zero.
20–16 VALUE2	GRAY2 value for 4-level histogram
15–13 RSVD1	Reserved, always set to zero.
12–8 VALUE1	GRAY1 value for 4-level histogram
7–5 RSVD0	Reserved, always set to zero.
4–0 VALUE0	GRAY0 (Black) value for 4-level histogram

43.4.38 8-level Histogram Parameter 0 Register. (ePXP_HIST8_PARAM0)

This register specifies four of the valid values for an 8-level histogram. If all pixels in a bitmap match these two values, ePXP_HIST_CTRL[STATUS[2]] will be set at the end of frame processing. All comparator values should be programmed such that they are consistent with ePXP_HIST_CTRL[PANEL_MODE].

EXAMPLE

Address: ePXP_HIST8_PARAM0 is 4100_C000h base + 4C0h offset = 4100_C4C0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	1	1	0	0	0	0	0	0	1	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ePXP_HIST8_PARAM0 field descriptions

Field	Description
31–29 RSVD3	Reserved, always set to zero.
28–24 VALUE3	GRAY3 value for 8-level histogram
23–21 RSVD2	Reserved, always set to zero.
20–16 VALUE2	GRAY2 value for 8-level histogram
15–13 RSVD1	Reserved, always set to zero.
12–8 VALUE1	GRAY1 value for 8-level histogram
7–5 RSVD0	Reserved, always set to zero.
4–0 VALUE0	GRAY0 (Black) value for 8-level histogram

43.4.39 8-level Histogram Parameter 1 Register. (ePXP_HIST8_PARAM1)

This register specifies four of the valid values for an 8-level histogram. If all pixels in a bitmap match these two values, ePXP_HIST_CTRL[STATUS[2]] will be set at the end of frame processing. All comparator values should be programmed such that they are consistent with ePXP_HIST_CTRL[PANEL_MODE].

Address: ePXP_HIST8_PARAM1 is 4100_C000h base + 4D0h offset = 4100_C4D0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	1	1	1	1	0	0	0	0	1	1	0	1	0	0	0	0	1	0	1	1	0	0	0	0	1	0	0	1

ePXP_HIST8_PARAM1 field descriptions

Field	Description
31–29 RSVD7	Reserved, always set to zero.
28–24 VALUE7	GRAY7 (White) value for 8-level histogram
23–21 RSVD6	Reserved, always set to zero.
20–16 VALUE6	GRAY6 value for 8-level histogram
15–13 RSVD5	Reserved, always set to zero.
12–8 VALUE5	GRAY5 value for 8-level histogram
7–5 RSVD4	Reserved, always set to zero.
4–0 VALUE4	GRAY4 value for 8-level histogram

43.4.40 16-level Histogram Parameter 0 Register. (ePXP_HIST16_PARAM0)

This register specifies four of the valid values for a 16-level histogram. If all pixels in a bitmap match these two values, ePXP_HIST_CTRL[STATUS[3]] will be set at the end of frame processing. All comparator values should be programmed such that they are consistent with ePXP_HIST_CTRL[PANEL_MODE].

Address: ePXP_HIST16_PARAM0 is 4100_C000h base + 4E0h offset = 4100_C4E0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ePXP_HIST16_PARAM0 field descriptions

Field	Description
31–29 RSVD3	Reserved, always set to zero.
28–24 VALUE3	GRAY3 value for 16-level histogram
23–21 RSVD2	Reserved, always set to zero.
20–16 VALUE2	GRAY2 value for 16-level histogram
15–13 RSVD1	Reserved, always set to zero.
12–8 VALUE1	GRAY1 value for 16-level histogram
7–5 RSVD0	Reserved, always set to zero.
4–0 VALUE0	GRAY0 (Black) value for 16-level histogram

43.4.41 16-level Histogram Parameter Register. (ePXP_HIST16_PARAM1)

This register specifies four of the valid values for a 16-level histogram. If all pixels in a bitmap match these two values, ePXP_HIST_CTRL[STATUS[3]] will be set at the end of frame processing. All comparator values should be programmed such that they are consistent with ePXP_HIST_CTRL[PANEL_MODE].

Address: ePXP_HIST16_PARAM1 is 4100_C000h base + 4F0h offset = 4100_C4F0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

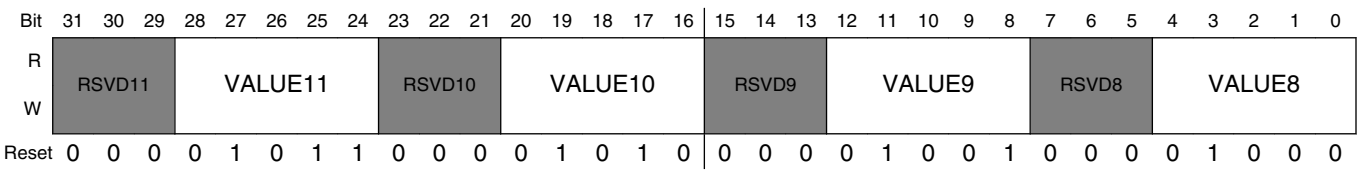
ePXP_HIST16_PARAM1 field descriptions

Field	Description
31–29 RSVD7	Reserved, always set to zero.
28–24 VALUE7	GRAY7 value for 16-level histogram
23–21 RSVD6	Reserved, always set to zero.
20–16 VALUE6	GRAY6 value for 16-level histogram
15–13 RSVD5	Reserved, always set to zero.
12–8 VALUE5	GRAY5 value for 16-level histogram
7–5 RSVD4	Reserved, always set to zero.
4–0 VALUE4	GRAY4 value for 16-level histogram

43.4.42 16-level Histogram Parameter Register. (ePXP_HIST16_PARAM2)

This register specifies four of the valid values for a 16-level histogram. If all pixels in a bitmap match these two values, ePXP_HIST_CTRL[STATUS[3]] will be set at the end of frame processing. All comparator values should be programmed such that they are consistent with ePXP_HIST_CTRL[PANEL_MODE].

Address: ePXP_HIST16_PARAM2 is 4100_C000h base + 500h offset = 4100_C500h



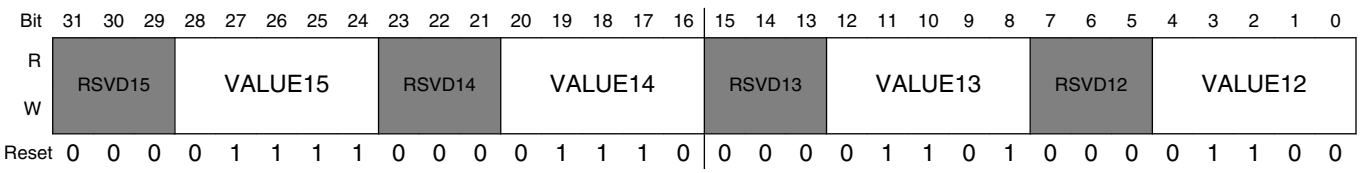
ePXP_HIST16_PARAM2 field descriptions

Field	Description
31–29 RSVD11	Reserved, always set to zero.
28–24 VALUE11	GRAY11 value for 16-level histogram
23–21 RSVD10	Reserved, always set to zero.
20–16 VALUE10	GRAY10 value for 16-level histogram
15–13 RSVD9	Reserved, always set to zero.
12–8 VALUE9	GRAY9 value for 16-level histogram
7–5 RSVD8	Reserved, always set to zero.
4–0 VALUE8	GRAY8 value for 16-level histogram

43.4.43 16-level Histogram Parameter Register. (ePXP_HIST16_PARAM3)

This register specifies four of the valid values for a 16-level histogram. If all pixels in a bitmap match these two values, ePXP_HIST_CTRL[STATUS[3]] will be set at the end of frame processing. All comparator values should be programmed such that they are consistent with ePXP_HIST_CTRL[PANEL_MODE].

Address: ePXP_HIST16_PARAM3 is 4100_C000h base + 510h offset = 4100_C510h



ePXP_HIST16_PARAM3 field descriptions

Field	Description
31–29 RSVD15	Reserved, always set to zero.
28–24 VALUE15	GRAY15 (White) value for 16-level histogram
23–21 RSVD14	Reserved, always set to zero.
20–16 VALUE14	GRAY14 value for 16-level histogram
15–13 RSVD13	Reserved, always set to zero.
12–8 VALUE13	GRAY13 value for 16-level histogram
7–5 RSVD12	Reserved, always set to zero.
4–0 VALUE12	GRAY12 value for 16-level histogram

Chapter 44
Quality of Service Controller (QoSC)

44.1 Introduction

This chapter describes the requirements for the Quality of Service Controller (herein referred to as QoSC). It describes the controller functionality and implementation in detail.

44.2 Overview of Quality of Service Controller APB Slave (QoSC)

The Quality of Service Controller APB Slave provides the following features:

- Provide software programmability of the AWQOS and ARQOS sideband signals of the master ports of the AXI fabric.
- Provide translation and passthrough of AXI QOS values to the AWPRIORITY and ARPRIORITY sideband signals of the DRAM Memory Controller (DRAM MC). Alternatively allow independent programmability of the DRAM MC priority sideband signals.
- Automatic qos/priority boost for EPDC and eLCDIF masters.
- Per port disabling of AXI master port traffic.

44.3 Top-Level Symbol and Functional Overview

Figure 44-1 shows the basic functional connections of the QoSC with other logic internal to the i.MX50.

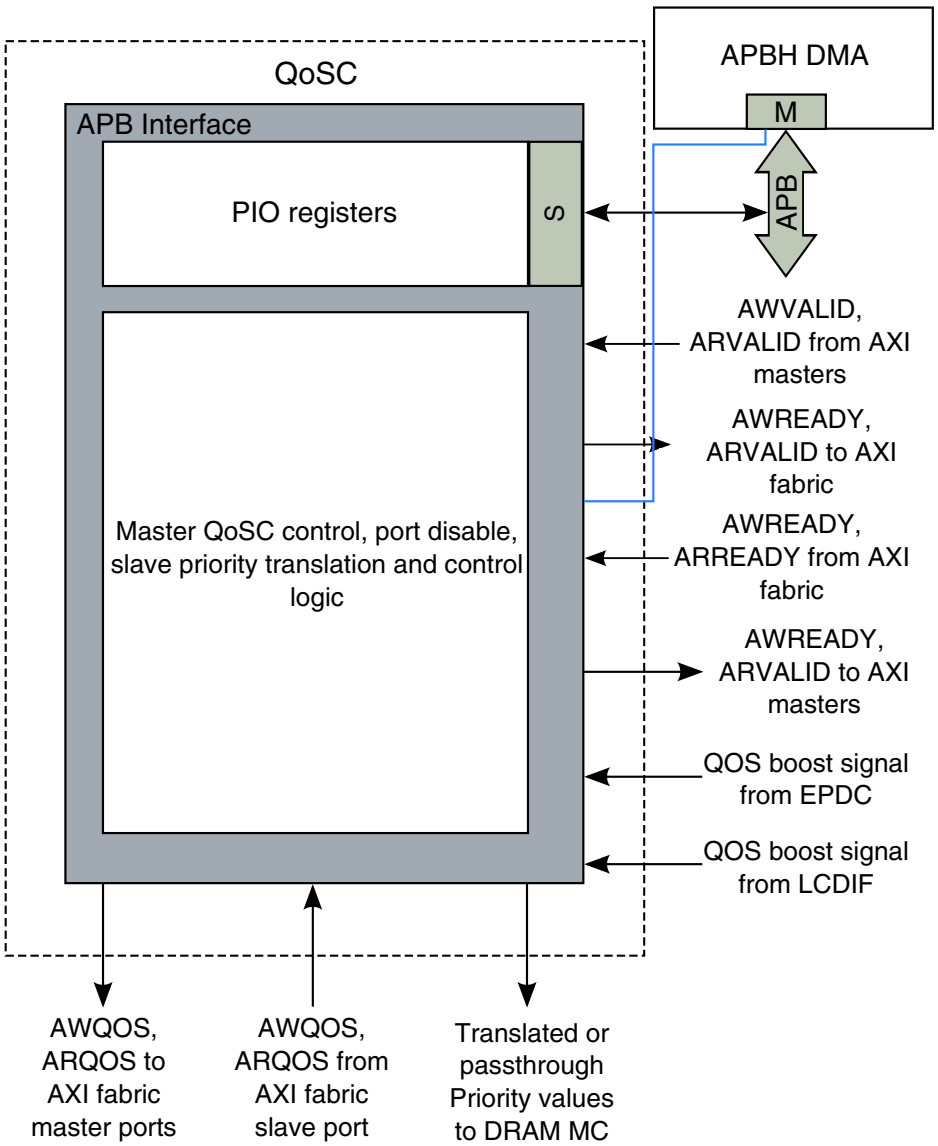


Figure 44-1. QoSC System Level Diagram

Figure 44-2 shows more detail of how the QoSC is connected to the pertinent blocks that surround it. It shows the connections for the AW (Address Write) channel for one AXI master and one AXI slave (the DRAM MC) in the system. This is done for simplicity. The reader should keep in mind that these channel signals are replicated for the AR (Address Read) channel of the master shown. And in turn, these two channels are replicated for each of the 12 i.MX50 masters in the system.

The following sections will reference this figure and explain the interactions between the blocks in the system.

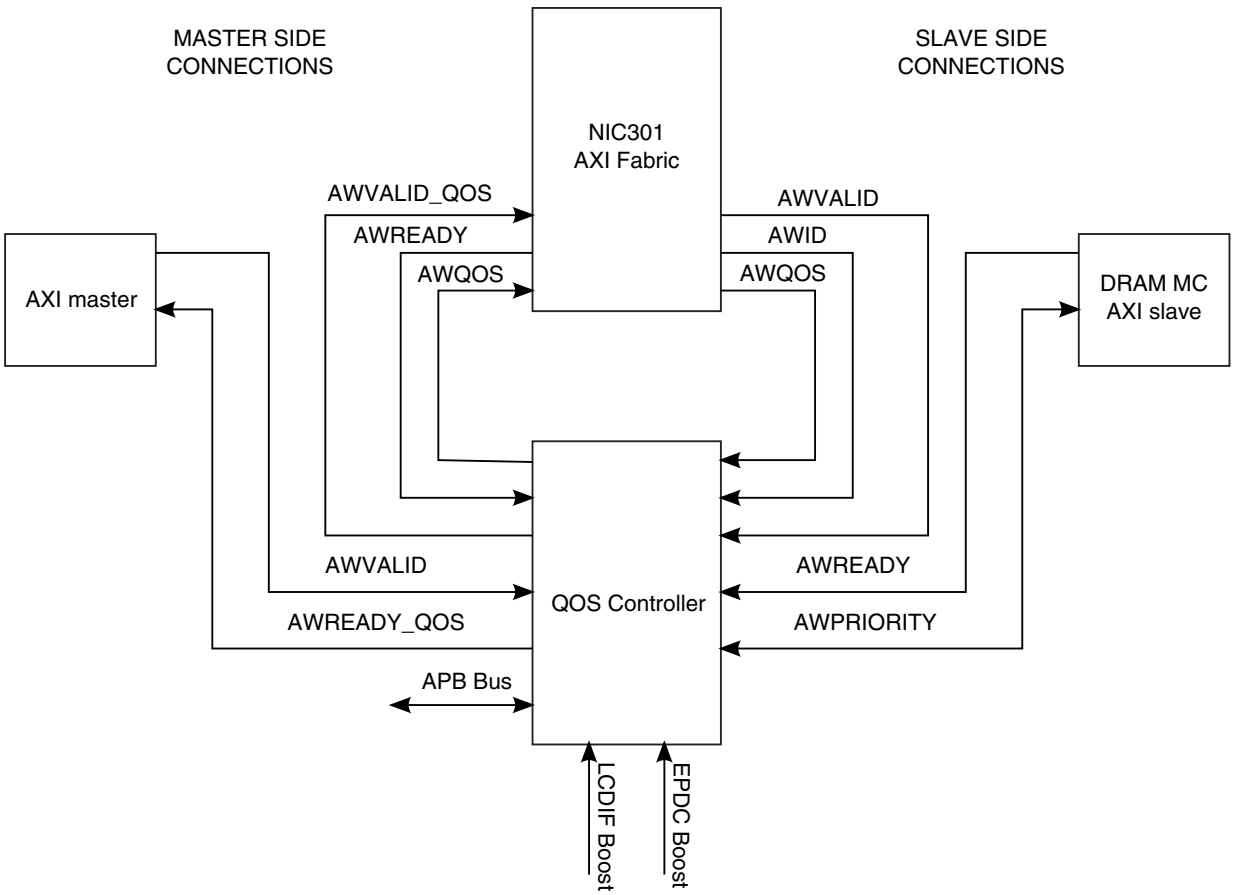

Figure 44-2. QOS Controller

The following table shows the AXI fabric port connection number and the functional block connected to it.

Table 44-1. AXI Fabric port to Functional Block Mapping

Master/Slave Port	Function
M0	ARM
M1_0	SDMA
M1_1	FEC
M1_2	MSHC
M2	DCP
M3	ePXP
M4	USBOH1
M5	GPU2D
M6	BCH
M7	AHB
M8	EPDC

Table continues on the next page...

Table 44-1. AXI Fabric port to Functional Block Mapping (continued)

Master/Slave Port	Function
M9	eLCDIF
S0	TZIC
S1	ROMCP
S2	OCRAM
S3	DRAM MC
S4	EIM
S5	APBH DMA

44.4 APB Slave

The APB interface of the QoSC provides access to programmable registers. Block control and AXI QOS and DRAM MC priority values are set through the interface.

The primary functional register fields are:

- QOS_CTRL[EMI_PRIORITY_MODE] selects whether the AxPRIORITY signals going to the DRAM MC are passed through from the AXI Fabric or the values come from the fields of the QOS_EMI_PRIORITYx registers.
- QOS_CTRL[XLATE_AXI_MODE] selects translate options when in DRAM MC Priority Passthrough mode.
- QOS_CTRL[EPDC_PRIORITY_BOOST] and QOS_CTRL[LCDIF_PRIORITY_BOOST] enable automatic boost of AxQOS and AxPRIORITY values of the EPDC and eLCDIF blocks based on the dynamic bandwidth requirements of those blocks.
- QOS_DISABLE[Mx_DIS] disables a master port from issuing any new transactions to the AXI Fabric.
- QOS_AXI_QOSx and QOS_PRIORITYx registers hold the manually programmed AxQOS and AxPRIORITY values for each master.

NOTE

The naming convention of the AXI Fabric calls the sideband signals that specify transaction priority through the fabric as "qos" signals. The DRAM MC specifies its similar inputs as "priority" signals. For consistency, and to differentiate between the master side and slave side signals, the same convention is followed in this document and in the naming of registers and register fields.

44.5 Master Side Signal Control

As is seen in Figure 44-2, the QoSC supplies the AxQOS sideband signal values. These values come from PIO registers. The register fields are 3 bits and define a range of values from 0-7. Seven being the highest priority and 0 being the lowest priority. For the i.MX50 only 8 relative AxQOS values are implemented even though these sideband signals are 4 bits and can decode priorities of 0-15. It was a design decision that 3 bits would be implemented instead of 4 as this would still provided enough flexibility in the system and would match the bit width of the AxPRIORITY signals on the slave side. Software is responsible for monitoring the system masters performance and setting and adjusting their relative priority based on their individual requirements and system loading. The AR and AW channels are controlled independently on both the master and slave sides of the fabric.

the QoSC is also connected to the AxVALID and AxREADY signals of each AXI master and the AXI fabric instead of the masters and fabric being connected directly. The QoSC needs to monitor these signals so it can safely change the AxQOS signals if software writes a new value to the register. The AXI protocol requires that the AxQOS signals not change during a bus transaction. So to ensure compliance, the QoSC will only allow an AxQOS change under the following conditions:

- On a transaction boundary. The condition of both AxVALID from the master and AxREADY from the fabric are both asserted. This indicates that a transaction has been completed by the fabric and a new transaction can be initiated on the next clock edge.
- When the bus is idle. The AXI channel is considered idle when the AxVALID signal from the master is deasserted. See **[AXI]** for AXI protocol details.

44.6 Slave Side Signal Control

The QoSC monitors all AW and AR channel transactions from the AXI fabric to the DRAM MC slave. For each transaction, the fabric passes the AxQOS bus directly to the QoSC instead of to the DRAM MC. In addition, the QoSC continuously snoops the AxID (master ID), AxVALID and AxREADY signals. (The slave side differs from the master side in that the AxVALID and AxREADY are also directly connected between the fabric and DRAM MC in addition to being connected to the QoSC.) The QoSC uses this information to set the AxPRIORITY signals to the slave for each address channel transaction. It does this according to the HW_QOS_CTRL[EMI_PRIORITY_MODE] register setting. The two modes are are explained below.

44.6.1 Passthrough Priority Mode

In Passthrough Priority mode (QOS_CTRL[EMI_PRIORITY_MODE] = 0) the AxQOS values coming from the AXI fabric are translated and passed on directly to the DRAM MC. They need to be translated first because the AXI fabric and the DRAM MC interpret transaction priorities differently. In the fabric, larger values have higher priority while in the DRAM MC, smaller values signify higher priority. They also differ in the number of bits used. As explained above, although the fabric uses 4 bits for AxQOS values this implementation of QoSC effectively uses 3 bits which matches the DRAM MC. Table 44-2 shows the straightforward translation of the AxQOS bits based on the setting of the QOS_CTRL[XLATE_AXI_MODE] bit.

Table 44-2. QoSC AXI QOS to DRAM MC Priority Translation

AXI Fabrix AxQOS Value	DRAM MC Translated AxPRIORITY value. XLATE_AXI_MODE = 0.	DRAM MC Translated AxPRIORITY value. XLATE_AXI_MODE = 1.
0	7	7
1	6	6
2	5	5
3	4	4
4	3	3
5	2	2
6	1	1
7	1	0

The DRAM MC documentation recommends that the highest priority value, 0, not be used so the system can use it exclusively to dynamically elevate priority to avoid starvation of low priority transactions. The QOS_CTRL[XLATE_AXI_MODE] bit exists, therefore, to provide this flexibility to the programmer.

44.6.2 Manual Priority Mode

In Manual Priority mode (QOS_CTRL[EMI_PRIORITY_MODE] = 1) the AxQOS values coming from the AXI fabric are not used at all. The AxPRIORITY values come from the fields of the QOS_EMI_PRIORITYx registers. The value given for each transaction is the programmed value for that master and transaction type.

44.7 Boost Functionality

QoSC functionality exists to automatically and dynamically boost the qos/priority values for AXI masters 8 (EPDC) and 9 (eLCDIF). This functionality can be enabled by programming the QOS_CTRL[EPDC_PRIORITY_BOOST] and/or QOS_CTRL[LCDIF_PRIORITY_BOOST] register fields.

This function is implemented by monitoring a single level-sensitive boost signal from the EPDC as shown in Figure 2 (identical functionality exists for the LCDIF master). When the boost signal is asserted the QoSC will raise the values of the AxQOS signals on the master side of the fabric. These elevated values will be translated and hence reflected on the slave side in the AxPRIORITY values in Passthrough Priority mode. (Note that AxPRIORITY values will not be boosted in Manual Priority mode as they come from register values directly.) How these values are boosted depends on the programming of the QOS_CTRL[EPDC_PRIORITY_BOOST] field. The qos/priority values can be incremented to the next higher priority or they can be boosted to the highest priority. As soon as the EPDC boost signal is deasserted the values return to their normal programmed values.

44.8 AXI Fabric Master Port Disable

The master ports connected to the AXI fabric can be disabled under software control in the QOS. The QOS_DISABLE register contains disable bits and disable status bits for each master port in the system. When a Mx_DIS disable bit is set, the QOS waits until an AXI transaction boundary or the bus to be idle and then it disables the port. This is accomplished by essentially breaking the AxVALID and AxREADY connections between the master and fabric. Keeping these signals deasserted at the receive end keeps the bus idle by not allowing the initiation of any new transactions. When a port is disabled the corresponding Mx_DIS_STAT bit is set telling software when the bus is actually disabled. It should be noted that this bit does not indicate when any in-flight transactions have finished. System software will have to discover by other means when all pending transaction have finished. The QOS will only hold off the initiation of new ones. Only 11 of the 12 master channels can be disabled. Master 0, which is the ARM processor connection, cannot be disabled through QOS control.

44.9 Programmable Registers

QOS Hardware Register Format Summary

QOS memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4101_2000	QOS Control Register (QOS_CTRL)	32	R/W	C000_0000h	44.9.1/ 2491
4101_2004	QOS Control Register (QOS_CTRL_SET)	32	R/W	C000_0000h	44.9.1/ 2491
4101_2008	QOS Control Register (QOS_CTRL_CLR)	32	R/W	C000_0000h	44.9.1/ 2491

44.9.1 QOS Control Register (QOS_CTRL*n*)

The Control Register specifies the reset state and the interrupt controls for the Performance Monitor.

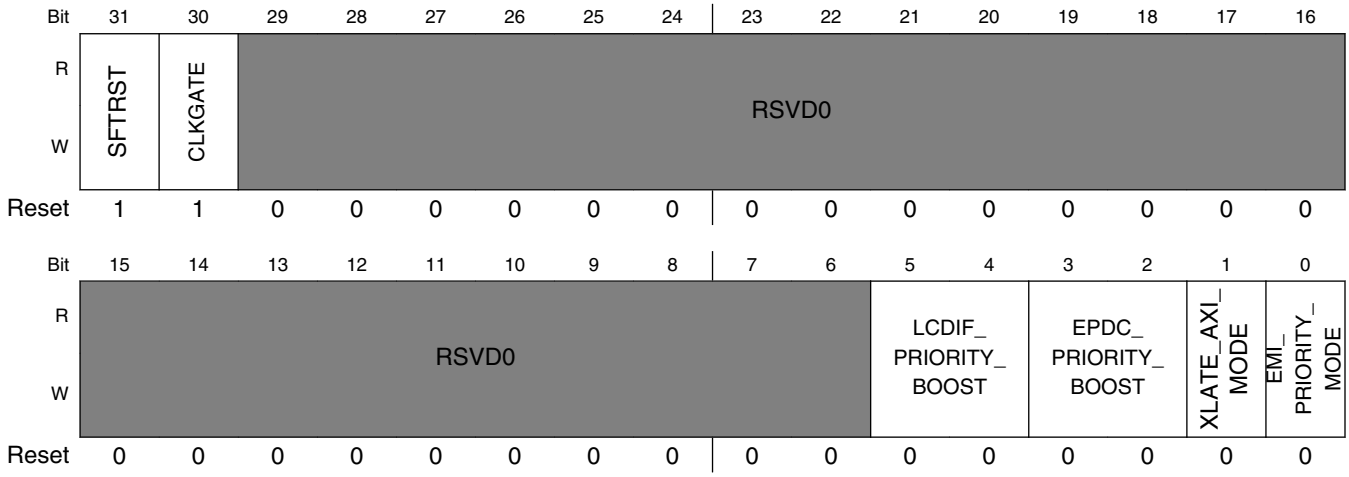
This register controls functions of the QoS module.

Addresses: QOS_CTRL is 4101_2000h base + 0h offset = 4101_2000h

QOS_CTRL_SET is 4101_2000h base + 4h offset = 4101_2004h

QOS_CTRL_CLR is 4101_2000h base + 8h offset = 4101_2008h

QOS_CTRL_TOG is 4101_2000h base + Ch offset = 4101_200Ch



QOS_CTRL*n* field descriptions

Field	Description
31 SFTRST	Set to zero for normal operation. When this bit is set to one (default), then the entire block is held in its reset state. 0x0 **RUN** — Allow QoS to operate normally. 0x1 **RESET** — Hold QoS in reset.
30 CLKGATE	This bit must be set to zero for normal operation. When set to one it gates off the clocks to the block. 0x0 **RUN** — Allow QoS to operate normally. 0x1 **NO_CLKS** — Do not clock QoS gates in order to minimize power consumption.
29–6 RSVD0	Always set this bit field to zero.
5–4 LCDIF_ PRIORITY_ BOOST	Set this field to enable a feedback path that allows the eLCDIF to request higher priority for its accesses when needed. This functionality works in both passthrough and manual priority modes. 0x0 **DISABLE** — Disable priority boost mode for the eLCDIF accesses. 0x1 **INC_PRIORITY** — This setting will raise the access priority level by 1 for the eLCDIF when it requests a priority boost. 0x2 **HIGHEST_PRIORITY** — This setting will raise the access priority to the highest level for the eLCDIF when it requests a priority boost. 0x3 **RESERVED** — Reserved.
3–2 EPDC_ PRIORITY_ BOOST	Set this field to enable a feedback path that allows the EPDC to request higher priority for its accesses when needed. This functionality works in both passthrough and manual priority modes. 0x0 **DISABLE** — Disable priority boost mode for the EPDC accesses. 0x1 **INC_PRIORITY** — This setting will raise the access priority level by 1 for the EPDC when it requests a priority boost. 0x2 **HIGHEST_PRIORITY** — This setting will raise the access priority to the highest level for the EPDC when it requests a priority boost. 0x3 **RESERVED** — Reserved.

Table continues on the next page...

QOS_CTRL*n* field descriptions (continued)

Field	Description
1 XLATE_AXI_ MODE	This bit selects the way in which AXI QoS information is translated into EMI priority values. This bit is only used when the EMI_PRIORITY_MODE bit in this register is set to PASSTHROUGH_PRIORITY. 0x0 **DISALLOW_PRIORITY0** — Never map transaction priorities to level 0 (highest priority). Allow the EMI itself to exclusively use this level to elevate transactions to through aging. 0x1 **ALLOW_PRIORITY0** — Map transactions to all EMI priority levels including level 0 (highest).
0 EMI_PRIORITY_ MODE	Set this bit to one to enable QoS and priority values to be set separately for the AXI fabric and EMI. 0x0 **PASSTHROUGH_PRIORITY** — Translate and pass the AXI fabric QoS settings for each master and command type through to the EMI with each command. 0x1 **MANUAL_PRIORITY** — Pass the register priority settings for each master and command type through to the EMI with each command.

44.9.2 AXI QOS Register (QOS_AXI_QOS0*n*)

This register specifies the AWQOS and ARQOS parameters for masters 0-3.

EXAMPLE

Addresses: QOS_AXI_QOS0 is 4101_2000h base + 10h offset = 4101_2010h

QOS_AXI_QOS0_SET is 4101_2000h base + 14h offset = 4101_2014h

QOS_AXI_QOS0_CLR is 4101_2000h base + 18h offset = 4101_2018h

QOS_AXI_QOS0_TOG is 4101_2000h base + 1Ch offset = 4101_201Ch

QOS_AXI_QOS0*n* field descriptions

Field	Description
31 RSVD7	Always set this bit field to zero.
30–28 M1_2_ARQOS	Specifies the QOS level for the read commands on MasterID 3. 15 = highest QOS. 0 = lowest QOS.
27 RSVD6	Always set this bit field to zero.
26–24 M1_2_AWQOS	Specifies the QOS level for the write commands on MasterID 3. 15 = highest QOS. 0 = lowest QOS.
23 RSVD5	Always set this bit field to zero.
22–20 M1_1_ARQOS	Specifies the QOS level for the read commands on MasterID 2. 15 = highest QOS. 0 = lowest QOS.
19 RSVD4	Always set this bit field to zero.
18–16 M1_1_AWQOS	Specifies the QOS level for the write commands on MasterID 2. 15 = highest QOS. 0 = lowest QOS.
15 RSVD3	Always set this bit field to zero.
14–12 M1_0_ARQOS	Specifies the QOS level for the read commands on MasterID 1. 15 = highest QOS. 0 = lowest QOS.
11 RSVD2	Always set this bit field to zero.
10–8 M1_0_AWQOS	Specifies the QOS level for the write commands on MasterID 1. 15 = highest QOS. 0 = lowest QOS.
7 RSVD1	Always set this bit field to zero.
6–4 M0_ARQOS	Specifies the QOS level for the read commands on MasterID 0. 15 = highest QOS. 0 = lowest QOS.
3 RSVD0	Always set this bit field to zero.
2–0 M0_AWQOS	Specifies the QOS level for the write commands on MasterID 0. 15 = highest QOS. 0 = lowest QOS.

44.9.3 AXI QOS Register (QOS_AXI_QOS1*n*)

This register specifies the AWQOS and ARQOS parameters for masters 4-7.

Addresses: QOS_AXI_QOS1 is 4101_2000h base + 20h offset = 4101_2020h

QOS_AXI_QOS1_SET is 4101_2000h base + 24h offset = 4101_2024h

QOS_AXI_QOS1_CLR is 4101_2000h base + 28h offset = 4101_2028h

QOS_AXI_QOS1_TOG is 4101_2000h base + 2Ch offset = 4101_202Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

QOS_AXI_QOS1*n* field descriptions

Field	Description
31 RSVD7	Always set this bit field to zero.
30–28 M5_ARQOS	Specifies the QOS level for the read commands on MasterID 7. 15 = highest QOS. 0 = lowest QOS.
27 RSVD6	Always set this bit field to zero.
26–24 M5_AWQOS	Specifies the QOS level for the write commands on MasterID 7. 15 = highest QOS. 0 = lowest QOS.
23 RSVD5	Always set this bit field to zero.
22–20 M4_ARQOS	Specifies the QOS level for the read commands on MasterID 6. 15 = highest QOS. 0 = lowest QOS.
19 RSVD4	Always set this bit field to zero.
18–16 M4_AWQOS	Specifies the QOS level for the write commands on MasterID 6. 15 = highest QOS. 0 = lowest QOS.

Table continues on the next page...

QOS_AXI_QOS1*n* field descriptions (continued)

Field	Description
15 RSVD3	Always set this bit field to zero.
14–12 M3_ARQOS	Specifies the QOS level for the read commands on MasterID 5. 15 = highest QOS. 0 = lowest QOS.
11 RSVD2	Always set this bit field to zero.
10–8 M3_AWQOS	Specifies the QOS level for the write commands on MasterID 5. 15 = highest QOS. 0 = lowest QOS.
7 RSVD1	Always set this bit field to zero.
6–4 M2_ARQOS	Specifies the QOS level for the read commands on MasterID 4. 15 = highest QOS. 0 = lowest QOS.
3 RSVD0	Always set this bit field to zero.
2–0 M2_AWQOS	Specifies the QOS level for the write commands on MasterID 4. 15 = highest QOS. 0 = lowest QOS.

44.9.4 AXI QOS Register (QOS_AXI_QOS2*n*)

This register specifies the AWQOS and ARQOS parameters for masters 8-11.

Addresses: QOS_AXI_QOS2 is 4101_2000h base + 30h offset = 4101_2030h

QOS_AXI_QOS2_SET is 4101_2000h base + 34h offset = 4101_2034h

QOS_AXI_QOS2_CLR is 4101_2000h base + 38h offset = 4101_2038h

QOS_AXI_QOS2_TOG is 4101_2000h base + 3Ch offset = 4101_203Ch

QOS_AXI_QOS2*n* field descriptions

Field	Description
31 RSVD7	Always set this bit field to zero.
30–28 M9_ARQOS	Specifies the QOS level for the read commands on MasterID 11. 15 = highest QOS. 0 = lowest QOS.
27 RSVD6	Always set this bit field to zero.
26–24 M9_AWQOS	Specifies the QOS level for the write commands on MasterID 10. 15 = highest QOS. 0 = lowest QOS.
23 RSVD5	Always set this bit field to zero.
22–20 M8_ARQOS	Specifies the QOS level for the read commands on MasterID 10. 15 = highest QOS. 0 = lowest QOS.
19 RSVD4	Always set this bit field to zero.
18–16 M8_AWQOS	Specifies the QOS level for the write commands on MasterID 10. 15 = highest QOS. 0 = lowest QOS.
15 RSVD3	Always set this bit field to zero.
14–12 M7_ARQOS	Specifies the QOS level for the read commands on MasterID 9. 15 = highest QOS. 0 = lowest QOS.
11 RSVD2	Always set this bit field to zero.
10–8 M7_AWQOS	Specifies the QOS level for the write commands on MasterID 9. 15 = highest QOS. 0 = lowest QOS.
7 RSVD1	Always set this bit field to zero.
6–4 M6_ARQOS	Specifies the QOS level for the read commands on MasterID 8. 15 = highest QOS. 0 = lowest QOS.
3 RSVD0	Always set this bit field to zero.
2–0 M6_AWQOS	Specifies the QOS level for the write commands on MasterID 8. 15 = highest QOS. 0 = lowest QOS.

44.9.5 EMI priority Registers (QOS_EMI_PRIORITY0*n*)

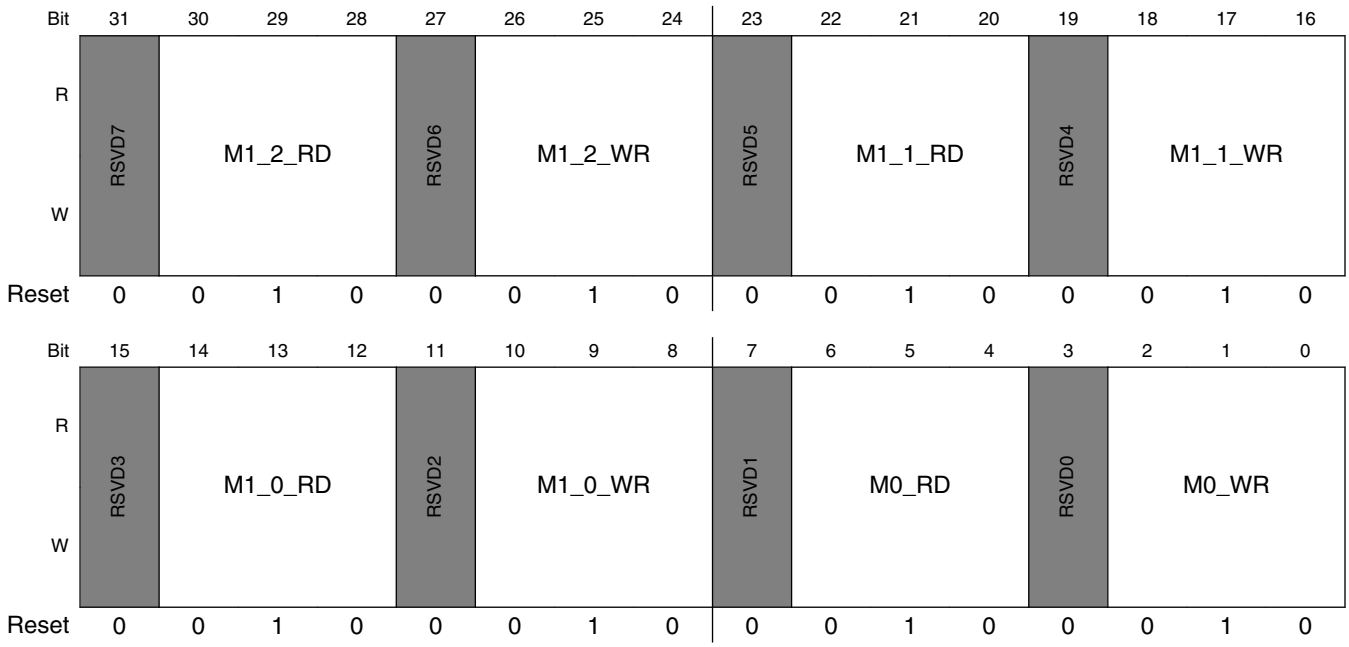
For EMI manual priority mode, this register specifies the AWPRIORITY and ARPRIORITY parameters for masters 0-3.

Addresses: QOS_EMI_PRIORITY0 is 4101_2000h base + 40h offset = 4101_2040h

QOS_EMI_PRIORITY0_SET is 4101_2000h base + 44h offset = 4101_2044h

QOS_EMI_PRIORITY0_CLR is 4101_2000h base + 48h offset = 4101_2048h

QOS_EMI_PRIORITY0_TOG is 4101_2000h base + 4Ch offset = 4101_204Ch



QOS_EMI_PRIORITY0*n* field descriptions

Field	Description
31 RSVD7	Always set this bit field to zero.
30–28 M1_2_RD	Specifies the priority level for the read commands on MasterID 3. 0 = highest priority. 7 = lowest priority.
27 RSVD6	Always set this bit field to zero.
26–24 M1_2_WR	Specifies the priority level for the write commands on MasterID 3. 0 = highest priority. 7 = lowest priority.
23 RSVD5	Always set this bit field to zero.
22–20 M1_1_RD	Specifies the priority level for the read commands on MasterID 2. 0 = highest priority. 7 = lowest priority.
19 RSVD4	Always set this bit field to zero.

Table continues on the next page...

QOS_EMI_PRIORITY0*n* field descriptions (continued)

Field	Description
18–16 M1_1_WR	Specifies the priority level for the write commands on MasterID 2. 0 = highest priority. 7 = lowest priority.
15 RSVD3	Always set this bit field to zero.
14–12 M1_0_RD	Specifies the priority level for the read commands on MasterID 1. 0 = highest priority. 7 = lowest priority.
11 RSVD2	Always set this bit field to zero.
10–8 M1_0_WR	Specifies the priority level for the write commands on MasterID 1. 0 = highest priority. 7 = lowest priority.
7 RSVD1	Always set this bit field to zero.
6–4 M0_RD	Specifies the priority level for the read commands on MasterID 0. 0 = highest priority. 7 = lowest priority.
3 RSVD0	Always set this bit field to zero.
2–0 M0_WR	Specifies the priority level for the write commands on MasterID 0. 0 = highest priority. 7 = lowest priority.

44.9.6 EMI priority Registers (QOS_EMI_PRIORITY1*n*)

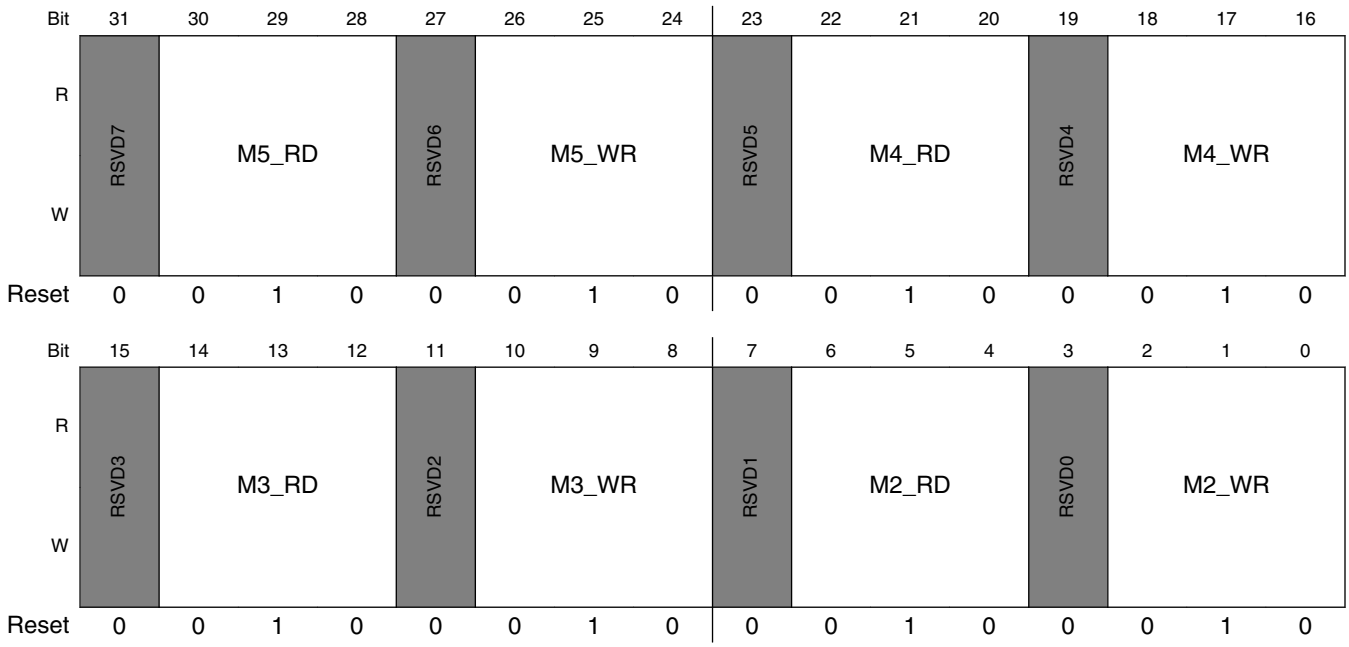
For EMI manual priority mode, this register specifies the AWPRIORITY and ARPRIORITY parameters for masters 4-7.

Addresses: QOS_EMI_PRIORITY1 is 4101_2000h base + 50h offset = 4101_2050h

QOS_EMI_PRIORITY1_SET is 4101_2000h base + 54h offset = 4101_2054h

QOS_EMI_PRIORITY1_CLR is 4101_2000h base + 58h offset = 4101_2058h

QOS_EMI_PRIORITY1_TOG is 4101_2000h base + 5Ch offset = 4101_205Ch



QOS_EMI_PRIORITY1*n* field descriptions

Field	Description
31 RSVD7	Always set this bit field to zero.
30–28 M5_RD	Specifies the priority level for the read commands on MasterID 7. 0 = highest priority. 7 = lowest priority.
27 RSVD6	Always set this bit field to zero.
26–24 M5_WR	Specifies the priority level for the write commands on MasterID 7. 0 = highest priority. 7 = lowest priority.
23 RSVD5	Always set this bit field to zero.
22–20 M4_RD	Specifies the priority level for the read commands on MasterID 6. 0 = highest priority. 7 = lowest priority.
19 RSVD4	Always set this bit field to zero.

Table continues on the next page...

QOS_EMI_PRIORITY1*n* field descriptions (continued)

Field	Description
18–16 M4_WR	Specifies the priority level for the write commands on MasterID 6. 0 = highest priority. 7 = lowest priority.
15 RSVD3	Always set this bit field to zero.
14–12 M3_RD	Specifies the priority level for the read commands on MasterID 5. 0 = highest priority. 7 = lowest priority.
11 RSVD2	Always set this bit field to zero.
10–8 M3_WR	Specifies the priority level for the write commands on MasterID 5. 0 = highest priority. 7 = lowest priority.
7 RSVD1	Always set this bit field to zero.
6–4 M2_RD	Specifies the priority level for the read commands on MasterID 4. 0 = highest priority. 7 = lowest priority.
3 RSVD0	Always set this bit field to zero.
2–0 M2_WR	Specifies the priority level for the write commands on MasterID 4. 0 = highest priority. 7 = lowest priority.

44.9.7 EMI priority Registers (QOS_EMI_PRIORITY2*n*)

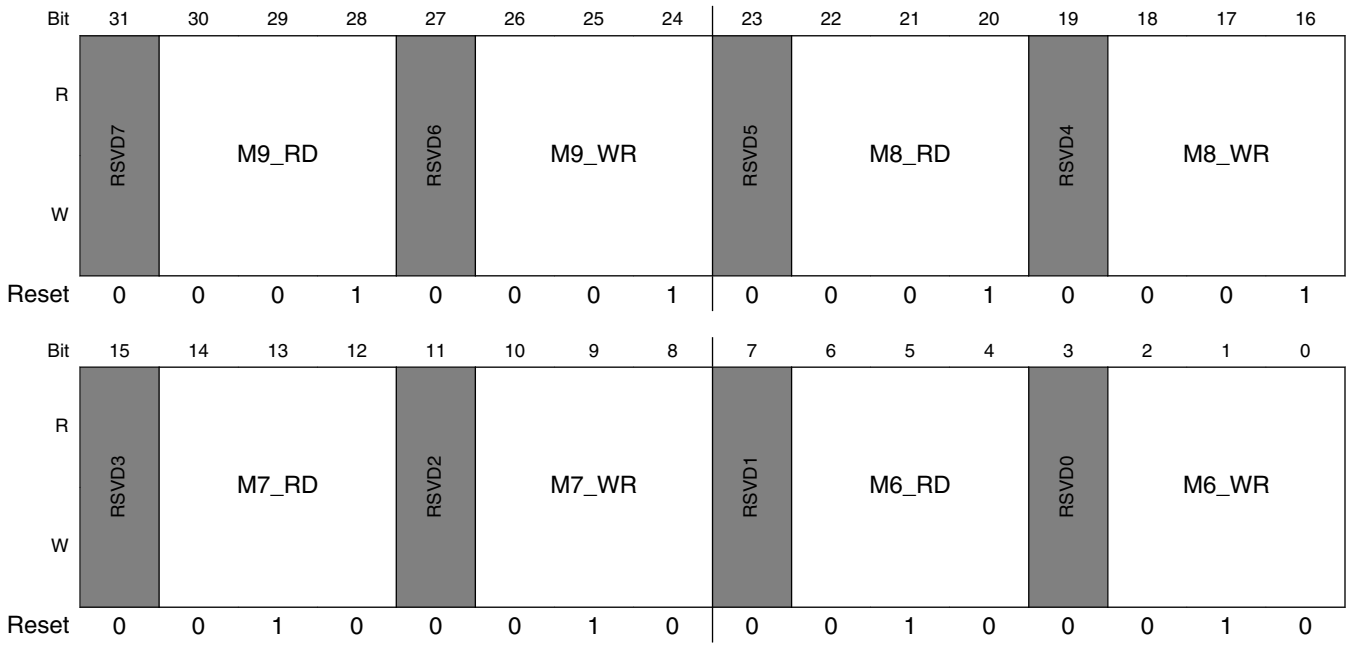
For EMI manual priority mode, this register specifies the AWPRIORITY and ARPRIORITY parameters for masters 8-11.

Addresses: QOS_EMI_PRIORITY2 is 4101_2000h base + 60h offset = 4101_2060h

QOS_EMI_PRIORITY2_SET is 4101_2000h base + 64h offset = 4101_2064h

QOS_EMI_PRIORITY2_CLR is 4101_2000h base + 68h offset = 4101_2068h

QOS_EMI_PRIORITY2_TOG is 4101_2000h base + 6Ch offset = 4101_206Ch



QOS_EMI_PRIORITY2*n* field descriptions

Field	Description
31 RSVD7	Always set this bit field to zero.
30–28 M9_RD	Specifies the priority level for the read commands on MasterID 11. 0 = highest priority. 7 = lowest priority.
27 RSVD6	Always set this bit field to zero.
26–24 M9_WR	Specifies the priority level for the write commands on MasterID 10. 0 = highest priority. 7 = lowest priority.
23 RSVD5	Always set this bit field to zero.
22–20 M8_RD	Specifies the priority level for the read commands on MasterID 10. 0 = highest priority. 7 = lowest priority.
19 RSVD4	Always set this bit field to zero.

Table continues on the next page...

QOS_EMI_PRIORITY2*n* field descriptions (continued)

Field	Description
18–16 M8_WR	Specifies the priority level for the write commands on MasterID 10. 0 = highest priority. 7 = lowest priority.
15 RSVD3	Always set this bit field to zero.
14–12 M7_RD	Specifies the priority level for the read commands on MasterID 9. 0 = highest priority. 7 = lowest priority.
11 RSVD2	Always set this bit field to zero.
10–8 M7_WR	Specifies the priority level for the write commands on MasterID 9. 0 = highest priority. 7 = lowest priority.
7 RSVD1	Always set this bit field to zero.
6–4 M6_RD	Specifies the priority level for the read commands on MasterID 8. 0 = highest priority. 7 = lowest priority.
3 RSVD0	Always set this bit field to zero.
2–0 M6_WR	Specifies the priority level for the write commands on MasterID 8. 0 = highest priority. 7 = lowest priority.

44.9.8 AXI Master Disble Register (QOS_DISABLE*n*)

This register allows disabling of the individual master ports of the AXI fabric. This can be useful during system clock frequency programming.

Addresses: QOS_DISABLE is 4101_2000h base + 70h offset = 4101_2070h

QOS_DISABLE_SET is 4101_2000h base + 74h offset = 4101_2074h

QOS_DISABLE_CLR is 4101_2000h base + 78h offset = 4101_2078h

QOS_DISABLE_TOG is 4101_2000h base + 7Ch offset = 4101_207Ch

QOS_DISABLE*n* field descriptions

Field	Description
31–28 RSVD2	Always set this bit field to zero.
27 M9_DIS_STAT	This bit indicates the enable/disable status for master port0 on the AXI fabric. 0 = enabled; 1 = disabled.
26 M8_DIS_STAT	This bit indicates the enable/disable status for master port0 on the AXI fabric. 0 = enabled; 1 = disabled.
25 M7_DIS_STAT	This bit indicates the enable/disable status for master port0 on the AXI fabric. 0 = enabled; 1 = disabled.
24 M6_DIS_STAT	This bit indicates the enable/disable status for master port0 on the AXI fabric. 0 = enabled; 1 = disabled.
23 M5_DIS_STAT	This bit indicates the enable/disable status for master port0 on the AXI fabric. 0 = enabled; 1 = disabled.
22 M4_DIS_STAT	This bit indicates the enable/disable status for master port0 on the AXI fabric. 0 = enabled; 1 = disabled.

Table continues on the next page...

QOS_DISABLE*n* field descriptions (continued)

Field	Description
21 M3_DIS_STAT	This bit indicates the enable/disable status for master port0 on the AXI fabric. 0 = enabled; 1 = disabled.
20 M2_DIS_STAT	This bit indicates the enable/disable status for master port0 on the AXI fabric. 0 = enabled; 1 = disabled.
19 M1_2_DIS_ STAT	This bit indicates the enable/disable status for master port1_2 on the AXI fabric. 0 = enabled; 1 = disabled.
18 M1_1_DIS_ STAT	This bit indicates the enable/disable status for master port1_1 on the AXI fabric. 0 = enabled; 1 = disabled.
17 M1_0_DIS_ STAT	This bit indicates the enable/disable status for master port1_0 on the AXI fabric. 0 = enabled; 1 = disabled.
16–12 RSVD1	Always set this bit field to zero.
11 M9_DIS	Setting this bit disables the interface between master9 and the AXI fabric.
10 M8_DIS	Setting this bit disables the interface between master8 and the AXI fabric.
9 M7_DIS	Setting this bit disables the interface between master7 and the AXI fabric.
8 M6_DIS	Setting this bit disables the interface between master6 and the AXI fabric.
7 M5_DIS	Setting this bit disables the interface between master5 and the AXI fabric.
6 M4_DIS	Setting this bit disables the interface between master4 and the AXI fabric.
5 M3_DIS	Setting this bit disables the interface between master3 and the AXI fabric.
4 M2_DIS	Setting this bit disables the interface between master2 and the AXI fabric.
3 M1_2_DIS	Setting this bit disables the interface between master1_2 and the AXI fabric.
2 M1_1_DIS	Setting this bit disables the interface between master1_1 and the AXI fabric.
1 M1_0_DIS	Setting this bit disables the interface between master1_0 and the AXI fabric.
0 RSVD0	Always set this bit field to zero.

44.9.9 QOS Version Register (QOS_VERSION)

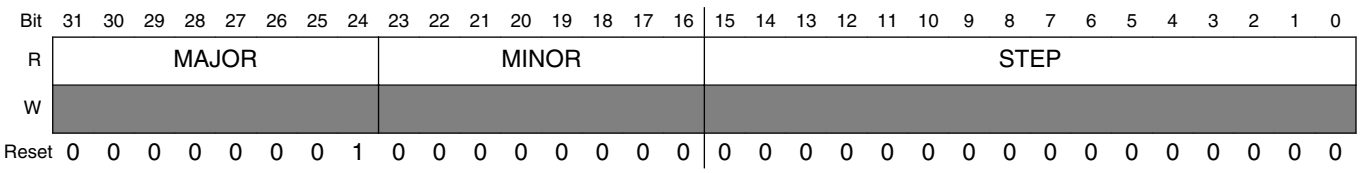
This register always returns a known read value for debug purposes it indicates the version of the block.

This register indicates the RTL version in use.

EXAMPLE

```
if (QOS_VERSION.B.MAJOR != 1) Error();
```

Address: QOS_VERSION is 4101_2000h base + 80h offset = 4101_2080h



QOS_VERSION field descriptions

Field	Description
31–24 MAJOR	Fixed read-only value reflecting the MAJOR field of the RTL version.
23–16 MINOR	Fixed read-only value reflecting the MINOR field of the RTL version.
15–0 STEP	Fixed read-only value reflecting the stepping of the RTL version.

Chapter 45
Read Only Memory Controller Patch (ROMCP)

45.1 Introduction

45.1.1 Overview

The Read Only Memory Controller module with ROM Patch (ROMCP) acts as an interface between the ARM advanced high-performance bus (AHB - Lite) and the Read Only Memory. The ROMCP module consists of a ROM Controller and a ROM Patch. The ROM Patch module is used to either patch code routines or fix data tables in the ROM area. Figure 45-1 depicts the main functional blocks of the ROMCP.

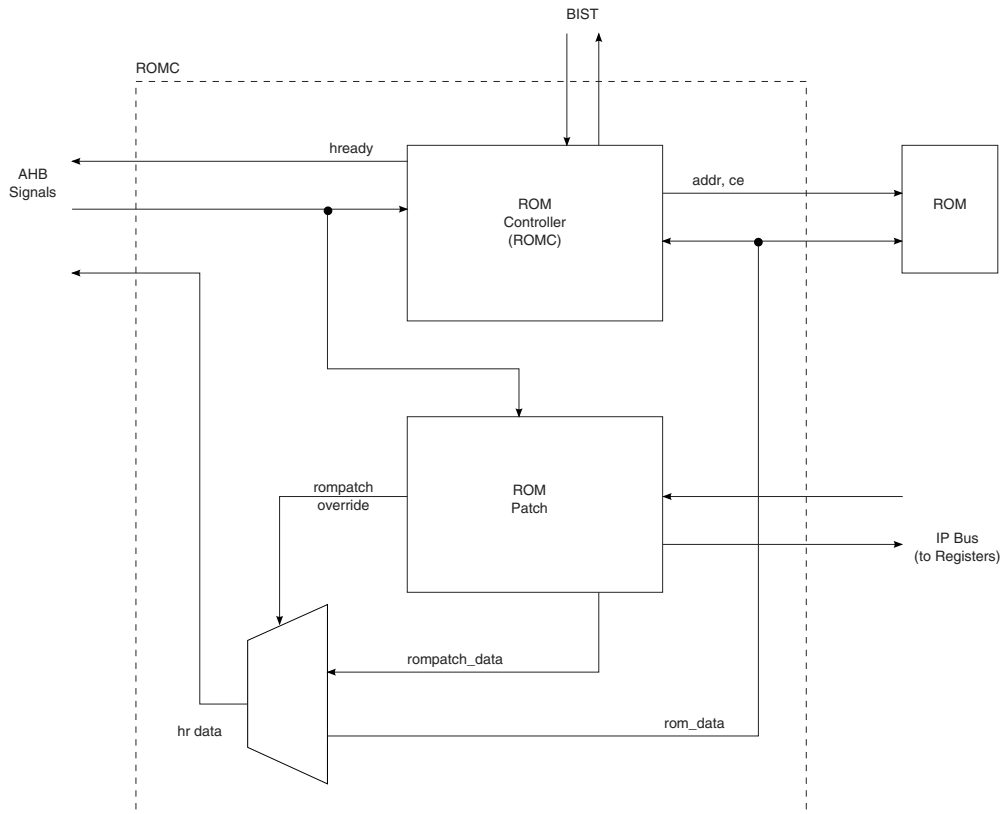


Figure 45-1. ROMCP Block Diagram

45.1.2 Features

The features are as follows:

- Supports ROM size ranges from 16 Kbyte up to 4 Mbyte with increments of 1 Kbyte
- Supports opcode patching for a maximum of 16 different addresses in 4 Mbytes of ROM space
- Supports one-word data fixes for a max of 8 memory locations in 4 Mbytes of ROM space
- Supports patching of the Reset Vector (at 0x0000_0000) to allow external booting

45.1.3 Modes of Operation

There are two modes of operation: normal mode and BIST mode. In normal mode the ROMCP ensures correct reads from the ROM, assuming the memory complies with the characteristics and requirements for which the ROMCP was designed. The ROMCP also performs hole decoding, aborting accesses into memory holes and converting the non-continuous ROM memory map into a continuous one for physical memory accesses.

45.1.3.1 Normal Operating Modes

This subsection should describe all the functional operation modes of the IP block.

45.1.3.2 Low Power Modes

There are two clock enables that are used to switch off parts of the ROMCP logic when inactive. The first clock enable is used to disable the ROM Controller when the master connected to the AHB interface is not initiating a read to the ROM. The second clock enable is used to disable the registers used to program the ROM patch feature when the registers are not being accessed.

45.2 Functional Description

This section is divided up into the ROM Controller Functional Description and the ROMPATCH functional description.

45.2.1 ROM Controller (ROMC) Functional Description

45.2.1.1 Functionality Overview

The ROMC serves two main functions. First, as an interface between the AHB-Lite bus on an ARM platform and the ROM. Second, it drives and receives several signals for the BIST engine. In normal mode of operation, the ROMC monitors the AHB-Lite for memory access requests and performs the memory operation to the ROM.

The ROMC includes the option to wait state all accesses from either the ARM or non-ARM masters to ROM in the event that timing requirements will not allow single hclk clock cycle reads. If a wait state is required, the static inputs rom_wait_arm11 or

rom_wait_alt_mstr can be set to 1 and accesses will take two hclk clock cycles. If wait states are not required, rom_wait_arm11 or rom_wait_alt_mstr can be set to 0 and accesses will take one hclk clock cycle to complete.

45.2.1.2 ROMC Architecture Diagram

A simple block diagram illustrating the internal architecture of the ROMC is shown in Figure 45-2. The basic logic blocks of the ROMC include an AHB-Lite interface, a ROM memory interface, a BIST block and a block for muxing between BIST mode and normal mode.

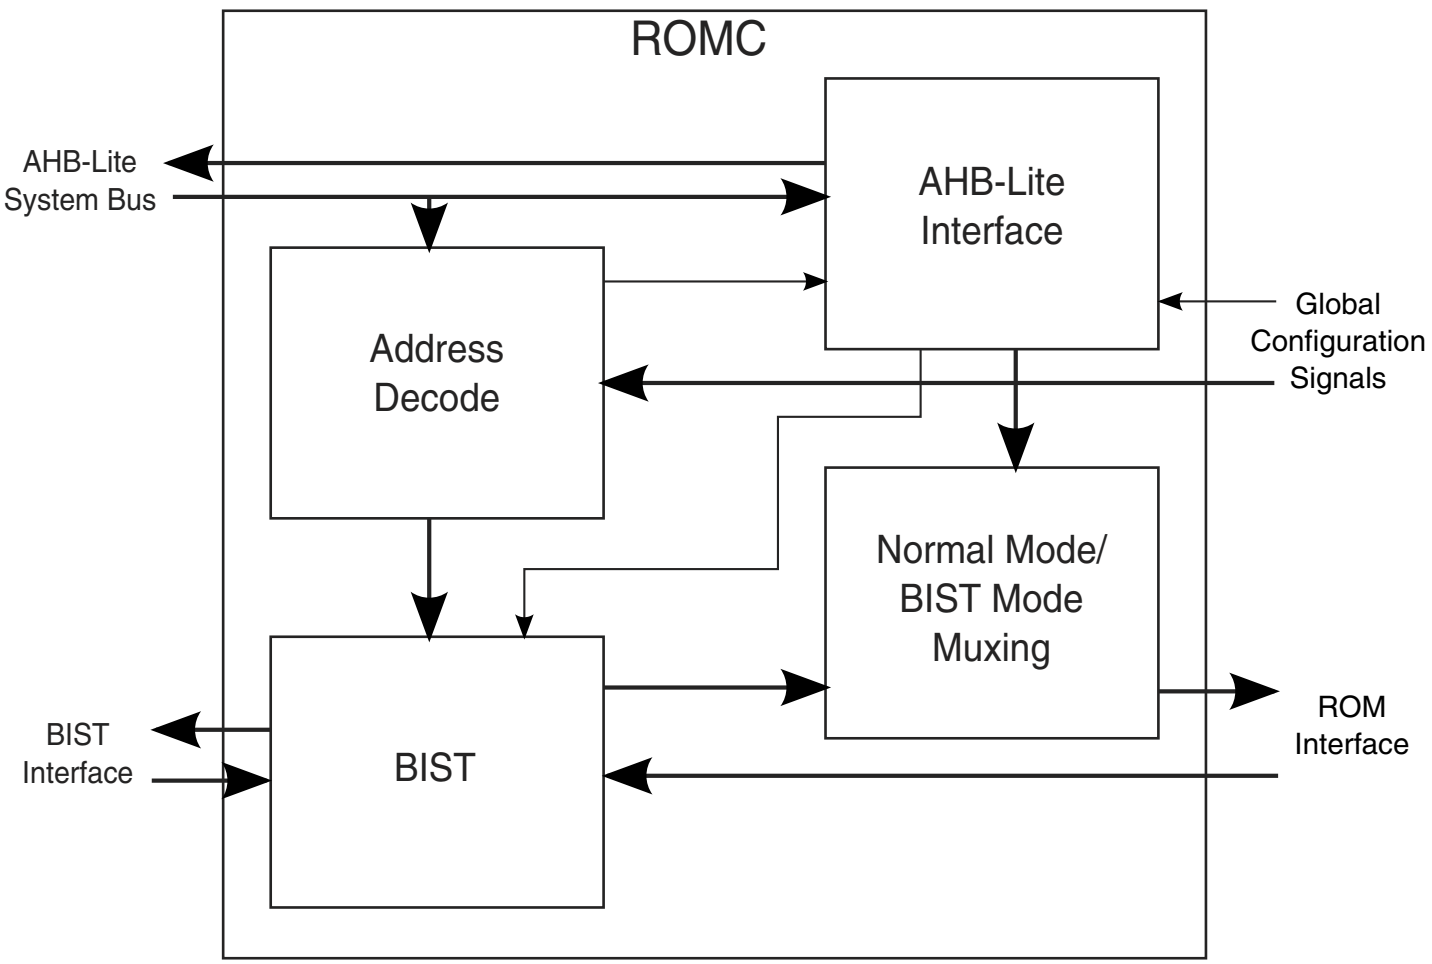

Figure 45-2. ROMC Internal Architecture

45.2.1.3 AHB-Lite Interface

The ROMC output signals on the AHB-Lite Interface indicate the timing of the response to any access (wait-stated or not) and any error conditions (writing to ROM or access to a valid ROM hole).

45.2.2 ROMPATCH Functional Description

45.2.2.1 ROMPATCH Disabling

All the bits in the ROMPATCHENL register are cleared on Reset, disabling all the address comparators. Once the comparators have been enabled, the ROMPATCH functions of data fixing and opcode patching can be quickly disabled by setting the DIS bit in the ROMPATCHCNTL register. This bit is used to enable secure operations in which patching functions need to be disabled. This bit is cleared on Reset.

45.2.2.2 ROMPATCH Event Priority

The ROMPATCH has a total of 16 address comparators. The first 8 (0 through 7) comparators can be programmed for the data fixing function (via the 8 data fix enable bits in the ROMPATCHCNTL register) while the rest are for opcode patching by default. This allows for potential multiple matching events involving both data fixing and opcode patch types. In these cases the ROMPATCH module assigns the highest priority to a data fixing event. For example, if the ROMPATCH is set up to data fix a certain address with comparator 4 and also opcode patch the same address with comparator 7, it will let comparator 4 have higher priority in indicating a match, and data from ROMPATCHD4 will be returned as the orverride value.

If multiple address matches of the same type level occur concurrently, then the ROMPATCH will choose the source with the highest source number. For example, the ROMPATCH is setup to data fix the same location with address comparators 4 and 7, then address comparator 7 will have higher priority in indicating a match, and the value from ROMPATCHD7 will be returned as the orverride value. The same priority applies for an opcode patch event, except the override data is in the form of an SWI instruction with the comment field set to the source number with the highest priority.

45.2.2.3 Data Fixing

The data fixing feature allows ROM data to be updated by direct replacement when it's being read. This data usually is from data tables but can include ARM instructions. To enable data fixing on a certain address, this address value is written into one of the first eight (0 through 7) of ROMPATCHAxx registers and the same numbered bit set in the ROMPATCHENL and ROMPATCHCNTL registers. The data to be used for replacement is placed in the corresponding ROMPATCHDxx. The ROMPATCH module looks for a read access to ROM (either code fetch or data load) by snooping the AHB interface for read transactions. The address is compared with the values stored in the ROMPATCHAxx[22:2] registers. If a match occurs from one of the comparators, the ROMPATCH places the value in the corresponding ROMPATCHDxx register on the read data bus by overriding the read data coming from the actual ROM (see the mux in Figure 45-1). In data fixing, the entire word is replaced so if a byte or half-word access occurs on a "data fix" location, the entire data word is replaced. The word being replaced is word aligned (The two LSBs of the matching ROMPATCHAxx are ignored in the data fix operation).

45.2.2.4 Opcode Patching

The opcode patch feature provides a mechanism to fetch updated versions of code routines that were originally programmed in ROM. This patching mechanism makes use of the SWI (software interrupt instruction) and a table of function pointers residing in writable memory. The opcode being patched is replaced with a SWI instruction by the ROMPATCH. Subsequent processing of the SWI reads from a function pointers table to obtain the address of the replacement code. Execution resumes with this code patch.

To enable opcode patching of a certain address, this address value is written into one of the ROMPATCHAxx registers and the corresponding bit set in the ROMPATCHENL to enable the associated comparator. The register's LSB (ROMPATCHxx[0]) should be set if THUMB mode patching is in effect for this address. The ROMPATCH module identifies a ROM read access by snooping the AHB interface. The address is compared with the values stored in the ROMPATCHAxx[22:2] registers. If a match occurs from one of the comparators, the ROMPATCH generates the opcode of a software interrupt (SWI) instruction with the comment field containing the number of the matching address comparator. This opcode and comment are placed on the read data bus

The type of SWI generated, either ARM or THUMB, is determined by the LSB of the ROMPATCHAxx register associated with the opcode patch. This bit is cleared for ARM mode (32 bits). The ROMPATCH generates a 32-bit SWI (opcode field is 0xEF, occupying bits [31:24] of the word), with the least significant 5 bits of the 24-bit comment field (bits [23:0]) containing the number of the matching address comparator.

The rest of the comment field is filled with zeros. This means that the ROMPATCH will use 16 of the 16777216 possible software interrupts. The ROMPATCH overrides the read data from the ROM.

If the LSB of the matching ROMPATCHAxx register is set, the opcode patch is in THUMB mode (16 bits or half word). The ROMPATCH generates a 16-bit SWI instruction (opcode field is 0xDF, occupying bits [15:8] of the half word) with the least significant 5 bits of the 8-bit comment field containing the source number of the address comparator. The rest of the comments field is filled with zeros. This means that the ROMPATCH will use 16 of the 256 possible software interrupts. The ROMPATCH puts this 16 bit SWI instruction value on the proper half of the rompatch_romc_hrdata bus. The other half is zeroed out. Which half of the bus contains the SWI opcode and comment depends on the mode (big endian or little endian) and the bit 1 of the matching ROMPATCHAxx register. In little endian mode, the lower half is bits {15:0] and the upper half is bits {31:16]. The order is reversed in Big Endian mode.

In little endian mode , if bit 1 of the matching ROMPATCHAxx is cleared (lower half word selected) then the SWI instruction is put on the lower 16 bits of the read data bus and the upper 16 bits are zeroed out. Only the lower 16 bits of the read data bus is overwritten by the rompatch data. If ROMPATCHAxx[1] is set (upper half word selected), the SWI instruction is put on the upper 16 bits of the read data bus and the lower 16 bits are zeroed out. Only the upper 16 bits of the read data bus is overwritten.

In big endian mode , if bit 1 of the matching ROMPATCHAxx is cleared (lower half word selected) then the SWI instruction is put on the upper 16 bits of the read data bus while the lower 16 bits are zeroed out. Only the upper 16 bits of the read data bus is overwritten. If ROMPATCHAxx[1] is set (upper word selected), the SWI instruction is put on the lower 16 bits and the upper 16 bits are zeroed out. Only the lower 16 bits of the read data bus is overwritten.

The eventual execution of the SWI causes the ARM to save the CPSR in SPSR_SVC, the address of the next instruction after the SWI in R14_SVC, enter Supervisor mode, and fetch the SWI vector at 0x8, which then takes it to a handler for further processing as described in the next section.

45.2.2.4.1 Typical Software Response to Opcode Patch

When the SWI handler executes it needs to determine whether the SWI was generated by the ROMPATCH. This is done by loading the SWI instruction and extracting its comment field. The state of the ARM Cortex-A8(ARM or THUMB) when the SWI was executed dictates whether to load the instruction word (ARM) or half word (THUMB). This state information can be determined by testing the T bit (bit 5) of the SPSR. If it's set, the execution was in THUMB mode.

By convention, if the comment field of the SWI is greater than 16, the software interrupt was initiated by software (i.e. an operating system call), and a branch is taken to the appropriate handler routine for further processing. If the comment field is less than 16, the SWI was generated by the ROMPATCH module performing a code patch operation. In this case, the software then reads from a table of function pointers, using the value in the SWI comment field as the index into the table. The value that is read is the address of the code patch. This value is loaded into the PC to begin the execution of the code patch. The following code segment illustrates a typical handling of the SWI.

```
stmfd        sp!, {r0-r1,lr}       @ push register onto SWI stack
mrs         r0, spsr        @ get saved status register
tst          r0, #0x20     @ check if call was in THUMB mode
ldrneh      r0, [lr,#-2]       @ yes: load opcode half-word and
bicne       r0, r0, #0xff00   @ yes: extract THUMB comment
ldreq       r0, [lr,#-4]       @ no: load opcode word and
biceq       r0, r0, #0xff000000 @ no: extract ARM comment
                    @ now r0 has comment field
cmp         r0, #16      @ compare to 16 (maximum for ROMPATCH)
ldrlt          lr, =rompatch_tbl_ptr @ < 16: get top of current ROMPATCH
                    @ table; global variable which is
                    @ changeable per context
ldrlt         r1, [lr, r0, lsl #2]   @ < 16: read function pointer from
                    @ table assumed an array of pointers
                    @ patch functions
strlt          r1, [sp, #8]     @ < 16: store function pointer onto
                    @ stack in position of link register
ldmltfd       sp!, {r0-r1,pc}^      @ < 16: "fake" return from SWI, will
                    @ vector core to appropriate patch
                    @ function and set core back to previous
                    @ mode of operating
ldr          r1, =swi_hdler   @ >= 16: pointer to standard SWI
                    @ handler
mov         lr, pc         @ >= 16: set link register
bx          r1          @ >= 16: jump to standard SWI
                    @ handler
ldmfd        sp!, {r0-r1,pc}^      @ >= 16: pop registers from stack
```

45.2.2.5 Alternate Masters and ROMPATCH

The ROMPATCH module sits on the AHB bus of the internal ROM (ROMC). This means that the ROMPATCH can modify values on the read data bus going to the master. Therefore, any master which reads an opcode patched or data patched location will read patched data.

45.3 Programmable Registers

The following figure shows a sample memory map.

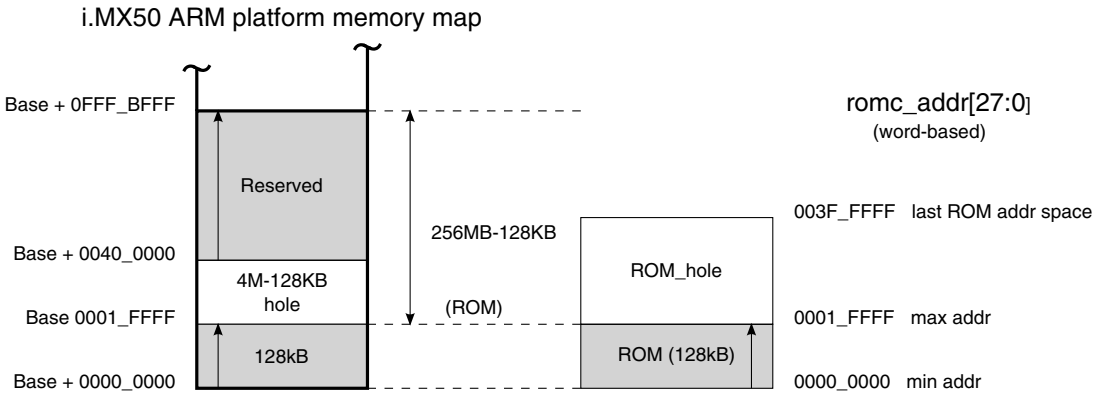

Figure 45-3. Memory Map-Example 128 K ROM Connected

The ROMCP supports ROM sizes with a range of 16 Kbyte to 4 Mbyte with an increment of 1 Kbyte. The 16 Kbyte lower limit was chosen because the minimum size of security code on an ARM platform is approximately 16 Kbyte of code, which is only accessible in supervisor mode. Note that it is the MMU that controls whether any region of memory is secure. For the i.MX50, ROMCP is designed to support 96 Kbyte ROM, and address decoding from continuous 0x0000_0000~0x0001_7FFF address space. Other addressess in 4 Mbyte range are reserved.

The exception vectors must be secured as well, and must be put in the same area as the security code. Since they must reside at address 0x0000_0000, the entire 16 Kbyte of ROM which can only be accessible in supervisor mode is located at the very beginning of the platform memory map.

If the user chooses not to use the security code, a memory size smaller than 16 Kbyte can be connected to the platform (minimum of 1 Kbyte). The MMU can be programmed to allow any kind of access into this memory.

The reason for the big memory hole is because the ROMCP is designed to be as flexible as possible to comply with demands of different operating systems. For example, the requirement of Windows CE OS is to be able to manage memory regions through the MMU page tables (to control accesses to privileged, cacheable, or bufferable areas) which requires regions to be separated into 1 Mbyte page tables. Since it is preferrable to offer the flexibility of having the first 16 Kbyte as a secure region with vectors and security code, but allowing the rest of the ROM to be user-mode accessible, two separate 1MB page tables are used.

To start a potentially unsecure region directly on a 1 MB boundary (starting on address 0010_0000) requires additional address translation within the ROMCP. That causes an extra delay in the address path through the complicated shifting logic in an already critical design timing path. To prevent the extra delay, the first bit above the maximum address of the maximum ROM size that can be connected to the platform is used to select

the region. After entering the ROMCP this bit is only used in the ROM hole decode, and is not passed to the ROM on the address bus. Therefore, no translation is necessary and the address timing path is unaffected by the mapping scheme.

The maximum size of ROM connectable to the ROMCP is 4 Mbyte. To address it the address bits haddr[21:2] are needed. The address range from 128KB to 4 Mbyte is the ROM hole in the i.MX50, and upper addresses above 4 Mbyte in the ROM region are reserved. It also implies that if an address outside the given regions is accessed, the ROMCP will respond with an error response.

45.3.1 ROMPATCH Data Registers (ROMCP_ROMPATCHD*n*)

The ROMPATCH data registers (ROMPATCHD7 through ROMPATCHD0) store the data to use for the 8 1-word data fix events. Each register is associated with an address comparator (7 through 0). When a data fixing event occurs, the value in the data register corresponding to the comparator that has the address match is returned as read data to the ARM core.

If more than one address comparators match, the highest-numbered one takes precedence, and the value in corresponding data register is used for the patching event.

Addresses: ROMCP_ROMPATCHD7 is 63FB_8000h base + D4h offset = 63FB_80D4h
ROMCP_ROMPATCHD6 is 63FB_8000h base + D8h offset = 63FB_80D8h
ROMCP_ROMPATCHD5 is 63FB_8000h base + DCh offset = 63FB_80DCh
ROMCP_ROMPATCHD4 is 63FB_8000h base + E0h offset = 63FB_80E0h
ROMCP_ROMPATCHD3 is 63FB_8000h base + E4h offset = 63FB_80E4h
ROMCP_ROMPATCHD2 is 63FB_8000h base + E8h offset = 63FB_80E8h
ROMCP_ROMPATCHD1 is 63FB_8000h base + ECh offset = 63FB_80ECh
ROMCP_ROMPATCHD0 is 63FB_8000h base + F0h offset = 63FB_80F0h

ROMCP_ROMPATCHD*n* field descriptions

Field	Description
31–0 DATAX	Data Fix Registers. Stores the data used for 1-word data fix operations. The values stored within these registers do not affect the writes to the memory system. They are selected over the read data from ROM when a data fix event occurs. If any part of the 1-word data fix is read, then the entire word is replaced. Therefore, a byte or half-word read will cause the ROMPATCH to replace the entire word. The word is word address aligned.

45.3.2 ROMPATCH Control Register (ROMCP_ROMPATCHCNTL)

The ROMPATCH control register (ROMPATCHCNTL) contains the module disable bit and the data fix enable bits. The module disable bit provides a means to disable the ROMPATCH data fix and opcode patching functions, even when the address comparators are enabled. The External Boot feature is not affected by this bit. The eight data fix enable bits (0 through 7), when set, assign the associated address comparators to data fix operations

NOTE

Bits 27 and 22 always read as 1s.

Address: ROMCP_ROMPATCHCNTL is 63FB_8000h base + F4h offset = 63FB_80F4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R W	-								DATAFIX							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ROMCP_ROMPATCHCNTL field descriptions

Field	Description
31–30 -	Reserved
29 DIS	ROMPATCH Disable. This bit, when set, disables all ROMPATCH operations. This bit is used to enable secure operations. 0 Does not affect any ROMPATCH functions (default) 1 Disable all ROMPATCH functions: data fixing, and opcode patching
28–8 -	Reserved N/A - Bits 27 and 22 always read as 1's
7–0 DATAFIX	Data Fix Enable. Controls the use of the first 8 address comparators for 1-word data fix or for code patch routine. 0 Address comparator triggers a opcode patch 1 Address comparator triggers a data fix

45.3.3 ROMPATCH Enable Registers Low (ROMCP_ROMPATCHENL)

The ROMPATCH enable register low (ROMPATCHENL) controls whether or not the associated address comparator can trigger an opcode patch or data fix event. This implementation of the ROMPATCH only has 16 comparators. Therefore, the upper half of ROMPATCHENL is reserved, and ROMPATCHENL[15:0] are associated with comparators 15 through 0.

Address: ROMCP_ROMPATCHENL is 63FB_8000h base + FCh offset = 63FB_80FCh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	-																ENABLE															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ROMCP_ROMPATCHENL field descriptions

Field	Description
31–16 -	Reserved
15–0 ENABLE	Enable Address Comparator. This bit enables the corresponding address comparator to trigger an event. 0 Address comparator disabled 1 Address comparator enabled, ROMPATCH will trigger a opcode patch or data fix event upon matching of the associated address

45.3.4 ROMPATCH Address Registers (ROMCP_ROMPATCHA*n*)

The ROMPATCH address registers (ROMPATCHA0 through ROMPATCHA15) store the memory addresses where opcode patching begins and data fixing occurs. ROMPATCHA0 through ROMPATCHA15 are associated with address comparators 0 through 15. Each of the ROMPATCH address registers is 21 bits wide and dedicated to one 4 Mbyte memory space. Bits 21 through 2 are address bits, to be compared for a match; bit 1 is also an address bit used for half word selection. Bit 0 is the mode bit (set to 1 for THUMB mode). All 16 registers can be used for code patch address comparison. Only the first 8 registers can be used for a 1-word data fix address comparison.

Addresses: 63FB_8000h base + 100h offset + (4d × *n*), where *n* = 0d to 15d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	-										ADDRX[21:1]

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ROMCP_ROMPATCHA*n* field descriptions

Field	Description
31–22 -	Reserved
21–1 ADDRX[21:1]	Address Comparator Registers. Indicates the memory address to be watched. Bit 1 is ignored if data fix. Only used in code patch

Table continues on the next page...

ROMCP_ROMPATCHA*n* field descriptions (continued)

Field	Description
0 THUMBX	THUMB Comparator Select. Indicates that this address will trigger a THUMB opcode patch or an ARM opcode patch. If this watchpoint is selected to be a data fix, then this bit is ignored as all data fixes are 1-word data fixes. 0 ARM patch 1 THUMB patch (ignore if data fix)

45.3.5 ROMPATCH Status Register (ROMCP_ROMPATCHSR)

The ROMPATCH status register (ROMPATCHSR) indicates the current state of the ROMPATCH and the source number of the most recent address comparator event.

Address: ROMCP_ROMPATCHSR is 63FB_8000h base + 208h offset = 63FB_8208h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	-														SW		-										SOURCE					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ROMCP_ROMPATCHSR field descriptions

Field	Description
31–18 -	Reserved
17 SW	ROMC AHB Multiple Address Comparator matches Indicator. Indicates that multiple address comparator matches occurred. Writing a 1 to this bit will clear this it. 0 no event or comparator collisions 1 a collision has occurred
16–6 -	Reserved
5–0 SOURCE	ROMPATCH Source Number. Binary encoding of the number of the address comparator which has an address match in the most recent patch event on ROMC AHB. If multiple matches occurred, the highest priority source number is used. 0 Address Comparator 0 matched 1 Address Comparator 1 matched 15 Address Comparator 15 matched

Chapter 46
Smart Direct Memory Access Controller (SDMA)

46.1 Introduction

The Smart Direct Memory Access (SDMA) controller offers highly-competitive DMA features combined with software-based virtual-DMA flexibility. It enables data transfers between peripheral I/O devices and internal/external memories.

The SDMA controller helps maximize system performance by off-loading the ARM core in dynamic data routing.

46.1.1 Overview

The figure below shows a block diagram of the SDMA controller. It includes the custom RISC core along with its RAM, ROM, DMA units, the CRC unit, and the scheduler.

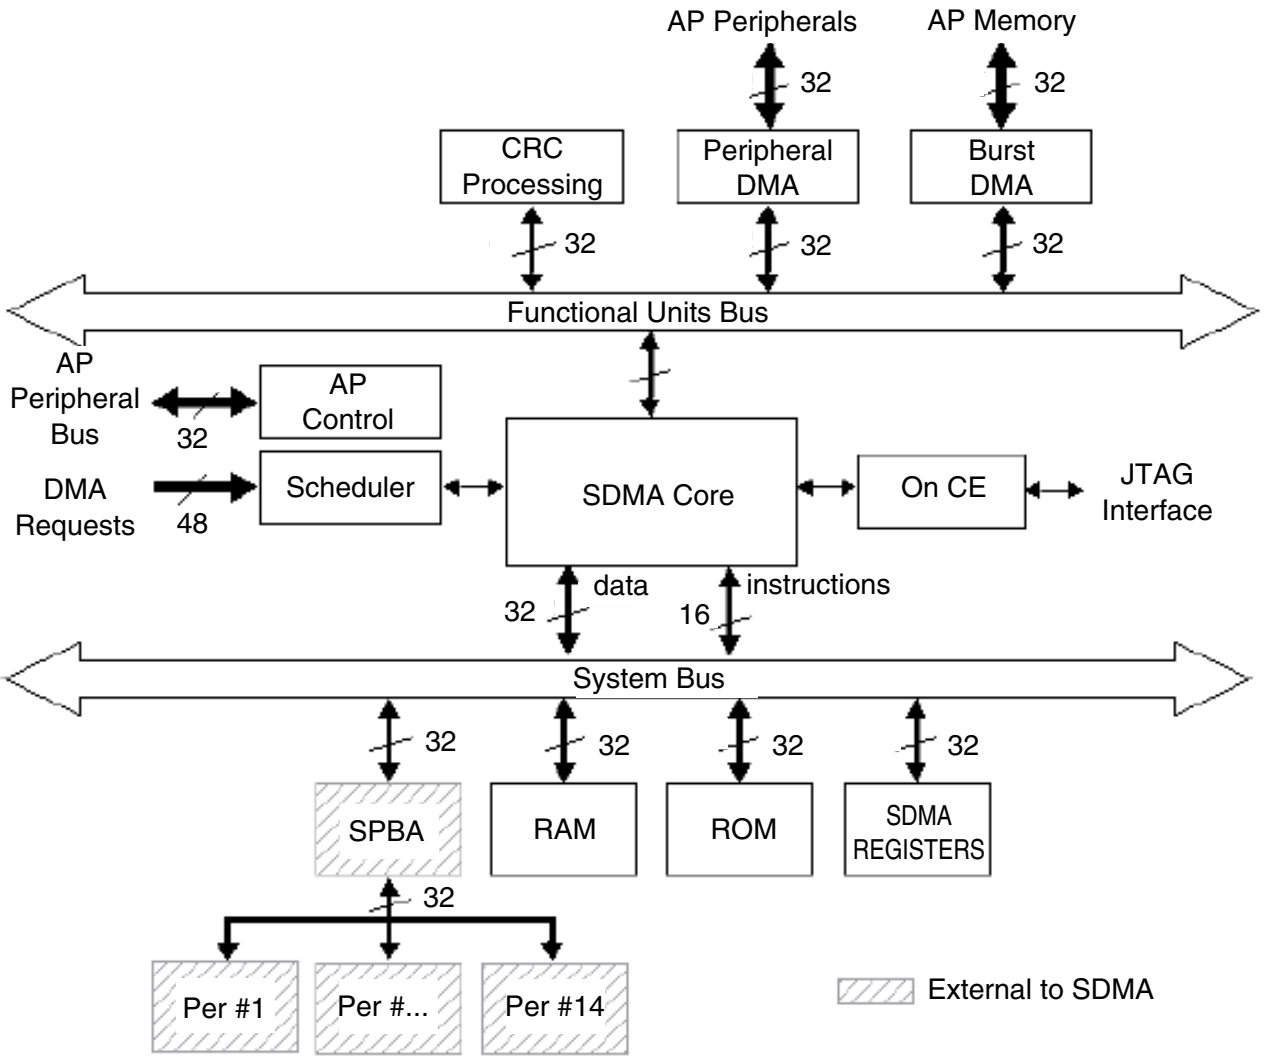

Figure 46-1. SDMA Block Diagram

The SDMA core executes short routines that perform DMA transfers; these routines are called *scripts*. The SDMA core interfaces to its own memory via the SDMA system bus. The SDMA system bus supports a 32-bit data path and a 16-bit address bus. The system bus datapath is used for both 16-bit instruction (program) memory access and 32-bit data access. DMA units interface to the core via the Functional Unit Bus and use dedicated registers to perform DMA transfers.

The SDMA memory contains a ROM and a RAM. The ROM contains startup scripts (for example, boot code) and other common utilities, which are referenced by the scripts that reside in the RAM. The internal RAM is divided into a context area and a script area (more details about this mapping are available in Instruction Memory Map and Data Memory Map).

Every transfer channel requires one context area to keep the contents of all the core and unit registers while inactive. Channel scripts are downloaded into the internal RAM by the SDMA using a dedicated channel that is started during the boot sequence. Downloads are invoked using commands and pointers provided by the ARM platform. Every channel contains a corresponding channel script located in RAM and/or ROM that can be reconfigured independently as-needed. Channel scripts can be stored in an external memory and downloaded when needed. The SDMA can be configured with any mixture of scripts to enable an endless combination of supported services.

The scheduler monitors and detects DMA requests, mapping them to channels, and mapping individual channels to a pre-configured priority. At any given point, the scheduler presents the highest priority channel that requires service to the SDMA core. A special SDMA core instruction is used to "conditionally yield" the current channel being executed to an eligible channel that requires service. If (and only if) there is an eligible channel pending, will the current channel execution be preempted.

There are two yield instructions that differently determine the eligible channels: In the first version, eligible channels are pending channels with a strictly higher priority than the current channel priority. In the second version (yieldge), eligible channels are pending channels with a priority that is greater or equal to the current channel priority. The scheduler detects devices that need service through its 48 DMA request inputs. After a request is detected, the scheduler determines the channel(s) that is (are) triggered by this request and marks it (them) as pending in the "Channel Pending (EP)" register. The priorities of all the pending channels are continuously evaluated in order to update the highest pending priority. The channel pending flag is cleared by the channel script when the transfer has completed.

The ARM platform control block contains the control registers used to configure the 32 individual channels. There are 48 Channel Enable registers, and every register maps one DMA request to any desired combination of channels. The 32 Priority registers are used to assign a programmable 1-of-7 level priority to every possible channel. This block also contains all other control registers that the ARM platform can access.

The 48 DMA requests that are connected to the scheduler come from a variety of sources. The "receive register full" and "transmit register empty" signals found in the UART and USB ports are typical examples of DMA requests that can be connected to the SDMA. These requests can be used to trigger a specific SDMA channel, or several channels.

There is an OnCE compatible debug port for product development. The OnCE includes support for setting breakpoints, single-step and trace, and register dump capability. In addition, all memory locations are accessible from the debug port.

46.1.2 Features

The following are the SDMA features:

- Multi-channel DMA supporting up to 32 time-division multiplexed DMA channels
- Hardware or software driven triggers for each channel
- 48 hardware driven triggers that can be mapped to any channel.
- Memory accesses including linear addressing, FIFO addressing and 2D addressing
- Fast context-switching with two-level, priority-based preemptive multi-tasking
- 16-bit instruction-set micro-RISC engine (the SDMA core)
- Two DMA units with some or all the following features:
  - Auto-flush and prefetch capability
  - Flexible address management (increment, decrement, and no address changes on source and destination address)
  - Misaligned data-transfer support
  - Uni-directional and bi-directional flows (copy mode)
  - Up to eight-word buffers for configurable burst transfers
- Support of byte-swapping and CRC calculations
- An available API and library of scripts
- Little-Endian and Big-Endian modes
- Hardware handshakes for low-power entry sequence
- Security support to lock contents of the SDMA script RAM.
- 4-Kbyte ROM containing startup scripts (for example, boot code) and other common utilities that can be referenced by RAM-located scripts
- 8-Kbyte RAM area is divided into a processor context area and a code space area used to store channel scripts that are downloaded from the system memory
- Debug support, including a OnCE port, real-time monitors, and embedded cross-trigger events
- Supported clock frequencies in process:
  - Configurable clock options for the SDMA core and the ARM platform DMA units
    - 1:2 ratio with maximum of SDMA core running at ARM platform Peripheral Bus speed and DMA running at max DMA frequency.
    - 1:1 ratio when both SDMA core and ARM platform DMA clocks are set to the ARM platform Peripheral Bus speed.
- Peripheral bus interface for configuration register programming by the ARM platform
- The SDMA RISC engine (arithmetic and logic operations, plus CRC acceleration), which is referred to as the "SDMA core."
- An internal peripheral bus connected to the Shared Peripherals Bus Interface (SPBA) that enables access to up to 14 shared peripherals. SDMA supports 32-bit accesses to word peripherals and 16-bit accesses to half-word peripherals.

- The peripheral DMA unit that is hooked-up to the ARM platform Crossbar Switch to service ARM peripherals
- The burst DMA unit is able to perform burst accesses to the external memory
- All the DMA units are 32-bit AHB masters. They are connected to different buses, thus allowing concurrent accesses.

46.2 Functional Description

Figure 46-2 shows the SDMA topology, and is composed of the following components:

- SDMA Core (SDMA Core)
- SDMA Scheduler (Scheduler)
- Functional Units:
  - CRC (CRC Calculation Unit)
  - Burst DMA (Burst DMA Unit)
  - Peripheral DMA (Peripheral DMA Unit)
- ARM platform Control for ARM control register access.
- Internal RAM and ROM Memory (SDMA Programming Model)
- OnCE debug Port (The OnCE Controller)

The functional unit bus provides access by the SDMA core to the CRC hardware accelerator and the DMA units. The system bus provides access to SDMA internal memory and also supports up to 14 peripherals.

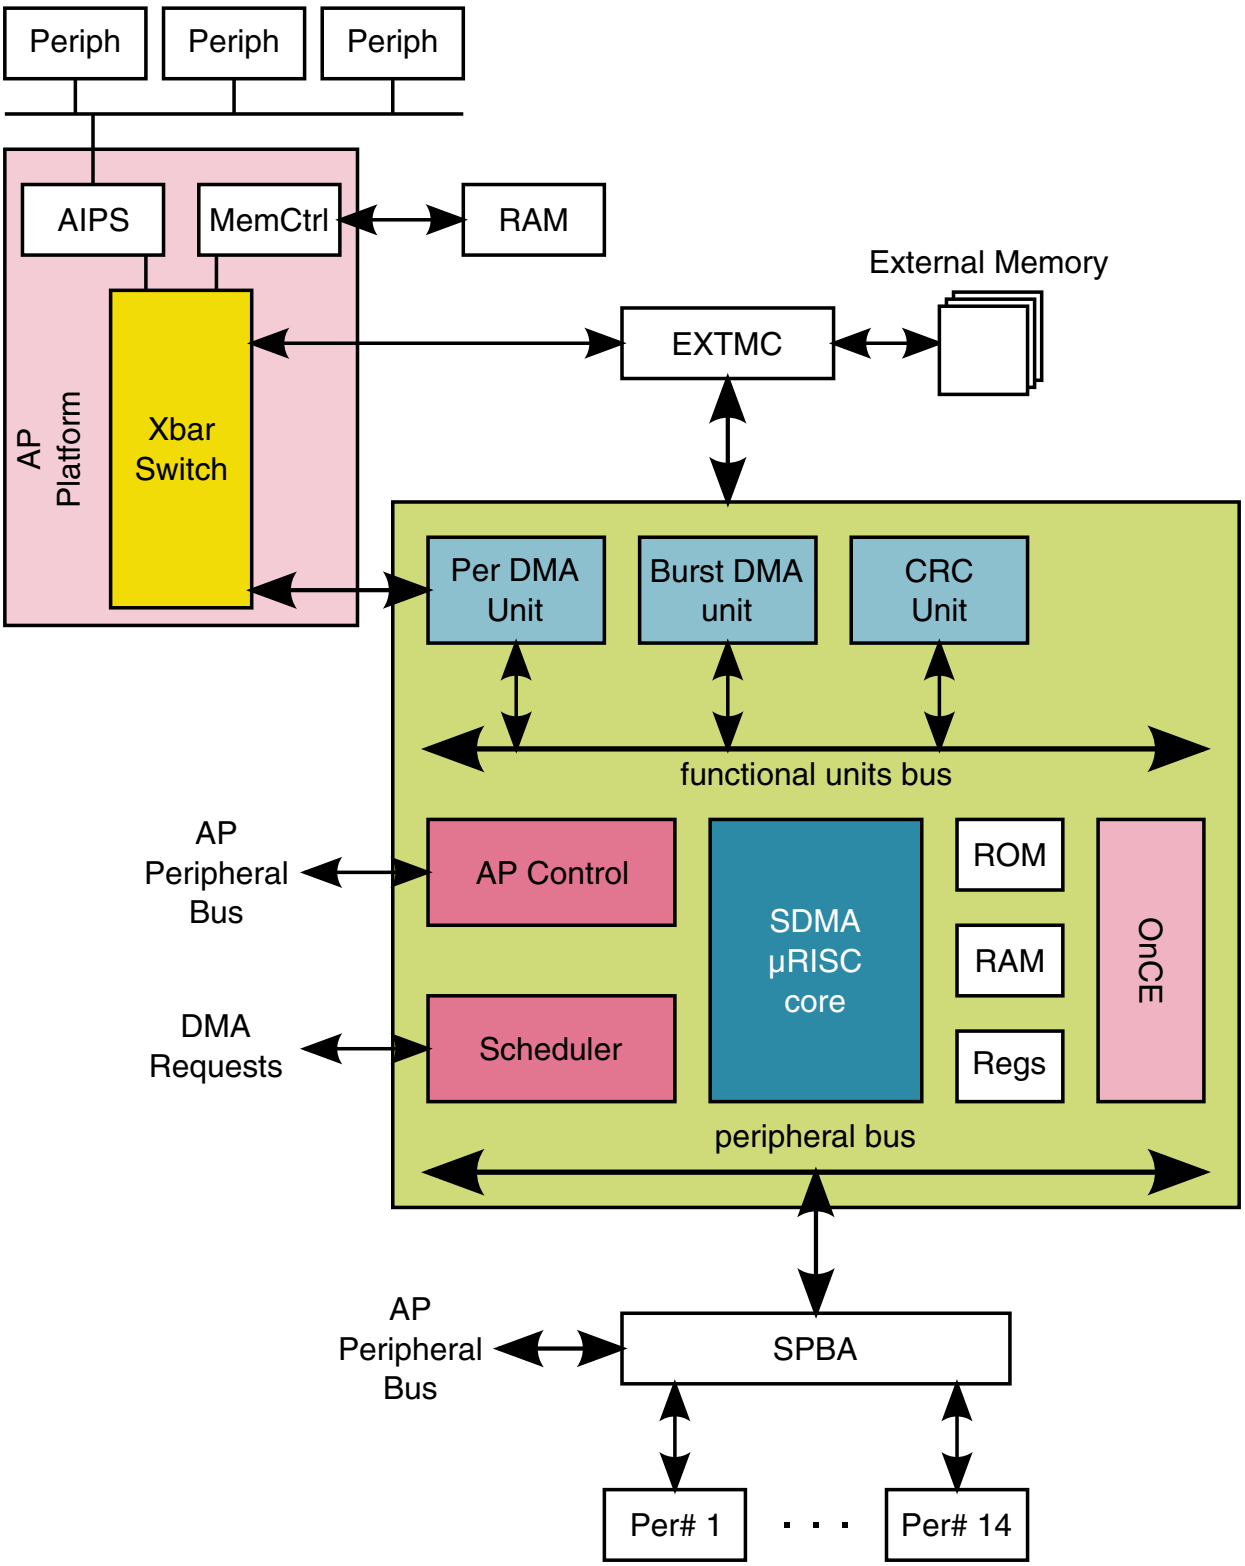

Figure 46-2. SDMA Connections

NOTE

EDITOR NOTE: This copy of the figure is for the case where the BP interfaces are NOT connected. Unconnected interfaces are removed from this diagram since not visible at all to the user.

46.3 SDMA Core

The SDMA core is a customized RISC-like processor that is specifically developed to control DMA units and perform L1 tasks like byte-stuffing or framing.

The SDMA core incorporates on-chip debug capability using the OnCE.

The SDMA core is based on a 32-bit register architecture with 16-bit instructions. There are eight general purpose 32-bit registers, four flags (T, LM, SF, and DF), and four PCU registers (PC, RPC, SPC, and EPC) that can address 16,384 16-bit instructions.

46.3.1 SDMA Core Structure

The following figure shows the structure of the SDMA core. It also shows the different registers, calculation resources, and possible data movements.

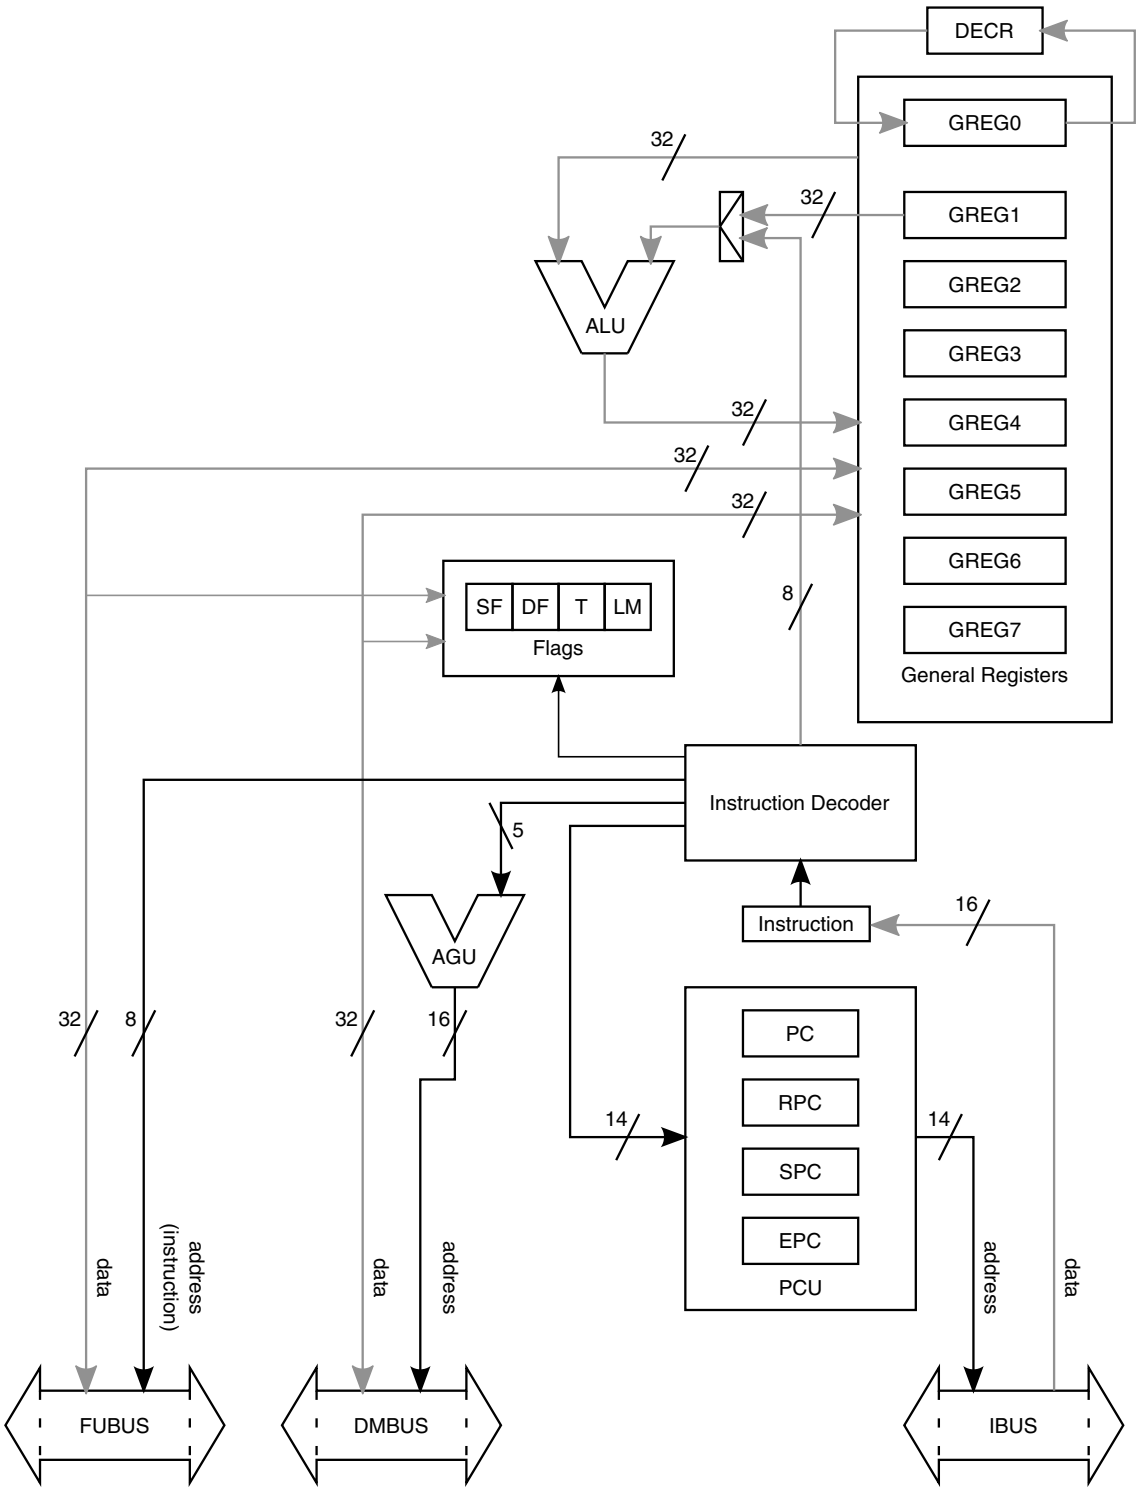

Figure 46-3. SDMA Core

- The Program Control Unit (PCU) is described in Program Control Unit (PCU). It handles the state of the core and generates the instruction fetch addresses. Instructions are retrieved from the Instruction Bus (IBUS) and stored in the SDMA

core instruction register prior to their decoding. The PCU contains the following registers:
    - The Program Counter (PC) contains the address of the current instruction.
    - The Return Program Counter (RPC) contains the address of the instruction that follows a jump to the subroutine.
    - The Start Program Counter (SPC) contains the address of the first instruction of the current hardware loop.
    - End Program Counter (EPC) contains the address of the last instruction of the current hardware loop.
- The other core registers are the general purpose registers (GREGn) and the flags.
    - The general purpose registers can be used to hold data and addresses. They can be loaded with immediate values (for example, 8-bit data that are encoded in the instruction), results of calculations that were performed with the ALU, 32-bit data that comes from the memory or peripherals via the Data Memory Bus (DMBUS), 32-bit data that comes from the DMAs or CRC via the Functional Units Bus (FUBUS) or another general purpose register. Their content can be the operands of the ALU, the data to send on either bus (DMBUS or FUBUS), or a pointer to memory (DMBUS address).
    - The general register 0 (GREG0) is also the hardware loop counter. In hardware loops, it cannot be used for any other purpose. This register uses a dedicated decrement unit (DECR) shown in Figure 46-3.
    - The flags reflect the status of operations:
        - SF and DF are set when the last load or store on either bus (FUBUS or DMBUS) received an error response.
        - LM is set when the core is executing instructions inside a hardware loop.
        - T is set when the ALU operation result was 0 or the loop counter reaches 0 (the latter is preponderant when an ALU operation is the last instruction of a hardware loop).
- The ALU has two operands: any general register and either a second general register or an immediate value. The result is always stored into the first general register. A NOP function can be utilized by moving a register's contents into itself (For example, the instruction: mov R0,R0).
- The 16-bit instructions are fetched via the instruction bus (IBUS) whose address is driven by the PC. The SDMA RAM and ROM are visible to the core as 16-bit devices through this interface.
- The memory (RAM and ROM), memory mapped registers, and external peripherals are accessed via the DMBUS. The address is always taken from a general register whose content is added to a 5-bit immediate value. This is the only available addressing mode. The DMBUS is a 32-bit data bus. Except for the peripherals that

are external to the SDMA, the address accuracy is the 32-bit word (for example, adding 1 to an address points to the next word, not the next byte).
- The functional units are accessed via the FUBUS connection. The data is exchanged with any general register, but the address (which in fact is the instruction and the selector of the functional unit) comes from an 8-bit field of the corresponding load or store.

46.3.2 Program Control Unit (PCU)

This part of the SDMA core is dedicated to the control of the RISC engine, as implied by the instructions that are executed. Its behavior is determined by the instruction type and the inputs of the SDMA.

It contains the PC, RPC, SPC, and EPC registers that are described in SDMA Core Structure.

46.3.2.1 Instruction Types

The state sequence and the delay of execution vary according to the type of the instruction. There are six possible categories of instructions, as follows:

1. Standard: Most of the instructions belong to this category, and always last 1 cycle.
2. ldf/stf: These are respectively the load and store instructions that access the functional units. They last 1+n cycles where n is the number of wait-states of the targeted functional unit.
3. ld/st: These are the load and store instructions that access the memory and peripherals. They last 1+n cycles where n is the number of wait-states of the targeted device (1 for the ROM, RAM, and memory mapped registers, 1 + the external peripheral wait-states). These instructions always last at least two cycles, but the core is able to handle them in one cycle. The first wait-state is inserted outside the core.
4. Branch: These are all the instructions that cause the Program Counter to point to another instruction other than the following one (for example, one that breaks the sequential flow). There are the absolute jumps, the conditional branches, the jump to the sub-routines, and the return from the sub-routine.
5. Loop,Modified Load or Store: The hardware loop instruction modifies the potential behavior of any load or store inside the loop (for example, when the LM flag is set). A jump may be implied after any such load or store if it received an error. The error causes an early exit of the loop, which means a jump to the instruction that follows the one that is pointed to by EPC. An additional cycle is required by the PCU to perform the jump (+1 to the ld/st/ldf/stf original execution delay). Although there is

usually an implicit jump after the last instruction of the loop when the PC goes back to SPC, this is performed at no cycle cost.

6. Done: The done, yield, or yieldge instructions are used to control channel switching. When no channel switching is performed, these instructions last a single cycle. When there is a change of channel or context switch, the delay is variable and depends on many factors (as detailed in Context Switching).

46.3.2.2 PCU States

The PCU state is visible through outputs of the SDMA (see Real-Time Debug Outputs) or the OnCE status register(see OnCE Status Register (OSTAT)).

The PCU state is a four-bit field that can take the values shown in the following table. Figure 46-4 shows the possible state transitions and the corresponding conditions.

Table 46-1. PCU States

Value	State	Description
0	Program	The is the usual instruction cycle.
1	Data	This state is inserted when there are wait-states during a load or a store on the data bus (ld/st type).
2	Change of Flow	This is the second cycle of any instruction that breaks the sequence of instructions (branch and done types). This state lasts only a single cycle; it is always followed by the Program state.
3	Error in Loop	This state is used when an error causes a hardware loop exit (loop-modified load or store type). This state only lasts a single cycle; it is always followed by the Program state.
4	Debug	he SDMA is stopped in debug mode.
5	Functional Unit	This state is inserted when there are wait-states during a load or a store on the functional units bus (ldf/stf type).
6	Sleep	No script is running: The core is idle after saving the last channel context.
7	Save	The context switch FSM is saving the current channel.
8	Program in Sleep	Same as Program except there is no associated channel, this state is used when instructions are executed after entering debug mode, whereas the core was in either Sleep mode.
9	Data in Sleep	This is the same as Data except there is no associated channel.
10	Change of Flow in Sleep	This is the same as Change of Flow except there is no associated channel. This state only lasts a single cycle, and is always followed by the Program in Sleep state.
11	Error in Loop in Sleep	This is the same as Error in Loop except there is no associated. channel. This state only lasts a single cycle, and is always followed by the Program in Sleep state.
12	Debug in Sleep	This is the same as Debug except the core was put in debug mode when no channel was active.

Table continues on the next page...

Table 46-1. PCU States (continued)

Value	State	Description
13	Functional Unit in Sleep	This is the same as Functional Unit except there is no associated channel.
14	Sleep after Reset	This shows that no script is running, and the core is idle after a reset. When a channel becomes active, no context is restored but the core starts its boot program located at address 0 (or the address available in register in Channel 0 Boot Address (SDMAARM_CHN0ADDR)).
15	Restore	The context switch FSM is restoring the next channel context.

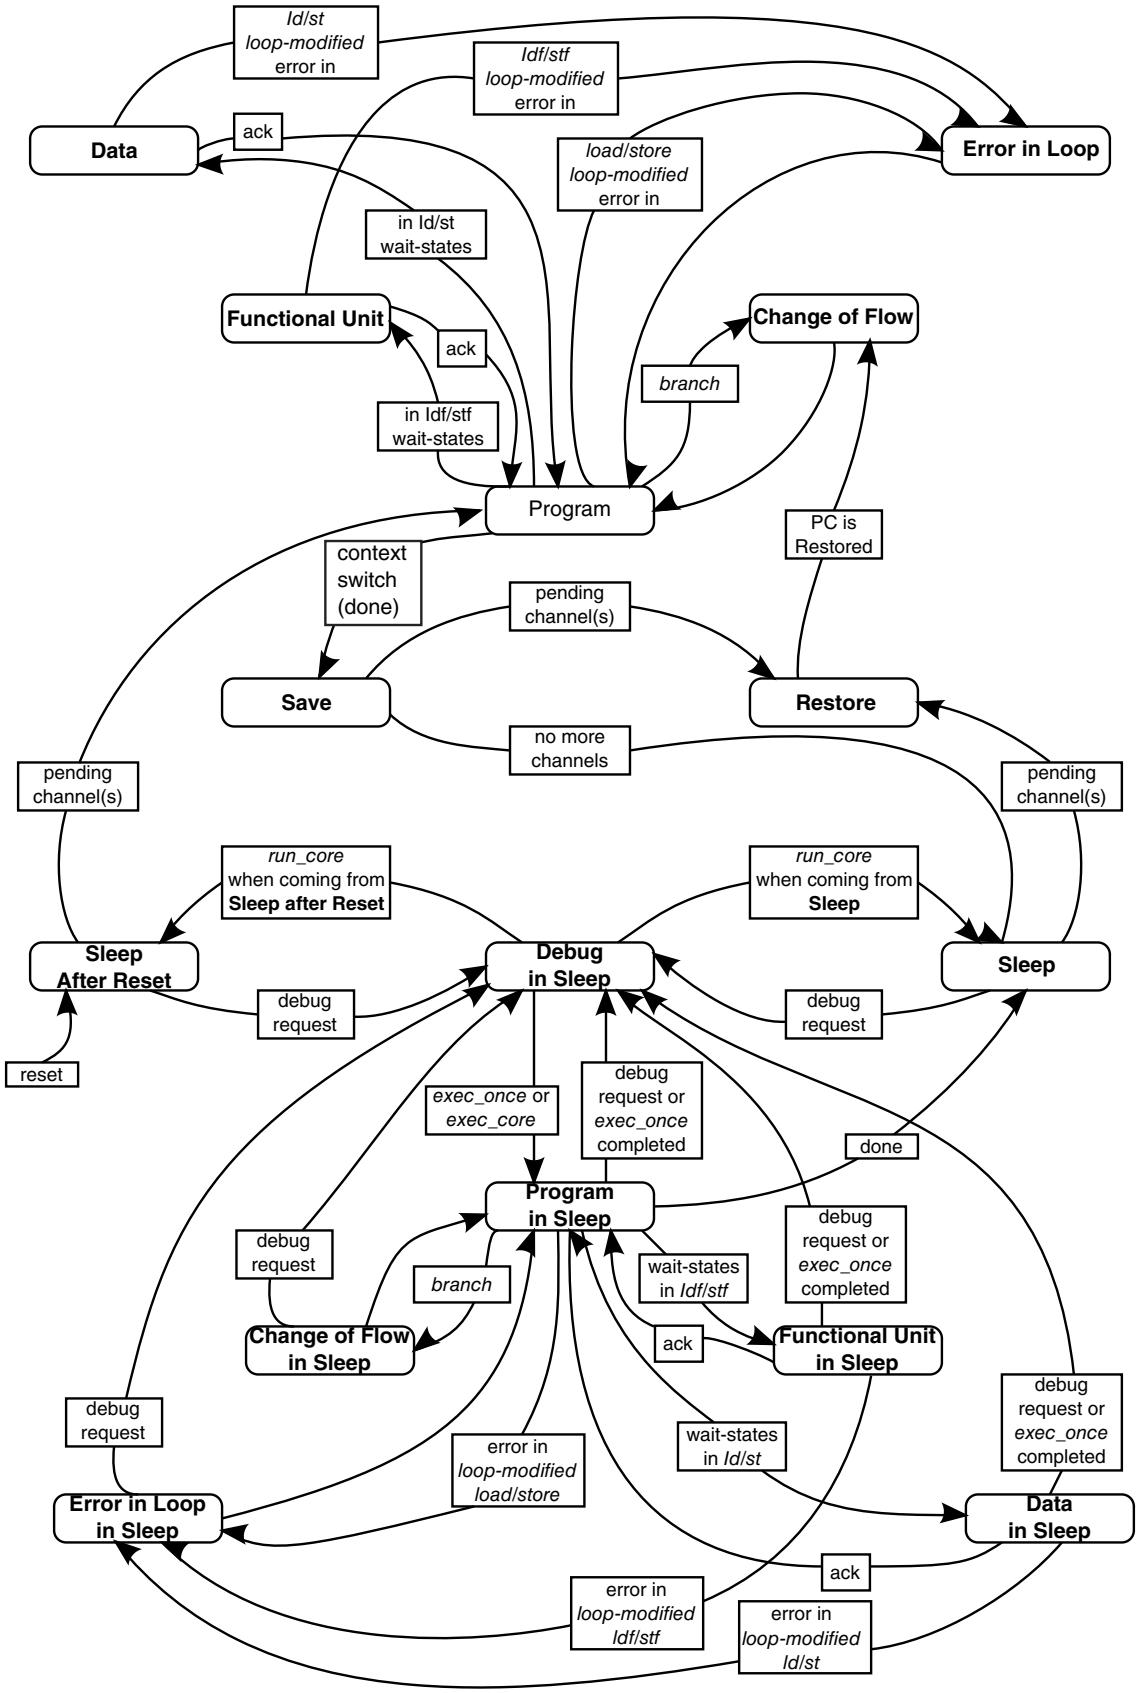

Figure 46-4. PCU State Diagram

46.3.3 SDMA Core Memory

The SDMA has two memory spaces: one for the instructions and one for the data. As both spaces share the same resources (ROM and RAM devices), the system bus manages possible conflicts when the core accesses the same resource for both an instruction read and a data read or write.

Program and data memory is further described in Address Space.

Instructions of 16-bit width are stored in 32-bit wide devices and can be accessed as data. The mapping is Big Endian: an even instruction address (terminated by 0) accesses the most significant part of the 32-bit data (bits [31:16]), and an odd instruction address (terminated by 1) accesses the least significant part of the 32-bit data (bits [15:0]). Instructions can be fetched out of internal ROM or RAM.

Data can be read from ROM, RAM, memory mapped registers, and external peripherals, and written to the same devices (except the ROM).

The ROM contains bootload scripts, channel scripts, and common subroutines which may be referenced by channel scripts elsewhere in the ROM or RAM.

The RAM is divided into a context area and a code space area which may be used to store channel scripts. The RAM contains undefined values after a hardware reset. Channel scripts and initial context values are downloaded into RAM using channel 0 which is reserved for bootload functions.

46.4 Scheduler

All channel scheduling hardware is included in the Scheduler.

46.4.1 Primary Functions

The scheduler is a hardware-based design used to coordinate the timely execution of 32 virtual DMA channels by the SDMA core on the basis of channel status and priority.

The scheduler performs the following functions:

- Monitors, detects, and registers the occurrence of any one of the 48 DMA requests
- Links a specific request to a channel or group of channels (channel mapping)
- Ignores requests that are not mapped to a previously configured channel
- Maintains a list of all the channels that are requesting service

- Assigns a pre-programmed priority level (1 of 7) to every channel requesting service
- Detects and flags overrun/underrun conditions

46.4.2 Channels and DMA Requests

46.4.2.1 Channels

A Virtual Channel (hereafter simply called a channel) manages a flow of data through the SDMA. Flows are typically unidirectional.

The SDMA can have up to 32 simultaneously operating channels, numbered from 0 to 31. Channel 0 is usually dedicated to control the SDMA script downloading. All the channels can be assigned by the ARM platform software.

46.4.2.2 DMA Requests

A DMA request is caused by externally (for example, external to the SDMA) controlled conditions (for example, UART receive FIFO reaches a threshold). The SDMA currently supports up to 48 DMA requests.

46.4.2.3 Mapping from DMA Requests to Channels and Priorities

A channel can stall waiting on a single DMA request. A single DMA request can awake more than one channel (in fact, any request can awake any combination of channels).

The mapping between DMA requests and channels is program-controlled. There is a storage element assigned for each of the 48 requests that contains a bitmap table of the channels that are awakened by the event.

Every channel also has a three-bit register that indicates its priority.

46.4.3 Scheduler Functional Description

Scheduler Overview describes the behavior of the SDMA scheduler-from the channel enabling conditions to the highest priority pending channel selection.

46.4.3.1 Scheduler Overview

The scheduler algorithm is built in hardware. It is provided with possibilities for the ARM platform to control its behavior.

The scheduler processes incoming DMA requests, maps detected requests to 0, one, or several channels, maintains a list of channels that are requesting service (pending channels), identifies the top priority and its associated channel, and selects the next active channel when the current channel yields.

The following figure shows a functional overview.

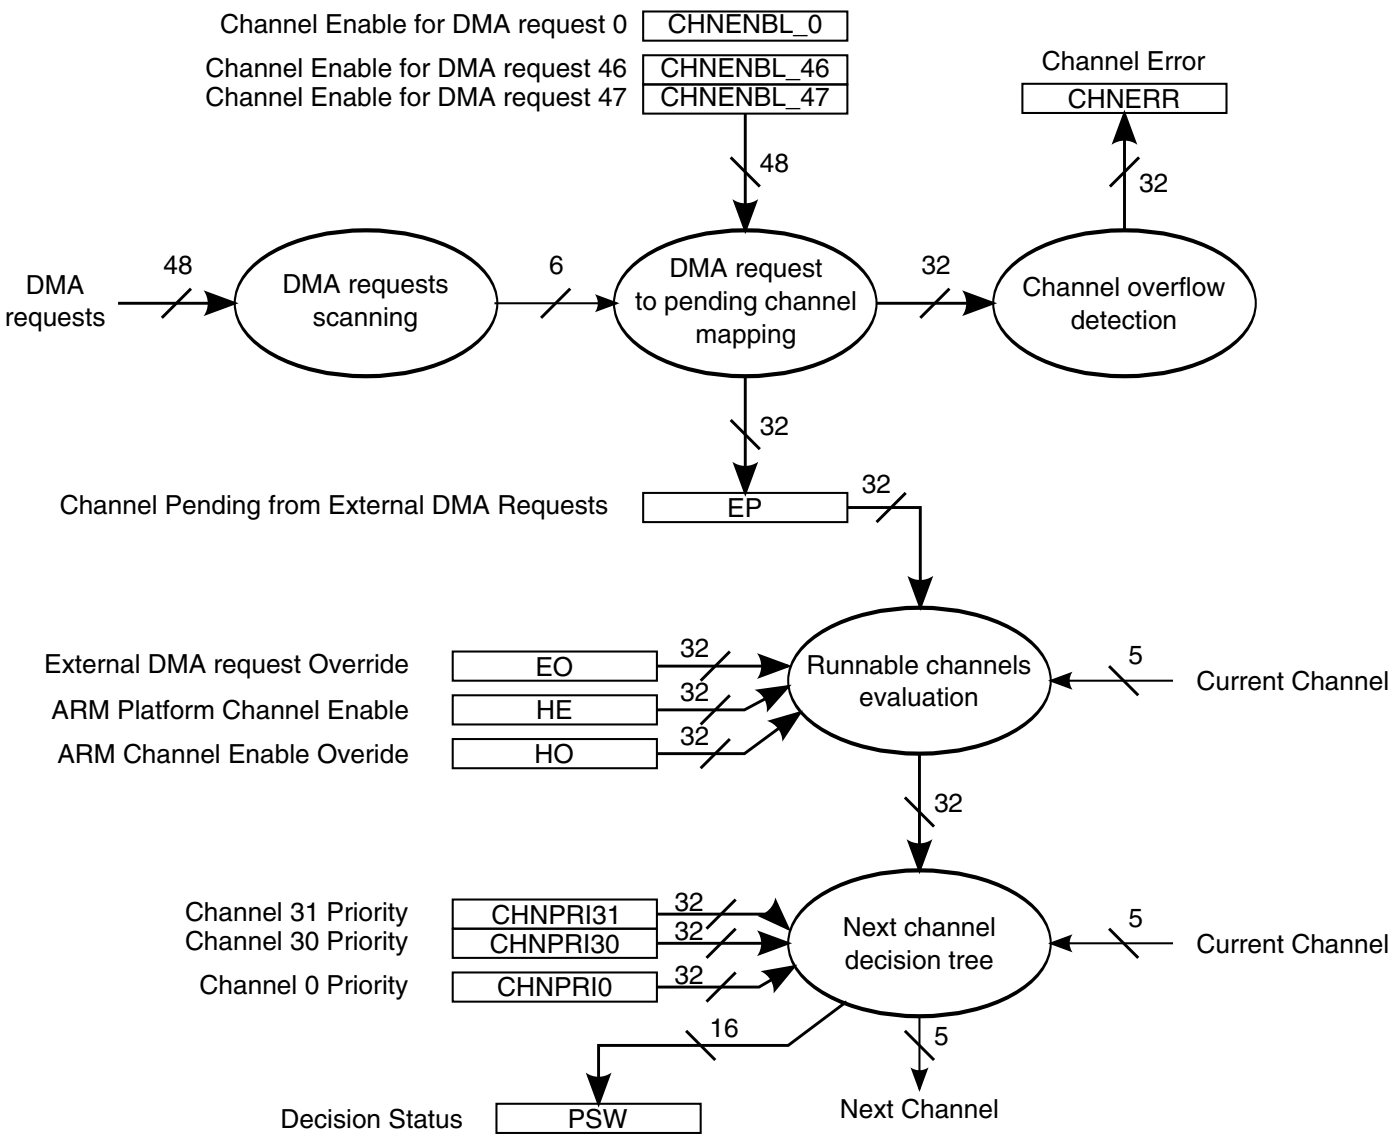

Figure 46-5. SDMA Hardware Scheduler

46.4.3.2 DMA Requests Scanning

The scheduler contains a 48-bit edge detection device that detects the rising edge of every DMA request and transmits the request number to the next stage.

The DMA requests are assumed to be generated on the same reference clock as the SDMA core clock; they are detected as soon as the signal goes from a 1-to-n-cycles low state to a 1-to-m-cycles high state.

This system is able to detect single-cycle pulses as well as level-based DMA requests such as a FIFO threshold crossing. In this case, the SDMA provides a memory mapped register that can be used by the channel script to monitor the DMA requests lines, and thus determines whether the data transfer is done or not done, and then continues with the transfer or closes the channel.

When several DMA requests are detected at the same time, they are forwarded to the next scheduler stage at the rate of one request per cycle. No request is lost.

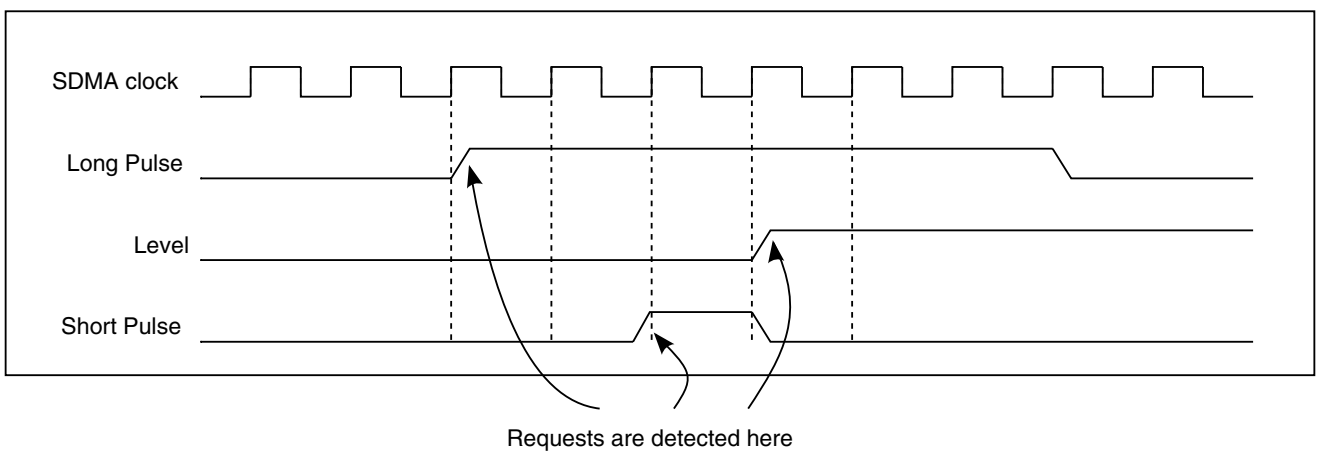

Figure 46-6. Examples of Valid DMA Requests

The DMA request inputs are connected to various sources that depend on the SoC. The exact list of DMA request inputs and their associated number is available in each respective project-specific chapter.

46.4.3.3 Mapping DMA Requests to Pending Channels

Whenever a DMA request is detected by the first stage, its number is used in the second stage to determine the channels that have to be activated.

This is performed with an array of 48 registers that are 32 bits wide: There are 48 Channel Enable Registers (CHNENBLn), one register per DMA request. The DMA request number selects the Channel Enable Registers, and every bit of this 32-bit register indicates that the corresponding channel must be activated when it is a 1.

This information is passed on the EP register. For every bit of the Channel Enable Register that is set, the corresponding bit of the EP register is also set, and the remaining bits of EP are left unchanged. The transformation of EP is summarized by the following equation:

EP = EP or CHNENBLn

The EP register is used to know which channels require service because they received a DMA request.

Typical contents of the CHNENBLn registers are all 0s, except for a single bit set. For example, a DMA request triggers one channel, but all 0s or several 1s are possible. One DMA request could activate several channels, and the channel execution sequence can be controlled by the channel priorities and numbers, as explained in the next sections. The following table illustrates an example configuration.

NOTE

From the table, the DMA request 0 is programmed to simultaneously trigger channels 0, 1, and 31. Also, DMA requests 30-47 are not used in this example. The remaining channels 2 to 30, are configured to be triggered by DMA requests 29 to 1, respectively.

46.4.3.4 Channel Overflow

A channel overflow occurs when a DMA request requires service from channel *n* by setting bit *n* of the register EP, but this bit is already set, meaning channel *n* is already pending. This can come from an overrun/underrun condition.

This detection is possible only when the DMA requests are pulses, because a level-based DMA request stays high until it is serviced, even though an underrun or overrun condition occurs, thus preventing another edge detection of the DMA request.

The channel overflow information is saved in the 32-bit CHNERR register (1 bit per channel). You can configure the SDMA to trigger an interrupt to the ARM platform when there are 1s in CHNERR. Every bit of CHNERR is masked with the corresponding bit of INTRMASK and if it gives a 1, the corresponding bit of INTR is set, triggering the interrupt.

46.4.3.5 Runnable Channels Evaluation

The EP register is used in conjunction with several other 32-bit registers to determine the channels that are runnable.

Registers EO, DO, HO and HE, are controlled by the ARM platform. EP is controlled by the DMA requests and their mapping to channels.

Several channels may be runnable at any given time. The i^{th} channel is runnable if (and only if) the condition below is true:

(HE[i] or HO[i]) and (DO[i]) and (EP[i] or EO[i])

After reset, the HE[i], HO[i], EP[i], and EO[i] bits are all cleared whereas the DO[i] bits are all set. The functions associated with DO are not available for this device. When DO[i] is set, the scheduler condition becomes:

(HE[i] or HO[i]) and (EP[i] or EO[i])

The registers in these equations are controlled as follows:

- ARM platform (host) channel enable flag HE[i] may be set or cleared by the ARM platform with the HSTART and STOP_STAT registers. It can also be cleared by the i^{th} channel script.

  Typical usage is for the ARM platform to set this flag to activate the channel. The flag is cleared by the SDMA core when the transfer is done.

- Externally triggered channel pending flag EP[i] is set by the scheduler when the channel was activated by a DMA request. It can be cleared by the i^{th} channel script.
- The ARM platform channel override flag HO[i] may be set or cleared by the ARM platform. When set, it enables the i^{th} channel to run without the involvement of the ARM platform.

  Typical usage is for the ARM platform to set this flag for channels that do not need ARM platform supervision such as channels that are controlled by DMA request events (EP).

- DO should always be set to 1 so that the runnable channel evaluation considers only HO, HE, EP, and EO.
- Externally triggered channel override flag EO[i] may be set or cleared by the ARM platform. When set, it prevents the i^{th} channel from stopping and stalling on incoming peripheral DMA requests. This is the case when the channel is not handling data transfers with peripherals (for example, a memory to memory transfer).

The SDMA can clear the HE[i], and EP[i] bits by means of adone or notify instruction. The done instruction causes a reschedule; thus, enabling another channel to preempt the current one, while the notify instruction does not. The done and notify instructions can clear either HE[i] or EP[i] (never more than one at a time).

Table 46-3. Runnable Channel Selection Control

Register	Set by	Cleared By
HO	Write to HOSTOVR register	Write to HOSTOVR register
HE	Write to HSTART register	Write to STOP_STAT register or by the channel script with the done or notify instructions.
DO	Write to DSPOVR register	Write to DSPOVR register
EO	Write to EVTOVER register	Write to EVTOVER register
EP	Set by external DMA request event input.	By the channel script with the done or notify instructions

46.4.3.6 Next Channel Decision Tree

The next channel number is computed from the runnable channels list, the current channel number, and their respective priorities.

It is re-evaluated every cycle, but is only used when the current channel yields or terminates by executing a yield, yieldge, or done instruction.

The decision tree is based on the selection of the runnable channel that has the highest priority.

The highest priority channel is selected according to the following rules:

- Runnable channels are sorted by priority.
- If one of the channels with the highest priority had been preempted by a channel with a higher priority, but did not want to yield to a channel of the same priority (for example, it executed a yield, not a yieldge), it is elected as the next channel.
- The channels that belong to the highest priority group are sorted by their number and the channel that has the highest number in this group becomes the next channel. For example, if priorities are the same, channel 31 will be selected before channel 30.

When the current channel requires a reschedule with a yield(ge) or a done instruction, the context switch decision is based on the instruction parameter, the current channel number and priority, and the next channel number and priority. The possible cases are all listed in the following table. The grayed cells correspond to unusual cases that should not occur with a typical usage of the SDMA.

Table 46-4. Channel Switching Decision with a yield, yield(ge), or done

Instruction	Current Channel	Next Channel	Priorities Comparison	New Running Channel/Comments
yield (done 0)	Runnable	Not runnable	none	Current
	Runnable	Runnable	Current > Next	Current
			Current = Next	Current
			Current < Next	Next[1]
	Not runnable	Not runnable	none	none[2] (occurs when the channel was disabled by the ARM platform)
	Not runnable	Runnable	none	Next[1] (occurs when the channel was disabled by the ARM platform)
yieldge (done 1)	Runnable	Not runnable	none	Current
	Runnable	Runnable	Current > Next	Current
			Current = Next	Next[1]
			Current < Next	Next[1]
	Not runnable	Not runnable	none	none[2] (occurs when the channel was disabled by the ARM platform)
	Not runnable	Runnable	none	Next[1] (occurs when the channel was disabled by the ARM platform)
done (done>1)	Not runnable	Not runnable	none	none[2]
	Runnable	Not runnable	none	Current[3] (occurs when the done instruction does not disable the channel runnable condition)
	Not runnable	Runnable	none	Next[1]
	Runnable	Runnable	none	Current[3] (occurs when the done instruction does not disable the channel runnable condition)

1. Current channel script execution is stopped, its context is saved; the next channel context is restored and its script execution resumes
2. Current channel context is saved and SDMA enters IDLE mode
3. Current channel context is saved, then restored, and the current channel script resumes execution

Finally, when the SDMA is in IDLE mode and a runnable channel is elected as the next channel, its context is immediately restored and the script execution resumes.

The *combinatorial-decision* tree supports dynamic modifications of the EP, EO, HE, HO, and DO flags as well as dynamic modifications of the channel priorities. The propagation times are detailed in Scheduler Pipeline Timing Diagram.

The decision tree status is available in the PSW register, which is continuously updated. It contains the next channel priority, the next channel number, the current channel priority, and the current channel number. When a priority is read as 0, it means the channel is not runnable.

A few examples of decisions are presented below:

- Channel 31 is running with priority 5, channels 13 and 24 are pending with the same priority 5; channel 24 is eligible as the next channel since 24 > 13.
- Channel 31 is running with priority 7, channels 13 and 24 are pending with priority 5; channel 31 is the next channel because its priority is greater than the other pending channels.
- Channels 7, 23, and 29 are pending with the same priority. Channel 7 is active and runs a yieldge; it is preempted by channel 29. After a period of time, channel 29 runs a yieldge, it is then preempted by channel 23 that is the selected channel since channel 29 is the current channel. Later, channel 23 runs a yieldge and is preempted by channel 29. Channels 23 and 29 will go on switching after every yieldge until one of them terminates. It is only at that point that channel 7 becomes eligible again.
- Channel 11 is running with priority 3, and channel 15 is pending with priority 4. When the channel 31 script executes a yield instruction, it gets preempted by channel 15; then channels 6 and 18 with priority 3 become pending. Because channel 11 was preempted after executing a yield and there is no pending channel with a strictly greater priority, it is eligible as the next channel (although its number 11 < 18).

46.4.3.7 Scheduler State Diagram

The Figure 46-7 summarizes the behavior of the SDMA scheduler with details about the exact mechanism of the priority decision tree. It is important to understand the scheduler is a hardwired pipeline, which means all the stages are performed simultaneously every cycle, but a change on any given stage is reflected on the next stage after the delays presented in Scheduler Pipeline Timing Diagram.

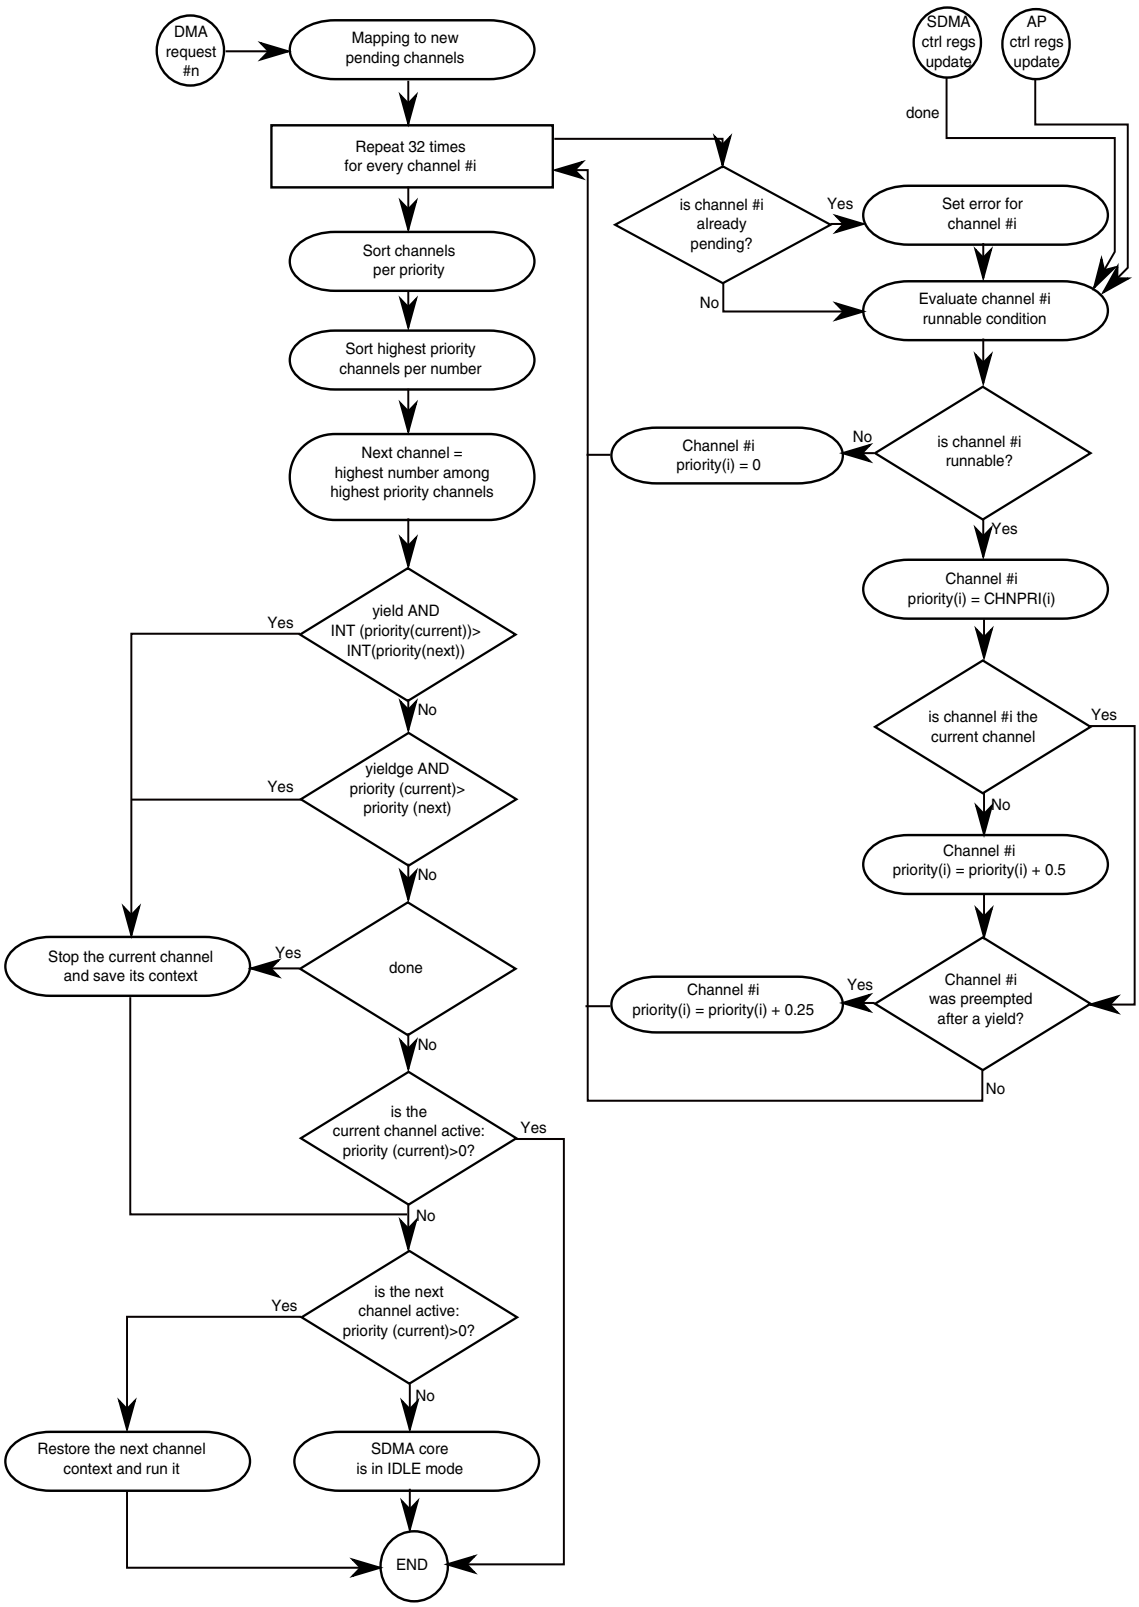

Figure 46-7. Scheduler State Diagram

46.4.3.8 Scheduler Pipeline Timing Diagram

The SDMA scheduler process of DMA-request and control-register modifications is not immediate.

The figure below shows the exact delays of all the tasks. The reference clock is the SDMA core clock.

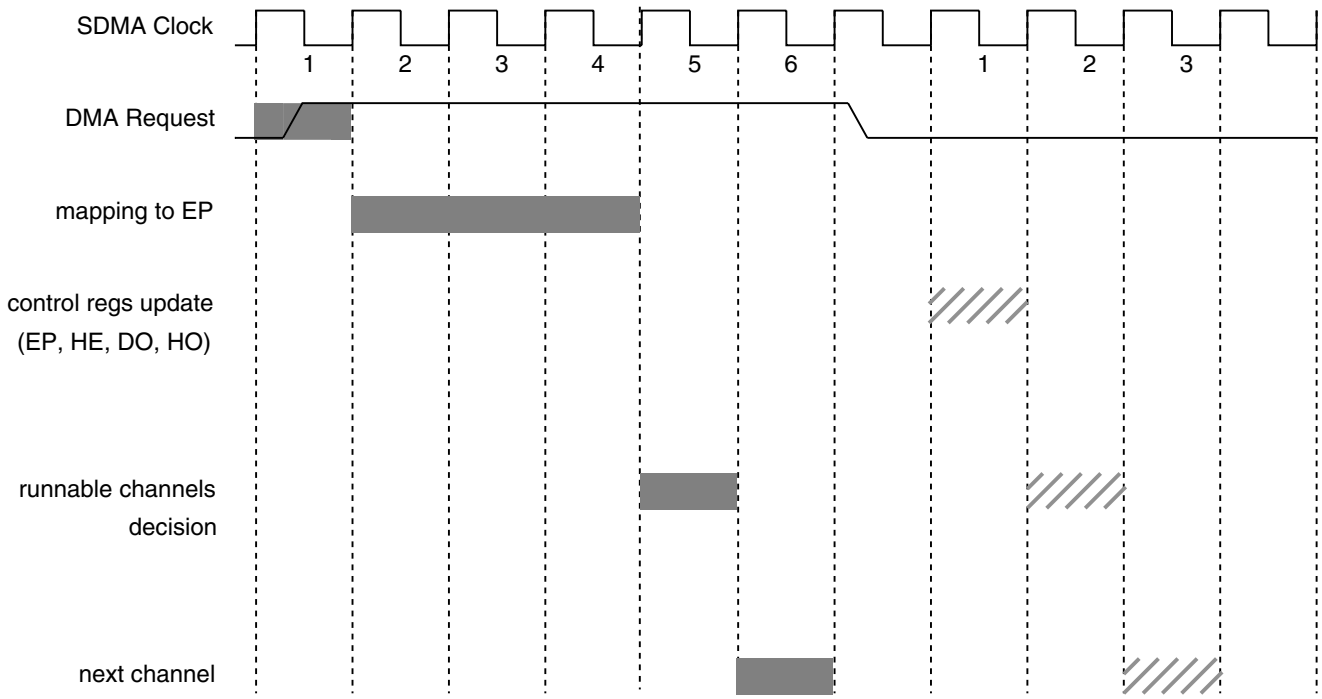

Figure 46-8. Scheduler Timing Diagram

Two numbers can be inferred from this timing diagram. First, it takes six SDMA core clock cycles to update the next channel from a DMA request. Second, it takes three SDMA core clock cycles to update the next channel from a direct modification of the condition registers (EP, DO, HE, or HO) by any processor. The processors that can modify these bits include SDMA with a done instruction or the ARM platform with a write access through the corresponding control port on their respective peripheral bus).

46.4.3.9 Channel-DMA Request Mapping

The 48 DMA request inputs to the SDMA scheduler are listed in project-specific chapters. Refer to the respective chapters for this information.

46.4.3.10 Examples: How to Start a Channel

A channel can be started when the following equation is true for channel *i*:

(HE[i] or HO[i]) and (DO[i]) and (EP[i] or EO[i])

Once this equation is true, the scheduler can start this channel according to the priority of all pending channels. Several examples of configuration are listed below:

1. To start a channel triggered by ARM platform software:
   - Initially, configure HO[i]=0, DO[i]=1, and EO[i]=1 using registers indicated in Table 46-3.
   - ARM platform software triggers the channel by writing to the HSTART register to set HE[i]=1, thereby setting the above equation true.
2. To start a channel triggered by DMA request event.
   - Initially, configure HO[i]=1, DO[i]=1, and EO[i]=0 using registers indicated in Table 46-3.
   - The DMA request is asserted to trigger the channel by setting EP[i]=1, which makes the above equation true.

46.4.4 Context Switching

On execution of a done or yield(ge) instruction, the current channel may be changed either because it has finished (which necessarily happens when the done instruction is executed), or it was preempted by a higher priority channel (which is possible but not systematic when the yield(ge) is executed).

Upon a channel change the SDMA goes through a context switch procedure. When the current channel yields or ends, the context for that channel is saved into the context RAM locations for that channel. When the next channel starts running, its context is first restored from RAM.

Since context RAM is not yet initialized by reset, there will be no context restore at the beginning of the first channel (bootload channel) run after reset. It is expected that the bootload channel will be used to initialize the context for all other channels. When the bootload channel finishes running or yields, SDMA will enter its SAVE state and save that channel's context into RAM. Then, if the bootload channel is called again later, the context will be restored from RAM when the channel starts again.

The context structure for each channel is defined in Context Switching-Programming andTable 46-10. There will be one context area reserved for each channel. When a channel ends or yields, the SDMA core registers are automatically saved into the context RAM and later restored from the context RAM when the channel is next run. The total

RAM space reserved for 32-channel contexts is either 3K or 4K depending on whether the SMSZ bit is set in the CHN0ADDR register, which enables an additional 8 words of scratch RAM for each context.

46.4.4.1 Context Switch Modes

The exact procedure to save the context of the old channel, and to restore the context of the new channel depends on the context switch mode selected by the ARM platform in the CONFIG control register.

The following are the context switch modes:

- By default, the "dynamic" context switch is set. This mode provides the most efficient context switch for an average of eight cycles to stop the current channel, save its context, restore the next channel context, and resume its execution. It consists of saving modified registers of the current channel in the background (for example, during the channel execution)-which leaves very few registers to save when the switch is decided-resuming execution of the next channel as soon as possible (for example, when the minimal set of registers is restored), and continuing the restore phase during this execution.
- In "dynamic with no loop" mode, the same principle is followed except the modified registers are only saved in the background when the loop flag is not set. This mode offers almost the same effectiveness as the previous one, but it prevents the system from accessing the RAM during loops to save power. This is the recommended mode for an efficient context-switch when the loop bodies are short.
- In "dynamic power" mode, no background saving is performed, which reduces power consumption to the minimum. The modified registers are only saved when the context switch starts. The restore phase is the same as before. This is the mode that achieves the optimal power consumption at the cost of a slower context-switch.
- In a "static" context switch, all the registers are saved when a context switch is decided, and all the registers are restored before starting the execution of the new channel. This mode enables a predictable behavior of the context switch since all the registers are restored prior to the channel start and all registers are saved after the channel termination.

NOTE

Static context mode should be used for the first channel called after reset to ensure that the all context RAM for that channel is initialized during the context SAVE phase when the channel is done or yields. Subsequent calls to the same channel or different channels may use any of the dynamic context modes. This will ensure that all context locations for the bootload

channel are initialized, and prevent undefined values in context RAM from being loaded during the context restore if the channel is re-started later.

46.4.4.2 Context Switch Procedure

The Program Control Unit goes into the *save* state, the current context is spilled into memory, and the next channel context is restored according to the context-switch mode that was selected by the ARM platform.

The context switch procedure is as follows:

1. Load the current context's spill base address.
2. Spill the modified registers of the current channel to memory according to the selected context switch mode while the channel is running.

   On a done or yield(ge) that causes the channel preemption, the PCU goes into the *save* state. In *static* mode, all the registers are saved; whereas, in either *dynamic* mode, the registers that were modified but not yet saved are then saved, and the PCU registers and flags are finally saved.

3. Put the SDMA core into *sleep* and wait for new channels to be serviced. This step is skipped if there are pending channels when the current channel is saved.

   As soon as there is at least one pending channel, the PCU goes into its *restore* state to restore the context of the channel that was elected by the scheduler.

   Once a channel is elected, it remains the current channel until its script requests a rescheduling operation with a done or yield(ge) instruction. That means the current channel cannot be modified by the ARM platform, even if it is no more runnable or if its priority is modified.

   The ARM platform can however force a reschedule by writing the corresponding bit in the CONFIG register, which has the same effect as if the script had executed a done instruction. That feature should only be used to stop the SDMA in emergency cases.

4. Load the context base-address of the new channel.

   In "static" mode, all the registers are restored. In either "dynamic" modes, only the PCU registers are restored.

   The new channel is running. In "static" mode, no more activity regarding context restoring or saving is performed. In either "dynamic" modes, the registers are restored in the background every time an access to the context RAM is possible, and

priority is given to restoring the registers that are required by the next instruction to be executed. When a register has not been restored and the next instruction needs it, this instruction gets stalled until the register was restored.

In "dynamic" and "dynamic with no loop" modes, background saving of dirty registers is performed every time an access to the context RAM is possible and allowed by the context switch mode.

NOTE

The contents of a channel context space in the context RAM depends on the selected context switch mode. In "dynamic" and "dynamic with no loop" modes, the contents of the context RAM tend to match the contents of the SDMA registers (except for the PCU registers and flags that are never saved in the background). In "dynamic power" and "static" modes, the contents of the context RAM remain unchanged until the channel terminates with a done or gets preempted.

46.4.4.3 Context Map in Memory

Refer to Context Switching-Programming.

46.5 Functional Units

The functional units are small systems that are used by the SDMA core to perform complex calculations like the CRC unit, or to handle data transfers between the core and a bus domain external to the SDMA.

The SDMA core is able to control and exchange data with these systems by sending instructions and reading or writing data from/to the functional units' registers via the FUBUS. This is done with the ldf and stf instructions.

The following sections provide introductions to the available functional units. Functional Units Programming Model provides descriptions the functional units' behaviors.

46.5.1 CRC Calculation Unit

The Cyclic Redundancy Check (CRC) unit can perform CRC calculation. A single byte of data can be processed every cycle, but up to four bytes can be simultaneously loaded.

The CRC unit supports the following set of polynomials:

CRC32: $X^{32}+X^{26}+X^{23}+X^{22}+X^{16}+X^{12}+X^{11}+X^{10}+X^8+X^7+X^5+X^4+X^2+X+1$

CRC16: $X^{16}+X^{15}+X^2+1$

CCITT16: $X^{16}+X^{12}+X^5+1$

IS136: $X^{12}+X^{10}+X^8+X^5+X^4+X^3+1$

CRC10: $X^{10}+X^9+X^5+X^4+X+1$

CRC8: X^8+X^2+X+1

parity: X^8+1

46.5.1.1 CRC Structure

The following figure describes the overall structure of the CRC unit and introduces its registers that are accessible by the SDMA core via the FUBUS.

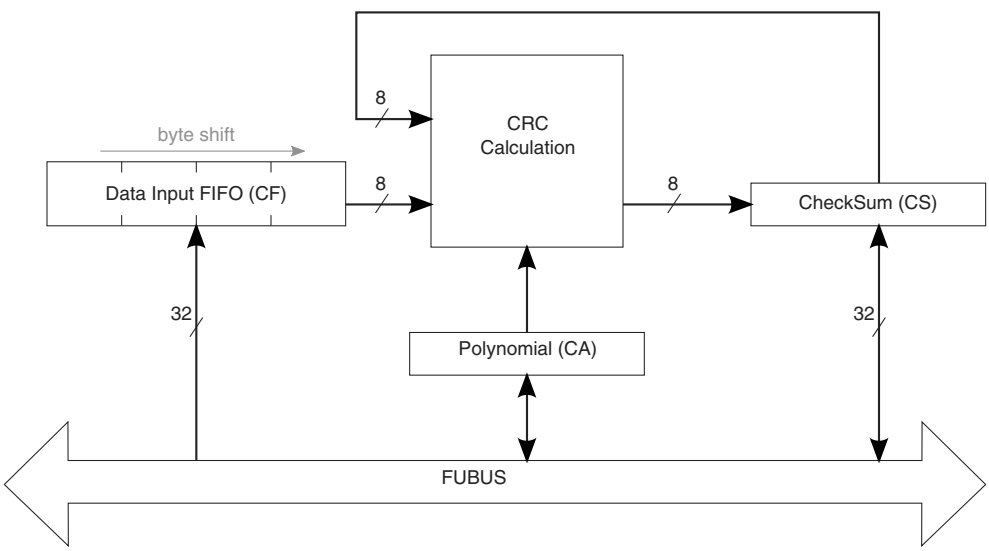

Figure 46-9. CRC Structure

46.5.1.2 CRC Data Processing

CRC processing requires the following three stages:

1. The preliminary initialization stage consists of selecting the desired polynomial, and storing the initialization pattern into the checksum register.
2. Data processing itself, which comes to feeding incoming bytes to the CRC input FIFO - bytes can be written one at a time (8-bit write access from the SDMA core), by pairs (16-bit write), or groups of four (32-bit write). One byte is processed every

cycle: Any subsequent access may stall the SDMA core until completion of the previous calculation.

3. The CRC result (or checksum) can be retrieved at any time, but all data must be processed before it is made available.

46.5.1.3 CRC Registers

The CRC enables reading and writing to three register addresses, which trigger the operations described in CRC Data Processing. The following are the three registers:

- *CA (CRC algorithm)*-The CA selects the desired polynomial. Reading and writing this register correspond to retrieving and changing the polynomial.
- *CS (CRC checksum)*-Writing to this register initializes the checksum accumulator, and reading this register yields the result from the CRC calculation (the result width depends on the polynomial size).
- *CF (CRC FIFO)*-Writing to this register loads the data into the input FIFO and triggers the CRC calculation process. It is not possible to read this register.

46.5.1.4 CRC Summary

Every operation mentioned in CRC Registers takes time to be executed by the CRC unit.

When the CRC receives a command, it immediately acknowledges the SDMA core provided it is not busy completing a previous operation. Therefore, wait-states are inserted by the CRC when a command succeeds another command that is not yet competed.

The following table lists the number of cycles that the CRC takes to execute every possible command. When an operation lasts one cycle, it means the CRC is able to process another command in the next clock cycle (for example, no wait-state is inserted by the CRC because of the former operation that is processing).

Table 46-5. CRC Processing Summary

Operation	Command	Delay	Comments
Set the polynomial	Write CA	1	
Retrieve the polynomial	Read CA	1	
Initialize the checksum	Write CS	1	
Retrieve the checksum	Read CS	1	
Store 1 byte to process	Write CF	1	
Store 2 bytes to process	Write CF	2	CRC is busy for 1 cycle

Table continues on the next page...

Table 46-5. CRC Processing Summary (continued)

Operation	Command	Delay	Comments
Store 4 bytes to process	Write CF	4	CRC is busy for 3 cycles

46.5.2 Burst DMA Unit

The burst DMA unit enables the SDMA core to perform data transfers to and from the ARM platform memory.

It is optimized for accessing SDRAM-like devices. It does not provide control to assign a privilege level to the DMA access. The burst DMA unit provides the SDMA with means to do the following:

- Perform up to 8-beat read and write bursts to the ARM platform memory, which optimizes throughput when accessing SDRAM-type devices because of an internal, 36-byte FIFO
- Access the ARM platform memory at once or twice the SDMA core frequency
- Copy data from one ARM platform memory location to another ARM platform memory location at the ARM platform bus speed, which provides a very high throughput
- Control the method for addressing the ARM platform memory (automatic increment of addresses or frozen addresses-the former aimed at accessing RAM-like memory and the latter aimed at accessing single-address FIFOs)
- Enable or disable automatic prefetch when reading data from the ARM platform memory. When the prefetch mode is selected, the burst DMA automatically triggers external bursts to fill its FIFO without waiting for the SDMA core to request the corresponding data, greatly improving throughput.
- Rely on the DMA to automatically flush its FIFO content when there is enough data to generate an 8-beat burst to the ARM platform memory. Or, it forces a flush when a data transfer must terminate.
- In the former case, the SDMA core may only be stalled when it tries writing data and there is not enough room left in the FIFO. In the latter case, the core is stalled until the data is effectively written to the ARM platform memory.

In automatic flush mode, the core receives an acknowledge that does not reflect the actual error status when the data is effectively written into the ARM platform memory. This error status is retrieved by a later access to the burst DMA. Terminating a write data transfer with a forced flush command guarantees that any bus error to the ARM platform memory is caught.

- Handle address alignment issues between the ARM platform memory map and the SDMA core data. This enables the core to read or write 32-bit data from the burst DMA, whereas the corresponding ARM platform address is not 32-bit aligned. This drastically improves the SDMA scripts' efficiency since the same loop that transfers 32 bits at a time can be used regardless of the start and end addresses in the ARM platform memory space.

This unit structure and registers are described in Burst DMA Structure and Burst DMA Registers.

46.5.2.1 Burst DMA Structure

The burst DMA is essentially made up of a 36-byte FIFO, address registers, and a controlling state-machine. The 36-byte FIFO enables eight-word buffering with address alignment, and the state-machine manages clock adaptation when required.

The burst DMA is depicted in the figure below.

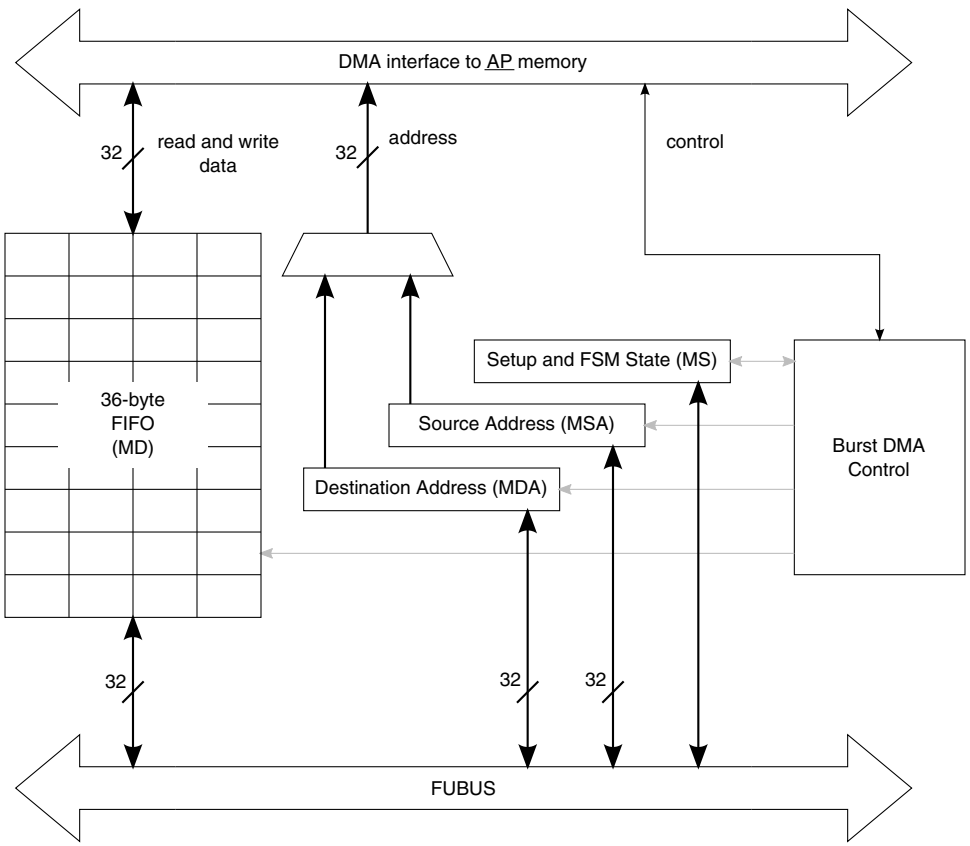

Figure 46-10. Burst DMA Structure

46.5.2.2 Burst DMA Registers

There are four registers, as follows, that may be accessed from the SDMA core:

- MSA (Memory Source Address) - Holds the source byte address in the ARM platform memory map for reading data from this location. This register is automatically modified every time the core reads new data from the FIFO.
- MDA (Memory Destination Address) - Holds the destination byte address in the ARM platform memory map for writing data to this location. This register is automatically modified every time the core writes new data into the FIFO.

- MD (Memory Data) - Labels the 36-byte FIFO access point: Reading a byte, halfword, or word from MD respectively retrieves the first 1, 2, or 4 bytes of the FIFO (for example, the bytes that were stored first by the DMA state-machine when transferring data from the ARM platform memory).
- When the FIFO does not hold as many bytes as required by the SDMA core, the core is stalled until the missing bytes are read from the ARM platform memory. In the case of prefetch mode, the DMA controller decides when it should start a burst to ARM platform memory in order to reduce the risk to not have the required data for the future accesses of the core. When there is no prefetching, a burst is triggered when the required data is not available in the FIFO.

  Writing a byte, halfword, or word to MD stores 1, 2, or 4 bytes, respectively, at the end of the FIFO (for example, these bytes are transmitted to the ARM platform memory after all the other bytes that were previously stored in the FIFO). When the FIFO does not have enough room left to hold the written data, the SDMA core is stalled until a sufficient amount of FIFO contents are flushed out to the ARM platform memory. Flushing is decided by the DMA controller when there are enough bytes in the FIFO to perform the largest allowed burst to ARM platform memory (the exact size depends on the burst start address and the AHB 1 Kbyte boundary rule). However, the SDMA core has the ability to force the flushing operation at any time, for example, when at the end of the data transfer, prior to channel closure.

- MS (Memory Setup) - Contains the state of the burst DMA control, the two flags that define whether each address register is incremented after every access to the external memory, and another flag that is set when a bus error occurred.

46.5.2.3 Burst DMA Data Transfers

Three typical usages have been identified that involve the burst DMA: the data transfer startpoint, the endpoint, or both.

Every case requires a different procedure, as listed in the following sections:

46.5.2.3.1 Data Retrieval from the ARM platform Memory

The following steps retrieve data from ARM platform memory using the burst DMA unit:

- Set up the MS flags to reflect the mode for the source address (incremented or frozen according to the type of accessed device: memory or peripheral FIFO), then initialize the source address register itself (MSA).
- Read data from the FIFO using the *ldf MD* instruction as many times as needed. If an error occurred during the fetch from ARM platform memory, the DMA control tags

the error status on the data and the SDMA core SF flag is set when reading this data from the FIFO.

46.5.2.3.2 Storing Data Into the ARM platform Memory

The following steps store data from ARM platform memory using the burst DMA unit:

- Set up the MS flags to reflect the mode for the destination address (incremented or frozen according to the type of accessed device: memory or peripheral FIFO), then initialize the destination address register itself (MDA).
- Store data into the FIFO using the *stf MD* instruction as many times as needed.
- When the transfer is finished and if the DMA worked in automatic flush mode, force the flush of the FIFO. This instruction is stalled until all the FIFO data is effectively sent to the ARM platform memory and the error status of the transfer is available in the DF flag.

46.5.2.3.3 Transferring Data Between Two ARM platform Memory Locations-Burst DMA Unit

The following steps copy data between two ARM platform memory locations using the burst DMA unit:

- Set up the MS flags to reflect the modes for the source and destination addresses (all the combinations are possible), then initialize the source address register (MSA) and the destination address register (MDA). Both addresses must be word-aligned.
- Use as many *stf MD* instructions with the *COPY* flag as needed. Every instruction triggers a burst read of a given number of words from the source address (this number is provided to the burst DMA via the SDMA core general purpose register, which is referenced in the *stf* instruction). Once all the data is loaded into the FIFO, the DMA empties it with a write burst of the same count to the destination address. The DMA acknowledges prior to instruction completion, which frees the SDMA core for other tasks at no delay cost.
- Once the transfer is done, there should be a final access to the burst DMA to check the error status.

46.5.3 Peripheral DMA Unit

The peripheral DMA unit is the second functional unit that connects the SDMA to the ARM platform memory.

Unlike the burst DMA, it does not support burst transfers and is optimized for accessing peripherals. It does not provide control to assign a privilege level to the DMA access. Its feature list comprises the following:

- Access to the ARM platform peripherals or memory at once or twice the SDMA core frequency
- Data copy from one ARM platform memory location to another ARM platform memory location at memory bus speed, improving throughput
- Control of the method for addressing the ARM platform memory (automatic increment or decrement of addresses or frozen addresses, the first ones aimed at accessing RAM-like memory and the last one aimed at accessing single-address FIFOs)
- Selectable automatic prefetch when reading data from the ARM platform memory. In prefetch mode, the peripheral DMA automatically fetches another data-without waiting for the SDMA core to request it-when its data register is empty, which improves the throughput
- Selectable automatic flush. In this mode, the SDMA core may only be stalled when it tries writing data and the previous write operation is not finished yet; whereas, in forced flush mode, the core is stalled until the data is effectively written to the ARM platform memory.
- In automatic flush mode, the core receives an acknowledge that does not reflect the actual error status when the data is effectively written into the ARM platform memory or the peripheral. This error status is retrieved by a later access to the peripheral DMA. Terminating a write data transfer with a forced flush command guarantees that any bus error to the ARM platform memory has been caught.

  This unit structure and registers are described in Peripheral DMA Structure and Peripheral DMA Registers.

46.5.3.1 Peripheral DMA Structure

The peripheral DMA is made up of a 32-bit data register, two address registers, and a controlling state-machine. The state-machine manages clock adaptation, when required.

It is shown in the following figure.

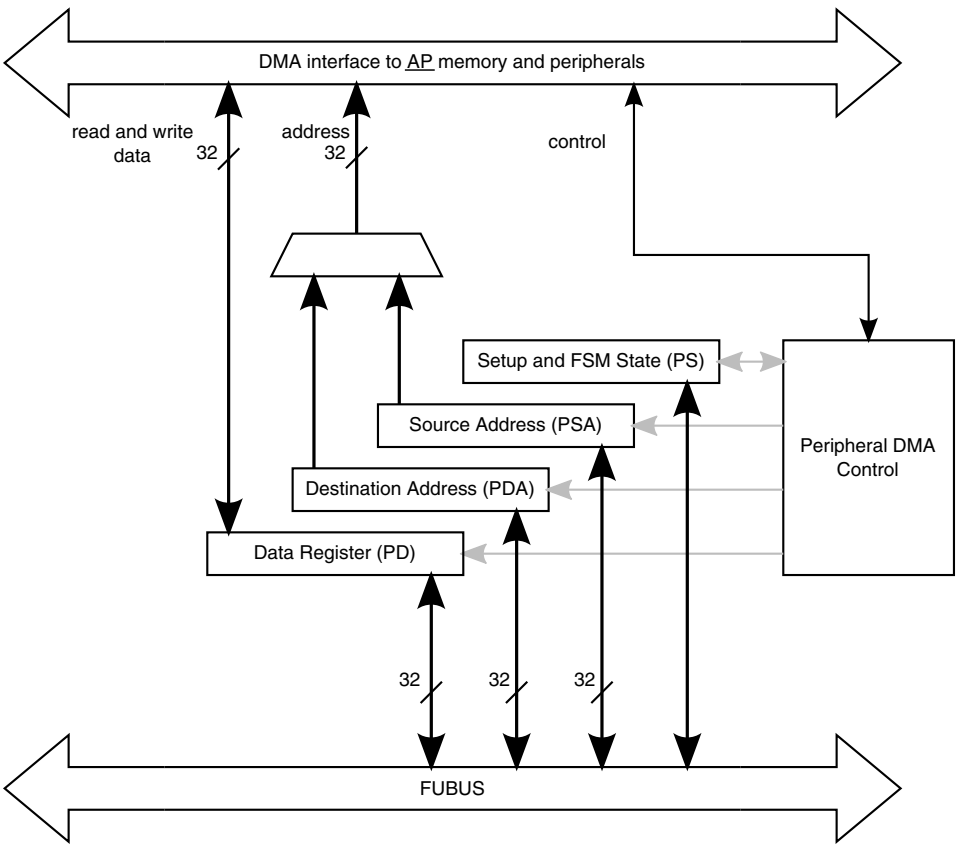

Figure 46-11. Peripheral DMA structure

46.5.3.2 Peripheral DMA Registers

According to Figure 46-11, the peripheral DMA has four registers that may be read or written by the SDMA core:

- *PD (Peripheral Data)* is the DMA 32-bit data register.
- *PSA (Peripheral Source Address)* holds the source byte address in the ARM platform memory map for reading data from this location. This register is automatically modified every time the core reads a new data from PD.

- *PDA (Peripheral Destination Address)* holds the destination byte address in the ARM platform memory map for writing data to this location. This register is automatically modified every time the core writes a new data into PD.
- *PS (Peripheral Setup)* contains the state of the peripheral DMA control, two configuration fields that define the way address registers are modified after every data access, two additional configuration fields that define the data size to access the source and destination devices, and another field that contains the latest transfer error status.

46.5.3.3 Peripheral DMA Data Transfers

There are three typical usages that involve the peripheral DMA, whether it is the data transfer start-point, endpoint, or both.

Every case requires a different procedure, as described in Data Retrieval from the ARM platform Memory or Peripheral, Storing Data into the ARM platform Memory or Peripheral, and Transferring Data Between Two ARM platform Memory Locations-Peripheral DMA Unit.

46.5.3.3.1 Data Retrieval from the ARM platform Memory or Peripheral

The following steps retrieve data from ARM platform memory using the peripheral DMA unit:

- Set up the PS fields to reflect the mode and data size for the source (incremented, decremented, or frozen address register; 8-bit, 16-bit, or 32-bit data transfers), then initialize the source address register itself (PSA) with an address that is aligned to the programmed data size.
- Read data from PD using the ldf PD instruction as many times as needed. If an error occurs during the fetch from the ARM platform memory or peripheral, the DMA control tags the error status on the data and the SDMA core SF flag is set when reading this data from PD.

46.5.3.3.2 Storing Data into the ARM platform Memory or Peripheral

The following steps store data to ARM platform memory using the peripheral DMA unit:

- Set up the PS fields to reflect the mode and data size for the destination (incremented, decremented, or frozen address register; 8-bit, 16-bit, or 32-bit data transfers), then initialize the destination address register itself (PDA) with an address that is aligned to the programmed data size.

- Store data into PD using the *stf PD* instruction as many times as needed.
- When the transfer is finished and if the peripheral DMA worked in automatic flush mode, force the flush of PD. This instruction is stalled until PD contents are effectively sent to the ARM platform memory or peripheral, and the error status of the transfer is available in the DF flag.

46.5.3.3.3 Transferring Data Between Two ARM platform Memory Locations-Peripheral DMA Unit

The following steps copy data between two ARM platform memory locations using the peripheral DMA unit:

- Set up the PS fields to reflect the modes and data size for the source and destination addresses (all the combinations of addressing modes are possible, but both data sizes must be identical), then initialize the source address register (PSA) and the destination address register (PDA). Both addresses must be aligned with the programmed data size.
- Use as many *stf PD* instructions with the *COPY* flag as needed. Every instruction triggers a single read from the source address; a single write of the received data immediately follows. The DMA acknowledges prior to instruction completion, which frees the SDMA core for other tasks at no delay cost.
- Once the transfer is done, there should be a final access to the peripheral DMA to check the error status.

46.6 SDMA Security Support

The SDMA provides support to SDMA software to block unauthorized updates to the scripts in RAM.

SDMA supports the following Security modes:

- Open Mode: has full control to load scripts and context into SDMA RAM. This is the default mode.
- Locked Mode: The ARM platform loads scripts and channel contexts at startup when it is still executing known safe software. When finished, it locks the SDMA to prevent further updates to RAM and selected registers. More details described in Locked Mode.

46.6.1 Locked Mode

The LOCK bit in the SDMA_LOCK register provides support for SDMA scripts to freeze RAM contents after the initial bootload routine to prevent future unauthorized updates to SDMA RAM.

After initial RAM contents are uploaded, ARM platform software can set the LOCK bit to secure the RAM contents to prevent future updates by an unauthorized. After the LOCK bit is written with a '1', the SDMA is "locked" until reset.

The LOCK bit can be read in the SDMA's internal memory map in the LOCK register (see Section SDMA LOCK (SDMAARM_SDMA_LOCK)). SDMA scripts which load information into RAM can check the value of the LOCK bit to determine if an upload to RAM is allowed. If not allowed, the script can refuse to allow the request to copy data into the RAM to continue. The exact use of the LOCK bit in SDMA scripts for security control will be described in SDMA software documentation (see SDMA Scripts).

While SDMA is locked, attempts to write to the SDMA_LOCK, CHN0ADR, ILLINSTADDR, and ONCE_ENB registers will be ignored. All registers remain readable. Writes to other registers are still allowed.

Once the SDMA is locked, the LOCK bit can only be cleared by a reset. A hardware reset will always clear the LOCK bit. A software reset initiated by writing to the RESET register will only clear the LOCK bit if the SRESET_LOCK_CLR bit in the SDMA_LOCK register is set. Since SDMA_LOCK register cannot be updated if SDMA is locked, the SRESET_LOCK_CLR bit must be configured before setting the LOCK bit. The SREST_LOCK_CLR bit will also be cleared by resets that clear the LOCK bit.

The SDMA RISC core uses the ILLINST and CHN0ADDR registers as pointers to determine where to jump to after an illegal instruction or upon boot after a reset. The LOCK bit prevents updates to these registers to protect against unauthorized changes to these pointers.

While SDMA is locked, the ONCE_ENB register cannot be written to prevent the OnCE under ARM platform control from being used to gain access to SDMA internal memory. If ARM platform control of the OnCE is enabled before setting the LOCK bit, the ARM platform can use the ONCE for debug purpose after LOCK is set.

46.7 OnCE and PCU Debug States

The SDMA has two different debug modes in which the OnCE performs debug instructions.

Refer to Figure 46-4 for an example of the PCU states in debug. The following are the two debug states:

- When a channel is running (that is, when CCR and CCPRI are different from 0, which can be read in the PSW register), SDMA can execute a SoftBkpt instruction from the channel script or receive a debug request. When either happens, the SDMA enters its "Classical" *Debug* state, which is described in OnCE and Real-Time Debug.
- When a channel is not running, the SDMA can be in *Sleep* state or in *Sleep after Reset* state. If a debug request is sent to the core, it enters its *Debug in Sleep* state. This debug mode works similarly to the "Classical" *Debug* state, except it returns to the original state (*Sleep* or *Sleep after Reset*) when the debug mode is left via the exec_core instruction of the OnCE. From this *Debug in Sleep* state, the SDMA can execute a program whereas no channel is running. If a new debug request is sent to the core or if a SoftBkpt is executed, it comes back to this *Debug in Sleep* state.

The OnCE is provided with several instructions that can be executed when the core is in either debug state. The following table summarizes the behavior of these OnCE debug instructions. There exists other secondary OnCE instructions that are described in OnCE and Real-Time Debug.

Table 46-6. SDMA in Debug Mode

Instruction	Debug	Debug in Sleep
exec_once	exec_once <instruction> SDMA executes the <instruction> and returns to the *Debug* state. The Program Counter (PC) is not incremented. This command must not be used with an instruction that modifies the PC value.	exec_once <instruction> SDMA executes the <instruction> and returns to the *Debug in Sleep* state. The Program Counter (PC) is not incremented. This command must not be used with an instruction that modifies the PC value.
run_core	run_core <instruction> SDMA executes the <instruction>, leaves the *Debug* state and continues executing the channel script from the position where it stopped. This command must not be used with an instruction that modifies the PC value.	run_core <instruction> SDMA executes the <instruction> and returns to its *Sleep* or *Sleep after Reset* initial state. This command must not be used with an instruction that modifies the PC value.
exec_core	exec_core <instruction> It is similar to run_core except it requires an instruction that changes the PC value (jump, branch...): the SDMA jumps to the new PC value, leaves the *Debug* state and starts executing instructions from this new PC value.	exec_core <instruction> If the previous state was *Sleep after Reset*, the SDMA returns to this state, and Chn0Addr value overrides the PC value. Otherwise, the SDMA jumps to the new PC value and starts executing instructions from this new PC.

NOTE

The feature exec_core in *Debug in Sleep* after *Sleep after Reset* was added for the Channel boot (channel 0) to allow the debugger to return to *Sleep after Reset* state with a new PC

value. The SDMA will be ready to boot at the Chn0Addr address.

46.8 SDMA Clocks and Low Power Modes

The SDMA receives several root clocks from the SoC clock controller block and performs adaptive clock gating to optimize its power consumption. From a user standpoint, clock gating and power mode selection are fully automatized inside the SDMA.

Root clock control is available from the SoC clock controller block.

There are numerous clock sources that are used in the SDMA. They belong to one of two possible clock domains listed in the following table, and have frequency constraints within each domain. Clocks are considered asynchronous between domains.

Within the ARM platform/SDMA clock domain, all clocks must come from the same DPLL. The ARM platform DMA interfaces (peripheral DMA and burst DMA) receive their clock from the ARM platform DMA clock source whose frequency can be once or twice the frequency of the SDMA core clock. The DMA interfaces are designed to work at the ARM platform DMA frequency, but the SDMA core is physically limited to a maximum 104 MHz frequency. Since this is lower than the maximum ARM platform DMA frequency, the SDMA core clock is tied to the ARM platform peripheral clock frequency.

The ARM platform Peripheral Bus Clock source must be an exact sub-frequency of the SDMA Core clock source (any integer value greater or equal to 1).

Table 46-7. Clocking Scheme

Clock Domain	Source Clock	Comments
ARM platform	SDMA core (SDMA main core)	Source clock for the core and all its operations; this clock is thus used by most of the SDMA sub-blocks.
	ARM platform DMA	DMA interface for the peripheral DMA and the burst DMA. It is balanced with the main clock source, and its frequency is either once or twice the main clock frequency.
	ARM platform peripheral	Connection to the ARM platform peripheral bus. It is a sub-frequency of the main clock frequency.
JTAG	TCK	Clock for JTAG access, limited to maximum of 1/8 of the SDMA core clock frequency.

The JTAG clock is sampled by the SDMA main clock to determine its rising edge. This simplifies design and clock management, but it also adds a ratio constraint between those two clocks. It is guaranteed the JTAG interface works properly when the frequency of TCK is lower than $1/8^{th}$ of the frequency of the SDMA main clock (which is about 8 MHz when the SDMA core clock frequency is 66 MHz).

46.8.1 Clock Gating and Low Power Modes

The SDMA automatically performs power saving without requiring user involvement. It implements two levels of automatic clock gating.

46.8.1.1 Coarse Clock Gating

Every sub-block clock comes from one of the five available sources, and is gated with the sub-block specific enabling condition.

The following table displays the sub-block clocks and their source. It also indicates the relationships that may exist between different sub-blocks clock enables.

Table 46-8. Sub-blocks Clocks

Sub-block	Source Clocks	Enabling Condition and Comments	Related Enabling Conditions
Core	SDMA Main Core	The core sub-block clock is running when the core is not in one of its sleep states (Sleep or Sleep after Reset) or there is a pending channel. Typically, the core sub-block clock is stopped once all the channels are processed and the core enters its sleep state. A new pending channel awakes the core sub-block clock.	None
Memories	SDMA Main Core	The clock activation only occurs during a core access.	Disabled when Core sub-block clock is disabled or no memory access in progress
Scheduler	SDMA Main Core	Its clock only runs when scheduling is needed: for example, when there are pending channels, upon reception of a DMA request, and anytime the ARM platform modifies the channel running conditions.	None
ARM platform Control	SDMA Main Core & ARM platform peripheral	The ARM platform peripheral clock is solely used to determine the frequency ratio with the SDMA main clock. The control registers' clock is based on *SDMA main clock*; it is active when the ARM platform or the SDMA modifies the contents of one of these registers.	None
CRC	SDMA Main Core	The CRC clock is based on *SDMA main clock* and is only active during data processing.	Disabled when Core sub-block clock is disabled

Table continues on the next page...

Table 46-8. Sub-blocks Clocks (continued)

Sub-block	Source Clocks	Enabling Condition and Comments	Related Enabling Conditions
Burst DMA	SDMA Main Core & ARM platform DMA	The burst DMA has two clocks: The first clock is derived from the SDMA main core clock and drives registers that are connected to the FUBUS. The second clock is derived from the ARM platform DMA clock and drives registers that are connected to the ARM platform DMA bus outside the SDMA. Both clocks are enabled during active phases of data transfers (for example, these clocks are turned off when the burst DMA is not used by the running channel script).	Disabled when Core sub-block clock is disabled
Peripheral DMA	SDMA Main Core & ARM platform DMA	The peripheral DMA has two clocks: The first clock is derived from SDMA main clock and drives registers that are connected to the FUBUS. The second clock is derived from the ARM platform DMA clock and drives registers that are connected to the ARM platform DMA bus outside the SDMA. Both clocks are enabled during active phases of data transfers (for example, these clocks are turned off when the peripheral DMA is not used by the running channel script).	Disabled when Core sub-block clock is disabled
OnCE	SDMA Main Core	The OnCE clock is derived from main source clock. It is disabled by default. In order to use the OnCE, its clock must be explicitly turned on, either by enabling the OnCE access from the ARM platform peripheral bus (register ONCE_ENB), or by driving the clk_gating_off input pin high. This is a SDMA input whose driver depends on the SoC implementation (typically a JTAG controller). The OnCE also receives the TCK input, which is the JTAG clock. It does not use it as a functional clock; the TCK input is sampled instead. Refer to Synchronization Implementation.	When enabled, all other clocks are systematically on (clock gating is off)

46.8.1.2 Refined Clock Gating

The SDMA implements a second level of clock gating on a register-per-register basis.

Unlike the first level that covers all the SDMA flip-flops, except the synchronizers (only five flip-flops are always running), the second level is only available for eligible registers, which amounts to about 90% of the SDMA flip-flops.

These gated registers are only clocked when the hardware logic detects a new data loading. This additional gating further reduces dynamic power consumption.

46.8.1.3 Low Power Modes and User Control

Power savings are automatically managed by the SDMA hardware without any user involvement; however, one can distinguish three different power modes: SLEEP, RUN, and DEBUG.

The following table describes these modes, and shows how to switch from one mode to another.

Table 46-9. Power Modes

Power Mode	Sub-blocks								Comments
	Core	Memories	Scheduler	ARM platform Control	CRC	Burst DMA	Peripheral DMA	OnCE	
SLEEP	off[1]	off	wait[2]	wait	off	off	off	off	Set when the PCU state is either *Sleep* or *Sleep after Reset* and the SDMA is not in DEBUG mode. This is the default mode after reset.
RUN	on[3]	wait	wait	wait	wait	wait	wait	off	Set for the other PCU states that are reachable out of debug: *Program*, *Data*, *Change of Flow*, *Error in Loop*, *Debug*, *Functional Unit*, *Save,* or *Restore*.
DEBUG	on	on	on	on	on	on	on	on	Set regardless of the PCU state when clock gating is turned off to use the OnCE features (either *clk_gating_off* pin high or ONCE_ENB[0] set).

1. *off*: no clock
2. *wait*: only clocked when accessed or stimulated
3. *on*: clock is always running

It is possible to control the SDMA power mode. The procedures to force the SDMA into either mode are described in SLEEP Mode.

46.8.1.3.1 SLEEP Mode

This is the default mode after reset; therefore, resetting the SDMA forces this mode.

However, the common procedure is as follows:

- Ensure the *clk_gating_off* pin is low and ONCE_ENB[0] is cleared.
- Disable all channels (via the STOP_STAT control register, and the HO, DO, EO if necessary).
- Wait for the active channels to complete or force a reschedule via the reschedule bit in the RESET register.
- The SDMA is in SLEEP mode making it possible to completely shut off its clock from the chip level clock controller using the procedure described in Stop Mode Response.

46.8.1.3.2 RUN Mode

This is the default mode when a channel is running:

- Ensure the *clk_gating_off* pin is low and ONCE_ENB[0] is cleared.
- Activate at least one channel (via the HSTART control registers, a DMA request, and/or the HO, DO, EO register bits).

46.8.1.3.3 DEBUG Mode

The DEBUG mode must be set when one needs to use the debugging facilities of the SDMA.

- Ensure the SDMA clocks are running from the CCM.
- Set the *clk_gating_off* pin high or use the SDMA to set ONCE_ENB[0].

46.8.1.4 Stop Mode Response

The SDMA receives a stop request from the chip level clock controller. This request may be asserted when the chip enters the stop low power mode.

If the SDMA is running when the request is received, then the SDMA will complete all pending channels before returning to the SLEEP state. The SDMA sends an acknowledgement to the clock controller when the SLEEP state is entered indicating that the SDMAs clocks can be turned off.

46.8.2 Reset

After reset (either received from the reset block or a software reset required by the ARM platform), the SDMA is in IDLE mode. It will start its boot code located at address 0 once a channel is activated.

Activating a channel can be done by the ARM platform after programming a positive priority and setting the channel bit in the EVTPEND register.

There will not be a context RESTORE for the first channel (bootload channel) called after a reset because the context data in RAM has not been initialized. Static context mode should be used for the first channel called after reset to ensure that the all context RAM for that channel is initialized. Subsequent calls to the same channel or different channels may use any of the dynamic context modes

46.9 Software Interface

Appendix A fully describes the SDMA Application Programming Interface (API).

46.10 Initialization Information

This section discusses the following:

- Hardware Reset
- Channel Script Execution
- Initialization and Script Execution Setup Sequence

46.10.1 Hardware Reset

After reset, the program RAM, context RAM, data RAM, and RAM containing the channel enable registers (CHNENBLn) have unpredictable contents.

The active register set is assigned to channel 0 and the PC is initialized to all zeros. However, since the channel enable register is all zeros, there are no active channels and the SDMA is halted waiting for the boot channel to start.

The ARM platform will have to setup the SDMA in order to boot it. The CONFIG register must be initialized to determine the DMA/core clock ratio (1 or 2). Channel Enable Registers must also be initialized.

To start up the SDMA, the ARM platform first creates some channel control blocks (CCB) and buffer descriptors (BD) in ARM platform memory for the boot channel (channel 0) and then initializes the channel 0 pointer register (SDMA_MC0PTR) to the address of the first control block. Data Structures for Boot Code and Channel Scripts provides an overview of the data structure for the CCB and BD's. The SDMA_HSTART, SDMA_HOSTOVR and SDMA_EVTOVR registers are then configured according to Runnable Channels Evaluation to allow channel 0 to run.

Upon being enabled, the SDMA begins executing the script located at the address indicated by the Channel 0 Boot Address register (SDMA_CHN0ADDR) in the program memory. The reset value of SDMA_CHN0ADDR points to the default bootload script in ROM. This ROM script will read the channel 0 pointer register (SDMA_MC0PTR) to determine the location of the Channel Control Block (SDMA_CCB) in ARM platform memory. The script will then begin fetching by DMA the first channel control block which contains a pointer to the location channel 0 Buffer Descriptor chain which is also fetched via DMA. If the buffer descriptor contains a valid command, the script interprets the command in each buffer descriptor and proceeds to implement the command and move on to the next buffer descriptor control block. The buffer descriptor commands for

channel zero are typically set up to load SDMA's program RAM, Data RAM, and initial values for the channel contexts. Some channel scripts expect particular parameters to be passed

There are two ways to make the SDMA boot on a user-defined script. The OnCE (either via its JTAG interface or its ARM platform Control interface) can be used to download any code in the SDMA RAM and force the SDMA to boot on that code. Also, the SDMA_CHN0ADDR register in the ARM platform programming model can be modified to point to user code in RAM which would need to either have been loaded via the ONCE or default bootload routine (ex before a S/W reset).

46.10.2 Channel Script Execution

The execution of an SDMA script depends on both the instructions that make up the script, the data context upon which it operates, and commands or parameters passed in the buffer descriptor or. All these items must be initialized before the script is allowed to execute.

Each of the 32 channels has a separate context, but may share scripts and locations in data RAM.

Channels are initialized by the ARM platform by using channel 0 to download any required scripts and data values and the channels initial context. The context contains all the initial values of the SDMA core registers. This includes the Program Counter (PC) which is set to the start of the desired script in SDMA program memory.

The ARM platform selects which trigger conditions that must occur for the channel to start by configuring the SDMA_CHNENBL, SDMA_HOSTOVR and SDMA_EVTOVR registers. The trigger events include ARM platform setting HE (SDMA_HSTART) or a hardware DMA request asserts an event input to SDMA. The channel can become active according to its priority compared with other runnable channels when the selected trigger(s) cause the condition described in Runnable Channels Evaluation to evaluate as true.

The specific parameters to be passed to each script in the buffer descriptor or context are documented in the software documentation for each script. Please refer to SDMA Scripts for complete script documentation. Buffer Descriptor Format provides an overview of the buffer descriptor format.

46.10.3 Initialization and Script Execution Setup Sequence

To summarize, the following steps are minimally required to setup SDMA and run channel scripts.

- Perform Hardware Reset. The program RAM, context RAM, data RAM and SDMA_CHNENBLn registers have unpredictable contents after this reset.
- Initialize SDMA_CHNENBLn registers to map DMA request events to desired channels.
- Configure SDMA_CHNPRIn registers to select priority for runnable channels, A non-zero priority is required for the channel to run.
- Configure the SDMA_CONFIG register to select DMA to SDMA core clock ratio .
- Set up channel control blocks and buffer descriptors in ARM platform to specify the loading of SDMA program RAM and channel contexts for each SDMA channel to be used. Reference Data Structures for Boot Code and Channel Scripts.
- Configure SDMA_MC0PTR register with base address of ARM platform Channel Control Block base address.
- Initialize SDMA_CHNENBLn registers to map DMA request events to associated channel. Reference Mapping DMA Requests to Pending Channels.
- Configure SDMA_CHNPRIn registers to set priority for each channel to be run.
- For each channel to be run, configure SDMA_HOSTOVR (HO) and SDMA_EVTOVR (EO) registers to select which events (hardware and/or software trigger events) must occur for the channel to be runnable. Reference Runnable Channels Evaluation.
- Set bit 0 of the SDMA_HSTART register to set HE[0] and allow Channel 0 to run (assumes EO[0] andDO[0] were both set in previous step). This will cause SDMA to load the program RAM and channel contexts configured previously.
- Wait for Channel 0 to finish running. This is indicated by HI[0]=1 in the SDMA_SDMA_INTR register, or by optional interrupt to the ARM platform.
- Set the LOCK bit in the SDMA_SDMA_LOCK register to prevent un-authorized uploads of data to SDMA RAM.
- Additional channel scripts can now be run by enabling the selected software or hardware trigger event according to Runnable Channels Evaluation.

46.11 SDMA Programming Model

The following section describes the programming model for the SDMA RISC engine, including its processor, memory, and internal control registers.

All addresses are related to the internal SDMA memory map, which is completely different from the ARM platform memory maps. The ARM platform processor has no access to any hardware resource described, except when those resources are described in ARM Platform Memory Map and Control Register Summary. .

46.11.1 State and Registers Per Channel

The SDMA can be seen as a set of 32 identical devices that are able to perform one data transfer channel each. Only one channel can work at a time, but every channel state is available at any time.

This chapter lists the components of every channel state.

46.11.2 General Purpose Registers

Each channel has eight general purpose registers of 32 bits for use by scripts. General register 0 has a dedicated function for the loop instruction, but otherwise can be used for any purpose.

46.11.3 Functional Unit State

Each channel context has some state that is part of the functional units.

The specific allocation of this state is part of the functional unit definition that is described in Burst DMA Unit Programming, Peripheral DMA Unit Programming .

This state must be saved/restored on context switches.

46.11.3.1 Program Counter Register (PC)

The PC is 14 bits. Since instructions are 16 bits in width and all memory in the SDMA is 32 bits in width, the low order bit of the PC selects which half of the 32-bit word contains the current instruction.

A low order bit of zero selects the most significant half of the word.[1]

1. For example, big-Endian.

46.11.3.2 Flags

Each channel has the following four flags:

- The T bit reflects the status of some arithmetic and test instructions. It is set when the result of an addition or a subtraction is zero and cleared otherwise. It is also the copy of the tested bits. Finally, it can also be set when the loop counter (GReg0) reaches zero. When the last instruction of the hardware loop is an operation that can modify the T flag, its effect on T is discarded and replaced by the GReg0 status.
- Two additional bits, SF and DF, are used to indicate error conditions resulting from loading data sources and storing to destinations, respectively. Access errors set these bits, and successful transactions clear them. They can also be cleared by specific instructions (CLRF and loop). The source fault (SF) is updated by the loads LD and LDF; the destination fault (DF) is updated by the stores ST and STF.
- Access errors are caused by several conditions including writing to the ROM, writing to a read-only memory mapped register, accessing an unmapped address, or any transfer error received by a peripheral when it is accessed.

  The SF and DF flags have a major impact on the behavior of the hardware loop: If SF or DF is set when starting a hardware loop and it is not masked by the loop instruction, the loop body will not be executed. Inside the loop body, if a load or store sets the corresponding SF or DF flag, the loop exits immediately. Testing the status of the T flag at the end of the loop (as well as testing both SF and DF) tells if the loop exited abnormally as any anticipated exit prevents GReg0 from reaching the zero value and thus setting the T flag. This is also valid if the fault occurs at the last instruction of the last loop.

- The last flag is the loop mode flag, LM, which is composed of two bits. The most significant bit indicates when the processor is currently operating in loop mode. It is set by the loop instruction and is cleared after execution of the last instruction of the last loop. The least significant bit is set when the program counter points to the last instruction of a loop on the last path. It is used for a channel that is restored with this configuration to know that the next program counter is EPC. As with the dynamic context switch Greg0, which indicates when the program must get out of the loop, it can be restored only on the last instruction of the loop. This, however, is too late to fetch the next instruction after the loop.

46.11.3.3 Return Program Counter (RPC)

The RPC is 14 bits. It is set by the jump to the subroutine instructions and used by the return from the subroutine instructions.

Instructions are available to transfer its contents to and from a general register.

46.11.3.4 Loop Mode Start Program Counter (SPC)

The SPC is 14 bits. It is set by the loop instruction to the location immediately following it.

46.11.3.5 Loop Mode End Program Counter (EPC)

The EPC is 14 bits. It is set by the loop instruction to the location of the next instruction after the loop.

46.11.4 Context Switching-Programming

Each channel has a separate context consisting of the eight general purpose registers and additional registers representing the state of the functional units.

The active registers and functional units contain the context of the active channel. The context of inactive channels is stored in SDMA RAM, which is part of the SDMA address space.

In a function of the selected context switching mode (Context Switching), modified registers by the program can be saved in the channel RAM space while the program is going on. In every cycle, a write access to the RAM is possible.

On a done or yield(ge) instruction, SDMA goes into "real" context switching. In one of the dynamic modes, modified registers not previously saved, as well as the PC-Loop registers, are stored into the context area of the channel that will be closed. The new PC-Loop registers are loaded from the context area of the new channel. All other registers are restored while the program is executed, giving priority to registers used by the decoded instruction. Therefore, in the best case, only the PC and Loop registers should be saved and restored during this context-switching phase, which only requires five SDMA cycles.

In static mode, the context switch stores all registers in the old channel RAM space, and restores all registers from the new channel RAM space. It requires 26 SDMA cycles.

The address of the context memory for channel *i* is *CONTEXT_BASE* + 24**i* or *CONTEXT_BASE* + *32*i w*here CONTEXT_BASE equals 0x0800. The table below presents the layout of a channel context in memory:

Table 46-10. Layout of a Channel Context in Memory for SDMA

46.11.5 Address Space

The SDMA has four internal buses, as follows:

- The Instruction bus reads instructions from the memory. Its address map is described in Instruction Memory Map.
- The Data bus (DMBUS) accesses the same memories as those visible on the Instruction bus, some memory-mapped registers (scheduler status and OnCE registers), and up to 14 peripherals. Its address map is described in Data Memory Map.
- The Functional Units bus (FUBUS) accesses the burst DMA, peripheral DMA, and CRC internal registers. The addressing mechanism is further detailed in Functional Units Programming Model.
- The Context Switch bus reads/writes registers into context-switch RAM space. It is a 64-bit bus dedicated for accessing this RAM space for updating the context of the running channel. While the program is going on, this bus has the lowest priority compared to the Instruction and Data buses, except for restoring a register needed for the decoded instruction to be executed. On the save part of a context switch (when the PCU is in its slave state), this is the only one used. On the restore part, the Instruction bus has the priority to read the next instruction at the restored PC and otherwise the Context Switch bus is used. It is not possible to control the actual data transfers that occur on this bus.

46.11.5.1 Instruction Memory Map

The instruction memory map is based on a 14-bit address bus and a 16-bit data (instruction) bus. Each address corresponds to a 16-bit data location.

Instructions are fetched from either program ROM or program RAM. An SDMA script is able to change the contents of the program RAM, which is also visible from the data bus.

The first two instruction locations (at 0 and 1) are special. Location 0 is where the PC is set on reset. Location 1 is where the PC is set upon the execution of an illegal instruction. It is expected that both of these locations will contain a jmp to handle routines.

Table 46-11. SDMA Instruction Memory Space

Device	SDMA Address (Hex)	Base Address Label	Block Name	WS	Description
ROM	0x0000 ↓ 0x07FF	SDMA_IBUS_ROM_ADDR	-	0	4 Kbyte internal ROM with boot code and standard routines.
RAM	0x1000 ↓ 0x1FFF	SDMA_IBUS_RAM_ADDR	-	0	8 Kbyte internal RAM with channels context and user data/routines.

46.11.5.2 Data Memory Map

All of the data accessible to SDMA scripts make up the data memory space of the SDMA.

This address space has several components:

- ROM (also visible on the Instruction bus)
- RAM (also visible on the Instruction bus)
- Shared Peripherals Registers
- SDMA Internal Registers (scheduler, OnCE, and registers that are also accessible by the ARM platform)

SDMA scripts can read and write to the context RAM, data RAM, shared peripheral registers, and internal registers.

The address range is 16 bits and the data width is 32 bits. Each address corresponds to a 32-bit data word. When accessing peripheral registers (USB and so on), the data width may be different. The exact address map for the peripherals depends on the project (as presented in each respective chapter).

The SDMA can perform only 32-bit access to shared peripheral registers. For this device, shared peripherals registers are aliased as if byte addressed. This is a consequence of connections through the SPBA shared peripheral bus outside of the SDMA. The result is that although address space 4 Kwords (16Kbyte) is allocated for each peripheral, only the first 4 Kbyte of the peripheral's register space can accessed. For example, the shared peripheral register at address 0x3000 is mapped also to addresses 0x3001, 0x3002, 0x3003. A read or write access to any of any of these 4 addresses will respond as if the access was to address 0x3000.

Data access is performed with *ld* and *st* instructions that take the address from a general purpose register in the core (GReg*n*). The mapping between the general purpose register contents and the address bus is given in the following table:

Table 46-12. GReg*n* to DMBUS Address Mapping

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
15	**14**	**13**	**12**	**11**	**10**	**9**	**8**	**7**	**6**	**5**	**4**	**3**	**2**	**1**	**0**
sz	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
address															

Grayed bits are simply discarded but they must be cleared to ensure forward-script compatibility.

- sz (bit 31) indicates the peripheral data width: 0 is used for a 32-bit peripheral and 1 is used for a 16-bit peripheral.
- address (bits 15 down to 0) is the address of the accessed resource (internal memory, internal register, or shared peripheral).

Table 46-13. SDMA Data Memory Space

Device	SDMA Address (Hex)	Size	Description
ROM	0x0000 → 0x03FF	4 Kbyte	4 Kbyte internal ROM with boot code and standard routines
Reserved	0x0400 → 0x07FF	4 Kbyte	4 Kbyte Reserved
RAM	0x0800 → 0x0FFF	8 Kbyte	8 Kbyte internal RAM with channels contexts and user data/routines
per1	0x1000 → 0x1FFF	16 Kbyte	*peripheral 1* memory space (4 Kbyte peripheral's address space)
per2	0x2000 → 0x2FFF	16 Kbyte	*peripheral 2* memory space (4 Kbyte peripheral's address space)
per3	0x3000 → 0x3FFF	16 Kbyte	*peripheral 3* memory space (4 Kbyte peripheral's address space)
per4	0x4000 → 0x4FFF	16 Kbyte	*peripheral 4* memory space (4 Kbyte peripheral's address space)
per5	0x5000 → 0x5FFF	16 Kbyte	*peripheral 5* memory space (4 Kbyte peripheral's address space)
per6	0x6000 → 0x6FFF	16 Kbyte	*peripheral 6* memory space (4 Kbyte peripheral's address space)
Registers	0x7000 → 0x7FFF	16 Kbyte	Memory mapped registers
per7	0x8000 → 0x8FFF	16 Kbyte	*peripheral 7* memory space (4 Kbyte peripheral's address space)
per8	0x9000 → 0x9FFF	16 Kbyte	*peripheral 8* memory space (4 Kbyte peripheral's address space)
per9	0xA000 → 0xAFFF	16 Kbyte	*peripheral 9* memory space (4 Kbyte peripheral's address space)
per10	0xB000 → 0xBFFF	16 Kbyte	*peripheral 10* memory space (4 Kbyte peripheral's address space)
per11	0xC000 → 0xCFFF	16 Kbyte	*peripheral 11* memory space (4 Kbyte peripheral's address space)
per12	0xD000 → 0xDFFF	16 Kbyte	*peripheral 12* memory space (4 Kbyte peripheral's address space)
per13	0xE000 → 0xEFFF	16 Kbyte	*peripheral 13* memory space (4 Kbyte peripheral's address space)
per14	0xF000 → 0xFFFF	16 Kbyte	*peripheral 14* memory space (4 Kbyte peripheral's address space)

46.12 SDMA Initialization

Appendix A describes the setup of the SDMA . This section provides a quick description of several initialization procedures.

NOTE

There may be differences with the actual implementation in the API.

46.12.1 Hardware Reset-SDMA

After reset, the RAM that holds contexts, data, scripts, and the DMA request-channels matrix has unpredictable content.

The core registers are all reset to 0, including the PC; the PCU state is *Sleep after Reset*. No channel can be activated because all of the priorities are also reset to 0.

46.12.2 Standard Boot Sequence

The following is the standard boot sequence:

1. Initialize the CONFIG register-detailed in Configuration Register (SDMAARM_CONFIG)-to determine the ARM platform DMA/core clock ratio (1 or 2)
2. Initialize the DMA request-channels matrix (seeChannel Enable RAM (SDMAARM_SDMA.CHNENBL*n*)).
3. Program the channel control registers-Channel Event Override (SDMAARM_EVTOVR), Channel BP Override (SDMAARM_DSPOVR), Channel BP Override (SDMA_HOSTOVR), and Channel Event Pending (SDMAARM_EVTPEND)-according to the channel allocation.
4. Perform any necessary setup as required by the standard boot script in ROM (this is described in Appendix A).
5. Trigger channel 0 with the Channel Start (SDMAARM_HSTART) register, which starts the execution of the ROM script starting at address 0. This boot downloads channel scripts and contexts in RAM.

46.12.3 User-Defined Boot Sequence

The following is a user-defined boot sequence:

1. Initialize the Configuration Register (SDMAARM_CONFIG)Channel Enable RAM (SDMAARM_SDMA.CHNENBL*n*), Channel Event Override (SDMAARM_EVTOVR), Channel BP Override (SDMAARM_DSPOVR), Channel ARM platform Override (SDMAARM_HOSTOVR), and Channel Event Pending (SDMAARM_EVTPEND).
2. Use the OnCE (either via its JTAG interface or its ARM platform control registers) to download any code in the SDMA RAM. Accessing the Memory describes how to write data to the RAM via the OnCE.
3. Use the OnCE instructions to make the PC default value point to the new boot script start address, or rely on the ROM startup script, which first jumps to the address in

Channel 0 Boot Address (SDMAARM_CHN0ADDR). (This register default address points to the standard boot script.)

46.12.4 Script Loading and Context Initialization

The execution of an SDMA script depends on both the instructions that make up the script and the data context upon which it operates. Both must be initialized before the script is allowed to execute.

Each of the 32 channels has a separate data context, but may share scripts and locations in the data RAM.

The ARM platform manages the space in program RAM and data RAM. It also manages the assignment of SDMA channels to the device drivers that need them. Channels are initialized by the ARM platform via the channel 0 boot script. The boot channel downloads any required scripts with their data and the channels' initial contexts. Every context contains all the initial values of the registers, including the PC. Then the ARM platform can enable any channel that becomes active and begins fetching and executing instructions from its script.

46.13 Instruction Description

The following sections introduce the instruction of the SDMA. Instruction set details are available in Instruction Set.

46.13.1 Scheduling Instructions

The following are scheduling instructions:

- done-The instruction causes certain scheduling or interrupt bits to be set or cleared, which may cause a change in the schedule-ability of the running channel. Then the instruction causes the SDMA to evaluate the current scheduling priorities and to choose the highest priority ready channel. If this channel is not the current channel, a context switch will take place. If there are no runnable channels, the SDMA will enter the stopped mode. The done 5 has a special usage reserved for debug, as explained in Debug Instructions.
- yield-These instructions are special cases of the done instruction. They do not modify the scheduling bits, but allow the highest pending channel (if it exists) to preempt the current channel if the pending channel priority is strictly greater than the current channel priority.

- yieldge-These instructions are special cases of the done instruction. They do not modify the scheduling bits, but allow the highest pending channel (if it exists) to preempt the current channel if the pending channel priority is strictly greater or equal to the current channel priority.
- notify-The notify instruction affects the scheduling bits, but does not cause rescheduling.

46.13.2 Conditional Branch Instructions

The conditional branch instructions of an 8-bit displacement, which is sign-extended and added to the current PC (which points to the next instruction) if the condition is satisfied.

Otherwise, control passes to the next sequential instruction.

- BF-Branch if False. The branch is taken if the T bit in the processor status is zero (false).
- BT-Branch if True. The branch is taken if the T bit in the processor status is one (true).
- BSF-Branch if Source Fault. The branch is taken if the SF bit in the processor status is one.
- BDF-Branch if Destination Fault. The branch is taken if the DF bit in the processor status is one.

46.13.3 Unconditional Jump Instructions

There are two varieties of unconditional control transfers: an absolute transfer and a through-register transfer.

Absolute transfers have a 14-bit address field that replaces the current PC.

- JMP-Jump. Causes the processor to jump to an absolute address encoded in the instruction itself.
- JSR-Jump to Subroutine. Causes the processor to jump to a subroutine, the address of which is encoded in the instruction itself.
- JMPR-Jump through Register. Causes the processor to jump to an absolute address contained in a General register. This instruction is meant to be used when more than one level of subroutines are required.
- JSRR-Jump to Subroutine through Register. Causes the processor to jump to a subroutine, the address of which is contained in a General register. This instruction is meant to be used when more than one level of subroutines are required.

46.13.4 Subroutine Return Instructions

The following are subroutine return instructions:

- RET-Return from Subroutine. The RET restores the contents of RPC to PC.
- LDRPC-Load from RPC to Register. THe LDRPC instruction is meant to be used when more than one level of subroutines are required. It stores the contents of RPC in any General register.

46.13.5 Loop Instruction

The following is a loop instruction:

LOOP-Enters Loop Mode. Before entering loop mode, the loop instruction can optionally clear the fault flags (SF and/or DF) based on a 2-bit field in the instruction. This feature is linked to the fact that setting SF or DF in loop mode will cause an immediate exit of the loop.

46.13.6 Miscellaneous Instructions

The following are miscellaneous instructions:

- CLRF-Clear Fault Flags. This instruction clears any combination of SF and DF.
- MOV r,s-This moves data from GReg[s] to GReg[r].
- LDI r,immediate-This loads GReg[r] with a zero-extended immediate value.

46.13.7 Logic Instructions

The following are logic instructions:

- XORr,s-This performs an exclusive or between GReg[r] and GReg[s], and stores the result in GReg[r].
- XORIr,immediate-This performs an exclusive or between GReg[r] and a zero-extended immediate value, and stores the result in GReg[r].
- ORr,s-This performs an or between GReg[r] and GReg[s], and stores the result in GReg[r].
- ORIr,immediate-This performs an or between GReg[r] and a zero-extended immediate value and, stores the result in GReg[r].

- ANDNr,s-This performs an and between GReg[r] and the negated GReg[s], and stores the result in GReg[r].
- ANDNIr,immediate-This performs an and between GReg[r] and the negated zero-extended immediate value, and stores the result in GReg[r].
- ANDr,s-This performs an and between GReg[r] and GReg[s], and stores the result in GReg[r].
- ANDIr,immediate-This performs an and between GReg[r] and a zero-extended immediate value, and stores the result in GReg[r].

46.13.8 Arithmetic Instructions

Arithmetic instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if the result is zero, otherwise it is cleared.

- ADD r,s-This performs the addition of GReg[r] and GReg[s], and stores the result in GReg[r].
- ADDI r,immediate-This performs the addition of GReg[r] and a zero-extended immediate value, and stores the result in GReg[r].
- SUB r,s-This performs the subtraction of GReg[s] from GReg[r], and stores the result in GReg[r].
- SUBIr,immediate-This performs the subtraction of a zero-extended immediate value from GReg[r], and stores the result in GReg[r].

46.13.9 Compare Instructions

Compare instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if the comparison is true, otherwise it is cleared.

NOTE

Only one version of the immediate form is implemented. Non-equality comparisons to immediate values will require two instructions.

- CMPEQ r,s-This sets T when registers GReg[r] and GReg[s] are equal.
- CMPEQIr,immediate-This sets T when register GReg[r] and the zero-extended immediate value are equal.
- CMPLTr,s-This sets T when register GReg[r] is less than and not equal to GReg[s]. The comparison is signed.
- CMPHS r,s-This sets T when register GReg[r] is greater than or equal to GReg[s]. The comparison is signed.

46.13.10 Test Instructions

Test instructions modify the T bit in the processor status according to the result of the operation. The T bit is set if any bit in the result is one, otherwise it is cleared.

- TSTr,s-This performs an and between GReg[r] and GReg[s], and sets T if the result is not zero.
- TSTIr,immediate-This performs an and between GReg[r] and a zero-extended immediate value, and sets T if the result is not zero.

46.13.11 Byte Permutation Instructions

These instructions shuffle the bytes in a register. For the purpose of describing these instructions, have the bytes in a register be numbered from the most significant as b_3, b_2, b_1, b_0.

- RORBr-The rotate right byte. The result is b_0, b_3, b_2, b_1.
- REVBr-The reverse bytes in word. The result is b_0, b_1, b_2, b_3.
- REVBLOr-The reverse, two low-order bytes. The result is b_3, b_2, b_0, b_1.

46.13.12 Bit Shift Instructions

The following are bit shift instructions:

- ROR1r-The rotate right 1 bit. This instruction does a circular right shift of 1 bit.
- LSR1r-The logical shift right 1 bit. This instruction shifts all bits to the right by 1. The high order bit is replaced by a 0.
- ASR1r-The arithmetic shift right 1 bit. This instruction shifts all bits to the right by 1. The high order bit is replaced by itself.
- LSL1r-The logical shift left 1 bit. This instruction shifts all bits to the left by 1. The low order bit is replaced by zero.

46.13.13 Bit Manipulation Instructions

- BCLRIr,n-The bit clear is immediate; clears bit number *i* in register *r*.
- BSETIr,n-The bit set is immediate; sets bit number *i* in register *r*.
- BTSTIr,n-The bit test is immediate; tests bit number *i* in register *r* (T becomes equal to the selected register bit).

46.13.14 SDMA Memory Access Instructions

All memory accesses are 32 bits.

Any memory location that is implemented with less than 32 bits (for example, peripheral registers) causes unimplemented bits to be read as 0s.

All memory accesses will cause either the SF or DF flags in the processor status to be set if they cause a fault.

What constitutes a fault, especially when accessing peripheral registers, is a property of the memory location.

- LDr,(b,d)-The load instruction creates an address by adding the displacement field (d) to the contents of the base register (b). The SDMA location at the resulting address is read and placed in the destination register (r).
- STr,(b,d)-The store instruction creates an address in the same manner as the load instruction. The register (r) is stored in the SDMA location at the resulting address.

46.13.15 Functional Unit Instructions

The functional unit instructions have an 8-bit field that is placed on the functional unit bus.

Some of these bits are used to select which functional unit should be involved in the transfer. The remaining bits are decoded by the selected functional unit so their specific use depends on the functional unit. See Functional Units Programming Model.

There are two functional unit instructions, as follows:

- LDFr,fub-The 8-bit field is placed on the functional unit bus and a read is issued to the selected functional unit. As a result of this instruction, the SF may be set in the processor status.
- STFr,fub-The 8-bit field is placed on the functional unit bus and a write is issued to the selected functional unit. As a result of this instruction, the DF may be set in the processor status.

46.13.16 Illegal Instructions

All instruction encodings that are illegal cause the following actions:

- The current PC (which points to one beyond the offending instruction) is put in the EPC register.
- The loop mode bit is cleared.
- The PC is set to the value stored in the Illegal Instruction Trap Address (SDMAARM_ILLINSTADDR) register (the default value is 0x0001).

ILLEGAL-Although any instruction other than those indicated in the SDMA specification will trigger the illegal instruction mechanism, the ILLEGAL instruction code is preferred as it will always be kept as *illegal* in the possible future versions of the SDMA core.

46.13.17 Debug Instructions

The following are debug instructions:

- SOFTBKPT-The software breakpoint instruction causes the core to stop and enter debug mode. The core can then be accessed and started by the OnCE debug block only.
- done 5-This instruction is used for debugging, as it copies the contents of the PCU registers and flags to the context memory. Information on this instruction is described in Saving the Context.
- CpShReg-This instruction copies the context memory into the PCU registers and flags. Modifying the corresponding memory location before executing this instruction enables you to have the channel continue from a new instruction address. This instruction is described in Restoring the Context.

46.14 Functional Units Programming Model

The functional unit instructions cause an 8-bit code, found in the low eight bits of the instruction, to be asserted on the functional unit control bus.

Some of these bits are used to select one of several functional units. Functional units which can be selected include SDMA registers such as MSA and MSD which are not mapped in the SDMA memory map, and are accessible only through the functional unit bus. These Functional Unit Registers are listed in the following table. In order to establish

a programming convention, assume the selection bits are some number of the most significant bits of the 8-bit code. Furthermore, some number of the least significant bits is decoded by a given functional unit to establish the type of operation to perform.

Table 46-14. Functional Unit Registers

Functional Unit	Register	Register Name	Section/Page
Burst DMA Unit Programming	SDMSA	Memory Source Address Register	Memory Source Address Register (MSA)
	MDA	Memory Source Address Register	Memory Destination Address Register (MDA)
	MD	Memory Data Buffer Register	Memory Data Buffer Register (MD) (Write) Burst DMA Write (stf) (Read) Burst DMA Read (ldf)
	MS	Memory State Register	State Register (MS)
Peripheral DMA Unit Programming	PSA	Peripheral Source Address Register	Peripheral Source Address Register (PSA)
	PDA	Peripheral Source Address Register	Peripheral Destination Address Register (PDA)
	PD	Peripheral Data Buffer Register	Peripheral Data Register (PD) (Write) Peripheral DMA Write (stf)-Write Mode (Read) Peripheral DMA Read (ldf)-Read Mode
	PS	Peripheral State Register	Peripheral State Register (PS)
CRC Unit	CA	Polynomial Register	Polynomial Register (CA)
	CS	Accumulator Register	Accumulator Register (CS)

More information regarding the functional units can be found in CRC Calculation Unit,Peripheral DMA Unit, and Burst DMA Unit.

46.14.1 Burst DMA Unit Programming

The DMA instructions control the DMA state machine and may cause a DMA cycle on the associated memory bus.

There are four registers associated with the burst DMA unit: a Memory Source Address register (MSA), a Memory Destination Address register (MDA), a Memory Data buffer (MD), and a state register (MS). The burst DMA has two different uses:

- A data transfer between External Memory Interface and SDMA general register
- A data transfer in copy mode where blocks of data are transferred from the source address to the destination address

46.14.1.1 Memory Source Address Register (MSA)

The source address register contains the pointer into EXTMC memory associated with the next read data transfer. It has byte granularity.

Reading the register with the ldf instruction has no side effects, and gives the address value in the EXTMC memory of the next data that is read by the SDMA during an ldf MD instruction.

Writing the source address register has two side effects: If the prefetch bit is set, a DMA read cycle (8-word read access) is issued with the new address. Any data still located in the buffer is lost. If there is valid write data in the buffer, it is necessary to force the DMA to completely flush it out before modifying MSA to guarantee all the data is effectively written to memory.

The MSA register has two modes of programming:

- Frozen-In frozen mode, the MSA register is not modified after DMA accesses.
- Incremented (default mode)-In incremental mode, MSA is incremented by the number of bytes transferred during read cycles.

46.14.1.2 Memory Destination Address Register (MDA)

The destination address register contains the pointer into EXTMC memory associated with the next write data transfer. It has byte granularity.

Reading the MDA register with the ldf instruction has no side effects. It gives the address value in the EXTMC memory where the next SDMA data (stf r,MD instruction) is stored when MD FIFO is flushed.

Writing the destination address register has one side effect. Any data still located in the buffer is lost. If there is valid write data in the buffer, it is necessary to force the DMA to completely flush it out before modifying MDA to guarantee all the data is effectively written to memory.

The MDA register has two modes of programming:

- Frozen-In frozen mode, the MDA register is not modified after DMA accesses.
- Incremented (default mode)-The MDA register is incremented by the number of bytes transferred during write cycles.

46.14.1.3 Memory Data Buffer Register (MD)

The data buffer register consists of a bank of 36 bytes that behave like FIFO.

This FIFO stores the eight words received when a read burst is triggered by the DMA (DMA is in read mode).

The MD register is in write mode after a writing in MDA or after an stf MD instruction.

In that case, a burst write access is automatically triggered when there are more than eight words in MD. For bandwidth optimization, any transfers between DMA and the EXTMC controller are based on burst accesses.

An ldf r,MD|SIZE instruction that reads the data buffer may cause a DMA cycle, as follows:

- If there are less bytes in the FIFO than the size parameter of the instruction. For instance, if only two bytes are available in MD and a 4-byte read is requested, a burst read access is executed to complete the two bytes.
- If the prefetch bit is set, and after reading there is enough space in the FIFO to store a full burst, a burst read access is triggered.

An stf r,MD|SIZE instruction that writes to the data buffer may cause a DMA cycle if the number of written bytes in MD is higher than 32 (eight words) or if the flush bit is set.

When DMA is used for data transfer between SDMA and EXTMC (reading or writing), no immediate error is possible because the block manages a data misalignment issue; therefore, it is allowed to read/write a word to/from a half-word address. However, the addresses (source or destination) must belong to the EXTMC memory mapping. The only potential error, in this mode, would be the error sent back by the EXTMC controller when an access to a super-user page is detected. The whole transfer on the DMA associated bus will be considered successful when there are no errors seen on the bus during the transfer. In copy mode, an immediate error could be returned to SDMA as described in Burst DMA Unit Error Management.

46.14.1.4 State Register (MS)

The state register contains the DMA state-machine value. It can be accessed in case of an error received during a transfer. MS is also accessed to set-up the conditional yielding feature.

The initialization value of this register is 0 and it consists of the following:

Table 46-15. SDMA_MS Structure

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	0	0	0	0	0	0	0	0	0	0	spriv	stype	0	0	dpriv	dtype
W																
R	0	0	0	0	y	d	e		0	0	n					
W																

Table 46-16. SDMA_MS Field Descriptions

Field	Description
31-22	Reserved
21 spriv	The spriv value is ignored for this device. 0 = valid value 1 = Reserved
20 stype	Source Mode. Indicates if MSA has to be incremented (or not) during accesses. 0 Frozen-MSA is not modified. 1 Incremented-MSA is incremented by the number of transferred bytes during read access.
19-18	Reserved
17 dpriv	The dpriv value is ignored for this device. 0 = valid value 1 = Reserved
16 dtype	Destination Mode. Indicates if MDA has to be incremented (or not) during accesses. 0 Frozen-MDA is not modified. 1 Incremented-MDA is incremented by the number of transferred bytes during write access.
15-12	Reserved
11 y	Conditional Yielding selector. When selected, theyield/yieldge instructions will not switch channels if the Burst DMA is in Write Mode, and it has less than four bytes in its FIFO. This is aimed at reducing the number of inefficient FIFO flushes due to context switches. 0 Always yields 1 Yields conditionally (when there are less than four bytes in the FIFO in write mode)

Table continues on the next page...

Table 46-16. SDMA_MS Field Descriptions (continued)

Field	Description
10 d	Access Direction or DMA Mode. DMA is in write mode when data was written into MD by stf MD instructions, or if a previous DMA cycle on the external bus was a write access. Writing MDA or MSA changes the DMA mode to the respective value. DMA is in read mode when a previous DMA cycle was a read access, and DMA stays in read mode when data is read by SDMA with an ldf MD instruction. Reading MDA or MSA does not change the DMA mode. 0 Read Mode 1 Write Mode
9-8 e	Error. Indicates if the previous access was acknowledged with a bus error. 00 No error was received. 01 *reserved* 10 Error mode 11 error read burst
7-6	Reserved
5-0 n	Number of bytes in the MD FIFO.

46.14.1.5 Burst DMA Write (stf)

When received from a stf instruction, the function code bits are interpreted as follows, depending on the addressed register:

Table 46-17. STF Code Bits

Register	7	6	5	4	3	2	1	0
MSA	s		p	freeze	r			spriv
MDA								dpriv
MD			f	cpy			sz	
MS								

Table 46-18. STF Code Bit Field Descriptions

Field	Description
7-6 s	Functional Unit selector 00 for Burst DMA
5 p (MSA)	Prefetch Flag 0 No prefetch 1 Prefetch required from new MSA

Table continues on the next page...

Table 46-18. STF Code Bit Field Descriptions (continued)

Field	Description
5 f (MD)	Forced Flush Flag 0 Automatic flush 1 FIFO contents are flushed (including the new written data).
4 freeze (MSA/MDA)	Address Freeze Mode 0 Address is normally incremented. 1 Address is frozen.
4 cpy (MD)	Copy Mode selection 0 Write Mode 1 Copy Mode
3-2 r	Register selection 00 MSA 01 MDA 10 MD 11 MS
1-0 sz (MD/MS)	Transfer Size 00 size 0 (no data stored in the FIFO) 01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
0 spriv (MSA)	The spriv value is ignored for this device. 0 = valid value 1 = Reserved
0 dpriv (MDA)	The dpriv value is ignored for this device. 0 = valid value 1 = Reserved

The possible write instructions are listed in the table below (unused bits should always be cleared).

Table 46-19. Burst DMA STF Instruction List

Binary	Assembly	Comments
00_0_0_00_00	stf r,MSA	Writes content of the SDMA general register (r) to the source address register. MSA is in incremented mode.
00_0_1_00_00	stf r,MSA|FR	Writes content of the SDMA general register (r) to the source address register. MSA is in frozen mode.
00_1_0_00_00	stf r,MSA|PF	Writes content of the SDMA general register (r) to the source address register, and starts a read burst access. MSA is in incremented mode.

Table continues on the next page...

Table 46-19. Burst DMA STF Instruction List (continued)

Binary	Assembly	Comments
00_1_1_00_00	stf r,MSA|PF|FR	Writes content of the SDMA general register (r) to the source address register, and starts a read burst access.
00_0_0_01_00	stf r,MDA	Writes content of the SDMA general register (r) to the destination address register. MDA is in incremented mode.
00_0_1_01_00	stf r,MDA|FR	Writes content of the SDMA general register (r) to the destination address register. MDA is in frozen mode.
00_1_0_10_00	stf r,MD|SZ0|FL	No data transfers between the SDMA and MD, but all valid written data of the MD is flushed to the memory. An acknowledge or error is sent back to the SDMA core on transfer completion.
00_0_0_10_01	stf r,MD|SZ8	8-bit (byte) transfer to write buffer MD
00_1_0_10_01	stf r,MD|SZ8|FL	8-bit (byte) transfer to write buffer MD and flush after transfer. All valid written data of the MD is flushed to memory.
00_0_0_10_10	stf r,MD|SZ16	16-bit (half-word) transfer to write buffer MD
00_1_0_10_10	stf r,MD|SZ16|FL	16-bit (half-word) transfer to write buffer MD and flush after transfer. All valid written data of the MD is flushed to memory.
00_0_0_10_11	stf r,MD|SZ32	32-bit (word) transfer to write buffer MD
00_1_0_10_11	stf r,MD|SZ32|FL	32-bit (word) transfer to write buffer MD and flush after transfer. All valid written data of MD is flushed to memory.
00_0_1_10_00	stf r,MD|CPY	No data transfer between SDMA and MD but starts a copy transfer whose length is given by the 4 LSB of *r* register. (Maximum burst length is eight words.)
00_0_0_11_11	stf r,MS	32-bit (word) transfer to status register MS
00_0_0_11_00	stf r,MS|SZ0	Clears the error flag (if set). Other MS bits are unchanged; this instruction is also known as clref MS.

NOTE

When a flush bit is set, the SDMA flushes the FIFO including the newly written data. An acknowledge is sent to the core before the flush completes (except if size 0 is used). The goal of this flush bit is to force a flush, but it is recommended to use it only when needed (for example, when finishing a row of pixels during 2D data transfers). Indeed, if this bit is omitted and if there are more than 32 bytes in the FIFO, a burst write access is automatically triggered.

Since all the stf r,MD instructions (including the copy mode) acknowledge the SDMA core before the store is effective (except if size 0 is used), it is recommended to perform an ldf from MS before terminating a channel in order to check the final error status. (The ldf from MS will stall the core until all the data was flushed out and the transfer status is known.)

After every stf MD instruction, the MDA is incremented by the number of bytes that are written in MD, except when it is programmed in frozen mode.

46.14.1.6 Burst DMA Read (ldf)

When received from an ldf instruction, the function code bits are interpreted as follows, depending on the addressed register:

Table 46-20. LDF Code Bits

Register	7	6	5	4	3	2	1	0
MSA	s				r			
MDA								
MD			p				sz	
MS								

Table 46-21. LDF Code Bit Field Descriptions

Field	Description
7-6 s	Functional Unit selector 00 for Burst DMA
5 p (MD)	Prefetch Flag 0 no prefetch 1 automatic prefetch
3-2 r	Register selection 00 MSA 01 MDA 10 MD 11 MS
1-0 sz (MD)	Transfer Size 00 reserved 01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)

The table below lists the possible write instructions (unused bits should always be cleared).

Table 46-22. Burst DMA LDF Instruction List

Binary	Assembly	Comments
00_0_0_00_00	ldf r,MSA	Copies the source address register value into an SDMA general register. It gives the memory address of the next data that will be read with an ldf MD instruction.
00_0_0_01_00	ldf r,MDA	Copies the destination address register value into an SDMA general register. It gives the memory address where the next incoming data will be flushed.
00_0_0_10_01	ldf r,MD|SZ8	8-bit (byte) read
00_1_0_10_01	ldf r,MD|SZ8|PF	8-bit (byte) read. If after this reading and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_10_10	ldf r,MD|SZ16	16-bit (half-word) read
00_1_0_10_10	ldf r,MD|SZ16|PF	16-bit (half-word) read. If after this reading, and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_10_11	ldf r,MD|SZ32	32-bit (word) read
00_1_0_10_11	ldf r,MD|SZ32|PF	32-bit (word) read. If after this reading and the MD FIFO is empty, a burst read access at the MSA address is triggered.
00_0_0_11_00	ldf r,MS	Copy the status register value into an SDMA general register.

NOTE

Read data is 0-extended before writing in the SDMA general registers. When reading the MD register, the DMA takes data from the FIFO if it is available. If part or whole data is not in the FIFO, an external burst read access is performed to provide the missing data. The SDMA is stalled as long as the required read data is not complete.

After every reading, MSA is incremented by the number of read bytes from MD FIFO, except when MSA is programmed in frozen mode.

46.14.1.7 Prefetch/Flush and Auto-Flush Management-Burst DMA Unit

The prefetch and auto-flush management enables the SDMA RISC machine to go on while a DMA access is performed.

When the RISC core requires a prefetch (p = 1) to the Burst DMA, it will receive an immediate transfer acknowledge before the DMA has finished the external access. This enables the RISC core to do other things like accessing another DMA machine.

The basic principle in prefetch mode is for the DMA to anticipate data reads from the SDMA RISC engine by fetching external bursts of data as soon as there is enough space in the DMA FIFO to store it. If ever the RISC engine required data that is not available in the FIFO, the read acknowledge is delayed until the data is available, but it does not have to wait until the burst completes.

The auto-flush basic principle is similar: An automatic flush is triggered every time there are eight words to be written in the FIFO. If the FIFO is full and the RISC engine requires another write, it is stalled until the burst has started and enough space was freed in the FIFO to store that new data. This means the SDMA RISC engine does not have to wait for the completion of a burst to receive its acknowledge and continue its processing.

In particular, an auto-flush is executed when DMA is in write mode and if the following is true:

- If the FIFO is empty and the first write is to a word-aligned address of any size (ex: the 2 LSB of MDA[1:0]= 0x0), the auto-flush is triggered immediately after the write of the 32'nd byte.
- If the FIFO is empty, and if MDA is an odd byte address (1, 3, 5, 7,...) and an stf MD|SZ8 is executed, the byte is flushed to memory. Once MDA increments to a word aligned address, the auto-flush will be triggered every 32 bytes.
- If the FIFO is empty, and if MDA is a half-word address (2, 6, 0xA,...) and an stf MD|SZ16 is executed, the two bytes of the incoming data are flushed to memory. Once MDA increments to a word aligned address, the auto-flush will be triggered every 32 bytes.
- If the FIFO is empty, and if MDA is not a word-aligned address (ex 1, 2, 3, 5, 6, 7, 9,...), and an stf MD|SZ32 is executed, the first 1 to 3 bytes will be flushed up to the next word aligned address. Afterwards, an auto-flush will be triggered each time the FIFO receives 32-bytes.
- Therefore, if an stf MD|SZ32 is executed with MDA equal to 0x1 and with an empty MD FIFO, the bytes located at addresses 1, 2, and 3 are flushed, and the byte located at address 4 remains in MD FIFO. This solves the misalignment issue. Additionally, the next write instructions (stf) complete the FIFO until it contains eight words; then a burst write is executed by the DMA to empty the FIFO. Protocol on the external bus does not support bursts of different data types (byte, half-word, or word).

  For example, consider the case where data is written using a byte access, stf MD| SZ8. The value of MDA during the very first byte write determines when the auto-flush will occur as follows:

- If MDA=0x0, the flush occurs following the write of byte 32
- If MDA=0x1, the flush occurs following the write of byte 1, byte 3 and byte 35.
- If MDA=0x2, the flush occurs following the write of byte 2 and byte 34.

- If MDA=0x3, the flush occurs following the write of byte 1 and byte 33.
- If MDA=0x4, the flush occurs following the write of byte 32

The flush command forces the DMA to flush all MD valid bytes to the EXTMC controller. An acknowledge is sent immediately to the SDMA, and any potential error is reported on a future access. It is thus essential to conclude a transfer with a last read from MS, which will stall the core until all data was flushed out and returned to the transfer status (acknowledge or error).

NOTE

During this kind of auto-flush (which occurs only at the beginning of a misaligned write transfer) no acknowledge is sent back to the SDMA, which is stalled until a flush is completed.

46.14.1.8 Data Alignment and Endianness-Burst DMA Unit

46.14.1.8.1 Burst DMA in Read Mode

For every read access to MD, the data returned to the SDMA core and the new FIFO state depends on the MSA status and the access size.

The FIFO is considered as a stack of 36 bytes: Data is fetched externally on a 32-bit bus, but the valid bytes only are stored in the FIFO and left-aligned (for a transfer of consecutive words, it is only the first word that may be truncated). The following table shows the FIFO byte alignment strategy and the corresponding MSA, the returned data, and the new FIFO state for any access size of an internal read from MD.

Table 46-23. FIFO Read Configuration

Before read		Internal read access size	Read data	After read	
MSA[1:0]	FIFO state			MSA[1:0]	FIFO state
00	x0 x1 x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 and so on...	sz8	00 00 00 x0	01	x1 x2 x3 y0 y1 y2 y3 z0
		sz16	00 00 x0 x1	10	x2 x3 y0 y1 y2 y3 z0 z1
		sz32	x0 x1 x2 x3	00	y0 y1 y2 y3 z0 z1 z2 z3

Table continues on the next page...

Table 46-23. FIFO Read Configuration (continued)

Before read		Internal read access size	Read data	After read	
MSA[1:0]	FIFO state			MSA[1:0]	FIFO state
01	x1 x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 t0 and so on...	sz8	00 00 00 x1	10	x2 x3 y0 y1 y2 y3 z0 z1
		sz16	00 00 x1 x2	11	x3 y0 y1 y2 y3 z0 z1 z2
		sz32	x1 x2 x3 y0	01	y1 y2 y3 z0 z1 z2 z3 t0
10	x2 x3 y0 y1 y2 y3 z0 z1 z2 z3 t0 t1 and so on...	sz8	00 00 00 x2	11	x3 y0 y1 y2 y3 z0 z1 z2
		sz16	00 00 x2 x3	00	y0 y1 y2 y3 z0 z1 z2 z3
		sz32	x2 x3 y0 y1	10	y2 y3 z0 z1 z2 z3 t0 t1
11	x3 y0 y1 y2 y3 z0 z1 z2 z3 t0 t1 t2 and so on...	sz8	00 00 00 x3	00	y0 y1 y2 y3 z0 z1 z2 z3
		sz16	00 00 x3 y0	01	y1 y2 y3 z0 z1 z2 z3 t0
		sz32	x3 y0 y1 y2	11	y3 z0 z1 z2 z3 t0 t1 t2

46.14.1.8.2 Burst DMA in Write Mode

For every write access to the MD, the new FIFO state depends on the MDA status and the access size.

The FIFO is considered as a stack of 36 bytes: Data is stored in the FIFO according to the internal access size and the former MDA value. The following table shows the FIFO byte alignment strategy corresponding to MDA, as well as the new FIFO state for any access size of an internal write to MD.

Table 46-24. FIFO Write Configuration

Before write		Internal write access size	Written data	After write	
MDA[1:0]	FIFO state			MDA[1:0]	FIFO state
00	tt uu vv ww ?? ?? ?? ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	01	tt uu vv ww x0 ?? ?? ?? ?? ?? ?? ??
		sz16	?? ?? x0 x1	10	tt uu vv ww x0 x1 ?? ?? ?? ?? ?? ??
		sz32	x0 x1 x2 x3	00	tt uu vv ww x0 x1 x2 x3 ?? ?? ?? ??

Table continues on the next page...

Table 46-24. FIFO Write Configuration (continued)

Before write		Internal write access size	Written data	After write	
MDA[1:0]	FIFO state			MDA[1:0]	FIFO state
11	tt uu vv ww xx yy zz ?? ?? ?? ?? ?? and so on...	sz8	?? ?? ?? x0	00	tt uu vv ww xx yy zz x0 ?? ?? ?? ??
		sz16	?? ?? x0 x1	01	tt uu vv ww xx yy zz x0 x1 ?? ?? ??
		sz32	x0 x1 x2 x3	11	tt uu vv ww xx yy zz x0 x1 x2 x3 ??

NOTE

If the FIFO mode changes from a write to a read mode, all remaining written bytes in MD are lost but no error is returned. Typically, this happens if an ldf MD is executed after stf MD instructions. Before a mode change, it is recommended to force the flush of a potential remaining byte by a stfMD|SZ0|FL instruction. In the same way, if a FIFO mode changes from a read to a write mode, all prefetched data present in the FIFO is lost and no error is returned.

46.14.1.8.3 Endianness-Burst DMA Unit

Big and Little Endian are supported by the Burst DMA, but data is always stored in MD in Big Endian.

Byte manipulation is performed when data is exchanged with an Burst controller (for example, during read or write burst accesses).

46.14.1.9 Burst DMA Unit Copy Mode

A mechanism is available to perform fast ARM-to-ARM transfers.

Data does not flow through the SDMA core: It is kept in the DMA FIFO. This mechanism is selected when writing MD with a special option in the instruction code (copy flag).

It is possible to transfer up to eight words in one SDMA instruction (this does not mean in one cycle). In this mode, every time an stf MD|CPY is executed, a read burst is executed and directly followed by a write burst transfer. Burst transfers are limited to eight words. The size of the transfer (in words)-given by the SDMA general register (4 LSB)-is also limited to eight. The following SDMA code shows how 100 bytes could be copied from the MSA address to the MDA address. This is sample code only.

Burst DMA copy mode example

```
          ldi r0,@src
          stf r0,MSA                          // Source address setup
          ldi r1,@dst
          stf r1,MSA                          // Destination address setup
          ldi r0,0x64                         // data transfer counter
          ldi r1,0x8
MAIN_XFER:
          cmphs r0,r1                         // Is r0 >= 0x8
          bf LAST_XFER                      // If not, jump to last transfer label
          stf r1,MD|CPY                        // Copy 8 words from MSA to MDA address.
          subi r0,0x8                         // Decrement counter
          jmp MAIN_XFER                     // return to main transfer loop
LAST_XFER:
          stf r0,MD|CPY
```

The main transfer loop is executed 12 times; then r0 equals 4 and the last transfer loop is run.

In this mode, an acknowledge is transmitted to the core as soon as the read burst can start; thus, a first copy instruction returns an immediate acknowledge and subsequent copy instructions will be acknowledged as soon as the previous copy has finished.

46.14.1.10 Burst DMA Unit Error Management

Another point to consider is the management of errors.

Because the DMA immediately sends an acknowledge to the RISC core (except for the stf MS|SZ0|FLS instruction), it assumes no error will occur. If an error occurs, it is flagged (transfer error acknowledge) for the following DMA access.

This should not be a problem if the DMA is used properly. The MD accesses are meant to stall the SDMA as little as possible to optimize throughput and hide calculation time. Therefore, final access to MS should be performed before closing a channel. This access waits until any pending operation is finished in the burst DMA and gather any remaining error.

In copy mode, an error could be immediately returned to the SDMA on execution of the ldf copy or stf copy instruction. It happens when MSA or MDA are not word addresses (for example, 0[4]). This is because copy mode must only be used for transferring a large packet of aligned data.

When an error is received during a *read* transfer to the external bus, which may occur during the burst accesses, the MD FIFO contains the valid beats of the burst, and the error flag of MS is set to 2'b11 (error read burst). It is possible to read MS ("n" field) to know how much valid data remains in MD and when MD is empty (after ldf instructions). The next read MD instruction sets the MS error flag to 2'b10 (error mode), and an error is sent back to the SDMA core. In error mode, it is possible to read MSA, which gives the address of the error data. Any attempt to read or write MD, or to modify MDA or MSA in error mode, gives rise to an error; therefore, an error flag must be reset by clearing MS at the end of the SDMA code section responsible for error management.

In "error read burst" mode, writing MDA, MSA, or MD, or starting a copy transfer by a stf MD|COPY instruction will cancel the error mode. The following table shows when an immediate error is sent back according to the executed instruction.

Table 46-25. Possibilities in ERROR READ BURST Mode

DMA Instruction	Immediate Error	Comments
stf rn, MD stf rn, MSA (|U |PF) stf rn, MDA stf rn,MD|COPY	NO	Error mode is reset. MSA, MDA, or MD are updated and a DMA cycle may start. For the stf MD|COPY, a copy loop is executed.
stf rn, MS	NO	MS is updated.
ldf rn, MS ldf rn, MSA ldf rn, MDA	NO	MS, MSA, and MDA could be read in ERROR READ mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, MD	YES/NO	Immediate error if there is no more data available for read in the FIFO.

When an error is received during a *write* transfer, the error is reported to the next DMA access. In this case, an error is sent to the SDMA core and the DMA goes to its error mode. Reading MS gives the number of bytes that remain in MD; reading MDA gives the address of the error data. Any attempt to read or write MD, or to modify MDA or MSA in error mode, give rise to an error; therefore, an error flag must be reset by clearing MS at the end of the SDMA code section responsible for error management.

Table 46-26. Possibilities in ERROR Mode

DMA Instruction	Immediate Error	Comments
stf rn, MD stf rn, MSA stf rn, MDA	Yes	Any attempt to modify MD, MSA, MDA will raise an immediate error and burst DMA remains in error mode. When address registers are write-accessed, an error is returned.
stf rn, MS	No	This is the only way to exit error mode. MS[9:8] must be reset by an stf MS|SZ0 instruction.
ldf rn, MS ldf rn, MSA ldf rn, MDA	No	MS, MSA, and MDA could be read in error mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, MD	Yes	Whatever the DMA direction (read or write), an ldf rn triggers an immediate error.

46.14.1.11 Conditional Yielding-Burst DMA Unit

The standard SDMA transfer is based upon a hardware loop that has the following structure:

Hardware Loop

```
loop
load Rn,source            // can be ldf or ld
<computation>            // can be done through functional units
store Rn,dest              // can be st or stf
done 0               // yield
```

This structure needs to be kept independent of the functional units' particularities regarding the context switch. However, there can be variations in the context switch's efficiency, which can depend on the number of data received up to that point, and on the data itself.

The DMA, with its 8-word burst capability, has a preferable context switch period when its address register is 8-word aligned: It is the only moment that occurs once every eight loops when the succession of bursts is not broken by the context switch. When this is not the case, a context switch requires the storing (or loading) of less than eight words, which requires separate accesses and is far less efficient. The rest of the 8-word packet is stored (or loaded) after the context restore, and this is done as separate accesses.

The proposed solution is a conditional yielding, which occurs only when the DMA is in an optimum state. It does not require any modification to the scripts. The condition is decided at the DMA level.

The DMA can be programmed in two modes-conditional or always-true-for every channel, which provides complete flexibility. By default, the DMA is not in conditional mode.

The DMA condition is computed from the FIFO fill level and the various modes, as follows:

- When copy mode is selected, regardless of the transfer direction ('read' or 'write'), the condition is always true.
- In read mode, the condition is always true.
- In write mode, the condition is true when there are four bytes or less in the FIFO; it is false when there are more than four bytes. The 4-byte limit comes from the possibility of saving those bytes as MD with absolutely no impact on the bus accesses.

The aim at conditional yielding is to avoid splitting bus accesses (especially bursts).

46.14.2 Peripheral DMA Unit Programming

The peripheral DMA unit is connected to the Multi-Layer DMA Crossbar Switch of the ARM platform. Its goal is to perform data transfers between any blocks connected to the DMA bus of this platform.

These blocks are either peripherals or memories. The peripheral DMA could be seen as the ARM platform DMA controller.

The DMA performs data transfers in three modes:

- Read mode, where data is read from peripherals or from memory connected to the ARM platform and copied in a SDMA general register.
- Write mode, where data of a general register has to be written in a peripheral or a memory.
- Copy mode, where data is read from a peripheral (or memory) at a source address (PSA) and automatically written to a peripheral (or memory) at a destination address (PDA).

In copy mode, no SDMA general register is involved as transferred data only goes through the data register of the DMA.

The peripheral DMA has three addressing modes: frozen, incremented, and decremented, as follows:

- Frozen mode-When source or destination addresses are frozen, their value is not modified after a transfer. This mode is typically used for addressing peripheral FIFOs located at a fixed address.

- Incremented mode-When source or destination addresses are in incremented mode, after every transfer they are incremented by the number of bytes transferred.
- Decremented mode-In decremented mode, addresses are decremented by the number of bytes transferred.

The peripheral DMA registers are as follows:

- Two, 32-bit address registers (PSA and PDA) that respectively contain the source address for a read access and the destination address for a write access
- A 32-bit status register (PS) that contains information on the peripheral DMA configuration, such as the number of valid bytes in the data register, the error flag, the source and destination address mode, and so on.
- A 32-bit data register (PD) that stores data involved in a data transfer

46.14.2.1 Peripheral Source Address Register (PSA)

The source address register contains a pointer to a source peripheral or a memory associated with the next read data transfer. It has byte granularity.

It is based on the following:

- A 32-bit register (PSA) to store the address value
- A 2-bit register (stype) to store the source address mode (frozen, incremented, or decremented)
- A 2-bit register (ssize) to store the source target data path size (byte, half-word, or word)

Reading the register with the ldf instruction has no side effects and gives the address value of the next data that will be read by the SDMA during an ldf MD instruction. Writing the source address register may have side effects. If there is valid write data in the data register and the source address is changed, the write data is discarded. If the prefetch bit is set, a DMA read cycle is issued with the new address.

When PSA is to be written, you must specify the source target address mode, providing its size (byte, half-word, or word). This enables omission of the size field in all ldf MD instructions. When DMA performs a read cycle, its size is given by the value of the PSA source size register (ssize). If source is a memory in incremented mode, first programmed in word mode (stf PSA|SZ32|I), and if an SDMA script needs to read bytes from this memory, the size of the source target must be updated before executing new accesses. The source address mode and its size are given by labels added to the stf PSA instruction as described in the write section. The ssize and stype registers are part of the DMA status register (PS).

Writing to PSA may issue an immediate error if the source size is not compatible with the value to be written into the PSA register. For instance, writing a 2 in PSA and specifying that it is memory-accessed in word mode creates an immediate error.

46.14.2.2 Peripheral Destination Address Register (PDA)

The destination address register contains a pointer to a source peripheral or a memory associated with the next write data transfer. It has byte granularity.

It is based on the following:

- A 32-bit register (PDA) to store the address value
- A 2-bit register (dtype) to store the destination address mode (frozen, incremented, or decremented)
- A 2-bit register (dsize) to store the destination target data path size (byte, half-word, or word)

Reading the register with the ldf instruction has no side effects, and gives the address value of the next data that will be written by SDMA during an stfMD instruction. Writing the destination register has no side effect. Similar to the PSA register, the destination address mode and source are specified in the stf PDA instruction and may also generate an error in case of incorrect programming.

46.14.2.3 Peripheral Data Register (PD)

The data register of the peripheral DMA is a 32-bit register. When the destination address is correctly set up, any writing to PD will automatically flush the new input data.

The number of SDMA bytes that will be transferred is given by the PDA size register. Unlike other SDMA DMAs, PD is not a FIFO: It is not used to accumulate bytes that from the SDMA and must be packed before being sent to external memories. In read mode, and if the source address is correctly set up, an ldf instruction will empty PD. If a prefetch is required along with the instruction, the DMA will initiate a new read transfer.

Reading PD in prefetch mode only stalls the SDMA when the prefetched data is not yet available. Writing PD only stalls the SDMA if the previous write operation was not completed. As soon as the previous operation is over, the acknowledge is sent back to the SDMA RISC engine.

An error flag-part of PS-is set when an external access fails. The error is thus reported to the next SDMA instruction that involves the peripheral DMA.

46.14.2.4 Peripheral State Register (PS)

The state register contains the DMA state-machine value. It can be accessed in case of an error received during a transfer.

Although all PS fields can be written by an stf instruction, it is recommended to access only the error bit (to reset it). Modifying other PS fields will provide an un-guaranteed DMA behavior.

The initialization value of PS is 0, and it consists of the following structure:

Table 46-27. PS Structure

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	ssize		stype		dsize		dtype	
W																
R	0	0	0	0	0	d	e		0	0	0	0	0	n		
W																

Table 46-28. PS Field Descriptions

Field	Description
31-24	Reserved
23-22 ssize	Source Target Size. Determines the size of the read transfers on the external bus. It should match the accessed device characteristics. 00 *reserved* 01 Byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
21-20 stype	Source address Mode. Determines whether PSA is incremented, decremented, or kept unmodified after every read from the external bus. 00 Frozen Mode 01 Incremented Mode 10 Decremented Mode 11 *reserved*
19-18 dsize	Destination Target Size. Determines the size of the write transfers on the external bus. It should match the accessed device characteristics. 00 *reserved* 01 Byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)

Table continues on the next page...

Table 46-28. PS Field Descriptions (continued)

Field	Description
17-16 dtype	Destination address Mode. Determines whether PDA is incremented, decremented, or kept unmodified after every write on the external bus. 00 Frozen Mode 01 Incremented Mode 10 Decremented Mode 11 *reserved*
15-11	Reserved
10 d	Direction Flag or DMA Mode. DMA is in write mode when data was written into PD by stf PD instructions, or if a previous DMA cycle on the external bus was a write access. Writing PDA or PSA does not change the DMA mode. DMA is in read mode when a previous DMA cycle was a read access, and DMA stays in read mode when data is read by the SDMA with an ldf PD instruction. Reading PDA or PSA does not change the DMA mode. 0 Read Mode 1 Write Mode
9-8 e	Error. Indicates if the previous access was acknowledged with a bus error. 00 No error was received. 01 *reserved* 10 Error mode 11 Error read
7-3	Reserved
2-0 n	number of bytes in PD

NOTE

dtype, dsize, stype, and ssize are updated when PSA and PDA are written.

46.14.2.5 Peripheral DMA Write (stf)-Write Mode

When written by an stf instruction, the function code bits are interpreted as follows:

Table 46-29. STF Code Bits

Register	7	6	5	4	3	2	1	0
PSA	s		p	ar	am		sz	
PDA								
PD			pdsel					
PS			pssel					

Table 46-30. STF Code Bits Field Descriptions

Field	Description
7-6 s	Functional Unit selector 11 for Peripheral DMA
5 p (PSA)	Prefetch Flag 0 no prefetch 1 automatic prefetch
4 ar (PSA/PDA)	Address Register Selector 0 PSA 1 PDA
3-2 am (PSA/PDA)	Address Mode. Determines how PSA or PDA is modified after every read or write access to the PD. 00 Frozen-Address registers are not modified after the transfer. 01 Incremented-Address registers are incremented by the number of transferred bytes. 10 Decremented-Address registers are decremented by the number of transferred bytes. 11 Updated-PSA and PDA are not modified. Either address mode is not modified, but the width of the data path is updated by the sz field.
1-0 sz	Transfer Size 00 *reserved* 01 byte (8 bits) 10 half-word (16 bits) 11 word (32 bits)
5-0 pdsel	PD access selector 001000 is the only valid option
5-0 pssel	PS access selector 111111 writes to PS 001100 only clears the error flag in PS

Due to the large number of possible stf instructions, the following table provides only a short list of all the possible write instructions:

Table 46-31. Peripheral DMA STF Instruction List

Binary	Assembly	Comments
11_00_00_01 11_00_00_10 11_00_00_11	stf Rn, PSA|SZ8 |F stf Rn, PSA|SZ16|F stf Rn, PSA|SZ32|F	• Source is a byte, half-word, or word target at the Rn address. Any further PD read instructions will trigger a byte, half-word, or word access to the source. • Source address is frozen.
11_10_00_01 11_10_00_10 11_10_00_11	stf Rn,PSA|SZ8 |F|PF stf Rn,PSA |SZ16|F|PF stf Rn,PSA |SZ32|F|PF	• Source is a byte, half-word, or word target at the Rn address. Any further PD read instructions will trigger a byte, half-word, or word access to the source. • 1, 2, or 4 bytes are *fetched* from the peripheral source. • Source address is frozen.

Table continues on the next page...

Table 46-31. Peripheral DMA STF Instruction List (continued)

Binary	Assembly	Comments
11_00_01_01 11_00_01_10 11_00_01_11	stf Rn, PSA|SZ8 |I stf Rn, PSA|SZ16|I stf Rn, PSA|SZ32|I	• Source is a byte, half-word, or word target at the Rn address. Any further PD read instructions will trigger a byte, half-word, or word access to the source. • Source address is in incremented mode: PSA = PSA + 1,2 or 4 after read PD.
11_10_01_01 11_10_01_10 11_10_01_11	stf Rn, PSA|SZ8 |I|PF stf Rn, PSA|SZ16|I|PF stf Rn, PSA|SZ32|I|PF	• Source is a byte, half-word, or word target at the Rn address. Any further PD read instructions will trigger a byte, half-word, or word access to the source. • Source address is in incremented mode: PSA = PSA + 1, 2, or 4 after read PD. • 1, 2, or 4 bytes are *fetched* from the peripheral source.
11_00_10_01 11_00_10_10 11_00_10_11	stf Rn, PSA|SZ8 |D stf Rn, PSA|SZ16|D stf Rn, PSA|SZ32|D	• Source is a byte, half-word, or word target at the Rn address. Any further PD read instructions will trigger a byte, half-word, or word access to the source. • Source address is in incremented mode: PSA = PSA-1,2, or 4 after read PD.
11_10_10_01 11_10_10_10 11_10_10_11	stf Rn, PSA|SZ8 |D|PF stf Rn, PSA|SZ16|D|PF stf Rn, PSA|SZ32|D|PF	• Source is a byte, half-word, or word target at the Rn address. Any further PD read instructions will trigger a byte, half-word, or word access to the source. • Source address is in incremented mode: PSA = PSA-1,2, or 4 after read PD. • 1, 2, or 4 bytes are *fetched* from the peripheral source.
11_00_11_01 11_00_11_10 11_00_11_11	stf Rn, PSA|SZ8 |U stf Rn, PSA|SZ16 |U stf Rn, PSA|SZ32 |U	• *Update* source pointer to memory, which becomes a pointer to a memory accessed in byte, half-word, or word. • PSA value is not modified by Rn. • Bytes present in PD are lost.
11_10_11_01 11_10_11_10 11_10_11_11	stf Rn, PSA|SZ8 |PF|U stf Rn, PSA|SZ16 |PF|U stf Rn, PSA|SZ32 |PF|U	• *Update* source pointer, which becomes a pointer to a target accessed in byte, half-word, or word. • PSA value is not modified by Rn. • Bytes present in PD are lost. • 1, 2, or 4 bytes are *fetched* from the memory source.
11_01_00_01 11_01_00_10 11_01_00_11	stf Rn, PDA|SZ8 |F stf Rn, PDA|SZ16|F stf Rn, PDA|SZ32|F	• Destination is a byte, half-word, or word target at the Rn address, and any further PD write instructions will trigger byte, half-word, or word access to the destination. • Destination address is frozen.
11_01_01_01 11_01_01_10 11_01_01_11	stf Rn, PDA|SZ8 |I stf Rn, PDA|SZ16|I stf Rn, PDA|SZ32|I	• Destination is a byte, half-word, or word target at the Rn address, and any further PD write instructions will trigger byte, half-word, or word access to the destination. • Destination address is in incremented mode: PDA = PDA + 1, 2, or 4 after write PD.
11_01_10_01 11_01_10_10 11_01_10_11	stf Rn, PDA|SZ8 |D stf Rn, PDA|SZ16|D stf Rn, PDA|SZ32|D	• Destination is a byte, half-word, or word target at the Rn address, and any further PD write instructions will trigger byte, half-word, or word access to the destination. • Destination address is in incremented mode: PDA = PDA-1, 2, or 4 after write PD.
11_01_11_01 11_01_11_10 11_01_11_11	stf Rn, PDA|SZ8 |U stf Rn, PDA|SZ16 |U stf Rn, PDA|SZ32 |U	• *Update* destination pointer to memory, which becomes a pointer to a memory accessed in byte, half-word, or word. • PDA value is not modified by Rn • bytes present in PD are lost

Table continues on the next page...

Table 46-31. Peripheral DMA STF Instruction List (continued)

Binary	Assembly	Comments
11_00_10_00	stf Rn, PD	• Write "dsize" bytes of Rn in PD and automatically flush to destination target
11_11_11_11	stf Rn, PS	• Write status register
11_00_11_00	stf Rn,clrefPS	• Clear error flag if set

NOTE

When writing PD, size information is not important: It is embedded in the dsize field of PDA register. If dsize is 1, 2, or 4, then one, two, or four bytes from Rn is written to the PD register, and automatically flushed out to the destination target.

46.14.2.6 Peripheral DMA Read (ldf)-Read Mode

When received from an ldf instruction, the function code bits are interpreted as follows.

Table 46-32. LDF Code Bits

Register	7	6	5	4	3	2	1	0
PSA	s			ar	a			
PDA								
PD			p	cpy				
PS			pssel					

Table 46-33. LDF Code Bits Descriptions

Field	Description
7-6 s	Functional Unit selector 11 for Peripheral DMA
5 p (PD)	Prefetch Flag 0 no prefetch 1 automatic prefetch
4 ar (PSA/PDA)	Address Register Selector 0 PSA 1 PDA
4 cpy (PD)	Copy Mode 0 standard access 1 copy mode access

Table continues on the next page...

Table 46-33. LDF Code Bits Descriptions (continued)

Field	Description
3 a	Register Set selection 0 PSA or PDA 1 PD or PS
5-0 pssel	PS access selector 111111 is the only valid option to read PS

Table 46-34. Peripheral DMA LDF Instruction List

Binary	Assembly	Comments
11_0_0_0_000	ldf Rn, PSA	Reads 32-bit of PSA value
11_0_1_0_000	ldf Rn, PDA	Reads 32-bit of PDA value
11_0_0_1_000	ldf Rn, PD	Reads programmed source size bytes of PD (0-extended)
11_1_0_1_000	ldf Rn, PD|PF	Reads programmed source size bytes of PD (0-extended), and starts a prefetch at PSA address.
11_0_1_1_000	ldf Rn, PD|COPY	Starts a copy transfer from the source target at the PSA address to the destination target at the PDA address. No data transmits through Rn, but Rn contents are lost (Rn is loaded with PD temporary contents that are *not* the copied data).
11_111111	ldf Rn, PS	Reads 32-bit of PS value

NOTE

When reading PD, size information is not important: It is embedded in the ssize field of the PSA register. If ssize is 1, 2, or 4, the one, two, or four bytes is transferred from PD to Rn. Read data is 0-extended.

46.14.2.7 Peripheral DMA Unit Copy Mode

Like burst DMA, the peripheral DMA unit has a copy mode that is used when data transfers do not involve SDMA general registers.

Data is read from the source target at a PSA address, stored in PD, and then automatically flushed to the destination target at the PDA address. Copy mode is only available for transfers that involve two targets of the same data path width.

Since copy mode is invoked with an ldf instruction, the *loaded* general purpose register loses its previous contents. (However, the new contents are unpredictable as they depend on temporary values that are seen on the external DMA bus.)

46.14.2.8 Error Management

Peripheral DMA generates two kinds of errors: the immediate error that sanctioned incorrect register programming; and the error triggered by the previous access and stored in the error flag of PS until a DMA instruction is executed.

46.14.2.8.1 Immediate Errors

The following table lists all incorrect DMA register setups.

Table 46-35. Immediate Errors with Peripheral DMA

Rn[1:0] values	DMA instruction	Comments
0x01 0x11	stf Rn, PSA|SZ16|F stf Rn, PSA|SZ16|I stf Rn, PDA|SZ16|F stf Rn, PDA|SZ16|I	If PSA points to a half-word peripheral or to a half-word address in memory, its value must be 0 modulo 2.
0x01 0x10 0x11	stf Rn, PSA|SZ32|F stf Rn, PSA|SZ32|I stf Rn, PDA|SZ32|F stf Rn, PDA|SZ32|I	If PSA points to a word peripheral or to a word address in memory, its value must be 0 modulo 4.
PSA[1:0]-PDA[1:0]	DMA instruction	Comments
0x01 0x10 0x11	stf Rn, PSA|SZ32|U stf Rn, PDA|SZ32|U	When PDA or PSA is updated and becomes a pointer to a word address in memory, its content must be 0 modulo 4.
0x01 0x11	stf Rn, PSA|SZ16|U stf Rn, PDA|SZ16|U	When PDA or PSA is updated and becomes a pointer to a half-word address in memory, its content must be 0 modulo 2.
Read/Write PD instruction	Comments	
stf Rn,PD ldf Rn,PD	If PDA size (dsize) has never been set up before an stf PD instruction (dsize=0) If PSA size (ssize) has never been set up before an ldf PD instruction (ssize=0)	
ldf Rn,PD|CPY	Copy mode is possible only between two targets whose data path width is identical. It is P8↔P8, P16↔P16, or P32↔P32 regardless of the way the address registers are incremented.	

46.14.2.8.2 Data Transfer Errors

When PSA and PDA are correctly set up, the only error that may arise for an ldf PD or stf PD instruction would be the error of the previous DMA cycle.

Error handling is driven by a single consideration: When an error occurred during a data read on the DMA interface, this error should appear as a transfer error to the core when the core attempts to retrieve the data that was not successfully read from the accessed device (memory or peripheral).

When an error occurred during a write access to the DMA interface, the data is still available in PD and should not be destroyed by subsequent core accesses: The core must be warned about the error issue.

There are three error handling mechanisms for each case: Read Error (First Phase), Write Error and Read Error (Second Phase), and Copy Mode Errors handling.

46.14.2.8.3 Read Error (First Phase)

If an error occurred during a prefetch command, the peripheral DMA enters its ERROR READ mode (PS[9:8]=11). In this mode, the error is reported on the next ldf PD instruction and writing PSA, PDA, or PD will cancel the error flag.

The block returns no error mode and instructions are normally executed (a DMA cycle may be triggered). Similarly, initiating a copy transfer will reset the error flag and start a copy transfer. The following table details which instructions can be executed in this mode.

Table 46-36. Possibilities in ERROR READ Mode

DMA Instruction	Immediate Error	Comments
stf rn, PD stf rn, PSA (IU IPF) stf rn, PDA ldf rn,PD|COPY	NO	Error mode is reset, PSA or PDA are updated, or a write cycle is started. For the ldf PD|COPY, a copy loop is executed.
stf rn, PS	NO	PS is updated.
ldf rn, PS ldf rn, PSA ldf rn, PDA	NO	PS, PSA, and PDA could be read in ERROR READ mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, PD	YES	Error of the previous read access is reported here and the peripheral DMA enters its ERROR mode.

46.14.2.8.4 Write Error and Read Error (Second Phase)

The peripheral DMA enters its ERROR mode (PS[9:8]=10) when the previous DMA write cycle failed, or, as explained in Read Error (First Phase), when an ldf PD is executed while the block is in ERROR READ mode. When a DMA cycle failed, address registers (PSA, PDA) are not modified and continue to point to the problematic address. In ERROR mode, stf instructions may raise an immediate error, and ldf instructions will not (as detailed in the table below).

Table 46-37. Possibilities in ERROR Mode

DMA Instruction	Immediate Error	Comments
stf rn, PD stf rn, PSA stf rn, PDA	YES	Any attempt to modify PD, PSA, or PDA will raise an immediate error, and the peripheral DMA stays in ERROR mode. When address registers are write accessed, an error is returned.
stf rn, PS	NO	This is the only way to exit the ERROR mode. PS[3] must be reset by an stf PS instruction.
ldf rn, PS ldf rn, PSA ldf rn, PDA	NO	PS, PSA, and PDA could be read in ERROR mode without any side effects (for example, no DMA cycle is triggered).
ldf rn, PD	YES	Whatever the DMA direction (read or write), an ldf rn, PD instruction will show an immediate error.

46.14.2.8.5 Copy Mode Errors

Because copy mode is a write access that follows a read access, there are two possible cases of bus error.

When the read access incurs a bus error, the peripheral DMA behaves exactly as described in Read Error (First Phase) and Write Error and Read Error (Second Phase) : It enters its ERROR READ mode, and so on.

When the error occurred during the write access of the copy transfer, the DMA enables the core to retrieve the data that was read because it is assumed the read from the peripheral removed the data from its source device. Therefore, the data to be flushed is still in PD. Any subsequent access to PD triggers an error to the core, which should execute its error handling procedure.

Once the ERROR mode is left (after writing to PS), it is possible for the core to retrieve the data in PD with an ldf instruction or try to flush PD contents once again (for example, when the error was due to a full FIFO and the script waited for the FIFO to be emptied) with another ldf instruction in copy mode. This latter instruction detects that there is valid data in PD, tries to flush it, and thus skips the read phase of the copy instruction. This is a different behavior from the usual stf PD instruction that overwrites PD with the selected General Purpose register contents. The same mechanism can be used any time PD holds data that is not written because of a bus error on the DMA interface; when the data was written via a copy instruction, or via the usual stf PD instruction.

46.14.2.8.6 Error Check Example

The following code illustrates an example checking for both immediate and data transfer errors on a store to the PD register. The first bdf instruction checks for an immediate error, but if a data transfer error occurred it is reported until the next instruction to access the Peripheral DMA. A second check of the error flags is done after the ldf PS

instruction. The value of PS here can be ignored. The act of reading any register in Peripheral DMA while it is in an error mode that returns the error to the core to set either the SF or DF flag. Any error returned on an ldf command sets the SF flag and any error returned on an stf instruction sets the DF flag. This can create a situation as shown in the example where a bus error during a DMA write which would normally be considered as a destination fault is reported as a source fault because the error was reported to the SDMA core during an ldf instruction.

Peripheral DMA Error Check

```
    clrf    0            // Clear SF and DF flags
 stf    R4, PD        // Write data to memory
bdf    error_routine    // Check for immediate error from write to PD.
ldf    r3, PS        // Read PS (PS value in R3 can be ignored)
    bsf    error_routine    // Check for bus error from "stf R4,PD"
            // SF is set because it is a ldf instruction, even though
            // the original error was a destination fault
```

46.14.2.9 Peripheral DMA Unit Prefetch/Flush Management

There is no flush bit because every time data is stored in PD by a stf PD instruction-assuming PDA is correctly programmed-it is automatically flushed to the destination.

An acknowledge is returned in the cycle of the DMA instruction, and the SDMA is only stalled by an instruction that addresses the peripheral DMA when the previous DMA access is not over.

46.14.3 CRC Unit

The Cyclic Redundancy Check (CRC) unit is connected to the SDMA core via the FUBUS. This unit can perform a CRC calculation for a set of given polynomials from degree 8 to 32.

When all CRC unit registers are loaded, the unit can process one byte of data every clock cycle. When loading new data to compute the CRC, the SDMA can perform 32-bit, 16-bit, or 8-bit accesses.

Two 32-bit registers comprise the unit:

- The CRC algorithm CA that describes the polynomial
- The CRC checksum CS to accumulate the data after each processing

46.14.3.1 Polynomial Register (CA)

This register defines the CRC algorithm currently used in the calculation, and the management of data ordering to/from the data register CS.

Before starting any CRC calculation, it must be loaded with the chosen polynomial reference number and data ordering mode as indicated in the following figure and table.

Table 46-38. CA Structure

	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0
W																
R	0	0	0	0	0	0	0	0	0	0	0	ri	ro	p		
W																

Table 46-39. CA Descriptions

Field	Description
31-5	Reserved
4 ri	Reverse bit order of data in 0 Must be used when the peripheral receives bytes as bit streams in LSB-first order (UART case). 1 Selects the reverse mode, which must be used when the peripheral receives bytes as bit streams in MSB-first order (MMC case).
3 ro	Reverse bit order of data out 0 Must be used when the peripheral transmits bytes as bit streams in LSB-first order (UART case). 1 Selects the reverse mode, which must be used when the peripheral transmits bytes as bit streams in MSB-first order (MMC case).
2-0 p	Polynomial selection 000 CRC32 ($X^{32}+X^{26}+X^{23}+X^{22}+X^{16}+X^{12}+X^{11}+X^{10}+X^8+X^7+X^5+X^4+X^2+X+1$) 001 CRC16 ($X^{16}+X^{15}+X^2+1$) 010 CCITT16 ($X^{16}+X^{12}+X^5+1$) 011 IS136 ($X^{12}+X^{10}+X^8+X^5+X^4+X^3+1$) 100 CRC10 ($X^{10}+X^9+X^5+X^4+X+1$) 101 CRC8 ($X^8+X^2+X+1$) 110 Parity ($X^8+1$) 111 Reserved

46.14.3.2 Accumulator Register (CS)

The accumulator register accumulates the division remainder during the CRC processing.

When writing the accumulator register (process bit is not set) if the *ro* bit is set, the write data has its order reversed whatever the data length (the length is specified by the selected polynomial).

When computing new CRC (writing CS and process bit set) if the *ri* bit is set in CA, any byte of write data will have its bit order reversed before storage and calculation. In the first byte, bit 7 is replaced by bit 0, bit 6 is replaced by bit 1, and so on. In the second byte, bit 7 is replaced by bit 0, bit 6 is replaced by bit 1, and so on, which means in the write data, bit 15 is replaced by bit 8, bit 14 will replaced by bit 9, and so on.

If the *ro* bit is set in CA, any read data will have its bit order reversed whatever the data length. If the valid data length is 16 bits, bit 15 is replaced by bit 0, bit 14 is replaced by bit 1, and so on.

When loading new data to compute the CRC, the SDMA can perform 32-bit, 16-bit, or 8-bit accesses. The CRC is computed in four clock cycles when performing a 32-bit access, in two clock cycles when performing a 16-bit access, and in one clock cycle when performing an 8-bit access. In all cases, an immediate acknowledge is sent back to the SDMA. A wait state is inserted if the SDMA tries to perform a new access before the end of the computation.

When performing a multi-bit access, the first byte used to compute the CRC is the most significant byte of the valid data.

46.14.3.3 Write Instruction (stf)

The following table shows the stf instructions.

Table 46-40. Stf Instructions for CRC

Byte Command								Description
1	0	0	0	0	0	0	0	Write polynomial encoded in the General Register (CA)
1	0	0	0	0	1	0	0	Write accumulator register (right-aligned)
1	0	0	1	0	1	0	0	Compute the CRC with the new incoming byte (b0)
1	0	0	1	0	1	0	1	Compute the CRC with the new incoming byte (b0)
1	0	0	1	0	1	1	0	Compute the CRC with the new incoming halfword (b1 b2) The bytes are used in the following order: b1 and b0.
1	0	0	1	0	1	1	1	Compute the CRC with the new incoming word (b3 b2 b1 b0) The bytes are used in the following order: b3, b2, b1, and b0.

46.14.3.4 Read Instruction (ldf)

The following table shows the ldf instructions.

Table 46-41. Ldf Instructions for CRC

Byte Command								Description
1	0	0	0	0	0	0	0	read the polynomial register encoded
1	0	0	0	0	1	0	0	read the accumulator register, right aligned

46.14.3.5 Operating Mode

The following is the operating mode example:

- Load the polynomial register to select the algorithm and preset the accumulator, if required.
- Data is right-aligned in the general register.
- Input data is fed byte-by-byte into the accumulator through stf instructions.
- When all data is fed into the CRC unit, the CRC checksum is read with ldf ca, sz.

16-bit CCITT CRC with $P(X) = X^{16}+X^{12}+X^5+1$

```
        .equ rL,0 // GReg[0] = rL; loop count register
.equ rA,1 // GReg[1] = rA; CCITT16 polynomial
.equ rP,2 // GReg[2] = rP; initial CRC value
.equ rT,3 // GReg[3] = rT; transferred byte register
.equ aT,4 // GReg[4] = aT; transferred byte address
// (MMC DAT_RX - 0xA003)
.equ CA,8 // CRC unit CA register
.equ CS,9 // CRC unit CS register
ldi rA,2 // init register with CCITT16 polynomial
stf rA,CA // updates the selected polynomial
ldi rP,0xff // initializes register with 0x000000ff
stf rP,CS,0 // presets the accumulator with 0x000000ff
ldi aT,0xA0 // initializes aT with 0xA003: aT = 0x000000A0
revblo aT // initializes aT with 0xA003: aT = 0x0000A000
ori aT,0x03 // initializes aT with 0xA003: aT = 0x0000A003
ldi rL,200 // expects to read 200 bytes from MMC DAT_RX
loop 2 // executes 200 times the next 2 instructions
```

```
ld rT,(aT,0) // loads next byte from MMC DAT_RX

stf rT,CS,1 // process checksum with new incoming byte

ldf rT,CS // read the final checksum at the end
```

46.14.4 OnCE and Real-Time Debug

The On-Chip Emulation block (OnCE) is the debug interface to the SDMA. It supports the access to all core internal devices (registers, memory, and so on), and provides a set of mechanisms that control the core.

The OnCE is accessed by JTAG ports at the chip's board level, or by the host via its peripheral bus.

To reduce the size of the hardware material involved, all tasks supported by the OnCE are performed on the SDMA core. The architecture of the SDMA OnCE is relatively simple and very flexible.

The commands supported by the SDMA OnCE are listed in the following sections.

46.14.4.1 Memory and Register Access

A set of mechanisms is provided to access SDMA memory and register locations. Both reading and writing are allowed. The access is supported if the processor is in debug mode.

Those registers can also be accessed through the ARM platform Control interface when the OnCE is controlled by the ARM platform, as described in the "Using BP" section.

46.14.4.2 Hardware Breakpoints

An event detection unit is implemented to support memory breakpoints. The unit watches the data exchanged between the SDMA memory bus and the core.

A debug request is sent to the core when matching conditions occur. The unit supports mixed conditions based on address range, access type, and data value. Event detection unit configuration registers are memory mapped in the SDMA space (see ARM platform Channel 0 Pointer (SDMAARM_MC0PTR)): You can modify them through a regular memory access or the ARM platform control interface.

46.14.4.3 Watchpoints

One output pin is provided to monitor matching trigger conditions that are defined in the event detection unit.

46.14.4.4 Software Breakpoints

The SDMA instruction set contains a software breakpoint. Upon executing a software breakpoint instruction, the core suspends normal execution and enters debug mode.

No hardware step execution mode is implemented in the OnCE, but this feature may be implemented at the software level with this instruction.

46.14.4.5 Core Control

Commands are provided to monitor and control processor activity. You can halt the core, rerun the core from another address location, and get processor status.

Any hardware breakpoint on the instruction bus is not supported, but this feature may be implemented by inserting a software breakpoints program.

46.15 The OnCE Controller

The OnCE controller receives commands from the ARM platform or from the JTAG controller. Each command is interpreted before being sent to the core.

46.15.1 OnCE Commands

A small set of commands supports the communication between the OnCE and the external world. This command set enables you to perform any of the following tasks: control processor activity, save core context, and execute an SDMA instruction from the OnCE.

Combined together, these tasks perform more complex commands.

A full OnCE command contains a 4-bit instruction (the OnCE command opcode) and a variable length data field (the OnCE data). During command execution, the OnCE data is transferred in a OnCE internal register before being exchanged with the SDMA. Some

data values are also exported. This mechanism creates a link between the processor and the external world. Nine commands are defined: The following table presents their formats.

Table 46-42. OnCE Command Opcode Values

Instruction Opcode	Name	Action	Register	Data Field Size	Mode
0000	rstatus	Reads the OnCE status register	STATUS	16-bit	normal/debug
0001	dmov	Updates general register GReg1	GREG1	32-bit	debug
0010	exec_once	Runs the instruction from the SDMA instruction register	INSTRUCTION	16-bit	debug
0011	run_core	Returns to normal execution	BYPASS	1-bit	debug
0100	exec_core	Returns to normal execution via a jump instruction that specifies the new address	INSTRUCTION	16-bit	debug
0101	debug_rqst	Stops the core after execution of current instruction	BYPASS	1-bit	normal
0110	rbuffer	Reads the real time buffer	RTB	32-bit	normal/debug
0111-1110	reserved	Reserved	BYPASS	1-bit	normal/debug
1111	bypass	Bypasses TARM platform controller	BYPASS	1-bit	normal/debug

Each instruction corresponds to a specific action performed on the OnCE. The nature of the associated data field is clearly identified. The dmov command is followed by a 32-bit data value (which is a data value for the SDMA); the exec_once and the exec_core commands are followed by a 16-bit data value (which is an instruction for the SDMA); the rstatus command is followed by a 16-bit control value (which is the content of the OnCE status register); the rbuffer command is followed by a 32-bit data value. The debug_rqst and the run_core commands are followed by a single bit data field (this is a bypass value). Finally, the bypass instruction enables the SDMA JTAG TAP controller to be daisy-chained with another JTAG TAP controller. This is a JTAG-only feature. The set of commands is simple, but enables you to perform any possible task on the SDMA during a debug process.

46.15.2 Sending Commands to the OnCE Controller

The JTAG access is the standard access to the OnCE, but sometimes the JTAG is not available to fix some bugs (if the chip is in production for instance), an additional access is then required. Therefore, one ARM platform access to the OnCE is provided.

46.15.2.1 Using the JTAG Interface

A serial access is performed through the five JTAG pins TCK, TRST, TMS, TDI, and TDO. A Test Access Port controller is provided to decode the TMS control signal.

It produces shift-enable signals (shift_ir and shift_dr), and updates enable signals (update_ir and update_dr). It is fully compliant with the IEEE 1149.1 testability (JTAG) standard.

During the shift_ir state, the command opcode is shifted into the OnCE controller (for example, the signal from the TDI pin is shifted into the command register and the TDO pin receives the signal shifted out). After transferring the four bits of the command, an update_ir signal is asserted and the command is decoded. The target data register is now clearly identified and the corresponding control signal is produced, as follows: bypass enable signal (bp_en), instruction enable signal (inst_en), data enable (data_en), and status enable signal (stat_en).

During the shift_dr state, the TDI signal is shifted into one of the following target registers: bypass register (1 bit), SDMA instruction register (16 bits), SDMA data register (32 bits), or OnCE status register (16 bits). The TDO pin is connected to the output of the selected register to receive the signals shifted out.

The JTAG access is disabled when the ARM platform access is enabled.

46.15.2.2 Using the ARM platform

The ARM platform access to the OnCE is not the standard access, but it is required if the JTAG is not available.

For example, if the SDMA ROM is out of use on a chip in production, and the ARM platform needs to download new code and restart the SDMA, the OnCE can easily perform this operation. This type of debug operation justifies the use of an ARM platform access to the OnCE.

To drive the OnCE, the ARM platform uses some registers contained in the ARM platform Control block of the SDMA. These registers are accessed through the ARM platform peripheral bus. Most of these registers are connected to another register in the OnCE controller. Thus, accessing one of these registers is equivalent to accessing the associated register in the OnCE controller.

The set of registers in the ARM platform Control block is listed below:

- ONCE_ENB register (1 bit, read/write)-This 1-bit register enables the ARM platform access to the OnCE. When this bit is set, the signals from the JTAG are ignored.

When it is cleared, all writing operations to the following registers through the Host Control interface are ignored. This register is reset on a JTAG reset.

- ONCE_CMD register (4 bits, read/write)-This 4-bit register receives the command opcode. It is connected to the command register in the controller. A write access to this register causes the associated command to be executed on the OnCE. For example, after writing "0001" in this register, a dmov command is executed.

NOTE

On the ARM platform side, the rstatus and bypass commands are not supported. This register is reset on a JTAG reset.

- ONCE_DATA register (32 bits, read/write)-This 32-bit register is connected to the SDMA data register. This register is used when executing a dmov or rbuffer command.

NOTE

Before requesting a dmov command, the 32-bit data to transfer must be written in the ONCE_DATA register. At the end of the execution, the register is updated with GReg1 former value. This register is reset on a JTAG reset.

- ONCE_INSTR register (16 bits, read/write)-This 16-bit register is connected to the SDMA instruction register. This register is used when executing an exec_core or an exec_once command.

NOTE

Before requesting an exec_core or an exec_once command, the appropriate instruction must be written in the ONCE_INSTR register. This register is reset on a JTAG reset.

- ONCE_STAT register (16 bits, read only)-A read access to the ONCE_STAT register returns the content of the OnCE status register (OSTAT). This register is read only.
- The bypass register is not useful when the ARM platform controls the OnCE, therefore no register is defined in the ARM platform Control block to access the bypass register.

46.15.2.3 Conflicts Between the JTAG and the ARM platform Accesses

When ARM platform access to the SDMA OnCE is enabled (that is, when the bit in the ONCE_ENB register is set), the JTAG access is disabled. This guarantees that the block is not accessed at the same time on both sides.

It is possible to check whether the JTAG access to the SDMA OnCE is enabled from the JTAG port. When the JTAG access is disabled, the SDMA TDO always returns 1. The check requires the following steps:

- Execute a dmov command from debug mode (with neither 0xffffffff nor 0x0 as dmov value: 0x5a5a5a5a is good).
- Execute another dmov command (the value here is not important).
- The returned value from the latter dmov command should be the original one if the JTAG access is enabled; if it is 0xffffffff instead of the original input value, this means the JTAG access is disabled.

46.15.3 Executing a Command from the OnCE

All the commands defined in OnCE Commands can be accessed through the JTAG. The ARM platform can access all these commands except the rstatus command.

On the ARM platform side, the OnCE status is directly accessed by reading the ONCE_STAT register.

46.15.3.1 Nature of the Commands

Two types of commands may be distinguished. First, there are two commands that do not interact with the core: rstatus and rbuffer. Those commands may be requested at any time: They do not depend on the core status.

NOTE

Each of these commands exports a data value or a status value from the SDMA.

There are also commands that interact with the core: dmov, run_core, exec_core, exec_once, and debug_rqst. These commands are core status dependent, as follows:

- During user mode only the debug_rqst is taken into account.
- During debug mode, all these commands are taken into account except the debug_rqst. For example, an exec_once command requested while not in debug mode has no effect.

46.15.3.2 Execution Request

The SDMA starts executing a task in debug mode when requested by the OnCE controller. The execution starting time depends on the type of access used to communicate with the OnCE.

If the JTAG is used, the request is send after decoding the update_dr state in the TAP controller. Therefore, always cross this state when sending a command through the JTAG. If the OnCE is driven from the ARM platform side, the request is sent after detecting a write access to the ONCE_CMD register. All the registers involved in this operation must be loaded first.

The following is an example of an exec_core command execution from the ARM platform side: After writing '010' in the ONCE_CMD register, the OnCE controller asks the SDMA to execute the instruction contained in the ONCE_INSTR register. The instruction involved should be available in the ONCE_INSTR register before the beginning of the execution.

46.15.3.3 Command Execution

The following list shows the commands and details how each command is executed:

- rstatus command execution-The rstatus command exports the content of the OnCE status register (OSR). If the JTAG is used, the status information is captured in the OnCE status register during the capture_dr state, and shifted out after 16 TCK clock cycles in the shift_dr state. The rstatus command is not supported on the ARM platform side, but a status register is provided instead. The rstatus may be performed in both debug and user modes.
- dmov command execution-The dmov command accesses SDMA internal registers. Executing a dmov instruction exchanges the 32-bit data values between the SDMA data register and the general register GReg[1].
- If the JTAG is used, the content of GReg1 is captured in the SDMA data register during the capture_dr state, then it is shifted out after 32 TCK clock cycles in the shift_dr state. During the update_dr state, GReg1 is updated with the new, shifted-in 32-bit data value. If the OnCE is driven from the ARM platform side, the data values contained in GReg1 and the SDMA data register are exchanged after detecting a write access to the ONCE_CMD register. The ONCE_DATA register must therefore be loaded first.

- exec_once command execution-The exec_once command executes the instruction loaded in the SDMA instruction register. The command may only be requested from debug mode. The SDMA returns to debug mode at the end of the execution.

- Change of flow instructions as well as instructions that may cause a context switch are not supported: The comprehensive list comprises done/yield/yiedge (except done 5), BF, BT, BSF, BDF, JMP, JSR, JMPR, JSRR, RET, and LOOP, as well as all the illegal instructions.

  No other command should be requested before the SDMA returns to debug mode. The SDMA status (for example, whether it is in debug mode or not) can be detected by polling with the rstatus OnCE command, monitoring the debug_mode pin, or checking the OnCE Status Register (SDMAARM_ONCE_STAT) register via the ARM platform control interface.

  NOTE

  Most of the instructions are single-cycle, which omits the step of polling the status. Loads and stores to DMA units are typical instructions that might require this polling.

  If the JTAG is used, the 16-bit instruction is shifted in the SDMA instruction register after 16 TCK clock cycles in the shift_dr state. A request is sent to the core when the update_dr state is decoded in the TAP controller. If the OnCE is driven from the ARM platform side, the request is sent to the SDMA when detecting a write access to the ONCE_CMD register. The ONCE_INSTR register must be therefore be loaded first.

- run_core command execution-The run_core command leaves debug mode and resume normal program execution. The next instruction executed is the last instruction decoded before entering debug mode. Be sure to restore core context before re-running the core. This procedure is detailed in Restoring the Context.
- If the JTAG is used, a 1-bit bypass value is shifted in the bypass register in the shift_dr state. The SDMA is rerun when the update_dr state is decoded in the TAP controller. If the OnCE is driven from the ARM platform side, the core is rerun when detecting a write access to the ONCE_CMD register.

- exec_core command execution-The exec_core command resumes program execution from any address. The 16-bit instruction provided with the exec_core overwrites the last instruction decoded before entering debug mode. This command is designed to support change of flow instructions, so that a program execution can be restarted from any address. After executing an exec_core command, the SDMA leaves debug mode. The exec_core command is usually used with a jmp instruction.
- If the JTAG is used, the 16-bit branch instruction is shifted in the SDMA instruction register after 16 TCK clock cycles in the shift_dr state. The SDMA is rerun when the update_dr state is decoded in the TAP controller. If the OnCE is driven from the ARM platform side, the SDMA reruns when detecting a write access to the

ONCE_CMD register. The ONCE_INSTR register must therefore be loaded first. For example, to restart the SDMA from the program address 0x100, the instruction loaded should be a jump to address 0x100 instruction.

- debug_rqst command execution-The debug_rqst command puts the SDMA in debug mode. If the JTAG is used, a 1-bit bypass value is shifted in the bypass register during the shift_dr state. A debug request is sent to the SDMA when the update_dr state is decoded in the TAP controller. If the OnCE is driven from the ARM platform side, the debug request is sent when detecting a write access to the ONCE_CMD register. When the SDMA is already in debug mode, this command is simply ignored.
- rbuffer command execution-The rbuffer command exports the content of the real time buffer (RTB). If the JTAG is used, the content of the real time buffer (RTB) is captured in the SDMA data register during the capture_dr state. The register is completely shifted out after maintaining the shift_dr state during 32 TCK clock cycles. If the OnCE is driven from the ARM platform side, the content of the RTB is captured in the ONCE_DATA register after detecting a write access to the ONCE_CMD register.
- bypass command execution-This command is only available from the JTAG interface. It enables daisy-chaining of the SDMA JTAG TAP controller with other JTAG TAP controllers. This command does not change the SDMA state and can be executed in any mode (run, debug, or sleep). It selects the bypass register of the TAP controller.

46.15.4 Registers Descriptions

See SDMACORE, and SDMAARM, for detailed information on each register.

46.15.4.1 Event Cell Counter Register (ECOUNT)

The event cell counter register is a 16-bit register that contains the number of times minus one that an event detection occurs before generating a debug request.

This register should be written before attempting to use the event detection counter during an event detection process. The event cell counter register is cleared on a JTAG reset.

46.15.4.2 Event Cell Address Registers (EAA or EAB)

The event cell contains two address registers-the event cell address register (a), called EAA, and the event cell address register (b), called EAB. Every address register is a 16-bit register that stores a user-defined address value. This value computes one of the following address conditions: addra_cond or addrb_cond. Every address register is cleared on a JTAG reset.

46.15.4.3 Event Cell Address Mask Register (EAM)

The event cell address mask register is a 16-bit register that contains a user-defined address mask value. This mask is applied to the address value latched from the memory address bus before comparing addresses.

NOTE

There is a common address mask value for the two address comparators. If bit *i* of this register is set, then bit *i* of the address value latched from the memory bus does not influence the result of the address comparison. The event cell address mask register is cleared on a JTAG reset.

46.15.4.4 Event Cell Data Register (ED)

The event cell data register is a 32-bit register that contains a user-defined data value. This data value is an input for the data comparator, which generates the data_cond condition.

The event cell data register is cleared on a JTAG reset.

46.15.4.5 Event Cell Data Mask Register (EDM)

The event cell data mask register is a 32-bit register that contains a user-defined data mask value. This mask is applied to the data value latched from the memory bus before comparing data.

Setting bit *i* of the event cell data mask register means that bit *i* of the data value latched from the address bus does not influence the result of the data comparison. The event cell data mask register is cleared on a JTAG reset.

46.15.4.6 Real Time Buffer Register (RTB)

The real Time Buffer register is a 32-bit register that stores and retrieves run-time information without putting the SDMA in debug mode.

Refer to Real Time Buffer for more details.

46.15.4.7 Event Control Register (ECTL)

The event cell control register is a 16-bit register that defines cell event occurrence conditions.

The event cell control register is cleared on a JTAG reset. See also OnCE Event Detection Unit for more details.

46.15.4.8 Trace Buffer (TB)

The Trace Buffer register retrieves the information in the Trace Buffer.

See Trace Buffer for more details.

46.15.4.9 OnCE Status Register (OSTAT)

The OnCE status register is a 16-bit register that contains processor and event detection unit status. The OSTAT is a read-only register.

Refer to OnCE Status Register (SDMAARM_ONCE_STAT) for detailed description of the individual fields in the OSTAT register.

The following figure shows the OSTAT structure.

Table 46-43. OnCE Status Register (OnCE)

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
PST[3:0]				RCV	EDR	ODR	SWB	MST					ECDR[2:0]		

Where PST[3:0] is the SDMA core state, RCV is set when the real-time buffer (RTB) is modified. EDR, ODR, and SWB are set, respectively, when the SDMA has entered debug mode because of an external debug request, a OnCE debug_rqst command, or a software breakpoint. MST is set when the OnCE is controlled from the ARM platform control interface, and when ECDR is a three-flag set that shows the event cell condition(s) that put the core in debug mode. The OSTAT never provides more than one reason for entering debug mode.

There are two ways of accessing OSTAT content, as follows:

1. Send an rstatus command to the OnCE controller through the JTAG, or read the ONCE_STAT register through the ARM platform access. Executing the rstatus command through the JTAG can be performed in both user and debug modes.
2. Perform an SDMA read access to the location in the SDMA core memory map (OSTAT register) debug mode using the exec_once command. With this method of access, the SDMA state reflected by the PST (processor status bit) is always DATA.

The register may also be accessed by a running application.

46.15.5 JTAG Interface Requirements

Because the signals received from the JTAG (running on TCK) are transferred to the OnCE controller (running on the SDMA clock), a synchronization mechanism is required.

46.15.5.1 TCK Speed Limitation

In the JTAG top-level layer, the TDO signal is always captured on a TCK falling edge. To guarantee a stable TDO signal from the SDMA during this operation, a falling edge detection is performed on TCK.

Before being latched in the *I* flip-flop (see Figure 46-12) on TCK falling edge, the TDO signal must be stable at the input of the flip-flop. This condition is verified if the TCK period is superior to the following delay:

worst-case edge detection delay + negative-edge signal propagation delay + JTAG top-level logic propagation delay

The frequency relationship, TCK < CLK/8, limitation guarantees that all operations are performed as expected.

46.15.5.2 Synchronization Implementation

The following figure shows the synchronization mechanism. Flip-flops tck0, tck1, and tck2 perform falling- and rising-edge detections on TCK. They generate the posedge_detected and negedge_detected nets that are used to sample the TDI and TMS inputs into the respective tdi and tms flip-flops, and update the tdo flip-flop to yield the

TDO output. In the design, the only signal that might go metastable is the output of the tck0 flip-flop. This signal is captured in the tck1 flip-flop and no logical operation is performed on it to minimize a metastability propagation risk.

The TDI and TMS flip-flops also cannot go metastable: The propagation time of the rising-edge detection signal through tck0, tck1, and tck2 guarantees that the TDI and TMS inputs are stable when captured in the TDI and TMS flip-flops.

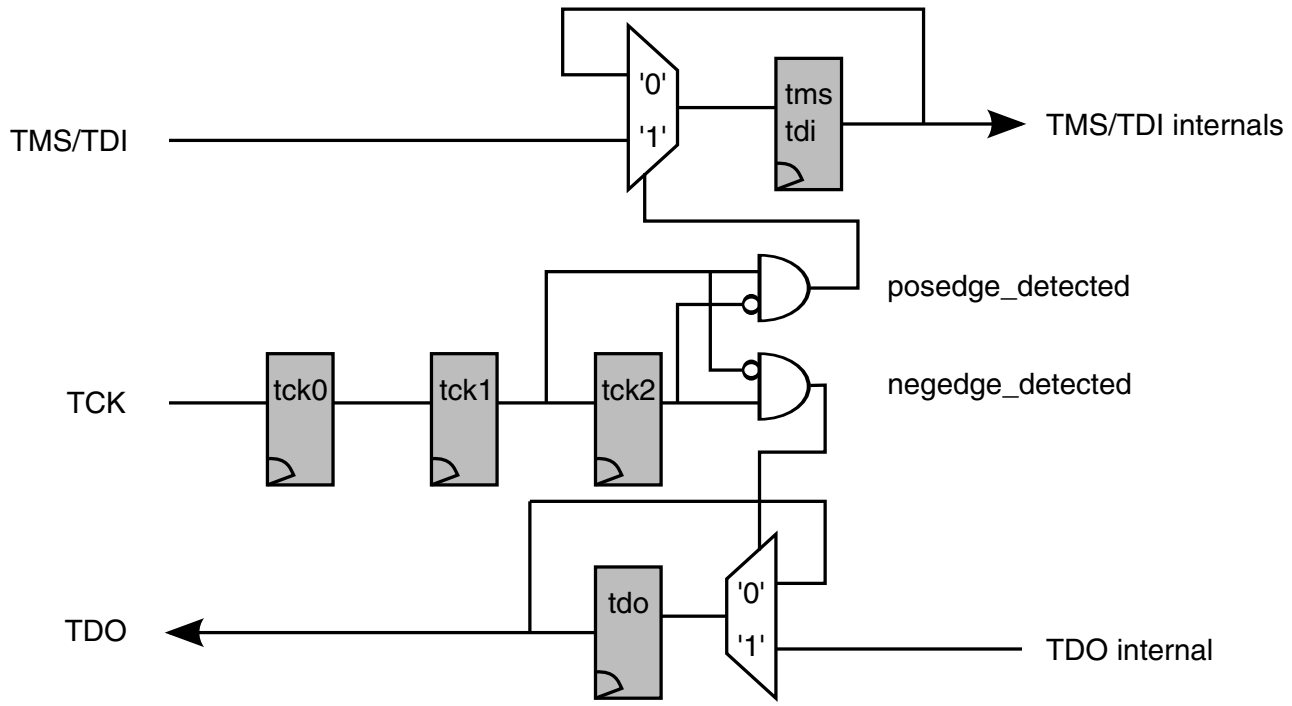

Figure 46-12. OnCE Synchronization Layer

The following figure shows synchronization timings. It takes three CLK clock cycles to synchronize TDI on the SDMA clock.

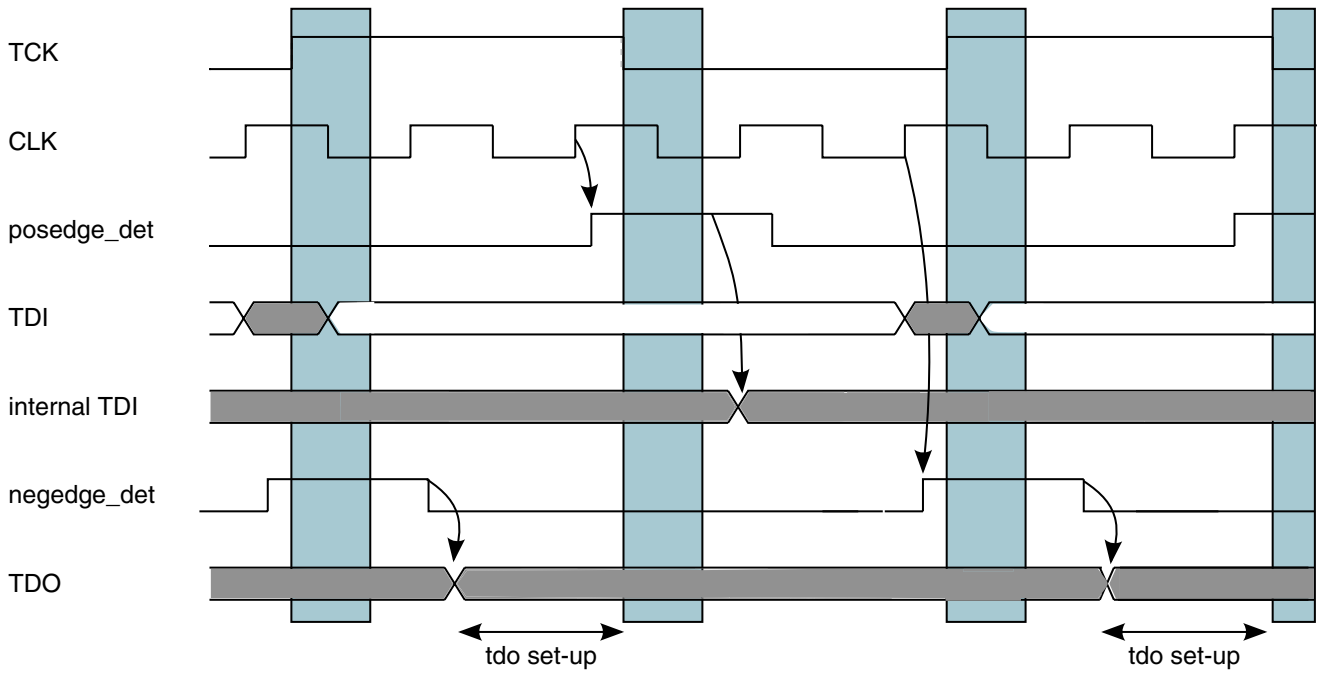

Figure 46-13. Synchronization Timings

46.15.5.3 JTAG Controller Start-Up Recommended Procedure

To ensure correct TAP controller initialization, it is recommended to use the following procedure:

1. Assert JTAG reset TRSTB (for example, set low).
2. Set TMS low.
3. Wait for 1 TCK clock.
4. Release JTAG reset TRSTB (for example, set high).
5. Wait for a minimum of five TCK cycles.

46.16 Using the OnCE

This section provides the elements necessary to run the OnCE during a debug process. In addition to the basic set of commands described in OnCE Commands, more complex commands can be built to meet users' requirements.

46.16.1 Activating Clocks in Debug Mode

For power consumption issues, some clocks in the SDMA are disabled when not needed. This is the case for instances when the SDMA is in sleep mode. Clock gating management depends on the interface used to control the OnCE.

- For the JTAG access, the SDMA clock gating must be turned off via the clk_gating_off input.
- For the ARM platform access, the SDMA clock gating is automatically turned off when the ARM platform access is enabled (see OnCE Enable (SDMAARM_ONCE_ENB)).

46.16.2 Getting the Current Status

Most of the commands the OnCE supports have an impact on the status of the SDMA.

It is not permissible to request the execution of an instruction on the SDMA from the OnCE while the SDMA is not in debug mode. Such a violation may cause unpredictable behavior, and it might be necessary to reset the SDMA.

Therefore, the value of the PST bits provided in the OnCE status register should always be checked before sending any request to the SDMA.

46.16.3 Methods of Entering Debug Mode

A debug request may be asserted at any time, but it is not always taken into account immediately. Debug mode cannot be entered in the middle of an instruction, or during the save or restore states of a context switch.

The request is ignored when the core is already in debug mode. Refer to Figure 46-4, which shows all possible transitions to the debug state, as there are several ways to enter debug mode.

46.16.3.1 External Debug Request During Reset

To enter debug mode after exiting reset, the external debug line has to be maintained high. This line is handled by the JTAG top-level block.

NOTE

The SDMA detects the debug requests only if the SDMA clock is running (see Activating Clocks in Debug Mode). The debug

request line should be not be maintained high when the SDMA is in debug mode.

NOTE

The debug_rqst command (from the OnCE command set) is not supported during system reset.

46.16.3.2 Debug Request During Normal Activity

During normal activity, the SDMA enters debug mode when the following is true:

1. If the debug request line from the JTAG top-level is asserted, or
2. If the OnCE controller receives a debug_rqst command.

   The debug_rqst command can be sent by the JTAG access or by an access on the ARM platform side (if the ARM platform access is enabled).

46.16.3.3 Software Breakpoint Instruction

The SDMA enters debug mode at the end of the execution of a software breakpoint instruction. This instruction must be inserted in program flow executed by the core.

46.16.3.4 Event Detection Unit Matching Condition

If the event detection is enabled, a debug request is sent to the core after detecting a matching condition on the SDMA memory bus.

See OnCE Event Detection Unit for more details.

46.16.4 Executing Instructions in Debug Mode

The OnCE supports a mechanism to execute instructions in debug mode. If the SDMA is in debug mode, then the exec_once command can be used to execute an SDMA instruction from the OnCE controller. The SDMA returns to debug mode at the end of each execution.

Some instructions are not supported by the exec_once command: done/yield/yiedge (except done 5), BF, BT, BSF, BDF, JMP, JSR, JMPR, JSRR, RET, and LOOP, as well as all the illegal instructions are not supported.

NOTE

While instructions are executed in debug mode from the OnCE, the program counter of the SDMA is not incremented.

46.16.5 Command Sequences Examples

This section provides examples of command sequences that run the SDMA in debug mode. These sequences are available for both the ARM platform and JTAG accesses.

The following presents the syntax used in this section. The data field provided with each command is put in parenthesis with the command name. A '-' is used if the data field provided is a *don't care* value.

```
my_command(data_field);                 // executing my_command with a data field
my_command(-);                        // executing my_command with a don't care data field
```

The value returned by the command (if there is one) is referred by an assignment. In case the value returned by the command is not used, the assignment is omitted. For an ARM platform access, the value returned (it is always a data value) is obtained by reading back into the SDMA data register.

```
data_out = my_command(data_in); // returning a data value
```

To clarify the syntax, the instructions' opcodes are referred to by their names. In practice, use the corresponding 16-bit encoding.

46.16.5.1 Getting the SDMA Status

NOTE

Before executing any command that affects the SDMA (like dmov or exec_once), check that the SDMA is in debug mode.

Use the following snippet:

```
rstatus();        // read SDMA status until the SDMA is in debug mode
...
rstatus();
```

If the SDMA is not in debug mode, then a debug request must be generated. In this case, the SDMA enters debug mode at the end of the execution of the current instruction. Use this snippet:

```
debug_rqst(-);   // debug request
```

In the following sections, it is assumed that the SDMA was successfully put into debug mode.

46.16.5.2 Saving the Context

The first debug task is to save the SDMA context, which is the content of the eight general-purpose registers, the loop and PC-related registers, and the flags. Use the general register GReg[1] as an intermediate register to export the entire context of the SDMA.

The following example shows how to save GReg[0], GReg[1], GReg[2] and GReg[3]. The sequence of commands used to export additional general registers is very similar to this.

Save GReg[0], GReg[1], GReg[2], and GReg[3]

```
GReg1_data = dmov(-);                          // the value exported is the content of
GReg[1]
exec_once("mov GReg1,GReg0");                      // puts the content of GReg[0] into
GReg[1]
GReg0_data = dmov(-);                          // the value exported is the content of
GReg[0]
exec_once("mov GReg1, GReg2");                     // puts the content of GReg[2] into
GReg[1]
GReg2_data = dmov(-);                          // the value exported is the content of
GReg[2]
exec_once("mov GReg1, GReg3");                     // puts the content of GReg[3] into
GReg[1]
GReg3_data = dmov(-);                          // the value exported is the content of
GReg[3]
```

Get the value of the internal flags (SF, DF, T, and LM), of the loop related registers (EPC and SPC), and of the PC-related registers (PC and RPC). Use a done 5, which is the formatting instruction dedicated to the debug. This instruction formats the flags and the values contained in the registers. It also writes the resulting values into the channel context memory. It should not be used when entering debug from the IDLE state (for example, with no active channel script running on the SDMA), because it will update a channel context that may belong to any channel.

```
exec_once("done 5");                    // formatting the value of flags and registers
```

At this point, the channel context should be up-to-date in memory, and debug operations should now be possible. However, the context can be exported with the following instructions:

Exporting the Context

```
dmov(ctx_base_addr);                              // loading GReg[1] with the channel
context base address
exec_once("ld GReg0,(GReg1,0)");                      // get RPC-PC into GReg0
exec_once("ld GReg1, (GReg1,1)");                     // get SPC-EPC into GReg1
Loop_data = dmov(-);                           // read back the value of Loop registers
exec_once("mov GReg1, GReg0");                     // puts the PC info into GReg1
PC_data = dmov(-);                             // reads back the content of the PC registers
```

After this sequence of operations, the entire SDMA context is exported via the OnCE.

46.16.5.3 Restoring the Context

At this point in the operation, restore the context of the SDMA. It can be different from the original context located in memory, and the content previously saved into the debugging application via the OnCE.

The following example shows how it is possible to modify the current channel context:

Modifying the Current Channel Context

```
dmov(Loop_data);                                  // put Loop former value into GReg[1]
exec_once("mov GReg0, GReg1");                         // copy to GReg[0]
dmov(PC_data);                                    // put PC former value into GReg[1]
exec_once("mov GReg2, GReg1");                         // copy to GReg[2]
dmov(ctx_base_addr);                                  // put channel context base address into
GReg[1]
exec_once("st GReg0, (GReg1,1)");                          // restore Loop context
exec_once("st GReg2, (GReg1,0)");                          // restore PC context
```

Once the context in memory is the desired context (with or without applying the previous instruction sequence), it can be restored to the *real* PC and loop registers in the SDMA core:

```
exec_once("cpShReg");                    // restore flags and PC & loop related registers
```

After this command, the SDMA core PC, RPC, SPC, EPC registers, as well as the flags contain the same data as what is stored in the context RAM for the current channel.

The following example shows how to restore the context of general registers GReg[0], GReg[1], GReg[2] and GReg[3].

Restoring the General Register Context

```
dmov(GReg3_data);                    // put GReg[3] restore value in GReg[1]
exec_once("mov GReg3, GReg1"); // restore GReg[3]
dmov(GReg2_data);                    // put GReg[2] restore value in GReg[1]
exec_once("mov GReg2, GReg1"); // restore GReg[2]
dmov(GReg0_data);                    // put GReg[0] restore value in GReg[1]
exec_once("mov GReg0, GReg1"); // restore GReg[0]
dmov(GReg1_data);                    // restore GReg[1]
```

At this point, it is possible to restart the normal program execution.

NOTE

Every SDMA core general register value can be modified by a mov instruction, which makes modification of these registers easy during debug. Unfortunately, there is no such instruction as a mov to directly modify the contents of either PCU register or flag (PC, RPC, SPC, EPC, T, LM, SF, or DF). The cpShReg instruction is meant to provide a means for changing these register contents via the context memory.

46.16.5.4 Accessing the Memory

In the following example, it is assumed that the SDMA context is entirely saved. If true, it is permissible to modify the general purpose registers during debugging activity.

To perform a memory read access, the target address is stored via the OnCE in GReg[1], then the load instruction is executed on the SDMA (the data loaded from the memory overwrites the address contained in GReg[1]), and then the result value is read back via the OnCE.

```
macro READ:            dmov(target_addr);                                  // put the target
address in GReg[1]
                    exec_once("ld GReg1,(GReg1,0)");                         // execute the
load instruction
                    res_data = dmov(-);                                 // exports the result
data value
```

For a memory write access, the target address is written in GReg[0], and the value to store is written in GReg[1]. Then the store instruction is executed on the SDMA.

```
macro WRITE:            dmov(target_addr);                                   // puts the
target address in GReg[1]
                    exec_once("mov GReg0,GReg1");                          // puts the target
address in GReg[0]
                    dmov(target_data);                                  // puts the target
data in GReg[1]
                    exec_once("st GReg1,(GReg0,0)");                          // performs the
store operation
```

This sequence is shown as an example; however, many other sequences are possible.

NOTE

This sequence of commands can also be applied to memory-mapped registers.

46.16.5.5 Resuming Program Execution

Before resuming program execution, it is assumed that the SDMA context is properly restored. There are two ways to restart the SDMA.

Start by executing the last instruction fetched before entering debug mode, as follows.

```
run_core(-);                          // resume execution from where we stopped before
```

If necessary, restart the execution from a different address. In this case, use the exec_core command. The data field provided with this command must be the encoding of a jump instruction.

```
exec_core("jmp start_addr"); // rerun the SDMA from another address
```

In these two examples, the SDMA exits debug mode and keeps executing the code fetched from the memory.

46.16.5.6 Single Stepping in RAM

To execute a program step-by-step from the RAM, insert software breakpoints in the program flow at appropriate places so that the SDMA only executes one instruction before returning to debug mode.

First, read the next instruction to execute in the RAM. Then, depending on the value of this instruction, compute the address where a software breakpoint instruction should be inserted. The instruction at the corresponding address must be saved, and, the software breakpoint instruction is inserted. After restarting the SDMA, there is only one instruction executed before meeting the software breakpoint.

The following example shows the macro functions READ and WRITE, which correspond to the sequence of commands (described above) used to access the memory.

NOTE

The data read from the memory are 32-bit values, while the instructions are 16-bit values only. This is why it is best to only use addresses divided by two when accessing the memory.

READ and WRITE Macro Functions

```
next_instr = READ(run_addr/2);                          // read the next instruction to execute
// the tool now has to compute the address where the breakpoint
// instruction should be inserted, this address is the "bkpt_addr"
instr_save = READ(bkpt_addr/2);                          // save the instruction before
overwriting
STORE("bkpt instruction",bkpt_addr/2);                         // store the bkpt instruction
in memory
exec_core("jmp run_addr");                              // rerun the SDMA
rstatus(-);                                           // wait for the SDMA to enter debug mode
...
rstatus(-);
STORE(instr_save,bpkt_addr/2);                           // restore the instruction
overwritten
```

In case of branched conditional instructions, a breakpoint instruction should be written at the two possible target addresses.

46.16.5.7 Single Stepping in ROM

No single-step mechanism is supported in ROM. The program code can be loaded in the RAM, where the single-step mechanism can be executed.

46.16.6 OnCE Event Detection Unit

The event detection unit watches signals from the data memory bus (DMBUS), which the SDMA core uses to access its RAM, ROM, and memory mapped registers.

A debug request is sent to the OnCE controller when user-defined conditions on address and/or data values are true.

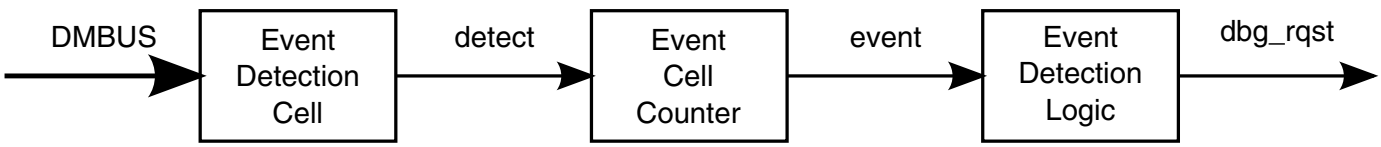

Figure 46-14. Event Detection Unit

A counter, provided with the detection cell, is decreased after an event detection. A debug request is sent to the core only when the counter reaches the value of 0. It is possible to disable the use of the counter if a debug request has to be generated after each event detection.

The event cell is the basic block that supports hardware breakpoints on an address value and/or data values coming from the SDMA memory bus. The trigger condition that generates the debug request is a mixed condition based on those values.

The following figure shows the event cell architecture. The event cell contains the address (stored in the memory address register) and the data (stored in the memory data register) used during the last memory access. There are some user-defined reference values located in memory mapped registers-the event cell addresses, the event cell address mask, the event cell data, and the event cell data mask. These registers are accessed by standard load/store instructions just like regular memory locations.

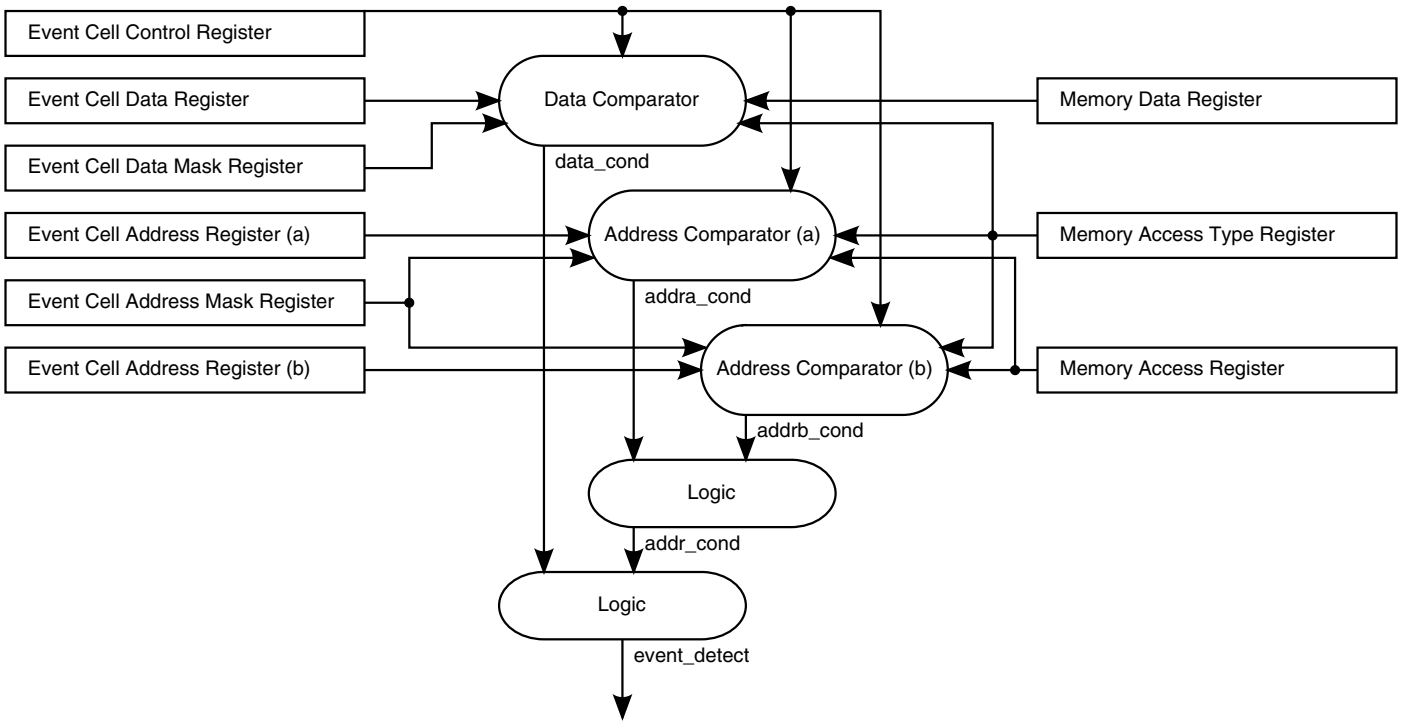

Figure 46-15. Event Cell Architecture

To define a memory breakpoint, three conditions are taken into account: The first two conditions are comparisons of the current memory address with user-defined reference addresses (these conditions are called addressA and addressB). The third condition consists of a comparison between the data received on the DMBUS and a user-defined reference data (this condition is called data). An intermediate address condition is set to express a dependency between addressA and addressB conditions.

46.16.7 Clock Gating and Reset

This section details how to use the clocks and handle the reset signals.

46.16.7.1 Clocks

Because the SDMA uses clock gating to save power, it is necessary to disable the clock gating and force the clocks to be enabled when using the OnCE.

When the OnCE is accessed through its JTAG interface, clock gating must be disabled outside the SDMA via a dedicated SDMA input port clk_gating_off. The reason why detection is not performed automatically by the SDMA internal hardware is that it would cost power to monitor activity on the JTAG interface.

This clk_gating_off input is controlled by a control bit in the System JTAG Controller. Refer to the System JTAG Controller chapter for more information.

When the OnCE is accessed through the ARM platform Control interface, clock gating is automatically turned off. This is done when bit 0 of the ONCE_ENB register (see OnCE Enable (SDMAARM_ONCE_ENB)) is set. A write access to this register is possible even when the OnCE clock is not running. If the ARM platform access is used, the bit in the ONCE_ENB register must be set before any attempt to access any other OnCE register.

46.16.7.2 Resets

The OnCE reset is different from the SDMA main reset. The OnCE reset is connected to the TRST_B pin.

Normally, activating the SDMA reset while keeping the OnCE reset inactive (when possible) enables you to reset the core without having to reprogram the OnCE.

46.16.8 Real Time Features

To rebuild the skeleton of a program execution, it is necessary to store the addresses of the program instructions where jumps are taken: A trace buffer is therefore provided. A real time buffer has also been added to receive data values written during a program execution.

The content of this register may be exported through JTAG ports without stopping the core.

46.16.8.1 Trace Buffer

The Trace Buffer is a 32-stage buffer that contains appropriate information to identify the 32 last changes of flow detected during a program execution.

The following figure shows an overview of the Trace Buffer.

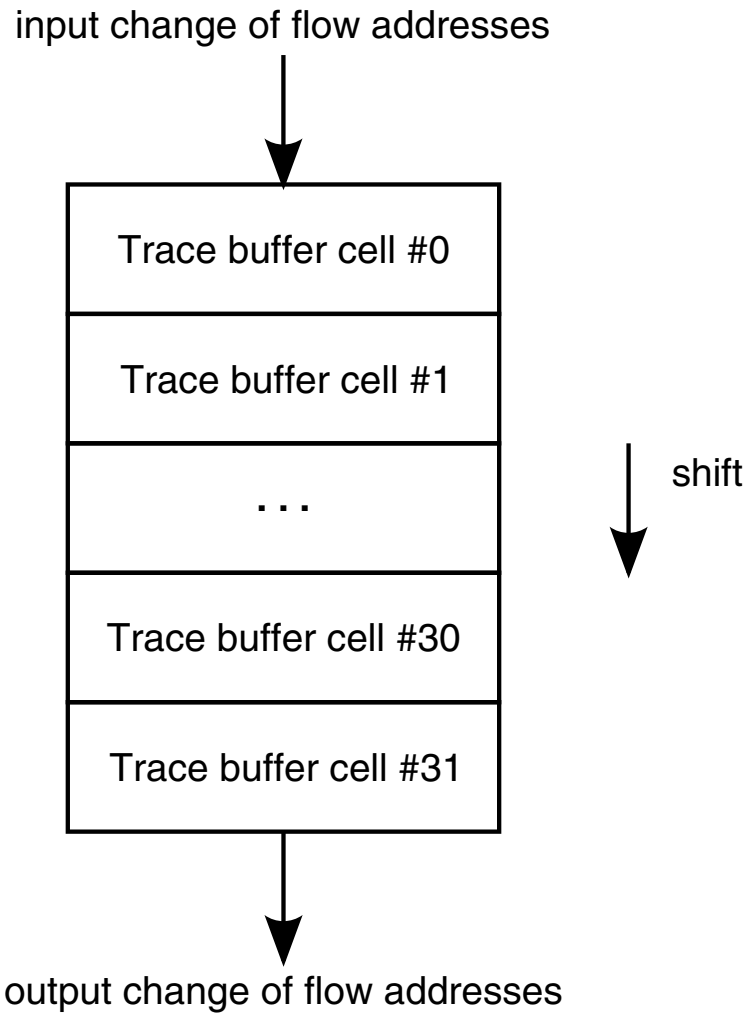

Figure 46-16. Trace Buffer

Each cell of the trace buffer contains two reference addresses and a flag. The flag is set when the addresses stored in the cell correspond to a valid change of flow; otherwise, the flag is cleared. The three most significant bits are unused.

After every change of flow detection, the address of current instruction and the address of the target instruction are stored at the top of the Trace Buffer (cell #0). The flag in the cell is set to indicate that a valid change of flow was detected. Former cell values are shifted one level down. The Trace Buffer contains the 32 last changes of flow. All the flags are reset on a software or a hardware reset, and after each transition from debug mode to user mode.

A memory mapped register of SDMA core, the Trace Buffer register (TB), is provided to read the content of the Trace Buffer. This operation should be done in debug mode. Performing a read access to the Trace Buffer register returns the content of the bottom of the Trace Buffer (cell #31). After every read access, the trace buffer is shifted one level down, and the flag at the top of the trace buffer is cleared.

A typical OnCE command sequence that retrieves the oldest change-of-flow information is a follows:

```
exec_once("mov r1, TB");                              // stores the oldest change-of-flow in
GReg1
dmov(-);                                          // retrieves GReg1 contents
```

This sequence requires the SDMA to be put in debug mode.

46.16.8.2 Real Time Buffer

The Real Time Buffer register (RTB) is a memory mapped register that can be accessed as a regular memory location by the SDMA core during program execution. This register is located in the OnCE.

Executing ar rbuffer command (see The OnCE Controller for further details) exports the content of this register through JTAG ports.

When a write access is performed at the memory location corresponding to the RTB, the receive flag (for example, the RCV bit) is set in the OnCE Status Register (OSR). This flag is cleared at the end of the execution of a rbuffer command.

NOTE

Every write access to the RTB memory location updates the RTB register even if the RCV flag is set. The RTB is cleared on a JTAG reset.

46.16.8.3 Emulation Pin

The debug_matched_event emulation pin reflects the matching condition status detected by the Event Detection Unit.

Since it can be necessary to detect conditions without triggering debug requests, it is possible to disable the generation of debug requests by the Event Detection Unit and still have the matching condition available on the emulation pin. This can be done by clearing the EN flag in the ECTL register.

46.16.8.4 Real-Time Debug Outputs

The folloing table shows the debug signals that are available at the SDMA boundaries. Their availability at chip boundaries depends on the project.

Table 46-44. Real-Time Debug Output Pins

Pin	Description
debug_core_state[3:0]	The core_state bits reflect the state of the SDMA core. • The "Program" state is the usual instruction execution cycle. • The "Data" state is inserted when there are wait-states during a load or a store on the data bus (ld or st). • The "Change of Flow" state is the second cycle of any instruction that breaks the sequence of instructions (jumps and channel switching instructions). • The "Change of Flow in Loop" state is used when an error causes a hardware loop exit. • The "Debug" state means the SDMA is in debug mode. • The "Functional Unit" state is inserted when there are wait-states during a load or a store on the functional units bus (ldf or stf). • In "Sleep" modes, no script is running (this is the core idle state); the "after Reset" is slightly different because no context restoring phase will happen when a channel is triggered: The script located at address 0 is executed (boot operation). • The "in Sleep" states are the same as above except they do not have any corresponding channel: they are used when entering debug mode after reset; the reason is that it is necessary to return to the "Sleep after Reset" state when leaving debug mode. 0 Program 1 Data 2 Change of Flow 3 Change of Flow in Loop 4 Debug 5 Functional Unit 6 Sleep 7 Context Switch Saving Channel 8 Program in Sleep 9 Data in Sleep 10 Change of Flow in Sleep 11 Change of Flow in Loop in Sleep 12 Debug in Sleep 13 Functional Unit in Sleep 14 Sleep after Reset 15 Context Switch Restoring Channel
debug_yield	Pulse that is active when a yield (done 0) or a yieldge (done 1) instruction is executed. 0 - 1 yield/yieldge executed

Table continues on the next page...

Table 46-44. Real-Time Debug Output Pins (continued)

Pin	Description
debug_core_run	Active when the SDMA core is executing instructions. 0 Debug or sleep mode 1 Run mode
debug_event_channel_sel	Indicates if debug_event_channel displays current channel or last received event 0- debug_event_channel[5:0] gives the number of the current channel 1- debug_event_channel[5:0] gives the number of the last received event
debug_event_channel[5:0]	Gives the number of any DMA request as soon as it is received or the number of the current channel. The value of debug_event_channel_sel indicates if debug_event_channel displays the current channel or last received event. The signal debug_event_channel_sel must be observed to determine what information is provided on debug_event_chanel at any given time.
debug_pc[13:0]	Program Counter value; it has a meaning when the core is in run mode.
debug_mode	Set when the core is in debug. 0 - 1 Core is in debug
debug_bus_error	Set when an error was received during a load or a store (ld, st, ldf, or stf instruction) and registered in SF or DF flag. 0 No error during last load/store 1 Error during last load/store

Table continues on the next page...

Table 46-44. Real-Time Debug Output Pins (continued)

Pin	Description
debug_bus_device[4:0]	Indicates the device or functional unit that is accessed by the current instruction. The debug_bus_device output is always valid when in sleep mode, debug mode, or executing any instruction that does not access the functional units or the memory mapped devices, "no access" is output. 0 No access 1 MSA 2 MDA 3 MD 4 MS 5 PSA 6 PDA 7 PD 8 PS 9 RESERVED 10 RESERVED 11 RESERVED 12 RESERVED 13 CA 14 CS 15 Reserved 16 Memory (RAM or ROM) 17 Memory mapped register 18 Peripheral #1 19 Peripheral #2 20 Peripheral #3 21 Peripheral #4 22 Peripheral #5 23 Peripheral #6 24 Peripheral #7 25 Peripheral #8 26 Peripheral #9 27 Peripheral #10 28 Peripheral #11 29 Peripheral #12 30 Peripheral #13 31 Peripheral #14

Table continues on the next page...

Table 46-44. Real-Time Debug Output Pins (continued)

Pin	Description
debug_bus_rwb	Indicates the direction of the access given by debug_bus_device 0 Write access (st or stf) 1 Read access (ld or ldf)
debug_matched_dmbus	Pulse indicating the OnCE event detection unit has detected a match on the data bus during an access to memory (RAM or ROM), a memory mapped register or a peripheral that is hooked to the SDMA. 0 - 1 data bus match detected
debug_rtbuffer_write	Pulse indicating when the real-time buffer is written by the core. 0 - 1 RTB was modified
debug_evt_chn_lines[7:0]	Eight lines that generate short pulses when DMA requests are received or channels are (re)started. Every line is controlled through two parameters defined in registers Cross-Trigger Events Configuration Register 1 (SDMAARM_XTRIG_CONF1) (as described in SDMAARM). The following two parameters are available for every line: • CNF-Indicates what is monitored on the line: 0 for a channel start, 1 for a DMA request reception • NUM[5:0]-Gives the number of the DMA request or channel to monitor

The matched_event emulation pin reflects the matching condition status detected by the Event Detection Unit. Because it can be necessary to detect conditions without triggering debug requests, it is possible to disable the generation of debug requests by the Event Detection Unit and still have the matching condition available on the emulation pin. This can be done by clearing the EN flag in the ECTL register.

All real-time debug outputs are disabled by default (for example, they are stuck to 0) to avoid power consumption when they are not used. They are enabled when bit 11 (RTDOBS) of the Configuration Register (SDMAARM_CONFIG) is set. Signals provided to the system JTAG controller for SDMA debug mode status will also be enabled when the *clk_gating_off* input is asserted.

46.17 Instruction Set

46.17.1 Instruction Encoding

This section presents a short summary of the instruction codes. All context switch instructions are listed for information only; they cannot function properly out of the context switch routine.

```
x...x - don't care

rrr - destination/source general register

sss - additional source general register

bbb - general register used as address base register

ddddd - address displacement

nnnnn - bit number
uuuuuuuu - function unit command bits

pppppppp - branch displacement (signed)

iiiiiiii - 8-bit immediate

jjj - control bit to clear

ff - flag to clear
00000jjj00000000        - done (done,yield,wait)

46.17.2 SDMA Instruction Set

This section describes all the useful instructions from the SDMA set.

Table 46-45. SDMA Instruction List

Instruction	Description	Page
ADD	Addition	ADD (Addition)
ADDI	Add with Immediate Value	ADDI (Add with Immediate Value)
AND	Logical AND	AND (Logical AND)
ANDI	Logical AND with Immediate Value	ANDI (Logical AND with Immediate Value)
ANDN	Logical AND NOT	ANDN (Logical AND NOT)

Table continues on the next page...

Table 46-45. SDMA Instruction List (continued)

Instruction	Description	Page
ANDNI	Logical AND with Negated Immediate Value	ANDNI (Logical AND with Negated Immediate Value)
ASR1	Arithmetic Shift Right by 1 Bit	ASR1 (Arithmetic Shift Right by 1 Bit)
BCLRI	Bit Clear Immediate	BCLRI1 (Bit Clear Immediate)
BDF	Conditional Branch if Destination Fault	BDF (Conditional Branch if Destination Fault)
BF	Conditional Branch if False	Functional Units Programming Model
BSETI	Bit Set Immediate	BSETI (Bit Set Immediate)
BSF	Conditional Branch if Source Fault	BSF (Conditional Branch if Source Fault)
BT	Conditional Branch if True	BT (Conditional Branch if True)
BTSTI	Bit Test immediate	BTSTI (Bit Test immediate)
CLRF	Clear ARM platform flags	CLRF (Clear ARM platform flags)
CMPEQ	Compare for Equal	CMPEQ (Compare for Equal)
CMPEQI	Compare with Immediate for Equal	CMPEQI (Compare with Immediate for Equal)
CMPHS	Compare for Higher or Same	CMPHS (Compare for Higher or Same)
CMPLT	Compare for Less Than	CMPLT (Compare for Less Than)
cpShReg	Update Context of PCU Registers and Flags	cpShReg (Update Context of PCU Registers and Flag)
DONE	DONE, Yield	DONE (DONE, Yield)
ILLEGAL	ILLEGAL Instruction	ILLEGAL (ILLEGAL Instruction)
JMP	Unconditional Jump Immediate	JMP (Unconditional Jump Immediate)
JMPR	Unconditional Jump	JMPR (Unconditional Jump)
JSR	Unconditional Jump to Subroutine Immediate	JSR (Unconditional Jump to Subroutine Immediate)
JSRR	Unconditional Jump to Subroutine	JSRR (Unconditional Jump to Subroutine)

Table continues on the next page...

Table 46-45. SDMA Instruction List (continued)

Instruction	Description	Page
LD	Load Register	LD (Load Register)
LDF	Load Register from Functional Unit	LDF (Load Register from Functional Unit)
LDI	Load Register with Immediate Value	LDI (Load Register with Immediate Value)
LDRPC	Load from RPC to Register	LDRPC (Load from RPC to Register)
LOOP	Hardware Loop	LOOP (Hardware Loop)
LSL1	Logical Shift Left by 1 Bit	LSL1 (Logical Shift Left by 1 Bit)
LSR1	Logical Shift Right by 1 Bit	LSR1 (Logical Shift Right by 1 Bit)
MOV	Logical Move	MOV (Logical Move)
NOTIFY	Notify to ARM platform	NOTIFY (Notify to ARM platform)
OR	Logical OR	OR (Logical OR)
ORI	Logical OR with Immediate Value	ORI (Logical OR with Immediate Value)
RET	Return from Subroutine	RET (Return from Subroutine)
REVB	Reverse Byte Order	REVB (Reverse Byte Order)
REVBLO	Reverse Low Order Bytes	Reverse Low Order Bytes(REVBLO)
ROR1	Rotate Right by 1 Bit	ROR1 (Rotate Right by 1 Bit)
RORB	Rotate Right by 1 Byte	RORB (Rotate Right by 1 Byte)
SOFTBKPT	Software Breakpoint	SOFTBKPT (Software Breakpoint)
ST	Store Register	ST (Store Register)
STF	Store Register in Functional Unit	STF (Store Register in Functional Unit)
SUB	Subtract	SUB (Subtract)
SUBI	Subtract with Immediate	SUBI (Subtract with Immediate)
TST	Test with Zero	TST (Test with Zero)
TSTI	Test Immediate	TSTI (Test Immediate)

Instruction	Description	Page
XOR	Logical Exclusive OR	XOR (Logical Exclusive OR)
XORI	Exclusive OR with Immediate	XORI (Exclusive OR with Immediate)

46.17.2.1 ADD (Addition)

Operation:

```
GReg[r] ← GReg[s] + GReg[r]

T ← (GReg[r] == 0)
```

Assembler:

```
Syntax: add r,s

Example: add 0,3
```

ADD GReg[3] and GReg[0] and store the result in GReg[0]

CPU Flags: T

Cycles: 1

Description: Performs the ADDition of the source general register *s* and the destination general register *r*, and stores the result in the destination general register *r*. The T flag is set if the result of the operation is 0. It is cleared if the result is not 0.

Instruction Format:

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	0	1	1	s	s	s

Instruction Fields:

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]
```

```
100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

46.17.2.2 ADDI (Add with Immediate Value)

Operation:

```
GReg[r] ← GReg[r] + immediate

T ← (GReg[r] == 0)
```

Assembler:

```
Syntax: addi r,immediate

Example: add 6,112
```

ADD GReg[6] and decimal value 112 and store the result in GReg[6]

CPU Flags: T

Cycles: 1

Description: Adds a 0-extended immediate value to a general register; stores the result in the general register. The flag T is set when the result of the operation is 0; otherwise, it is cleared. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	1	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]
```

```
111 - GReg[7]
```

iiiiiiii - immediate value:

```
00000000 - 0

00000001 - 1

 ...

11111110 - 254

11111111 - 255
```

46.17.2.3 AND (Logical AND)

Operation:

```
GReg[r] ← GReg[s] & GReg[r]
```

Assembler:

```
Syntax: and r,s

Example: and 1,2
```

AND GReg[1] and GReg[2] and store the result in GReg[1]

CPU Flags: Unaffected

Cycles: 1

Description: Performs the AND of the source general register *s* and the destination general register *r*, and stores the result in the destination general register *r*.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	1	1	s	s	s

Instruction Fields:

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]
```

110 - GReg[6]

111 - GReg[7]

46.17.2.4 ANDI (Logical AND with Immediate Value)

Operation:

GReg[r] ← GReg[r] & immediate

Assembler:

Syntax: andi r,immediate

Example: andi 7,45

AND GReg[7] and decimal value 45 and store the result in GReg[7]

CPU Flags: unaffected

Cycles: 1

Description: Performs an AND between a 0-extended immediate value and a general register; stores the result in the general register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	1	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]

iiiiiiii - immediate value:

00000000 - 0

```
00000001 - 1

...

11111110 - 254

11111111 - 255
```

46.17.2.5 ANDN (Logical AND NOT)

Operation:

```
GReg[r] ← ~GReg[s] & GReg[r]
```

Assembler:

```
Syntax:andn r,s

Example: andn 3,4
```

AND GReg[3] and NOT GReg[4] (bit inverted) and store the result in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Performs the AND of the negation of the source general register *s* and the destination general register *r*, and stores the result in the destination general register *r*.

Instruction Format:

Table 46-46. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	1	0	s	s	s

Instruction Fields:

rrr /sss - destination register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

46.17.2.6 ANDNI (Logical AND with Negated Immediate Value)

Operation:

```
GReg[r] ← GReg[r] & ~immediate
```

Assembler:

```
Syntax: andni r,immediate

Example: andni 0,2
```

AND GReg[0] and decimal value -3 (inverted 32-bit value 2) and store the result in GReg[0]

CPU Flags: unaffected

Cycles: 1

Description: Performs an AND between the negation of a 0-extended 8-bit immediate value and a general register; stores the result in the general register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	1	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiiiiii - immediate value:

```
00000000 - 0

00000001 - 1
```

```
...

11111110 - 254

11111111 - 255
```

46.17.2.7 ASR1 (Arithmetic Shift Right by 1 Bit)

Operation:

```
GReg[r]:{b31,b30,...,b1,b0} ← GReg[r]:{b31,b31,b30,...,b1}
```

Assembler:

```
Syntax: asr1 r

Example: asr1 3
```

divide by 2 the signed value of GReg[3] and store the result in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Shift the bits of any general register to the right and keep the same sign: The left bit (bit 31) is kept untouched.

Instruction Format:

Table 46-47. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	1	0

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

46.17.2.8 BCLRI1 (Bit Clear Immediate)

Operation:

```
GReg[r]:{b31,...,b(i+1),0,b(i-1),...,b0} ← GReg[r]:{b31,...,b(i+1),b(i),b(i-1),...,b0}
```

Assembler:

```
Syntax: bclri r,i

Example: bclri 1,12
```

clear bit 12 in GReg[1]

CPU Flags: Unaffected

Cycles: 1

Description: Clear the bit of register r specified by the 5-bit immediate field

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	1	i	i	i	i	i

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiii - immediate value:

```
00000 - 0

00001 - 1

...

11110 - 30

11111 - 31
```

46.17.2.9 BDF (Conditional Branch if Destination Fault)

Operation:

```
if (DF == 1) PC ← PC + 1 + displacement else PC ← PC + 1
```

Assembler:

```
Syntax:bdf label

Example: bdf LLL
```

Jump to LLL if DF is set, or go to the next instruction if DF is cleared; the displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: If flag DF is set, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag DF is cleared, no jump is performed: The next instruction is located at the next PC address.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	1	1	p	p	p	p	p	p	p	p

Instruction Fields:

pppppppp - signed displacement field:

```
00000000 - 0

00000001 - 1

...

01111110 - 126

01111111 - 127

10000000 - (-128)

10000001 - (-127)

...

11111110 - (-2)

11111111 - (-1)
```

46.17.2.10 BF (Conditional Branch if False)

Operation:

```
if (T == 0)

PC ← PC + 1 + displacement

else

PC ← PC + 1
```

Assembler:

```
Syntax: bf label

Example: bf LLL
```

Jump to LLL if T is cleared, or go to the next instruction if T is set. The displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: Conditional branch: If flag T is cleared, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag T is set, no jump is performed: The next instruction is located at the next PC address.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	0	0	p	p	p	p	p	p	p	p

Instruction Fields:

pppppppp - signed displacement field:

```
00000000 - 0

00000001 - 1

...

01111110 - 126

01111111 - 127

10000000 - (-128)

10000001 - (-127)

...

11111110 - (-2)

11111111 - (-1)
```

46.17.2.11 BSETI (Bit Set Immediate)

Operation:

```
GReg[r]:{b31,...,b(i+1),1,b(i-1),...,b0} ← GReg[r]:{b31,...,b(i+1),b(i),b(i-1),...,b0}
```

Assembler:

```
Syntax: bseti r,i

Example: bseti 6,5
```

Set bit 5 in GReg[6]

CPU Flags: Unaffected

Cycles: 1

Description: Sets bit number i in the selected General Register.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	1	0	i	i	i	i	i

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiii - bit number field:

```
00000 - 0

00001 - 1

...

11110 - 30

11111 - 31
```

46.17.2.12 BSF (Conditional Branch if Source Fault)

Operation:

```
if (SF == 1) PC ← PC + 1 + displacement else PC ← PC + 1
```

Assembler:

```
Syntax: bsf label

Example: bsf LLL
```

Jump to LLL if SF is set, or go to the next instruction if SF is cleared. The displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: Conditional branch: If flag SF is set, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag SF is cleared, no jump is performed: The next instruction is located at the next PC address.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	1	0	p	p	p	p	p	p	p	p

Instruction Fields:

pppppppp - signed displacement field:

```
00000000 - 0

00000001 - 1

...

01111110 - 126

01111111 - 127

10000000 - (-128)

10000001 - (-127)

...

11111110 - (-2)

11111111 - (-1)
```

46.17.2.13 BT (Conditional Branch if True)

Operation

```
if (T == 1)

PC ← PC + 1 + displacement

else

PC ← PC + 1
```

Assembler

```
Syntax: bt label

bt LLL
```

Jump to LLL if T is set, or go to the next instruction if T is cleared. The displacement value is calculated by the assembler.

CPU Flags: Unaffected

Cycles: 2 when the branch is done, 1 otherwise

Description: Conditional branch: If flag T is set, jump to the new address that is calculated by adding the sign-extended 8-bit displacement to the next PC address. If flag T is cleared, no jump is performed: The next instruction is located at the next PC address.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	1	0	1	p	p	p	p	p	p	p	p

pppppppp - signed displacement field:

```
00000000 - 0

00000001 - 1

...

01111110- 126

01111111 - 127

10000000 - (-128)

10000001 - (-127)

...

11111110 -  (-2)

11111111 - (-1)
```

46.17.2.14 BTSTI (Bit Test immediate)

Operation:

```
T ← GReg[r]:b(i)
```

Assembler:

```
Syntax: btsti r,i

Example: btsti 2,29
```

Test bit 29 in GReg[2] and copy its value in flag T

CPU flags: T

Cycles: 1

Description: T is loaded with the value of bit number i from the selected general register.

Instruction Format:

Table 46-48. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	1	1	i	i	i	i	i

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiii - bit number field:

```
0000 - 0

0001 - 1

...

11110 - 30
```

```
11111 - 31
```

46.17.2.15 CLRF (Clear ARM platform flags)

Operation:

```
 if (ff%2 == 0)

SF ← 0

if (ff/2 == 0)

DF ← 0
```

Assembler:

```
Syntax: clrf ff

Example: clrf 2
```

Clear flag SF and keep flag DF unchanged

CPU Flags: SF, DF

Cycles: 1

Description: Clears a selection of the ARM platform fault flags: SF, DF, both SF and DF or none can be cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	f	f	0	0	0	0	0	1	1	1

Instruction Fields:

ff - flags field:

```
00 - clear SF and clear DF

01 - clear DF

10 - clear

SF 11 - no clear
```

46.17.2.16 CMPEQ (Compare for Equal)

Operation:

```
T ← (GReg[s] == GReg[r])
```

Assembler:

```
Syntax: cmpeq r,s

Example: cmpeq 7,5
```

Compare GReg[7] and GReg[5] and set flag T if they are equal

CPU flags: T

Cycles: 1

Description: Subtracts the destination general register *r* from the source general register *s*, and sets T if the result is 0, clears T if the result is not 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	0	1	s	s	s

Instruction Fields:

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

46.17.2.17 CMPEQI (Compare with Immediate for Equal)

Operation:

```
T ← (GReg[r] == immediate)
```

Assembler:

```
Syntax: cmpeqi r,immediate

Example: cmpeqi 2,13
```

Compare GReg[2] and decimal value 13 and set flag T if they are equal

CPU Flags: T

Cycles: 1

Description: Subtracts the 0-extended 8-bit immediate value from the general register, and sets T if the result is 0, clears T if the result is not 0. The immediate value is the low-order byte of the instruction.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - destination register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiiiiii - immediate value:

```
00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255
```

46.17.2.18 CMPHS (Compare for Higher or Same)

Operation:

```
T ← (GReg[r] ≥ GReg[s])
```

Assembler:

```
Syntax: cmphs r,s

Example: cmphs 0,1
```

Compare GReg[0] and GReg[1] and set flag T if GReg[0] is higher than or equal to GReg[1]

CPU Flags: T

Cycles: 1

Description: Compares the destination general register *r* and the source general register *s*, and sets T if the destination general register *r* is higher than or equal to the source general register *s*, clears T otherwise. The comparison is unsigned.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	1	1	s	s	s

Instruction Fields:

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

46.17.2.19 CMPLT (Compare for Less Than)

Operation:

```
T ← (GReg[r] < GReg[s])
```

Assembler:

```
Syntax: cmplt r,s

Example: cmplt 7,4
```

Compare GReg[7] and GReg[4] and set flag T if GReg[7] is lower than GReg[4]

CPU Flags: T

Cycles: 1

Description: Compares the destination general register *r* and the source general register *s*, and sets T if the destination general register *r* is lower than the source general register *s*, clears T otherwise. The comparison is signed.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	1	0	s	s	s

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

46.17.2.20 cpShReg (Update Context of PCU Registers and Flag)

Assembler:

```
Syntax: cpShReg
```

CPU Flags: none

Cycles: 1

Description: SF, RPC, T, PC,LM, EPC, DF, and SPC registers are updated according to the value of their corresponding bits in the context memory. This instruction must only be used in debug mode via the OnCE. It reverses the done *5* operation.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	1	1	0	1	1	1	0	0	0	1	0

46.17.2.21 DONE (DONE, Yield)

Operation:

```
if (jjj&6 == 2) HE[CCR] ← 0

if (jjj == 3) HI[CCR] ← 1

if (jjj == 4) EP[CCR] ← 0

if ((jjj == 0) && (NCP > CCP)) CCR ← NCR

else if ((jjj == 1) && (NCP >= CCP))

CCR ← NCR

else

CCR ← NCR
```

(CCR stands for Current Channel Register; NCR stands for Next Channel Register)

Assembler:

```
Syntax: done jjj

Example: done 3
```

Clear HE bit for the current channel, send an interrupt to the ARM platform for the current channel and reschedule.

CPU Flags: Unaffected

Cycles: Variable if a context switch is done, 1 otherwise

Description: Clears one of the channel enabling bits (HE or EP for the corresponding channel number) if required. Sends an interrupt to the corresponding ARM platform by setting the appropriate flag, if required (HI for the corresponding channel number). Reschedules according to the mode and the NCP (Next Channel Priority) and CCP (Current Channel Priority) values. According to the scheduling decision, the NCR (Next Channel Register) is copied to the CCR (Current Channel Register) and channel contexts are switched. If several channels with the same highest priority are pending, they are ordered by their number from 31 down to 0. The higher number is selected (for example, channel 26 is selected if channels 3, 12, 14, and 26 with the same highest priority are pending). If no flag is modified, the reschedule can allow the replacement of the current channel by another channel with a priority strictly greater than the current channel priority (yield). Or, it can allow the replacement of the current channel by another channel with a priority greater than or equal to the current channel priority (yieldge). In the latter case, the selected channel will always be the first one with the same priority, starting from channel number 31 down to channel 0 (the current channel does not belong to the set of selectable channels).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	j	j	j	0	0	0	0	0	0	0	0

jjj - Channel Flags field:

000 - No channel flags affected: Reschedule only if the next channel priority is greater than current channel priority (yield)

001 - No channel flags affected: Reschedule only if the next channel priority is greater than or equal to the current channel priority (yieldge)

010 - Clear HE for the current channel and reschedule 011 - Clear HE, set HI for the current channel and reschedule 100 - Clear EP for the current channel and reschedule

101 - Reserved for debug to copy relevant registers into context memory

110 - RESERVED

111 - RESERVED

For the scheduling rules, refer to Scheduler Functional Description. Every possible done instruction is further described as follows:

- done 0/yield is executed by a channel script when it accepts preemption by a higher priority channel;
- done 1/yieldge is executed by a channel script when it accepts preemption by a higher priority channel and it also accepts a roll-up with other channels that have the same priority;
- done 2 is executed by a channel script that was triggered by a ARM platform start via the Channel Start (SDMAARM_HSTART) register, when its task is completed and it requires termination;
- done 3 is executed by a channel script that was triggered by a ARM platform start via the Channel Start (SDMAARM_HSTART) register, when its task is completed, it requires termination and it needs to trigger an interrupt to the ARM platform upon closure;
- done 4 is executed by a channel script that was triggered by a DMA request, when its task is completed and it requires termination;
- done 5 is used in debug mode only; it copies the PCU registers and flags to the context memory of the current channel;

46.17.2.22 ILLEGAL (ILLEGAL Instruction)

Operation:

```
PC ← 0001
```

Assembler:

```
Syntax: illegal
```

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the Illegal instruction routine located at address 0001. All unauthorized instructions result in an Illegal instruction behavior; however, the ILLEGAL instruction must be used to guarantee software compatibility with future versions of the SDMA.

Instruction Format

Table 46-49. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	1	1	1	0	0	0	0	0	1	1	1

46.17.2.23 JMP (Unconditional Jump Immediate)

Operation:

```
PC ← absolute_address
```

Assembler:

```
Syntax: jmp label
```

```
Example: jmp LLL
```

The assembler translates the label to the exact address

CPU Flags:Unaffected

Cycles: 2

Description: Jumps to the absolute address contained the lower 14 bits of the instruction (the PC is a 14-bit register).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	0	a	a	a	a	a	a	a	a	a	a	a	a	a	a

aaaaaaaaaaaaa - address field:

```
00000000000000 - 0
```

```
00000000000001 - 1
```

```
...

11111111111110 - 16382

11111111111111 - 16383
```

46.17.2.24 JMPR (Unconditional Jump)

Operation:

```
PC ← GReg[r]
```

Assembler:

```
Syntax: jmpr r

Example: jmpr 0
```

Jump to address stored in GReg[0]

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the absolute address contained in a General Register.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	0	1	0	0	0

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

46.17.2.25 JSR (Unconditional Jump to Subroutine Immediate)

Operation:

```
RPC ← PC + 1

PC ← absolute_address
```

Assembler:

```
Syntax: jsr r

Example:jsr LLL
```

Jumps to subroutine starting at LLL; the assembler translates the label to exact address

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the subroutine located at the absolute address contained the lower 14 bits of the instruction (the PC is a 14-bit register).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
1	1	a	a	a	a	a	a	a	a	a	a	a	a	a	a

aaaaaaaaaaaaaa - address field:

```
00000000000000 - 0

00000000000001 - 1

...

11111111111110 - 16382

11111111111111 - 16383
```

46.17.2.26 JSRR (Unconditional Jump to Subroutine)

Operation:

```
RPC ← PC + 1

PC ← GReg[r]
```

Assembler:

```
Syntax: jsrr r

Example:jsrr 5
```

Jumps to subroutine located at address stored in GReg[5]

CPU Flags: Unaffected

Cycles: 2

Description: Jumps to the subroutine at address contained in a General Register

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	0	1	0	0	1

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

46.17.2.27 LD (Load Register)

Operation:

```
GReg[r] ← [GReg[b] + displacement]

if (transfer_error)

SF ← 1

else

SF ← 0
```

Assembler:

```
Syntax: ld r,(b,displacement)

Example: ld 1,(2,23)
```

Loads data into GReg[1]; the data is located at address obtained by adding decimal value 23 to GReg[2]

CPU Flags: SF

Cycles: 2+n where n is 0 for ROM, RAM or memory mapped registers, and n is the number of wait-states of the peripheral for a peripheral access

Description: Adds a 5-bit 0-extended displacement to a base address in General Register b; the result is the address of the data to fetch on the DM bus. The data received from the bus is stored in the destination General Register r. If an error occurs during the transfer, the flag SF is set, else it is cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	0	r	r	r	d	d	d	d	d	b	b	b

rrr / bbb - register field:

```
000 - GReg[0]

001 - GReg[1]

...

111 - GReg[7]
```

ddddd - displacement value:

```
00000 - 0

00001 - 1

...

11111 - 31
```

46.17.2.28 LDF (Load Register from Functional Unit)

Operation:

```
GReg[r] ← [fu_address]

if (transfer_error)

SF ← 1

else

SF ←0
```

fu_address is an 8-bit field and depends on addressed functional unit

Assembler:

```
Syntax: ldf r,fu_address

Example: ldf 0,13
```

Loads data coming from the Burst DMA register MD into GReg[0]; it is a 32-bit access with no prefetch

CPU Flags: SF

Cycles: 1+n where n is the number of wait-states that may be inserted by the functional unit

Description: Sends an 8-bit address on the Functional Unit Bus (FU bus) and stores the data received from the bus in the destination General Register r. If an error occurs during the transfer, the flag SF is set, else it is cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	0	0	r	r	r	f	f	f	f	f	f	f	f

See the following sections for more details of the LDF instruction usage with each functional unit:

- Burst DMA Read (ldf) for Burst DMA
- Peripheral DMA Read (ldf)-Read Mode for Peripheral DMA
- Read Instruction (ldf) for CRC unit

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

ffffffff - functional unit source register and action (unspecified values are reserved):

```
00000000 - MSA

00000100 - MDA

00001001 - MD byte

00001010 - MD halfword

00001011 - MD word
```

```
00001100 - MS

00101001 - MD byte - prefetch

00101010 - MD halfword - prefetch

00101011 - MD word - prefetch

01000000 - DSA

10000000 - CA

10000100 - CS (CRC checksum)

11000000 - PSA

11001000 - PD

11010000 - PDA

11011000 - PD in copy mode (rrr contents are lost)

11101000 - PD - prefetch next data

11111111 - PS
```

46.17.2.29 LDI (Load Register with Immediate Value)

Operation:

```
GReg[r] ← immediate
```

Assembler:

```
Syntax: ldi r,immediate

Example: ldi 6,1
```

loads decimal value 1 into GReg[6]

CPU Flags: Unaffected

Cycles: 1

Description: Stores a 0-extended immediate value in a General Register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiiiiii - immediate value:

```
00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255
```

46.17.2.30 LDRPC (Load from RPC to Register)

Operation:

```
GReg[r] ← RPC
```

Assembler:

```
Syntax: ldrpc r

Example: ldrpc 3
```

copies RPC to GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Stores the contents of the RPC in a General Register. That instruction may be used to have more than one level of subroutines.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	0	1	0	1	0

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

46.17.2.31 LOOP (Hardware Loop)

Operation:

```
if (ff%2 == 0)
   SF ← 0
if (ff/2 == 0)
  DF ← 0
if ((GReg[0] == 0) || (SF == 1) || (DF == 1))
   PC ← PC + loop_size + 1
else
   {
      SPC ← PC + 1
      EPC ← PC + loop_size + 1
      LM ← 1
      PC ← PC + 1
   }
```

during every instruction execution in the loop:

```
if ((SF == 1) || (DF == 1))
 {
    LM ← 0
    PC ← EPC
  }
else if ((PC + 1) == EPC)
```

```
 {
    GReg[0] ← GReg[0] - 1
    if (GReg[0] == 0)
      {
         LM ← 0
         PC ← EPC
       }
     else
         PC ← SPC
   }
else
  PC ← nextPC(instruction)
```

after the execution of the last instruction of the loop body:

```
if (GReg[0] == 0)
   T ← 1
else
   T ← 0
```

Assembler:

```
Syntax: loop n{,ff}
Example: loop 3,1
```

Executes GReg[0] times the instructions comprised between PC+1 and PC+3 (included); ff=1 clears the DF flag before starting the loop. When omitted, the ff field is set to 0 (clearing both SF and DF).

CPU Flags: LM[1:0], T

Cycles: 2 when the loop count (GReg[0]) is 0 or SF or DF is set at loop start, 1+1 when the loop starts but exits abnormally (SF or DF set inside the loop which adds 1 cycle to the offending load or store to jump to EPC), 1 when the loop is executed normally

Description: The loop instruction executes a sequence of instructions several times. The number of times is given by the contents of GReg[0], the loop counter. SDMA will jump to the first instruction after the end of the loop if the value in GReg[0] is 0. Otherwise the SDMA enters loop mode. It sets the most significant bit of the LM flag that will only be reset once the last instruction of the last loop is executed. The instructions in the loop are executed GReg[0] times. The management of fault flags (SF and DF) is as follows. When entering the hardware loop, SF and DF can be cleared according to the ff field of the

instruction. After that operation, if any flag is still set the loop will not be executed. The SDMA will jump to the first instruction after the end of the loop without entering loop mode. During the execution of the loop, if any fault flag is set by a LD, LDF, ST, or STF instruction, the SDMA will immediately exit loop mode and jump to the first instruction after the end of the loop. In that case, GReg0 is not decremented for that last piece of the loop body execution (even if the SF or DF flag is set at the last instruction of the loop body). The T flag reflects the state of GReg[0] after the end of the loop, which is an indicator of the complete execution of the loop. If the loop exited because of an error (SF or DF set), GReg[0] will not be 0 at the end of the loop, hence T will be cleared. If the loop executes without fault, GReg[0] will be 0 at the end of the loop, hence T will be set. The boundary case when a source or destination fault occurs at the last instruction of the last loop is considered as an anticipated exit of the loop, which causes the T flag to be cleared. If the last instruction executed before leaving the hardware loop also tries to modify the T flag, the flag is updated according to the value of GReg[0], NOT according to the result of the last executed instruction.

Limitations:

1. 1. Jump instructions (JMP, JMPR, JSR, JSRR, BF, BT, BSF, BDF) are not allowed inside the hardware loop.
2. 2. GReg[0] cannot be written to inside the hardware loop (it can be read).
3. 3. The empty loop (0 instruction in the body) is forbidden.
4. 4. If GReg[0] == 0 at the start of the loop, which causes a jump to EPC, the T flag is not updated.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	1	1	0	f	f	n	n	n	n	n	n	n	n

Instruction Fields:

```
ff - flags field:

00 - clear SF and clear DF

01 - clear DF

10 - clear SF

11 - no clear
```

nnnnnnnn - loop size

```
00000000 - empty loop: forbidden value

00000001 - 1 instruction in the loop

00000010 - 2 instructions in the loop
```

```
...

11111111 - 255 instructions in the loop
```

46.17.2.32 LSL1 (Logical Shift Left by 1 Bit)

Operation:

```
GReg[r]:{b30,...,b1,b0,0} ← GReg[r]:{b31,b30,...,b1,b0}
```

Assembler:

```
Syntax: lsl1 r

Example: lsl1 2
```

multiplies by 2 the value in GReg[2]

CPU Flags: Unaffected

Cycles: 1

Description: Shift the bits of any General Register to the left. The right bit (bit 0) is set to 0. No overflow is detected by the hardware.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	1	1

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

46.17.2.33 LSR1 (Logical Shift Right by 1 Bit)

Operation:

```
GReg[r]:{0,b31,b30,...,b1} ← GReg[r]:{b31,b30,...,b1,b0}
```

Assembler:

```
Syntax: lsr1 r

Example: lsr1 4
```

divides by 2 the unsigned value contained in GReg[4]

CPU Flags: Unaffected

Cycles: 1

Description: Shift the bits of any General Register to the right. The left bit (bit 31) is set to 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	0	1

Instruction Fields:

rrr - destination register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

46.17.2.34 MOV (Logical Move)

Operation:

```
GReg[r] ← GReg[s]
```

Assembler:

```
Syntax: mov r,s

Example: mov 4,0
```

copies GReg[0] to GReg[4]

CPU Flags: Unaffected

Cycles: 1

Description: Move the contents of the source General Register s to the destination General Register r.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	0	0	1	s	s	s

Instruction Fields:

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

46.17.2.35 NOTIFY (Notify to ARM platform)

Operation:

```
 if (jjj & 4 == 0)
 {
   if (jjj&2 == 2)
      HE[CCR] ← 0
   if (jjj&1== 1)
       HI[CCR] ← 1
  }
else if (jjj == 4)
   EP[CCR] ← 0
else
```

(CCR stands for Current Channel Register)

Assembler:

```
Syntax: notify jjj

Example: notify 3
```

clears the HE bit for the current channel and sends an interrupt to the Host for the current channel

CPU Flags: Unaffected

Cycles: 1

Description: Clears one of the channel enabling bits (HE or EP for the corresponding channel number) if required, sends an interrupt to the corresponding ARM platform by setting the appropriate flag if required (HI for the corresponding channel number).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	j	j	j	0	0	0	0	0	0	0	1

jjj - Channel Flags field:

```
000 - unused

001 - set HI for the current channel

010 - clear HE for the current channel

011 - clear HE, set HI for the current channel

100 - clear EP for the current channel

101 - RESERVED

110 - RESERVED

111 - RESERVED
```

46.17.2.36 OR (Logical OR)

Operation:

```
GReg[r] ← GReg[s] | GReg[r]
```

Assembler:

```
Syntax: or r,s

Example: or 3,6
```

ORs GReg[3] and GReg[6] and stores the result in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Performs the OR of the source General Register s and the destination General Register r, and stores the result in the destination General Register r.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	0	1	s	s	s

Instruction Fields:

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

46.17.2.37 ORI (Logical OR with Immediate Value)

Operation:

```
GReg[r] ← GReg[r] | immediate
```

Assembler:

```
Syntax: ori r,immediate

Example: ori 1,56
```

ORs GReg[1] and the decimal value 56 and stores the result in GReg[1]

CPU Flags: unaffected

Cycles: 1

Description: Performs an OR between a 0-extended 8-bit immediate value and a General Register; stores the result in the General Register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	0	1	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiiiiii - immediate value:

```
00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255
```

46.17.2.38 RET (Return from Subroutine)

Operation:

```
PC ← RPC
```

Assembler:

```
Syntax: ret
```

CPU Flags: Unaffected

Cycles: 2

Description: Return from subroutine.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	0

46.17.2.39 REVB (Reverse Byte Order)

Operation:

```
GReg[r]:{B3,B2,B1,B0} ← GReg[r]:{B0,B1,B2,B3}
```

Assembler:

```
Syntax: revb r

Example:  revb 5
```

reverses bytes order in GReg[5]

CPU Flags: Unaffected

Cycles: 1

Description: Reverse the byte order of any General Register.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	0	0	0

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

46.17.2.40 Reverse Low Order Bytes(REVBLO)

Operation:

```
GReg[r]:{B3,B2,B0,B1} ← GReg[r]:{B3,B2,B1,B0}
```

Assembler:

```
Syntax: revblo r

Example: revblo 0
```

reverses low order bytes in GReg[0]

CPU Flags: Unaffected

Cycles: 1

Description: Reverse both low order bytes of any General Register.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	0	0	1

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

46.17.2.41 ROR1 (Rotate Right by 1 Bit)

Operation:

```
GReg[r]:{b0,b31,b30,...,b1} ← GReg[r]:{b31,b30,...,b1,b0}
```

Assembler:

```
Syntax: ror1 r

Example: ror1 3
```

rotates bits to the right in GReg[3]

CPU Flags: Unaffected

Cycles: 1

Description: Rotate the bits of any General Register to the right.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	1	0	0

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

46.17.2.42 RORB (Rotate Right by 1 Byte)

Operation:

```
GReg[r]:{B0,B3,B2,B1} ← GReg[r]:{B3,B2,B1,B0}
```

Assembler:

```
Syntax: rorb r

Example: rorb 2
```

rotates bytes to the right in GReg[2]

CPU Flags: Unaffected

Cycles: 1

Description: Rotate the bytes of any General Register to the right.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	0	0	0	1	0	0	1	0

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

46.17.2.43 SOFTBKPT (Software Breakpoint)

Operation:

Stops the current script and enters debug mode

Assembler:

```
softbkpt
```

CPU Flags: Unaffected

Description: When the core executes this instruction, it has the same effect as receiving a debug request from the OnCE or via the external debug request input: the script execution halts, the PCU enters its debug state and waits for the OnCE commands that are described in OnCE and Real-Time Debug.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	1

46.17.2.44 ST (Store Register)

Operation:

```
[GReg[b] + displacement] ← GReg[r]

if (transfer_error)

 DF ← 1

 else

DF ← 0
```

Assembler:

```
Syntax: st r,(b,displacement)

Example: st 7,(0,9)
```

stores the value from GReg[7] into memory at address obtained by adding decimal value 9 to GReg[0]

CPU Flags: DF

Cycles: 2+n where n is 0 for ROM, RAM or memory mapped registers, and n is the number of wait-states of the peripheral for a peripheral access

Description: Adds a 5-bit 0-extended displacement to a base address in General Register b; the result is the address of the data to store on the DM bus. The data sent on the bus comes from the source General Register r. If an error occurs during the transfer, the flag DF is set, else it is cleared.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	1	1	r	r	r	d	d	d	d	d	b	b	b

Instruction Fields:

rrr / bbb - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]
```

```
111 - GReg[7]
```

ddddd - displacement value:

```
00000 - 0

00001 - 1

...

11111 - 31
```

46.17.2.45 STF (Store Register in Functional Unit)

Operation:

```
[fu_address] ← GReg[r] 0

if (transfer_error) 0

DF ← 1 0

else 0

DF ← 0
```

fu_address is an 8-bit field

Assembler:

```
Syntax: stf r,fu_address

Example: stf 3,0x2B
```

stores the 32-bit contents of GReg[3] to the Burst DMA register MD; waits until the flush to external memory is completed

CPU Flags: DF

Cycles: 1+n where n is the number of wait-states that may be inserted by the functional unit

Description: Sends an 8-bit address on the Functional Unit Bus (FU bus) and sends the contents of the source General Register r on the bus. If an error occurs during the transfer, the flag DF is set, else it is cleared.

Table 46-50. Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	1	0	1	r	r	r	f	f	f	f	f	f	f	f

See the following sections for more details of the STF instruction usage with each functional unit:

- Burst DMA Write (stf) for Burst DMA
- Peripheral DMA Write (stf)-Write Mode for Peripheral DMA
- Write Instruction (stf) for CRC

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

ffffffff - functional unit destination register and action (unspecified values are reserved):

00000000 - MSA in incremented mode

00000100 - MDA in incremented mode

00001001 - MD byte

00001010 - MD halfword

00001011 - MD word

00001100 - clear MS error flag

00001111 - MS

00010000 - MSA in frozen mode

00010100 - MDA in frozen mode

00011000 - MD in copy mode - number of words in rrr

00100000 - MSA in incremented mode - start prefetch

00101000 - MD no data - flush

00101001 - MD byte - flush

00101010 - MD halfword - flush

00101011 - MD word - flush

00110000 - MSA in frozen mode - start prefetch

10000000 - CA

10000100 - init CRC accumulator

10010100 - CS byte - compute CRC

10010101 - CS byte - compute CRC

10010110 - CS halfword - compute CRC

10010111 - CS word - compute CRC

11000001 - PSA in frozen mode - 8-bit data width

11000010 - PSA in frozen mode - 16-bit data width

11000011 - PSA in frozen mode - 32-bit data width

11000101 - PSA in incremented mode - 8-bit data width

11000110 - PSA in incremented mode - 16-bit data width

11000111 - PSA in incremented mode - 32-bit data width

11001000 - PD

11001001 - PSA in decremented mode - 8-bit data width

11001010 - PSA in decremented mode - 16-bit data width

11001011 - PSA in decremented mode - 32-bit data width

11001100 - clear PS error flag

11001101 - PSA data width becomes 8-bit

11001110 - PSA data width becomes 16-bit

11001111 - PSA data width becomes 32-bit

11010001 - PDA in frozen mode - 8-bit data width

11010010 - PDA in frozen mode - 16-bit data width

11010011 - PDA in frozen mode - 32-bit data width

11010101 - PDA in incremented mode - 8-bit data width

11010110 - PDA in incremented mode - 16-bit data width

11010111 - PDA in incremented mode - 32-bit data width

11011001 - PDA in decremented mode - 8-bit data width

11011010 - PDA in decremented mode - 16-bit data width

11011011 - PDA in decremented mode - 32-bit data width

11011101 - PDA data width becomes 8-bit

11011110 - PDA data width becomes 16-bit

11011111 - PDA data width becomes 32-bit

11100001 - PSA in frozen mode - 8-bit data width - prefetch data

11100010 - PSA in frozen mode - 16-bit data width - prefetch data

11100011 - PSA in frozen mode - 32-bit data width - prefetch data

11100101 - PSA in incremented mode - 8-bit data width - prefetch data

11100110 - PSA in incremented mode - 16-bit data width - prefetch data

11100111 - PSA in incremented mode - 32-bit data width - prefetch data

11101001 - PSA in decremented mode - 8-bit data width - prefetch data

11101010 - PSA in decremented mode - 16-bit data width - prefetch data

11101011 - PSA in decremented mode - 32-bit data width - prefetch data

11101101 - PSA data width becomes 8-bit - prefetch data

11101110 - PSA data width becomes 16-bit - prefetch data

11101111 - PSA data width becomes 32-bit - prefetch data

11111111- PS

46.17.2.46 SUB (Subtract)

Operation:

```
GReg[r] ← GReg[r] - GReg[s]

T ← (GReg[r] == 0)
```

Assembler:

```
Syntax: sub r,s

Example: sub 4,7
```

SUBtracts GReg[7] from GReg[4] and stores the result in GReg[4]

CPU Flags: T

Cycles: 1

Description: Subtracts the source General Register s from the destination General Register r, and stores the result in the destination General Register r. The T flag is set if the result of the operation is 0; it is cleared if the result is not 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	1	0	0	s	s	s

Instruction Fields:

rrr / sss - register fields:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

46.17.2.47 SUBI (Subtract with Immediate)

Operation:

```
GReg[r] ← GReg[r] - immediate

T ← (GReg[r] == 0)
```

Assembler:

```
Syntax: sub r,immediate

Example: sub 1,255
```

SUBtracts decimal value 255 from GReg[1] and stores the result in GReg[1]

CPU Flags: T

Cycles: 1

Description: Subtracts a 0-extended 8-bit immediate value from a General Register; stores the result in the General Register. The flag T is set when the result of the operation is 0; otherwise, it is cleared. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	1	0	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiiiiii - immediate value:

```
00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255
```

46.17.2.48 TST (Test with Zero)

Operation:

```
T ← ((GReg[s] & GReg[r]) != 0)
```

Assembler:

```
Syntax: tst r,s

Example: tst 2,3
```

ANDs GReg[2] and GReg[3] and sets T if the result is non-null

CPU Flags: T

Cycles: 1

Description: Performs the AND of the source General Register s and the destination General Register r, and sets T if the result is not 0, clears T if the result is 0.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	1	0	0	0	s	s	s

Instruction Fields:

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

46.17.2.49 TSTI (Test Immediate)

Operation:

```
T ← ((GReg[r] & immediate) != 0)
```

Assembler:

```
Syntax: tsti r,immediate

Example: tsti 5,13
```

ANDs GReg[5] and decimal value 13 and sets T if the result is non-null

CPU Flags: T

Cycles: 1

Description: Performs the AND of a 0-extended 8-bit immediate value and the destination General Register r, and sets T if the result is not 0, clears T if the result is 0. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	1	0	0	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - destination register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiiiiii - immediate value:

```
00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255
```

46.17.2.50 XOR (Logical Exclusive OR)

Operation:

```
GReg[r] ← GReg[s] ^ GReg[r]
```

Assembler:

```
Syntax: xor r,s

Example: xor 0,3
```

XORs GReg[0] and GReg[3] and stores the result in GReg[0]

CPU Flags: Unaffected

Cycles: 1

Description: Performs the eXclusive OR of the source General Register s and the destination General Register r, and stores the result in the destination General Register r.

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	0	0	r	r	r	1	0	0	1	0	s	s	s

Instruction Fields:

rrr / sss - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

46.17.2.51 XORI (Exclusive OR with Immediate)

Operation:

```
GReg[r] ← GReg[r] ^ immediate
```

Assembler:

```
Syntax: xori r,immediate

Example: xor 7,5
```

XORs GReg[5] and decimal value 5 and stores the result in GReg[7]

CPU Flags: Unaffected

Cycles: 1

Description: Performs an eXclusive OR between a 0-extended 8-bit immediate value and a General Register; stores the result in the General Register. The immediate value is the low-order byte of the instruction and has a maximum value of 255 (0xFF).

Instruction Format

15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
0	0	0	1	0	r	r	r	i	i	i	i	i	i	i	i

Instruction Fields:

rrr - register field:

```
000 - GReg[0]

001 - GReg[1]

010 - GReg[2]

011 - GReg[3]

100 - GReg[4]

101 - GReg[5]

110 - GReg[6]

111 - GReg[7]
```

iiiiiiii - immediate value:

```
00000000 - 0

00000001 - 1

...

11111110 - 254

11111111 - 255
```

46.17.2.52 YIELD, YIELDGE (DONE, Yield)

By default, unsupported assembler syntax. Can be aliased to the corresponding done instructions (yield = done 0; yieldge = done 1). Refer to the done instruction description DONE (DONE, Yield) .

46.18 Software Restrictions

46.18.1 Unsupported Burst DMA Access Sequence

The SDMA does not support triggering a pre-fetch followed by a flush of the Burst DMA without reading or writing any data. If the flush occurs while the background pre-fetch DMA operation is still in progress, it could result in un-defined behavior.

An example of the sequence which could result in undefined results is shown in the following example:

Instruction sequence not supported

```
          stf r1, MSA|PF              ; Update source address, triggers data pre-fetch in the
background
          mov R0,R0                ; Execute multiple assembly instructions, none of which
read
          mov R0,R0                ; or write data to/from MD
          stf MD|SZ0|FL               ; Flush FIFO without writing data. If the pre-fetch is
still in
                                  ; progress when this instruction is executed, there could be
```

; undefined operation.

A work-around to avoid any undesirable results is to first read MD to ensure the pre-fetch is complete before the flush is attempted.

Work-Around to previous example

```
          stf r1, MSA|PF              ; Update source address, triggers data pre-fetch
          mov R0,R0                ; Execute multiple assembly instructions, none of which
read
          mov R0,R0                ; or write data to/from MD
          ldf r2, MD                 ; dummy read of MD to ensure pre-fetch is complete before
the
                                  ; next instruction
```

stf MD|SZ0|FL ; Flush FIFO without writing data.

46.19 Application Notes

46.19.1 Data Structures for Boot Code and Channel Scripts

SDMA boot code downloads the different channel contexts and the scripts that will be executed on SDMA channels during the application. The boot code is run after reset when channel 0 is started by the ARM platform.

The boot code is also known as channel 0 script.

The boot code is based on the Channel Control Block (CCB) and Buffer Descriptor (BD) mechanisms that are data structures located into the ARM platform memory space. With these data structures, it is possible to instruct SDMA to download scripts and contexts but also to dump a context or a script to a destination data buffer. Channel scripts also use the CCB and BD data structures to pass instructions and/or pointers to data to be copied.

The format, processing, and field definition of the CCB and BD are defined and performed entirely by the software script rather than the SDMA hardware. An overview of the format and structure is provided here, but for complete details refer to the SDMA software documentation (see SDMA Scripts).

The CCB and BD data structures are accessed by SDMA using DMA and processed by the SDMA scripts. The ROM contains common sub-routines for processing these data structures which may be called by the bootload and channel scripts.

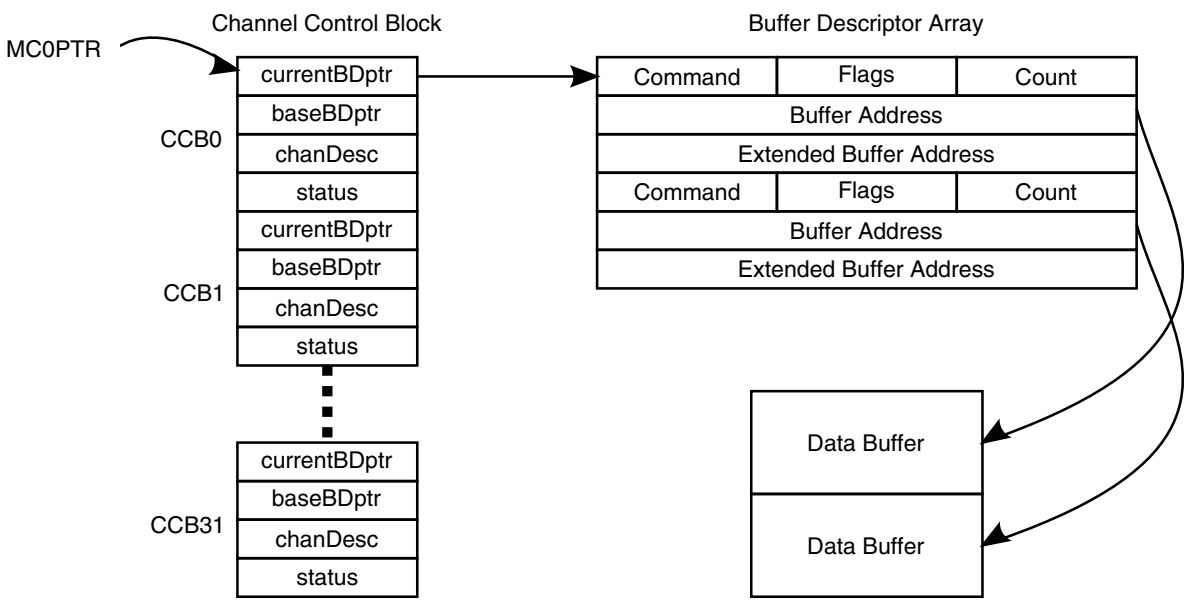

Figure 46-17. Data Structures Layout

The previous figure shows an example how these data structures are linked to pass command and pointers to data buffers. The SDMA's MC0PTR register holds the base address of the Channel 0 Control Block (CCB0). The Channel 0 control block holds a pointer to the array of buffer descriptors. The buffer descriptors are used to tell the channel 0 (boot channel) what to do as described Buffer Descriptor Format.

46.19.1.1 Buffer Descriptor Format

Buffer descriptors are three longs (32-bit words) in size as, shown in the following figure. A buffer descriptor describes the properties of the data buffer it points to. The buffer descriptors can be used for linear or circular data buffers in the ARM platform processor memory. The CCB contains a pointer to the base BD as well as the current BD.

Table 46-51. Buffer Descriptor

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
Command								-	-	L	R	I	C	W	D	Count															
Buffer Address																															
Extended Buffer Address																															

Table 46-52. Buffer Descriptor Field Descriptions

Field	Description
31-24 Command	Command. The command field is used to differentiate operations performed within a script when the script accesses this particular buffer descriptor. The use of this field can be defined by the script. The command values defined for the bootload script are defined in Buffer Descriptor Commands for Bootload scripts. Refer to the individual script definition in script library documents in SDMA Scripts for command field definitions for other scripts.
23	Reserved
22	Reserved
21 L	Last Buffer Descriptor: This bit is set in SDMA IPC scripts to indicate to the receiving Core that the transfer has ended. Whenever the source finishes transferring the count it wanted to transfer, it sets LAST_BIT in the destination BD, to let the destination know that transfer is over.This bit also tells the destination software that when it processes the destination BDs, they need not process any BD after the BD with the LAST_BIT set.For example, when the DSP prepares a single buffer descriptor with count equals to 25 and ARM platform prepares a single buffer descriptor with count equals 100. When 25 bytes have been transferred from DSP to ARM platform, the DSP buffer descriptor is normally closed while the ARM platform buffer descriptor will have the L bit set and the byte count updated to 25.
20 R	erroR. Indicates an error occurred on the channel's buffer descriptor requested command. Some scripts may overwrite the command field with an error code indicating the source of the error. 0 No Error 1 Error
19 I	Interrupt. When SDMA has finished to process data transfer attached to this buffer descriptor, send an interrupt to the ARM platform. 0 No Interrupt 1 Interrupt the processor when BD is complete
18 C	CONTinuous. This buffer is allowed to receive multiple transmit buffers or is allowed to transmit to multiple receive buffers.The Continuos bit is decoded at the end of the processing of a BD to determine if the SDMA script must open a new BD to potentially continue the data transfer. 0 No further buffer descriptors 1 SDMA should move to the next Buffer descriptor after this one

Table continues on the next page...

Table 46-52. Buffer Descriptor Field Descriptions (continued)

Field	Description
17 W	Wrap. Indicates if this buffer descriptor is the last one for the channel control block. When encountering this bit set, the SDMA scripts updates the CurrentBD pointer to point to the first Buffer Descriptor of the array. This bit is set if the ARM platform wants to organize the array of BD in a circular way (like a ring). When all BD have been processed and if Wrap bit and CONtinuous bit are set in the last BD, the SDMA script will wrap around and it will try to re-open the first BD. 0 No Error 1 Wrap to first buffer descriptor after this one is processed.
16 D	D - "Done": bit 16: indicates the "ownership" of the buffer descriptor. When D=0 the host owns the buffer descriptor; when D=1 SDMA owns the buffer descriptor. In the case of the channel 0, D=1 indicates the SDMA has not yet processed this buffer, D=0 indicates the SDMA has processed this buffer. 0 ARM platform owns the buffer. 1 SDMA owns the buffer
15-0 Count	Count. the count field (bit 15-0) indicates the size of the data to be transmitted, the size of the data buffer pointed to by the buffer descriptor. The SDMA memory structure is different for program memory (16-bits shorts/ half-words) and data memory (32-bits long). For channel 0 buffer descriptors, Count is expressed in 16-bit half-words when PM is addressed and in 32-bit words when DM is addressed. Count is typically expressed in bytes for other channel scripts, but the unit is dependant on the script.
31-0	Buffer address. Address pointer to the data buffer.
31-0	Extended buffer address. Additional pointer or other information required by some scripts.

The buffer descriptors form an array of programmable size. If the last buffer descriptor is marked by the Wrap flag-bit W=1, the array of buffer descriptor is treated as a ring with some logically continuous portion owned by the ARM platform with D=0, and the remainder owned by the SDMA with D=1. The count field of the buffer descriptor indicates how much data has been transmitted.

If ARM platform has prepared 3 buffers to be filled by the SDMA script, it has also prepared 3 BD, one for each buffer. The *Cont* and *Wrap* bits are used to organize the buffers in a circular way. For example, *CONT*inous bit is set to 1 in the 2 first BDs and *Wrap* is set in the 3rd BD. The SDMA script opens and processes BD#1. Since *CONT*inous bit is set for this BD, the SDMA will open the second BD and it will process it. Each time a BD is processed, its *Done* bit is reset by the SDMA. After the 3rd BD, if *CONT*inous is not set but if *Wrap* is set, the SDMA script stops here and the next time the channel will be triggered, the script will open the BD pointed by the currentBDptr pointer of the CCB and it will correspond to the first buffer descriptor.

If the *CONT*inous bit and *Wrap* bits are both set in the 3rd BD, the script will close it and it will try to open the first BD. An error may occur at this point if the BD#1 has already been processed and its *Done* bit is 0. The SDMA script cannot process a BD with a *Done* bit to 0. It means the BD is not ready to be processed. To avoid this situation, the *CONT*inous bit should not be set for the last BD if *Wrap* is set, and the Interrupt flag must set for the last BD. It will warn the owner of the BD that all the BDs have been processed and it has to re-set to 1 the *Done* bit of all the BD's if it desires the SDMA to

fill them again. Basically, if the ARM platform expects the SDMA to fill up the buffers in a circular fashion, then it's the responsibility of the ARM platform to set the *Done* bit of a buffer descriptor at an appropriate time.

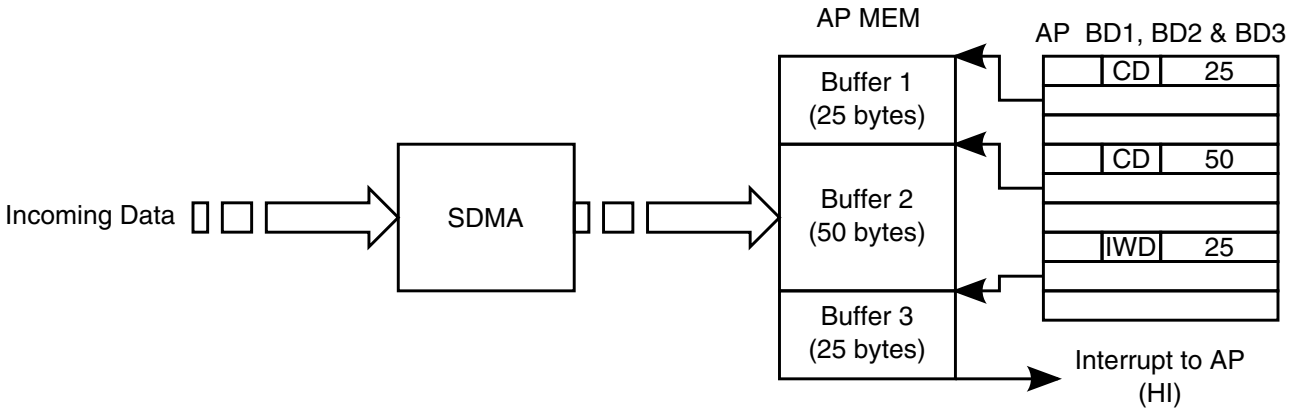

Figure 46-18. Buffer Descriptor Flow

The previous figure shows an example buffer descriptor flow. When the incoming data is stored and fills the first buffer of 25 bytes, the SDMA script opens the second BD because the CONTinuous bit was set. Then next incoming data is put in the second buffer. After receiving 50 bytes, the second buffer descriptor is also closed. The Done bit is reset and the third BD is opened. After receiving another 25 bytes, the third buffer is full and an interrupt is sent to the ARM platform because the Interrupt flag is set in the 3rd BD. The CONTinuous flag is not present the transfer is over. The next time the script will be triggered, the BD to be opened will be the first buffer descriptor since the Wrap flag was set in the 3rd BD. It is the ARM platform responsibility to set the Done bit of all the BD if it wants to use the same buffers.

46.19.1.2 Buffer Descriptor Commands for Bootload scripts

The command field of the buffer descriptor is defined separately for each script.

The following table lists the buffer descriptor commands defined for the channel 0 bootload script.

Table 46-53. Channel Zero Buffer Descriptor Commands

Command Field (binary)	Command	Description	Buffer Address	Extended Buffer Address
0000_0001 (0x01)	C0_SET_DM	Load SDMA data memory (RAM) from ARM platform memory buffer	ARM platform memory source address	SDMA memory destination address
0000_0010 (0x02)	C0_GET_DM	Copy SDMA data memory (RAM) to ARM platform memory buffer	ARM platform memory destination address	SDMA memory source address
0000_0100 (0x04)	C0_SET_PM	Load SDMA program memory (RAM) from ARM platform memory buffer	ARM platform memory source address	SDMA memory destination address
0000_0110 (0x06)	C0_GET_PM	Copy SDMA program memory (RAM) to ARM platform memory buffer	ARM platform memory destination address	SDMA memory source address
cccc_c111 (0x07 | CHN)	C0_SETCTX	Load Context for channel cccc into SDMA RAM from ARM platform memory buffer	ARM Platform memory source address	-
cccc_c011 (0x03 | CHN)	C0_GETCTXT	Copy Context for channel ccccc from SDMA RAM to ARM platform memory buffer	ARM platform memory destination address	-

The Channel 0 bootload commands are summarized as follows:

- C0_SET_[PM-DM]: load the buffer descriptor data in the SDMA local memory at the address pointed to by the "extended buffer address" field. The SDMA RAM can be seen as a Program Memory (PM, 16-bit address) or Data Memory (DM 32-bit address). When C0_SET_PM is used, the count field is expressed in "shorts" (16-bit half words), this command can be used to download scripts. When C0_SET_DM is used, the count field is expressed in "long" (32-bit words), this command can be used to download channel contexts to the context channel area in RAM.
- C0_GET_[PM-DM]: write to the buffer descriptor's data buffer the content of the SDMA local memory from the address pointed to by the "extended buffer address" field for the length defined by the count in the buffer descriptor. C0_GET_PM is used to dump some part of the Program Memory (may be used to dump context of a channel), therefore count is expressed in "shorts"; while C0_GET_DM is used to dump to the buffer descriptor's data buffer, so the count field is in "longs."
- C0_SETCTX: load a context into the SDMA context page area. The handling script decodes the channel number from the 5 MSB of the command field of the buffer descriptor. Using the channel number the script computes the offset of the context data pointer for the channel relative to the context page base to use as the destination

address in SDMA memory. Then the C0_SET_DM command explained above is invoked to load SDMA RAM from memory. The counter indicates the size in words of the context structure.

- Command value: (in binary) cccc c111, where ccccc is the channel number (5 bits). For instance, 0x0F means set context for channel 1, 0xFF means set context for channel 31.

- C0_GETCTX: write to the buffer descriptor's data buffer the content of the SDMA context page area. The handling script decodes the channel number from the 5 MSB of the command field of the buffer descriptor. Using this channel number, the script computes the offset of the context data pointer for the channel relative to the context page base to use as the source address for the copy. Then the C0_GET_DM command explained above is invoked to copy the context to memory. The counter indicates the size in words of the context structure.
- Command value: (in binary): cccc c011, where ccccc is the channel number (5 bits). For instance, 0x03 means get context of channel 1, 0xFB means get context of channel 31.

NOTE

To download channel context, C0_SETDM and C0_SETCTXT command can be used but the second one is easier because the channel number is embedded into the command field, whereas with the C0_SETDM, the pointer to the channel context area must be written into the extended buffer address field of the buffer descriptor.

46.19.1.3 Example of Buffer Descriptors for Channel 0.

Figure 46-20 illustrates the buffer descriptors that must be set in ARM platform memory space, before execution of boot code, to download contexts and scripts of channels 1, 4, and 10. After boot code execution, SDMA memory will be populated with the different contexts and scripts as presented in the following figure.

46.19.1.4 Channel Context

There are 32 channel context memory structures pointed to by the local save area pointer. These channel context memory structures are fixed.

The script in the SDMA computes the memory offset for a given channel based on the structure length and channel number. Figure below shows the structure of the channel context as it is saved in the SDMA local memory (RAM).

A channel context consists in 24 words, one per register. A total of 32 words are reserved for every channel. The additional 8 words are called scratch ram and they are dedicated to each channel. This memory area is commonly used for stack management.

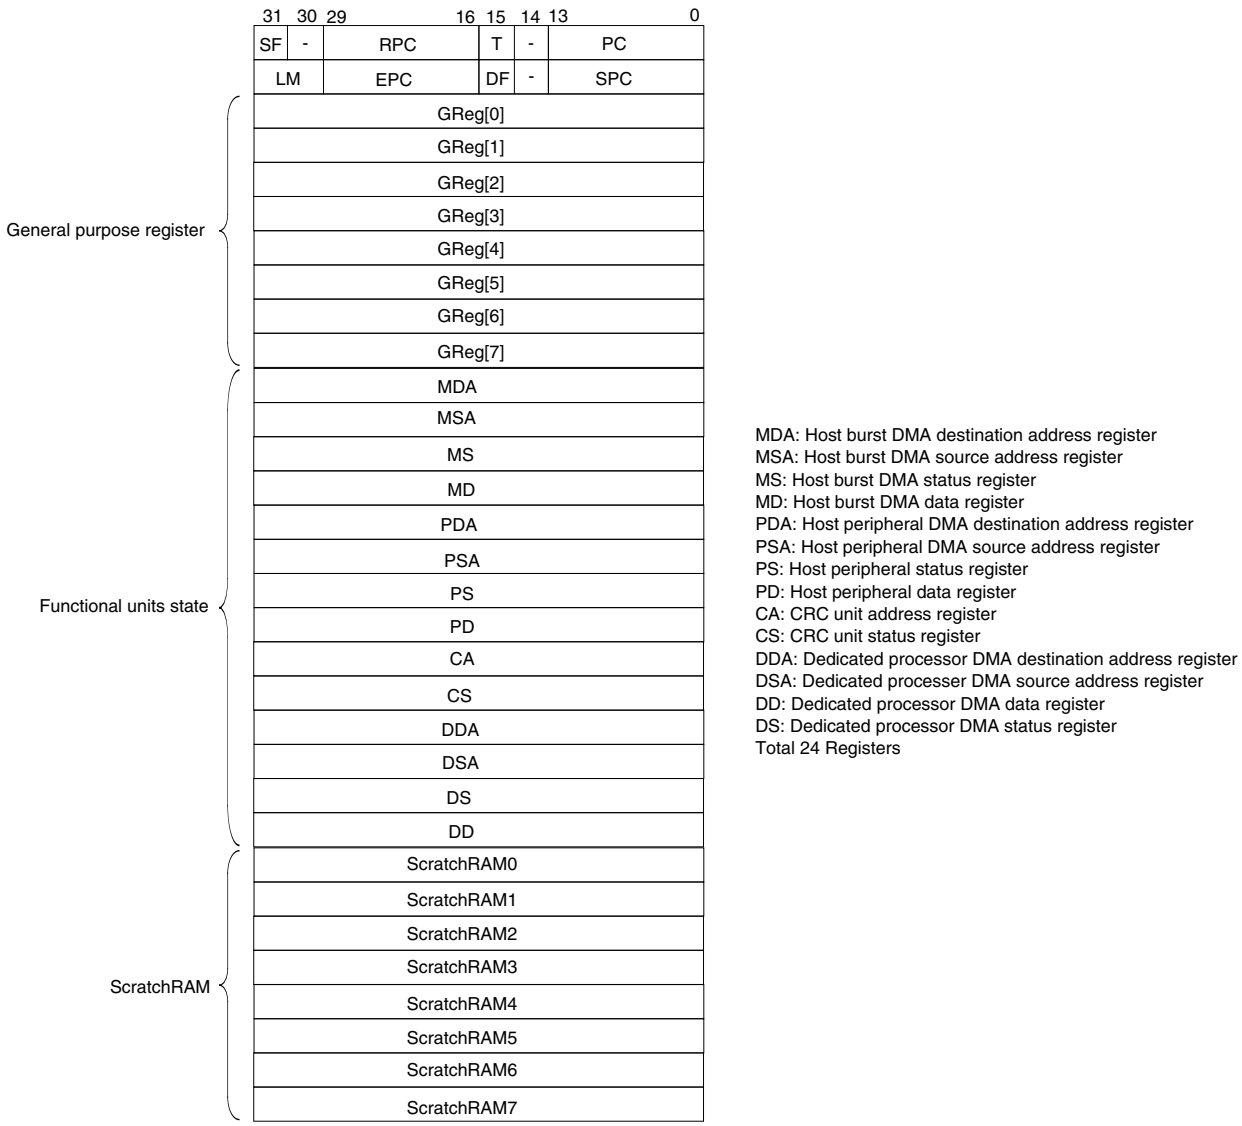

Figure 46-21. Channel Context Memory Structure

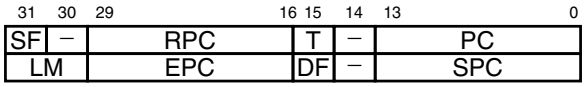
The structure is divided in 4 areas:

- Channel status registers
- General purpose registers
- Functional units state registers reflecting the state of the ARM platform DMAs (Burst and Peripheral DMA) and the CRC unit.
- Scratch RAM

The details of the channel context status registers are described in the following figure.

The PC field of the first long register must point to the SDMA RAM address where the script that will be executed on the channel is located and this value equals the one stored in the extended buffer address of the buffer descriptor with C0_SETPM command.



SF: Source fault while loading data
RPC: Return program counter
T: Test bit: status of arithmetic and test instructions
PC: Program counter
LM: Loop mode
EPC: Loop end program counter
DF: Destination fault while storing data
SPC: Loop Start program counter

Figure 46-22. SDMA State Registers (ShPC, ShLoop)

46.19.2 Typical Data Transfer Supported by SDMA DMA Units

This section presents a library of SDMA scripts that perform data transfers through the peripheral DMA and the burst DMA units.

The ARM platform memory and peripherals are devices that either the peripheral DMA or the burst DMA can access. The scripts are given for a peripheral DMA whose address registers are programmed in incremented mode when internal memory is involved. See the following table for the summary.

Table 46-54. Typical Data Transfers Summary

Data Transfer	Peripheral DMA	Burst DMA	Comments
ARM platform External Memory ↔ ARM platform External Memory		3	Copy mode Script example, see Burst DMA Unit Copy Mode and External Memory to External Memory.
ARM platform Peripheral ↔ ARM platform Peripheral	3		Copy mode if same data path width Script example, see Peripheral to Peripheral Transfer.
ARM platform External Memory ↔ ARM platform Peripheral	3	3	Data transit through SDMA Script example, see Transfer Between Peripheral and External Memory.
ARM platform External Memory ↔ ARM platform Internal Memory		3	Copy mode Script example, see Transfer Between External Memory and Internal Memory.

Table continues on the next page...

Table 46-54. Typical Data Transfers Summary (continued)

Data Transfer	Peripheral DMA	Burst DMA	Comments
ARM platform Internal Memory ↔ ARM platform Internal Memory		3	Copy mode Script example, see Internal Memory to Internal Memory.
ARM platform Internal memory ↔ ARM platform Peripheral	3		Data transit through SDMA Script example, see Transfer Between Peripheral and Internal Memory.

NOTE

These scripts are provided as examples of how to use DMA blocks to perform required data transfers: They are not "official" programs.

46.19.2.1 External Memory to External Memory

This section describes the SDMA script that performs data moves in external memory.

For this particular data transfer, only the burst DMA is used. It is programmed in copy mode, so no data transmits through an SDMA general register.

The SDMA core only monitors data transfer status. It is assumed source and destination address values are already present in two SDMA general registers (r1 and r2). For this example, it is also assumed that a 32-bit word-to-move for source-to-destination address is present in r0 and equals 64.

Data Moves in External Memory

```
1          stf r1,MSA                          // Source address setup

2          stf r2,MDA                          // Destination address setup

3          ldi r0,0x64                         // 64 words must be transferred from MSA to
MDA

4          ldi r1,0x8

MAIN_XFER:

5          cmphs r0,r1                         // Is r0 >= 0x8

6          bf LAST_XFER                      // If not, jump to last transfer label

7          stf r1,MD|CPY                        // Copy 8 words from MSA to MDA address.

8          subi r0,0x8                         // Decrement counter

9          jmp MAIN_XFER                     // return to main transfer loop

LAST_XFER:

10         stf r0,MD|CPY                        // perform last transfer
```

All instructions are performed in one cycle (jumps excepted). Instruction 7 triggers a copy transfer: A read burst access of 8-word starts, data is staged in MD and then a write burst of 8 words is executed. Instruction 8, 9, 5, and 6 are executed while the burst access is in progress. If this access is not complete when instruction 7 is executed a second time, SDMA stalls on this instruction as long as the previous copy transfer is not over. In this case, the instruction is no longer a one-cycle instruction.

During the main loop (MAIN_XFER), r1 always equals 8, so burst lengths are 8 words. On the last ldf |CPY instruction (10), r1 equals the reminder of r0 divided by 8; therefore, the length of bursts triggered in copy mode equal r1 value, which is between 1 and 7.

46.19.2.2 Peripheral to Peripheral Transfer

For this data transfer, only the peripheral DMA is used. It is programmed in copy mode, so no data will transmit through the SDMA general register used in the ldf instruction, but the contents of the general register are lost.

The SDMA core only monitors the transfer.

46.19.2.2.1 Source and Destination Target Have the Same Data Path Width

When the source and destination target have the same data path width, the following is true:

- Source target is a *half-word* (16-bit) peripheral located at address 0x1002.
- Destination is a *half-word* (16-bit) peripheral located at address 0x2006.

It is assumed the address values are already present in two SDMA general registers (r1, r2). The script for a transfer of 10 half-word is as follows:

Same Data Path Width for Source and Destination

```
//SETUP SECTION
1         stf r1, PSA|SZ16|F                    //r1=0x1002 Source address register setup
2         stf r2, PDA|SZ16|F                    //r2=0x2006 Destination address register
setup
3         bdf ERROR_ADDR_SETUP
4         ldi r0,0xa                          //loop counter is 10
//MAIN LOOP TRANFER
copy_loop:

5         loop 2,0
6           ldf r7,PD|CPY                     //Reads 1 half-word from src and writes to
dest.
7           yield
8         bdf ERROR_DURING_XFER
ERROR_ADDR_SETUP:
                    //correction of PSA/PDA setup and jumps to main loop transfer
ERROR_DURING_XFER:
//flag error is set,
//PS can be read to know if error occurs during read or write access.
```

If a data transfer must occur between two word peripherals, only the setup section should be updated. The transfer itself is always performed by the hardware loop instruction.

All instructions are executed in one cycle (change of flow excepted). On instruction 6, a single read access is triggered, read data is staged in PD, and a write-to-destination is executed. When the transfers are in progress, the SDMA can execute he next instructions in parallel. If instruction 6, which performs the copy transfer, is executed while the previous access is not over, SDMA is stalled and instruction ldf is a multi-cycle instruction.

46.19.2.2.2 Source and Destination Target Have a Different Data Path Width

When the source and destination target have a different data path width, copy mode cannot be used, and any attempt to initiate a copy transfer immediately raises an error, which is stored in the SF flag.

The following example shows the SDMA code that could transfer 10 words from a *word* (32-bit) peripheral to a *half-word* peripheral whose addresses are preliminary and stored in r1 and r2.

Different Data Path Width for Source and Destination

```
//SETUP SECTION
1         stf r1, PSA|SZ32|F|PF                  //r1=0x1000 and prefetch data
2         stf r2, PDA|SZ16|F                    //r2=0x2006
3         bdf ERROR_ADDR_SETUP
4         ldi r0,0xa                           //loop counter is 10
//MAIN LOOP TRANFER
main_loop_xfer_16_16:
5         loop 6,0
6           ldf r7,PD                         //copy 32-bit of PD in r7
7           stf r7,PD                          //store 16 LSB of r7 in PD and a flush is
executed
8           rorb r7
9           rorb r7                          //16 MSB --> 16 LSB
10          stf r7,PD                          //store 16 LSB of r6 in PD and a flush.
11          yield
```

On instruction 1, when the source address register is programmed and a data prefetch is required, a read access is executed. In parallel, the SDMA executes instructions 2 to 5. On instruction 6, the SDMA tries to read data that was fetched by instruction 1. If data is ready, the ldf will be a one cycle instruction; otherwise, the SDMA is stalled as long as the read access is not finished. Then, the 16 LSB of the read data is stored in PD and automatically flushed to the destination peripheral. In parallel, the SDMA executes the rotation instructions (8, 9), and stores the 16 MSB of the read data into PD. If a previous write access is finished, instruction 10 will be a one-cycle instruction.

The main loop transfer may appear inefficient, but due to wait states imposed to the peripheral DMA each time an external access is performed, a software pipeline is in place. During the time needed to flush PD, the SDMA executes the move and rotation operations. SDMA executes instructions in parallel with DMA accesses.

46.19.2.3 Transfer Between Peripheral and External Memory

46.19.2.3.1 Peripheral to External Memory Transfer

A transfer from a peripheral to the external memory controller involves the peripheral DMA and the burst DMA.

The code for transferring 100 word from word peripheral to the external memory would be as follows:

Peripheral to External Memory Transfer

```
//SETUP SECTION source and destination addresses are already in r1 and r2
1         stf r1, PSA|SZ16|F|PF                  //r1=0x1000 and prefetch 32-bit data
2         stf r2, MDA                          //r2=0x2000, setup burst DMA destination
address
3         bdf ERROR_ADDR_SETUP
4         ldi r0,0x64                           //loop counter is 100
5
          //MAIN LOOP TRANFER
6         loop 3,0
7           ldf r1,PD|PF                        // read 32 bits of PD and initiate a new read
access.
8           stf r1,MD|32                         // store 32 bits of r1 in the MD fifo.
9           yield
10        ldf r1,PD                            // last word data is read
11        stf r1,MD|32|FL                        // to flush all remaining bytes of MD
```

On instruction 1, the source address register of the peripheral DMA is programmed and data is fetched. This data is stored in PD and the SDMA reads PD during instruction 7, which is a one-cycle instruction that is read-access finished. On the same instruction (7), a data prefetch is required and a read access to the source peripheral is executed. In parallel, the SDMA stored the previous read data into the data register of MD. When MD (which is an eight-word FIFO) is full, a burst write access is executed to empty the FIFO. As long as the next SDMA instructions do not access the burst DMA, they will be one-cycle instructions. The following figures show how the peripheral DMA and burst DMA work in parallel.

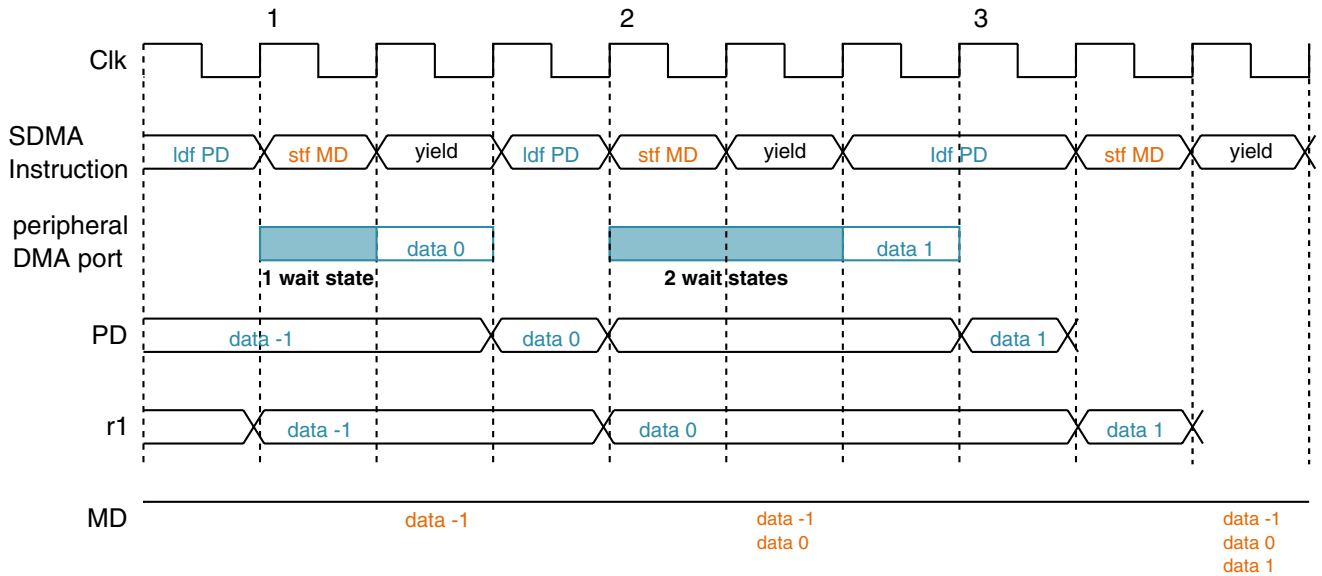


Figure 46-23. Peripheral to External Memory Example (1)

As seen in the figure above, the read access triggered by the ldf PD instruction is symbolized by the blue bar when in progress. After wait states, the read data (data 0, data 1) is stored in PD on the clk rising edge. On edge 2, data 0 is available in PD so it can be transferred to the SDMA general register r1, and then stored in MD FIFO. On edge 3, data 1 is not in PD; therefore, SDMA is stalled on the ldf instruction, which lasts two cycles. The figure below shows an example of when MD FIFO is full with data.

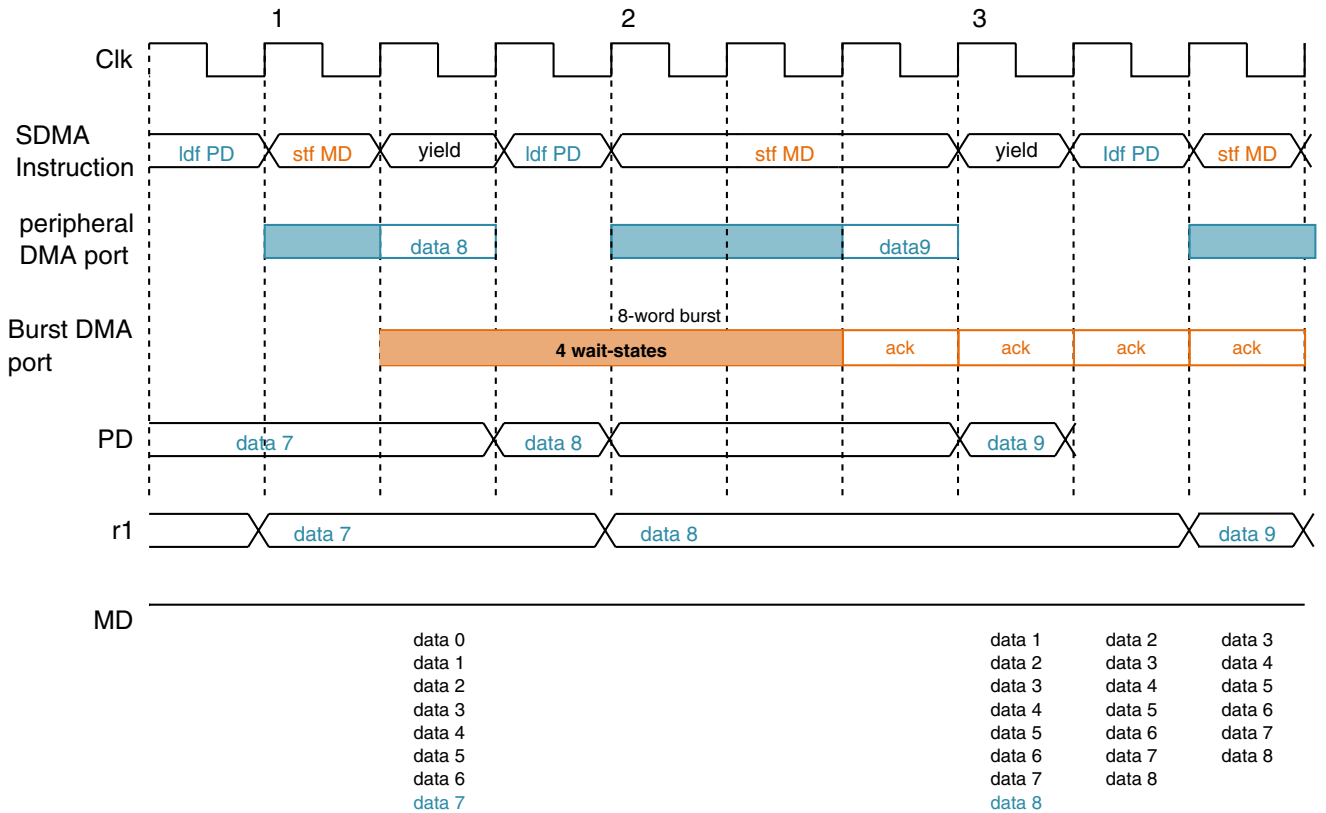

Figure 46-24. Peripheral to External Memory Example (2)

In the previous figure, the write bar means the burst DMA is performing a write burst access. The latency to have the first write acknowledge is four cycles. SDMA is stalled on instruction stf because no acknowledge was received, MD FIFO is full, and there is no empty slot to store data 9. When an acknowledge is sampled by the burst DMA, FIFO is shifted and data 8 is written. As long as there is at least one empty slot in MD FIFO, the stf MD instruction lasts one cycle.

46.19.2.3.2 External Memory to Peripheral Transfer

A transfer from the external memory to a peripheral involves the peripheral DMA and the burst DMA.

The code for transferring 100 word from external memory to a word peripheral would be as follows:

External Memory to Peripheral Transfer

```
//SETUP SECTION source and destination addresses are already in r1 and r2
1         stf r1, MSA|PF              //r1=0x1000 and starts a 8-word read burst
2         stf r2, PDA|SZ32|P           //r2=0x2010, setup peripheral DMA destination address
3         bdf ERROR_ADDR_SETUP
4         ldi r0,0x64                //loop counter is 100
//MAIN LOOP TRANFER
6         loop 3,0
```

```
7           ldf r1,MD|32|PF          // read 32 bits of MD and initiate a new read access
                                  // if MD is empty after this reading.
8           stf r1,PD              // store 32 bits of r1 in the PD.
9           yield
          10 ldf r1,MD|32           // last word data is read
11        stf r1,PD                // last write access
```

On instruction 1, a read burst of 8 words begins. Read data is staged into MD. On instruction 7 (and if data is available in MD), 32 bits are copied into r1. Then instruction 8 writes them into PD and an automatic flush is executed. The SDMA core, peripheral DMA, and burst DMA can work in parallel as long as no SDMA instruction tries to start a new write access on the peripheral DMA while the previous access is still in progress, or as long as there is data in MD when the SDMA tries to read it.

46.19.2.4 Transfer Between External Memory and Internal Memory

Since the internal memory (ARM platform RAM) is accessed via the peripheral DMA and the external memory is accessed via the burst DMA, the SDMA scripts that are described in Transfer Between Peripheral and External Memory can be reused. The exception is that the peripheral DMA address registers (PSA or PDA, depending on the script) should be programmed in incremented mode rather than frozen mode.

46.19.2.4.1 Internal Memory to Internal Memory

The internal memory can only be accessed via the peripheral DMA, so the script described in Peripheral to Peripheral Transfer can be reused with a different programming of the peripheral DMA address registers.

46.19.2.4.2 Transfer Between Peripheral and Internal Memory

For this transfer, the peripheral DMA is also used in copy mode.

The SDMA script is very similar to the one described in Peripheral to Peripheral Transfer, except for the peripheral DMA address registers programming.

46.20 ARM Platform Memory Map and Control Register Definitions

The ARM platform controls the SDMA by means of several interface registers. Those registers are described in the current section.

All registers are clocked with the SDMA clock (which means the ARM platform must ensure that the SDMA clock is running when it wants to access any register).

SDMAARM memory map

SDMAARM_MC0PTR field descriptions

Field	Description
31–0 MC0PTR	**Channel 0 Pointer** contains the 32-bit address, in ARM platform memory, of channel 0 control block (the boot channel). Appendix A fully describes the SDMA Application Programming Interface (API). The ARM platform has a read/write access and the SDMA has a read-only access.

46.20.2 Channel Interrupts (SDMAARM_INTR)

Address: SDMAARM_INTR is 63FB_0000h base + 4h offset = 63FB_0004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

SDMAARM_INTR field descriptions

Field	Description
31–0 HI[31:0]	The ARM platform Interrupts register contains the 32 HI[i] bits. If any bit is set, it will cause an interrupt to the ARM platform. This register is a "write-ones" register to the ARM platform. When the ARM platform sets a bit in this register the corresponding HI[i] bit is cleared. The interrupt service routine should clear individual channel bits when their interrupts are serviced, failure to do so will cause continuous interrupts. The SDMA is responsible for setting the HI[i] bit corresponding to the current channel when the corresponding `done` instruction is executed.

46.20.3 Channel Stop/Channel Status (SDMAARM_STOP_STAT)

Address: SDMAARM_STOP_STAT is 63FB_0000h base + 8h offset = 63FB_0008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	HE																															
W	w1c																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMAARM_STOP_STAT field descriptions

Field	Description
31–0 HE	This 32-bit register gives access to the ARM platform Enable bits. There is one bit for every channel. This register is a "write-ones" register to the ARM platform. When the ARM platform writes 1 in bit i of this register, it clears the HE[i] and HSTART[i] bits. Reading this register yields the current state of the HE[i] bits.

46.20.4 Channel Start (SDMAARM_HSTART)

Address: SDMAARM_HSTART is 63FB_0000h base + Ch offset = 63FB_000Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W	w1c																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMAARM_HSTART field descriptions

Field	Description
31–0 HSTART/HE	The HSTART/HE registers are 32 bits wide with one bit for every channel. When a bit is written to 1, it enables the corresponding channel. Two physical registers are accessed with that address (HSTART and HE), which enables the ARM platform to trigger a channel a second time before the first trigger is processed. • This register is a "write-ones" register to the ARM platform. Neither HSTART[i] bit can be set while the corresponding HE[i] bit is cleared. • When the ARM platform tries to set the HSTART[i] bit by writing a one (if the corresponding HE[i] bit is clear), the bit in the HSTART[i] register will remain cleared and the HE[i] bit will be set. • If the corresponding HE[i] bit was already set, the HSTART[i] bit will be set. The next time the SDMA channel *i* attempts to clear the HE[i] bit by means of a `done` instruction, the bit in the HSTART[i] register will be cleared and the HE[i] bit will take the old value of the HSTART[i] bit. • Reading this register yields the current state of the HSTART[i] bits. This mechanism enables the ARM platform to pipeline two HSTART commands per channel.

46.20.5 Channel Event Override (SDMAARM_EVTOVR)

Address: SDMAARM_EVTOVR is 63FB_0000h base + 10h offset = 63FB_0010h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	EO																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

SDMAARM_EVTOVR field descriptions

Field	Description
31–0 EO	The Channel Event Override register contains the 32 EO[i] bits. A bit set in this register causes the SDMA to ignore DMA requests when scheduling the corresponding channel.

46.20.6 Channel BP Override (SDMAARM_DSPOVR)

Address: SDMAARM_DSPOVR is 63FB_0000h base + 14h offset = 63FB_0014h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	DO																															
Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

SDMAARM_DSPOVR field descriptions

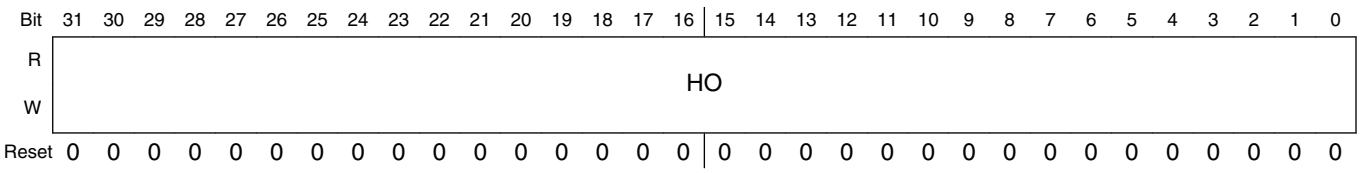
Field	Description
31–0 DO	This register is reserved. All DO bits should be set to the reset value of 1. A setting of 0 will prevent SDMA channels from starting according to the condition described in Runnable Channels Evaluation.

SDMAARM_DSPOVR field descriptions (continued)

Field	Description
	0 - Reserved 1 - Reset value.

46.20.7 Channel ARM platform Override (SDMAARM_HOSTOVR)

Address: SDMAARM_HOSTOVR is 63FB_0000h base + 18h offset = 63FB_0018h

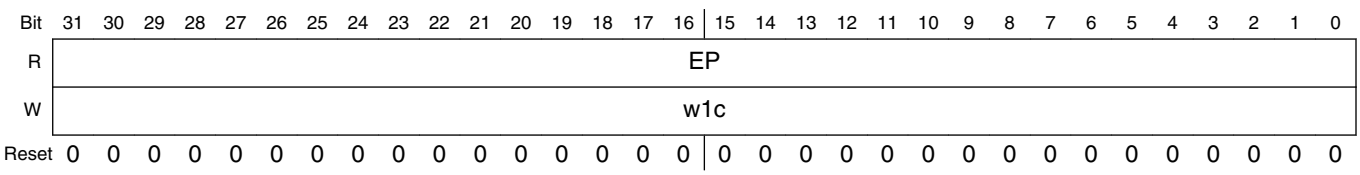


SDMAARM_HOSTOVR field descriptions

Field	Description
31–0 HO	The Channel ARM platform Override register contains the 32 HO[i] bits. A bit set in this register causes the SDMA to ignore the ARM platform enable bit (HE) when scheduling the corresponding channel.

46.20.8 Channel Event Pending (SDMAARM_EVTPEND)

Address: SDMAARM_EVTPEND is 63FB_0000h base + 1Ch offset = 63FB_001Ch

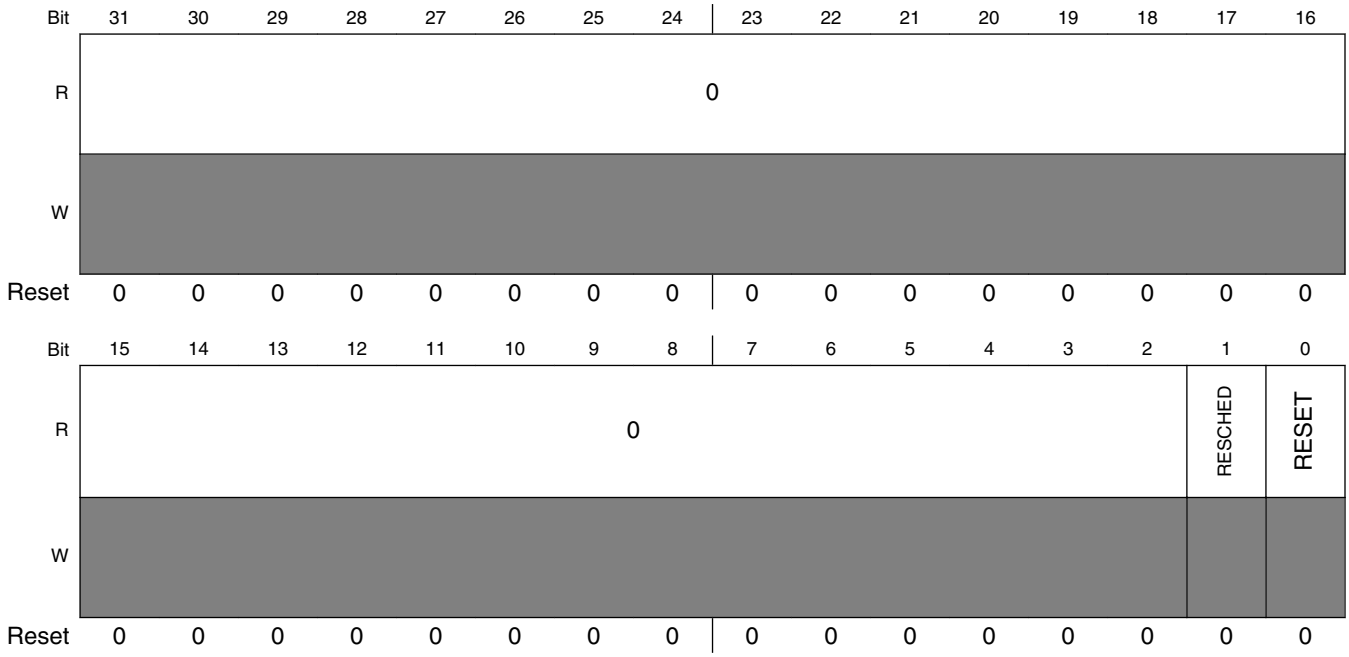


SDMAARM_EVTPEND field descriptions

Field	Description
31–0 EP	The Channel Event Pending register contains the 32 EP[i] bits. Reading this register enables the ARM platform to determine what channels are pending after the reception of a DMA request. • Setting a bit in this register causes the SDMA to reevaluate scheduling as if a DMA request mapped on this channel had occurred. This is useful for starting up channels, so that initialization is done before awaiting the first request. The scheduler can also set bits in the EVTPEND register according to the received DMA requests. • The EP[i] bit may be cleared by the `done` instruction when running the channel *i* script. This a "write-ones" mechanism: Writing a '0' does not clear the corresponding bit.

46.20.9 Reset Register (SDMAARM_RESET)

Address: SDMAARM_RESET is 63FB_0000h base + 24h offset = 63FB_0024h



SDMAARM_RESET field descriptions

Field	Description
31–2 Reserved	This read-only field is reserved and always has the value zero. Reserved
1 RESCHED	When set, this bit forces the SDMA to reschedule as if a script had executed a `done` instruction. This enables the ARM platform to recover from a runaway script on a channel by clearing its HE[i] bit via the STOP register, and then forcing a reschedule via the RESCHED bit. The RESCHED bit is cleared when the context switch starts.
0 RESET	When set, this bit causes the SDMA to be held in a software reset. The internal reset signal is held low 16 cycles; the RESET bit is automatically cleared when the internal reset signal rises.
