Chapter 1
Introduction

1.1 About This Document....125

1.1.1 Audience....125

1.1.2 Organization....125

1.1.3 Conventions....126

1.1.4 Register Access....127

1.1.4.1 Register Diagram Field Access Type Legend....127

1.1.4.2 Register Macro Usage....128

1.1.5 Acronyms and Abbreviations....128

1.2 Target Applications....130

1.3 Features....130

1.4 Architectural Overview....134

1.4.1 Block Diagram....134

1.4.2 Major Subsystems....135

1.4.3 Architectural Partitioning....136

1.5 i.MX50 Modules List....137

Chapter 2
Memory Map

2.1 Introduction....145

2.2 ARM Platform Memory Map....145

2.3 DMA Memory Map....150

Chapter 3
Interrupts and DMA Events

3.1 Overview....153

3.2 AP Interrupts....153

3.3 SDMA Event Mapping....157

Chapter 4
External Signals and Pin Multiplexing

4.1 Introduction....159

4.2 External Signals....159

Chapter 5
Clock Controller Module (CCM)

5.1 Introduction....279

5.1.1 Overview....280

5.1.2 Features....281

5.1.3 CCM Block Diagram....281

5.2 CCM External Signals Description....283

5.3 Functional Description....284

5.3.1 Clock Generation....284

5.3.1.1 External Low Frequency Clock—CKIL....285

5.3.1.2 External High Frequency Clock—CKIH and Internal Oscillator....285

5.3.1.3 DPLL Reference Clock....285

5.3.1.4 Analog PLL Reference Clock....285

5.3.1.5 CCM Internal Clock Generation....286

5.3.1.5.1 CCM_CLK_SWITCHER....286

5.3.1.5.2 PLL Bypass Procedure....288

5.3.1.5.3 DPLLC Reference Clock Connectivity....288

5.3.1.5.4 PLL Clock Change....288

5.3.1.5.5 CCM_CLK_IGNITION....289

5.3.1.5.6 CCM_CLK_PUSM Reset Sequence....291

5.3.1.5.7 Reset Values for DPLLC....292

5.3.1.5.8 Analog 480 PLL and PFD....292

5.3.1.5.9 CCM_CLK_ROOT_GEN....292

5.3.1.5.10 Initial Reset Values Controlled by SJC....296

5.3.1.5.11 Divider Change Handshake....296

5.3.1.5.12 CKIL Synchronizing to ipg_clk....297
5.3.1.6 DPLL's Disabling/Enabling....298
5.3.1.7 Observability Output Signals....298
5.3.1.8 Low Power Clock Gating Module (LPCG)....298
5.3.2 DVFS Support....301
5.3.2.1 ARM Clock Domain Frequency Change....301
5.3.2.2 Peripheral Clock Domain Frequency Change....303
5.3.2.3 Peripherals Restrictions in DVFS Scenario....304
5.3.3 Auto-Slow Mode....305
5.3.4 Power Modes....305
5.3.4.1 Run Mode....305
5.3.4.2 Wait Mode....306
5.3.4.2.1 Wait Mode Procedure....306
5.3.4.2.2 Exiting Wait Mode....308
5.3.4.3 Stop Mode....308
5.3.4.3.1 Entering Stop Mode....309
5.3.4.3.2 Exiting Stop Mode....311
5.3.4.3.3 PMIC Signal Description....315
5.3.4.4 Low Power Audio Playback Mode (LP-APM)....316
5.3.4.4.1 Low Power APM Mode Definition....316
5.3.4.4.2 LP-APM Mode Restrictions....317
5.3.4.4.3 LP-APM Entry and Exit....317
5.3.4.5 Recomendations for Using Low Power Consumption from CCM....320
5.4 CCM Memory Map/Register Definition....321
5.4.1 CCM Control Register (CCM_CCR)....323
5.4.2 CCM Control Divider Register (CCM_CCDR)....324
5.4.3 CCM Status Register (CCM_CSR)....325
5.4.4 CCM Clock Switcher Register (CCM_CCSR)....326
5.4.5 CCM ARM Clock Root Register (CCM_CACRR)....328

5.4.6 CCM Bus Clock Divider Register (CCM_CBCDR).....329
5.4.7 CCM Bus Clock Multiplexer Register (CCM_CBCMR).....332
5.4.8 CCM Serial Clock Multiplexer Register 1 (CCM_CSCMR1).....333
5.4.9 CCM Serial Clock Multiplexer Register 2 (CCM_CSCMR2).....336
5.4.10 CCM Serial Clock Divider Register 1 (CCM_CSCDR1).....336
5.4.11 CCM SSI1 Clock Divider Register (CCM_CS1CDR).....339
5.4.12 CCM SSI2 Clock Divider Register (CCM_CS2CDR).....340
5.4.13 CCM DI Clock Divider Register (CCM_CDCDR).....342
5.4.14 CCM HSC Clock Divider Register (CCM_CHSCCDR).....342
5.4.15 CCM Serial Clock Divider Register 2 (CCM_CSCDR2).....343
5.4.16 CCM Serial Clock Divider Register 3 (CCM_CSCDR3).....344
5.4.17 CCM Serial Clock Divider Register 4 (CCM_CSCDR4).....344
5.4.18 CCM Wakeup Detector Register (CCM_CWDR).....345
5.4.19 CCM Divider Handshake In-Process Register (CCM_CDHIPR).....346
5.4.20 CCM DVFS Control Register (CCM_CDCR).....348
5.4.21 CCM Testing Observability Register (CCM_CTOR).....349
5.4.22 CCM Low Power Control Register (CCM_CLPCR).....351
5.4.23 CCM Interrupt Status Register (CCM_CISR).....354
5.4.24 CCM Interrupt Mask Register (CCM_CIMR).....356
5.4.25 CCM Clock Output Source Register (CCM_CCOSR).....358
5.4.26 CCM General Purpose Register (CCM_CGPR).....361
5.4.27 CCM Clock Gating Register 0 (CCM_CCGR0).....361
5.4.28 CCM Clock Gating Register 1 (CCM_CCGR1).....364
5.4.29 CCM Clock Gating Register 2 (CCM_CCGR2).....366
5.4.30 CCM Clock Gating Register 3 (CCM_CCGR3).....369
5.4.31 CCM Clock Gating Register 4 (CCM_CCGR4).....371
5.4.32 CCM Clock Gating Register 5 (CCM_CCGR5).....374
5.4.33 CCM Clock Gating Register 6 (CCM_CCGR6).....376
5.4.34 CCM Clock Gating Register 7 (CCM_CCGR7).....379

5.4.35 CCM Module Enable Override Register (CCM_CMEOR)....382
5.4.36 CCM Control Status Register 2 (CCM_CSR2)....383
5.4.37 CCM Clock Sequence Bypass (CCM_CLKSEQ_BYPASS)....385
5.4.38 CCM System Clock Register (CCM_CLK_SYS)....387
5.4.39 CCM DDR Clock Register (CCM_CLK_DDR)....388
5.4.40 CCM ELCDIF PIX Clock Serial Divide Register (CCM_ELCDIFPIX)....389
5.4.41 CCM EPDC PIX Clock Serial Divide Register (CCM_EPDCPIX)....390
5.4.42 CCM DISPLAY_AXI Clock Divide Register (CCM_DISPLAY_AXI)....392
5.4.43 CCM EPDC_AXI Clock Divide Register (CCM_EPDC_AXI)....394
5.4.44 CCM GPMI Clock Divide Register (CCM_GPMI)....395
5.4.45 CCM BCH Clock Divide Register (CCM_BCH)....396
5.4.46 CCM MSHC_XMSCKI Clock Divide Register (CCM_MSHC_XMSCKI)....397
5.4.47 Clock Gating bits (CG(i))....398
5.5 CCM Analog Memory Map/Register Definition....404
5.5.1 Fractional Clock Control Register 0 (CCM_ANALOG_FRAC0*n*)....406
5.5.2 Fractional Clock Control Register 1 (CCM_ANALOG_FRAC1*n*)....408
5.5.3 Miscellaneous Register Description (CCM_ANALOG_MISC*n*)....410
5.5.4 PLL Control Register (CCM_ANALOG_PLLCTRL*n*)....411

Chapter 6
System Boot

6.1 Introduction....413
6.2 Boot Modes....414
6.2.1 Boot Mode Pin Settings....414
6.2.2 High Level Boot Sequence....415
6.2.3 Overview of USB Low Power Boot....416
6.2.4 Internal Boot (BOOT_MODE [1:0] = 00)....417
6.2.5 Internal Boot-Fuses Only (BOOT_MODE [1:0] = 10)....418
6.2.6 USB Downloader (BOOT_MODE [1:0] = 11)....418
6.2.7 Boot Security Settings....419

6.3 Device Configuration....419
6.3.1 Boot OCOTP bit Descriptions....420
6.3.2 GPIO Boot Overrides....423
6.3.3 Device Configuration Data....424
6.4 Device Initialization....424
6.4.1 Memory Map....424
6.4.2 Boot Module Activation....425
6.4.3 Clocks at Boot Time....426
6.4.4 Clock Initialization....426
6.4.4.1 NORMAL Mode....426
6.4.4.2 USB Low-Power Boot Mode (LPB)....428
6.4.5 Enabling MMU/Caches....428
6.4.6 Error Logging....429
6.4.7 Exception Handling....429
6.4.8 Interrupt Handling During Boot....430
6.5 Boot Devices (Internal Boot)....430
6.5.1 NOR/OneNAND Boot from EIM Interface....430
6.5.1.1 IOMUX Configuration for EIM....431
6.5.1.2 NOR Flash Boot Operation....432
6.5.1.3 OneNAND Flash Boot Operation....432
6.5.2 Raw NAND Boot from GPMI-2 Interface....433
6.5.2.1 NAND eFUSE/GPIO Configuration....433
6.5.2.2 NAND Flash Boot Flow and Boot Control Blocks(BCB)....434
6.5.2.3 Firmware Configuration Block....437
6.5.2.4 Discovered Bad Block Table....440
6.5.2.5 Bad Block Handling in the ROM....441
6.5.2.6 Toggle Mode DDR NAND Boot....442
6.5.2.6.1 Configures GPMI and BCH Clocks to Run at 33 MHz....442
6.5.2.6.2 Setup DMA for DDR Transfers....442

6.5.2.6.3 Reconfigure Timing and Speed Using Values in FCB....442
6.5.2.7 Typical NAND Page Organization....443
6.5.2.7.1 BCH ECC Page Organization....443
6.5.2.7.2 Metadata....444
6.5.2.8 IOMUX Configuration for NAND Flash....444
6.5.3 Expansion Device Support....445
6.5.3.1 IOMUX Configuration of eSDHC....447
6.5.3.2 MMC and eMMC Boot....447
6.5.4 SD and eSD....453
6.5.5 Serial ROM Support via SPI and I2C....454
6.5.5.1 I2C EEPROM Boot....455
6.5.5.2 SPI EEPROM/Flash Boot....456
6.6 Program Image....458
6.6.1 Image Vector Table and Boot Data....459
6.6.1.1 Image Vector Table Structure....460
6.6.1.2 Boot Data Structure....461
6.6.2 Device Configuration Data (DCD)....461
6.6.2.1 Write Data Command....464
6.6.2.2 Check Data Command....465
6.6.2.3 NOP Command....467
6.7 Plugin Image....467
6.8 USB Low-Power Boot....468
6.8.1 LPB Mode Flow....469
6.9 USB Downloader (BOOT_MODE[1:0] = 11)....471
6.9.1 USB....472
6.9.1.1 USB Configuration....473
6.9.1.2 Serial Download protocol....474
6.9.1.3 SDP Command....474
6.9.1.3.1 READ REGISTER....475

6.9.1.3.2 WRITE REGISTER....475
6.9.1.3.3 WRITE_FILE....476
6.9.1.3.4 ERROR_STATUS....477
6.9.1.3.5 DCD WRITE....478
6.9.1.3.6 JUMP ADDRESS....479
6.9.2 External Entry....480
6.9.2.1 pu_irom_boot_decision....480
6.10 High Assurance Boot (HAB)....481
6.10.1 ROM Vector Table Addresses....482
6.10.2 SRTC Initialization....482

Chapter 7
System Debug

7.1 Overview....483
7.1.1 Debug Strategy....483
7.2 System JTAG Controller-SJC....484
7.2.1 JTAG Topology....484
7.2.2 System JTAG Controller Main Features....485
7.2.3 SJC TAP Port....486
7.2.4 SJC Main Blocks....486
7.2.5 i.MX50 Specific SJC Features....486
7.2.5.1 JTAG Disable Mode....486
7.2.5.2 SJC i.MX50 Specific Registers Summary....487
7.2.5.3 JTAG ID....487
7.3 CoreSight Design Kit....487
7.3.1 Memory Map and Register Definition....487
7.3.2 CoreSight Clock Enable....488
7.3.3 CoreSight Debug Access Port (DAP) and DAP_SYS....488
7.3.4 Embedded Cross Trigger (ECT)....489
7.3.4.1 CoreSight CTM....491

7.3.4.2 CoreSight CTI....491
7.3.4.3 Extended CTI (CTI Wrapper)....494
7.3.5 CoreSight Trace Port Interface (TPIU)....495
7.4 Cortex-A8 Core and Platform....495
7.4.1 Cortex-A8 Core Debug Support Features....495
7.4.2 Embedded Cross Trigger Interface....496
7.4.3 Additional Platform Debug Functionality....496
7.5 Smart DMA (SDMA) Core....496
7.5.1 SDMA On Chip Emulation Module (OnCE) Feature Summary....497
7.5.2 Other SDMA Debug Functionality....497
7.6 Debug Visibility-IOMUX....498
7.7 Supported Tools....499
7.8 Interrupt Visibility....499
7.9 Miscellaneous....499
7.9.1 SOC-Level Bus Trace....499
7.9.2 Clock/Reset/Power....500

Chapter 8
ARM Cortex A8 Platform (ARM Platform)

8.1 Introduction....501
8.2 Overview....501
8.2.1 Core Platform Sub-Blocks....504
8.2.1.1 ARM platform....504
8.2.1.2 Instruction Fetch....505
8.2.1.3 Instruction Decode....505
8.2.1.4 Instruction Execute....506
8.2.1.5 Load/Store....506
8.2.1.6 L2 Cache....506
8.2.1.7 NEON....507
8.2.1.8 Processor Debug Unit....507

8.2.1.9 Embedded Trace Marcocell (ETM).....507
8.2.1.10 Cross Trigger Interface 0 (CTI0).....508
8.2.2 Summary of Remaining Platform Components.....508
8.2.2.1 Platform Controller 508
8.2.2.2 Debug Sub-Blocks.....509
8.2.2.2.1 Embedded Trace Buffer (ETB).....509
8.2.2.2.2 AMBA Trace Bus (ATB) Replicator.....509
8.2.2.2.3 Cross Trigger Interface 1 (CTI1).....510
8.2.2.2.4 Cross Trigger Matrix - CTM.....510
8.2.2.2.5 Advanced Peripheral Bus - APB Debug Bus.....510
8.2.2.3 Asynchronous Wrapper.....510
8.2.3 Configuration.....511
8.2.4 Endian Modes.....511
8.2.5 Bus Interfaces.....511
8.2.5.1 AMBA AXI Interface.....511
8.2.5.2 APB CoreSight Interface.....511
8.2.5.3 ATB CoreSight Interface.....512
8.2.5.4 Peripheral Interface (IP Bus).....512
8.3 Memory Map and Register Definition.....512
8.3.1 Platform Version ID (ARM_PVID).....513
8.3.2 General Purpose Control (ARM_GPC).....514
8.3.3 Low Power Control (ARM_LPC).....515
8.3.4 NEON Low Power Control (ARM_NLPC).....516
8.3.5 Internal Clock Generation Control (ARM_ICGC).....517
8.3.6 ARM Memory Configuration (ARM_AMC).....519
8.3.7 NEON Monitor Control (ARM_NMC).....520
8.3.8 NEON Monitor Status (ARM_NMS).....521
8.4 Platform Clocks.....521

8.5 Platform Power Management....522
8.5.1 Voltage and Frequency Scaling....522
8.5.1.1 Asynchronous Interface Logic....522
8.5.1.2 Level Shifting between SoC-logic and ARM-logic....523
8.5.2 Power Gating in the ARM platform....523
8.5.2.1 Isolation Circuitry at the ARM platform Interface....523
8.5.2.2 Power Gating the Memory Peripheries....523
8.5.2.3 Retaining the State of the ARM platform Registers....523
8.5.2.4 Power Gating the ARM platform High Performance Logic Gates....524
8.5.2.5 Power Gating the L2 Bit Arrays....524
8.5.2.6 Controlling Power Gating using the General Power Controller (GPC) 524
8.5.2.7 Power Gating the NEON Block....525
8.5.3 Modes of Operation....529

Chapter 9
ARM Platform Debug

9.1 Introduction 531
9.1.1 Overview....531
9.1.2 ARM Debug Blocks....532
9.1.2.1 Processor Debug Unit....533
9.1.2.1.1 Halting Debug-Mode Debugging....533
9.1.2.1.2 Monitor Debug-Mode Debugging....533
9.1.2.1.3 Programming the Debug Unit....533
9.1.2.2 ARM embedded trace macrocell (ARM ETM)....534
9.1.2.3 CoreSight Embedded Trace Buffer (CSETB)....535
9.1.2.4 CoreSight Replicator (CSREPLICATOR)....536
9.1.2.5 CoreSight trace port interface unit (CSTPIU)....537
9.1.2.6 CoreSight cross trigger interface (CSCTI)....537
9.1.2.7 CoreSight Cross Trigger Matrix (CSCTM)....539

9.1.2.8 Debug Access Port (DAP)....540
9.1.2.8.1 DAP_SYS....541
9.1.3 Modes of Operation....542
9.1.3.1 ARM Invasive Debug Mode....542
9.1.3.2 ARM Non-Invasive Debug Mode (Real-time Trace)....542
9.1.3.3 Normal Operating Modes....543
9.1.3.4 Low Power Modes....543
9.2 Memory Map and Register Definition....543
9.2.1 Register Summary....544
9.2.1.1 DAP JTAG DP Registers....545
9.2.1.2 DAP ROM Register Summary....546
9.2.1.3 Processor Debug Unit Register Summary....546
9.2.1.3.1 Coprocessor Registers Summary....546
9.2.1.3.2 Memory Mapped Registers Summary....547
9.2.1.4 ETB Register Summary....548
9.2.1.5 ETM Register Summary....550
9.2.1.6 CSCTI Register Summary....552
9.2.1.7 TPIU Register Summary....554
9.2.2 Clocks....557
9.2.3 Reset....557

Chapter 10
Multi-Layer AHB Crossbar Switch (AHBMAX)

10.1 Overview....559
10.2 Features....561
10.2.1 Limitations....561
10.2.2 General Operation....561
10.3 AHBMAX Interface Signals....563
10.3.1 AHBMAX Signal Descriptions....563
10.3.1.1 max_halt_request....563

10.3.1.2 max_halted....563
10.4 Coherency....563
10.5 Detailed Functional Description....564
10.5.1 Arbitration....564
10.5.1.1 Arbitration During Undefined Length Bursts....564
10.5.1.2 Fixed Priority Operation....565
10.5.1.3 Round-Robin Priority Operation....565
10.5.2 Priority Assignment....566
10.5.3 Master Port Functionality....566
10.5.3.1 Master Port General Information....566
10.5.3.2 Master Port Decoders....569
10.5.3.3 Master Port Capture Unit....569
10.5.3.4 Master Port Registers....569
10.5.3.5 Master Port State Machine....569
10.5.3.5.1 Master Port State Machine States....569
10.5.3.5.2 Master Port State Machine Slave Swapping....570
10.5.4 Slave Port Functionality....571
10.5.4.1 Slave Port General Information....571
10.5.4.2 Slave Port Muxes....572
10.5.4.3 Slave Port Registers....573
10.5.4.4 Slave Port State Machine....573
10.5.4.4.1 Slave Port State Machine States....573
10.5.4.4.2 Slave Port State Machine Arbitration....574
10.5.4.4.3 Slave Port State Machine Master Handoff....574
10.5.4.4.4 Slave Port State Machine Parking....577
10.5.4.4.5 Slave Port State Machine Halt Mode....580
10.6 Initialization/Application Information....581
10.7 AHBMAX Interface....581
10.7.1 AHBMAX Interface Overview....581

10.7.2 Master Ports-AHBMAX Interface....581
10.7.2.1 Terminated Accesses....581
10.7.2.2 Taken Accesses....581
10.7.2.3 Stalled Accesses....582
10.7.2.4 Error Response Terminated Accesses....582
10.7.3 Slave Ports-AHBMAX Interface....582
10.8 Programmable Registers....583
10.8.1 Master Priority Register for Slave port n (AHBMAX_MPR*n*)....584
10.8.2 General Purpose Control Register for Slave port n (AHBMAX_SGPCR*n*)....586
10.8.3 General Purpose Control Register for Master port n (AHBMAX_MGPCR*n*)....588

Chapter 11
AHB-to-APBH Bridge with DMA (APBH-Bridge-DMA)

11.1 Overview....591
11.2 APBH DMA....593
11.3 NAND Read Status Polling Example....598
11.4 Programmable Registers....600
11.4.1 AHB to APBH Bridge Control and Status Register 0 (APBH_CTRL0*n*)....607
11.4.2 AHB to APBH Bridge Control and Status Register 1 (APBH_CTRL1*n*)....608
11.4.3 AHB to APBH Bridge Control and Status Register 2 (APBH_CTRL2*n*)....612
11.4.4 AHB to APBH Bridge Channel Register (APBH_CHANNEL_CTRL*n*)....617
11.4.5 AHB to APBH DMA Device Assignment Register (APBH_DEVSEL)....618
11.4.6 AHB to APBH DMA burst size (APBH_DMA_BURST_SIZE)....619
11.4.7 AHB to APBH DMA Debug Register (APBH_DEBUG)....620
11.4.8 APBH DMA Channel n Current Command Address Register (APBH_CH*n*_CURCMDAR)....621
11.4.9 APBH DMA Channel n Next Command Address Register (APBH_CH*n*_NXTCMDAR)....622
11.4.10 APBH DMA Channel n Command Register (APBH_CH*n*_CMD)....623
11.4.11 APBH DMA Channel n Buffer Address Register (APBH_CH*n*_BAR)....625
11.4.12 APBH DMA Channel n Semaphore Register (APBH_CH*n*_SEMA)....626
11.4.13 AHB to APBH DMA Channel n Debug Information (APBH_CH*n*_DEBUG1)....627

11.4.14 AHB to APBH DMA Channel n Debug Information (APBH_CH*n*_DEBUG2).....630
11.4.15 APBH Bridge Version Register (APBH_VERSION).....630

Chapter 12
Digital Audio Multiplexer (AUDMUX)

12.1 Overview.....633
12.1.1 Features.....635
12.1.2 Modes and Operations.....635
12.2 External Signal Description.....635
12.3 Default Register Configuration.....636
12.3.1 Default Port Configuration.....636
12.4 Functional Description.....636
12.4.1 Operating Modes.....636
12.4.1.1 Port Receive Data Modes.....637
12.4.1.1.1 Normal Mode.....638
12.4.1.1.2 Internal Network Mode.....639
12.4.1.1.3 Transmit Data Output Enable Assertion.....646
12.4.1.2 Tx/Rx Switch and External Network Mode.....647
12.4.1.3 Timing Modes.....648
12.4.1.3.1 Synchronous Mode (4-Wire Interface).....648
12.4.1.3.2 Asynchronous Mode (6-Wire Interface).....650
12.4.2 Connectivity Between Ports.....653
12.4.2.1 Internal Port to External Port Connectivity.....654
12.4.2.2 External Port to External Port Connectivity.....655
12.4.2.3 Internal Port to Internal Port Connectivity.....655
12.4.2.4 Loopback Connectivity.....656
12.4.3 AUDMUX Clocking.....656
12.4.3.1 AUDMUX Clock Inputs.....656
12.4.3.2 AUDMUX Clock Diagram.....656
12.4.3.3 Clocking Restrictions.....657

12.5 Programmable Registers....657
12.5.1 Port Timing Control Register 1 (AUDMUX_PTCR1)....658
12.5.2 Port Data Control Register 1 (AUDMUX_PDCR1)....660
12.5.3 Port Timing Control Register 2 (AUDMUX_PTCR2)....661
12.5.4 Port Data Control Register 2 (AUDMUX_PDCR2)....663
12.5.5 Port Timing Control Register 3 (AUDMUX_PTCR3)....664
12.5.6 Port Data Control Register 3 (AUDMUX_PDCR3)....666
12.5.7 Port Timing Control Register n (AUDMUX_PTCR*n*)....667
12.5.8 Port Data Control Register 4 (AUDMUX_PDCR4)....670
12.5.9 Port Data Control Register 5 (AUDMUX_PDCR5)....671
12.5.10 Port Data Control Register 6 (AUDMUX_PDCR6)....672

Chapter 13
AHB to IP Bridge (AIPSTZ)

13.1 Introduction....675
13.1.1 Features....675
13.2 General Operation....676
13.2.1 AIPSTZ Registers....676
13.2.2 Overview....676
13.2.3 Control Registers....677
13.3 Register Descriptions....678
13.3.1 Master Privilege Registers....678
13.3.2 Off-Platform Peripheral Access Control Registers (AIPSTZ_OPACRs)....679
13.4 Functional Description....680
13.5 Access Protections....680
13.6 Access Support....680
13.7 Initialization Information....681

Chapter 14
32-Bit Correcting ECC Accelerator (BCH)

14.1 Introduction....683

14.2 Overview....683
14.3 Operation....686
14.3.1 BCH Limitations and Assumptions....687
14.3.2 Flash Page Layout....687
14.3.3 Determining the ECC layout for a Device....689
14.3.3.1 4K + 218 Flash, 10 bytes Metadata, 512 byte Data Blocks, Separate Metadata, Assuming GF(2^13)....689
14.3.3.2 4K + 128 flash, 10 bytes Metadata, 1024 byte Data Blocks, Separate Metadata, Assuming GF(2^14) for Data and GF(2^13) for Metadata....690
14.3.4 Data buffers in System Memory....690
14.4 Memory to Memory (Loopback) Operation....693
14.5 Programming the BCH/GPMI Interfaces....694
14.5.1 BCH Encoding for NAND Writes....694
14.5.1.1 DMA Structure Code Example 1....698
14.5.1.2 Using the BCH Encoder....702
14.5.2 BCH Decoding for NAND Reads....703
14.5.2.1 DMA Structure Code Example 2....707
14.5.2.2 Using the Decoder....710
14.5.3 Interrupts....712
14.6 Behavior During Reset....713
14.7 Programmable Registers....713
14.7.1 Hardware BCH ECC Accelerator Control Register (BCH_CTRL*n*)....715
14.7.2 Hardware ECC Accelerator Status Register 0 (BCH_STATUS0)....717
14.7.3 Hardware ECC Accelerator Mode Register (BCH_MODE)....719
14.7.4 Hardware BCH ECC Loopback Encode Buffer Register (BCH_ENCODEPTR)....719
14.7.5 Hardware BCH ECC Loopback Data Buffer Register (BCH_DATAPTR)....720
14.7.6 Hardware BCH ECC Loopback Metadata Buffer Register (BCH_METAPTR)....720
14.7.7 Hardware ECC Accelerator Layout Select Register (BCH_LAYOUTSELECT)....721
14.7.8 Hardware BCH ECC Flash 0 Layout 0 Register (BCH_FLASH0LAYOUT0)....722

14.7.9 Hardware BCH ECC Flash 0 Layout 1 Register (BCH_FLASH0LAYOUT1).....724
14.7.10 Hardware BCH ECC Flash 1 Layout 0 Register (BCH_FLASH1LAYOUT0).....725
14.7.11 Hardware BCH ECC Flash 1 Layout 1 Register (BCH_FLASH1LAYOUT1).....727
14.7.12 Hardware BCH ECC Flash 2 Layout 0 Register (BCH_FLASH2LAYOUT0).....728
14.7.13 Hardware BCH ECC Flash 2 Layout 1 Register (BCH_FLASH2LAYOUT1).....730
14.7.14 Hardware BCH ECC Flash 3 Layout 0 Register (BCH_FLASH3LAYOUT0).....731
14.7.15 Hardware BCH ECC Flash 3 Layout 1 Register (BCH_FLASH3LAYOUT1).....733
14.7.16 Hardware BCH ECC Debug Register0 (BCH_DEBUG0*n*).....735
14.7.17 KES Debug Read Register (BCH_DBGKESREAD).....736
14.7.18 Chien Search Debug Read Register (BCH_DBGCSFEREAD).....737
14.7.19 Syndrome Generator Debug Read Register (BCH_DBGSYNDGENREAD).....737
14.7.20 Bus Master and ECC Controller Debug Read Register (BCH_DBGAHBMREAD).....738
14.7.21 Block Name Register (BCH_BLOCKNAME).....738
14.7.22 BCH Version Register (BCH_VERSION).....739

Chapter 15
Clock Amplifier (CAMP)

15.1 Introduction.....741
15.1.1 Overview.....742
15.1.2 Features.....742
15.1.3 Modes of Operation.....742
15.1.3.1 Normal Mode.....742
15.1.3.2 Power Down Mode.....742
15.1.3.3 Test Mode (Fault Bypass or Scan).....742
15.2 External Signal Description.....742
15.2.1 Signals Overview.....743
15.2.2 Detailed Signal Description.....743
15.2.2.1 CKIH - External Clock Input.....743
15.2.2.2 VDD - Power supply.....743
15.2.2.3 VSS - Ground.....743

15.2.2.4 IPT_SCAN_MODE - Scan Signal....743
15.2.2.5 PWD - Power Down Signal....744
15.2.2.6 FAULT_BYP - Control Signal for Test Mode....744
15.2.2.7 CAMP_OUT - Clock Output from CAMP....744
15.3 Memory Map/Register Definition....744
15.4 Functional Description....744
15.4.1 CAMP Sub-Blocks....744
15.4.1.1 Main Clock Amplifier....745
15.4.1.2 Output Buffer....745
15.4.1.3 Level Shifter....745
15.4.2 CAMP Modes of Operation....745
15.4.2.1 Normal Mode....745
15.4.2.2 Power Down Mode....745
15.4.2.3 Test Mode....746
15.5 Initialization/Application Information....746

Chapter 16
Configurable Serial Peripheral Interface (CSPI)

16.1 Overview....747
16.1.1 Features....748
16.1.2 Modes and Operations....748
16.2 External Signals....749
16.3 Functional Description....750
16.3.1 Operating Modes....751
16.3.1.1 Master Mode....751
16.3.1.2 Slave Mode....752
16.3.2 Low Power Modes....752
16.3.3 Operations....752
16.3.3.1 Typical Master Mode....752
16.3.3.1.1 Master Mode with SPI_RDY....753

16.3.3.1.2 Master Mode with Wait States....755
16.3.3.1.3 Master Mode with SSCTL Control....755
16.3.3.1.4 Master Mode with Phase Control....757
16.3.3.2 Typical Slave Mode....757
16.3.4 Clocks....758
16.3.5 Reset....759
16.3.6 Interrupts....759
16.3.7 DMA....760
16.3.8 Byte Order....761
16.4 Initialization....761
16.5 Applications....762
16.6 Programmable Registers....764
16.6.1 Receive Data Register (CSPI_RXDATA)....764
16.6.2 Transmit Data Register (CSPI_TXDATA)....765
16.6.3 Control Register (CSPI_CONREG)....766
16.6.4 Interrupt Control Register (CSPI_CSPI_INTREG)....769
16.6.5 DMA Control Register (CSPI_CSPI_DMAREG)....770
16.6.6 Status Register (CSPI_CSPI_STATREG)....771
16.6.7 Sample Period Control Register (CSPI_PERIODREG)....772
16.6.8 Test Control Register (CSPI_TESTREG)....773

Chapter 17
Data Co-Processor (DCP)

17.1 Overview....775
17.1.1 DCP Limitations for Software....777
17.2 Operation....778
17.2.1 Memory Copy, Blit, and Fill Functionality....778
17.2.2 Advanced Encryption Standard (AES)....779
17.2.2.1 Key Storage....780
17.2.2.2 AES OTP Key....780

17.2.2.3 Encryption Modes....780
17.2.3 Hashing....782
17.2.4 One Time Programmable (OTP) Key....782
17.2.5 Managing DCP Channel Arbitration and Performance....783
17.2.5.1 DCP Arbitration....783
17.2.5.2 Channel Recovery Timers....784
17.2.6 Programming Channel Operations....784
17.2.6.1 Virtual Channels....785
17.2.6.2 Context Switching....786
17.2.6.3 Working with Semaphores....787
17.2.6.4 Work Packet Structure....788
17.2.6.4.1 Next Command Address Field....788
17.2.6.4.2 Control0 Field....789
17.2.6.4.3 Control1 Field....791
17.2.6.4.4 Source Buffer....791
17.2.6.4.5 Destination Buffer....792
17.2.6.4.6 Buffer Size Field....792
17.2.6.4.7 Payload Pointer....792
17.2.6.4.8 Status....793
17.2.6.4.9 Payload....793
17.2.7 Programming DCP Functions....794
17.2.7.1 Basic Memory Copy Programming Example....795
17.2.7.2 Basic Hash Operation Programming Example....796
17.2.7.3 Basic Cipher Operation Programming Example....797
17.2.7.4 Multi-Buffer Scatter/Gather Cipher and Hash Operation Programming Example....799
17.3 Programmable Registers....802
17.3.1 DCP Control Register 0 (DCP_CTRL)....804
17.3.2 DCP Status Register (DCP_STAT)....806
17.3.3 DCP Channel Control Register (DCP_CHANNELCTRL)....808

17.3.4 DCP Capability 0 Register (DCP_CAPABILITY0)....809
17.3.5 DCP Capability 1 Register (DCP_CAPABILITY1)....810
17.3.6 DCP Context Buffer Pointer (DCP_CONTEXT)....811
17.3.7 DCP Key Index (DCP_KEY)....811
17.3.8 DCP Key Data (DCP_KEYDATA)....812
17.3.9 DCP Work Packet 0 Status Register (DCP_PACKET0)....813
17.3.10 DCP Work Packet 1 Status Register (DCP_PACKET1)....813
17.3.11 DCP Work Packet 2 Status Register (DCP_PACKET2)....816
17.3.12 DCP Work Packet 3 Status Register (DCP_PACKET3)....817
17.3.13 DCP Work Packet 4 Status Register (DCP_PACKET4)....817
17.3.14 DCP Work Packet 5 Status Register (DCP_PACKET5)....818
17.3.15 DCP Work Packet 6 Status Register (DCP_PACKET6)....818
17.3.16 DCP Channel 0 Command Pointer Address Register (DCP_CH0CMDPTR)....819
17.3.17 DCP Channel 0 Semaphore Register (DCP_CH0SEMA)....820
17.3.18 DCP Channel 0 Status Register (DCP_CH0STAT)....821
17.3.19 DCP Channel 0 Options Register (DCP_CH0OPTS)....823
17.3.20 DCP Channel 1 Command Pointer Address Register (DCP_CH1CMDPTR)....824
17.3.21 DCP Channel 1 Semaphore Register (DCP_CH1SEMA)....825
17.3.22 DCP Channel 1 Status Register (DCP_CH1STAT)....826
17.3.23 DCP Channel 1 Options Register (DCP_CH1OPTS)....827
17.3.24 DCP Channel 2 Command Pointer Address Register (DCP_CH2CMDPTR)....828
17.3.25 DCP Channel 2 Semaphore Register (DCP_CH2SEMA)....829
17.3.26 DCP Channel 2 Status Register (DCP_CH2STAT)....830
17.3.27 DCP Channel 2 Options Register (DCP_CH2OPTS)....832
17.3.28 DCP Channel 3 Command Pointer Address Register (DCP_CH3CMDPTR)....833
17.3.29 DCP Channel 3 Semaphore Register (DCP_CH3SEMA)....834
17.3.30 DCP Channel 3 Status Register (DCP_CH3STAT)....835
17.3.31 DCP Channel 3 Options Register (DCP_CH3OPTS)....836
17.3.32 DCP Debug Select Register (DCP_DBGSELECT)....837

17.3.33 DCP Debug Data Register (DCP_DBGDATA).....838
17.3.34 DCP Page Table Register (DCP_PAGETABLE).....838
17.3.35 DCP Version Register (DCP_VERSION).....839

Chapter 18
Digital Control (DIGCTL) and On-Chip RAM

18.1 Overview.....841
18.2 eSDHC Version control.....842
18.3 OCRAM Pipeline Controls.....842
18.4 Speed Sensor Controls.....842
18.5 Programmable Registers.....843
18.5.1 DIGCTL Control Register (DIGCTL_CTRL*n*).....844
18.5.2 DIGCTL OCRAM Register (DIGCTL_OCRAM*n*).....845
18.5.3 Transistor Speed Control Register (DIGCTL_SPEEDCTL*n*).....847
18.5.4 Transistor Speed Status Register (DIGCTL_DIGCTL_SPEEDSTAT).....847

Chapter 19
DPLL Controller (DPLLC)

19.1 Overview.....849
19.1.1 Feature Description.....850
19.1.2 Modes and Operation.....850
19.2 Functional Description.....850
19.2.1 Operating Modes.....851
19.2.1.1 Normal Mode.....851
19.2.1.2 DPLL Desense Mode.....851
19.2.1.3 DVFS Support: HFS Mode.....853
19.2.2 Operations.....853
19.2.2.1 DPLLC_DP_CTL, DPLLC_DP_OP, DPLLC_DP_MFD Register Update.....853
19.2.2.2 DP_MFN Register Update.....854
19.2.2.3 Multiple Options for DPLL Control.....855
19.2.2.4 Calculating the Output Frequency.....856

19.3 Programmable Registers....856
19.3.1 DPLLC Memory Map/Register Definition....856
19.31.1 DPLLC Control Register (DPLLC*x*_CTL)....859
19.31.2 DPLLC Configuration Register (DPLLC*x*_CONFIG)....861
19.31.3 DPLLC Operation Register (DPLLC*x*_OP)....862
19.31.4 DPLLC Multiplication Factor Denominator Register (DPLLC*x*_MFD)....863
19.31.5 DPLLC Multiplication Factor Numerator Register (DPLLC*x*_MFN)....863
19.31.6 DPLLC Multiplication Factor Numerator PLUS/MINUS Registers (DPLLC*x*_MFN*n*)....864
19.31.7 DPLLC High Frequency Support, Operation Register (DPLLC*x*_HFS_OP)....865
19.31.8 DPLLC High Frequency Support Multiplication Factor Denominator Register (DPLLC*x*_HFS_MFD)....866
19.31.9 DPLLC High Frequency Support Multiplication Factor Numerator Register (DPLLC*x*_HFS_MFN)....867
19.31.10 DPLLC Multiplication Factor Numerator Toggle Control Register (DPLLC*x*_MFN_TOGC)....867
19.31.11 DPLLC Desense Status Register (DPLLC*x*_DESTAT)....869

Chapter 20
DRAM Memory Controller (DRAM MC)

20.1 Overview....871
20.1.1 Block Diagram....871
20.1.2 DRAM MC Special Signal Considerations....872
20.2 DRAM MC Address Mapping....873
20.2.1 DDR SDRAM Address Mapping Options....873
20.2.2 Maximum Address Space....874
20.2.3 Memory Mapping to Address Space....874
20.2.4 Out-of-Range Address Checking....875
20.3 DRAM MC Clocking....875
20.3.1 Changing the Input Clock Frequency....875
20.4 DRAM MC AHB and AXI Interface....876
20.4.1 AHB Register Port....876

20.4.2 AXI Interface....877
20.4.2.1 Internal Command Handling....877
20.4.2.2 Configured Options....878
20.4.3 Port Clocking....880
20.4.4 AXI Interface FIFOs....881
20.4.4.1 In-Port Arbitration....882
20.4.5 AXI Write Response Channel....884
20.4.5.1 Bufferable, Coherent Bufferable and Non-Bufferable Response Types....884
20.4.6 AXI Transactions....885
20.4.7 Exclusive Access....885
20.4.7.1 Initiating an Exclusive Access Request....885
20.4.7.2 Verifying the Request....885
20.4.7.3 Processing Exclusive Accesses....886
20.4.7.4 Validity of an Exclusive Request....887
20.4.7.5 Read Commands to Exclusive Access Regions....887
20.4.7.6 Non-Exclusive Write Commands to Exclusive Access Regions....888
20.4.7.7 Exclusive Writes....888
20.4.7.8 Passing Exclusive Access Check....888
20.4.7.9 Failing Exclusive Access Check....888
20.4.8 Error Responses....889
20.4.8.1 AXI Error Response....889
20.4.8.2 AXI Error Reporting....889
20.4.9 Arbiter....889
20.4.10 Write Data Queue....890
20.4.11 DRAM Command Processing....890
20.4.12 Latency....890
20.5 DRAM MC Core-Logic....891
20.5.1 Command Queue with Placement Logic....892

20.6 Core Command Queue with Placement Logic....893
20.6.1 Rules of the Placement Algorithm....893
20.6.1.1 Address Collision/Data Coherency Violation....893
20.6.1.2 Source ID Collision....894
20.6.1.3 Write Buffer Collision....894
20.6.1.4 Priority....894
20.6.1.5 Bank Splitting....895
20.6.1.6 Read/Write Grouping....895
20.6.2 Command Execution Order After Placement....896
20.6.2.1 Command Aging....896
20.6.2.2 High-Priority Command Swapping....896
20.7 Notes for Programming of the Timing Parameters....898
20.7.1 Command to Command Timing....898
20.7.2 Refresh Per Chip-select....899
20.7.3 Programming of the tref Parameter....899
20.7.4 Programming of the tref_interval Parameter....900
20.8 DRAM Low Power Operation....900
20.8.1 Low Power Modes....900
20.8.2 Low Power Mode Control....902
20.8.3 Automatic Entry....902
20.8.4 Automatic Exit....903
20.8.5 Manual "On-Demand" Entry....903
20.8.6 Manual "On-Demand" Exit....904
20.8.7 Register Programming....904
20.9 Interface for LPDDR2 Devices....906
20.9.1 Restrictions....906
20.9.2 ZQ Calibration for off-chip LPDDR2 Devices....906
20.9.3 Programmable Control....907
20.9.4 ZQ Short Calibration....908

20.9.5 ZQ Long Calibration....909
20.9.6 ZQ Initialization....909
20.9.7 ZQ Reset....909
20.10 DDR PHY....910
20.10.1 High Level Block Diagram....910
20.10.2 DFI....911
20.10.3 The I/O Timing of Address & Command....911
20.10.4 The Address Timing of LP-DDR2....912
20.10.5 Data Slice Overview....913
20.10.6 Read Data Capture....914
20.10.7 Synchronize Read Data From delayed_dqs To PHY_CLK domain....914
20.10.8 Write Data Path....916
20.10.8.1 The Low-Latency Option of Write Data Path....917
20.10.9 Digital DLL and the Delay-Line....918
20.10.10 Configure the "output enable" of I/O Control....920
20.11 Programmable Registers....921
20.11.1 DRAM CTL Register 00 (DRAM_CTL00)....928
20.11.2 DRAM CTL Register 01 (DRAM_CTL01)....929
20.11.3 DRAM CTL Register 02 (DRAM_CTL02)....929
20.11.4 DRAM CTL Register 03 (DRAM_CTL03)....930
20.11.5 DRAM CTL Register 04 (DRAM_CTL04)....930
20.11.6 DRAM CTL Register 05 (DRAM_CTL05)....931
20.11.7 DRAM CTL Register 06 (DRAM_CTL06)....932
20.11.8 DRAM CTL Register 07 (DRAM_CTL07)....933
20.11.9 DRAM CTL Register 08 (DRAM_CTL08)....934
20.11.10 DRAM CTL Register 09 (DRAM_CTL09)....935
20.11.11 DRAM CTL Register 10 (DRAM_CTL10)....937
20.11.12 DRAM CTL Register 11 (DRAM_CTL11)....938
20.11.13 DRAM CTL Register 12 (DRAM_CTL12)....939

20.11.14 DRAM CTL Register 13 (DRAM_CTL13).....940
20.11.15 DRAM CTL Register 14 (DRAM_CTL14).....941
20.11.16 DRAM CTL Register 15 (DRAM_CTL15).....942
20.11.17 DRAM CTL Register 16 (DRAM_CTL16).....943
20.11.18 DRAM CTL Register 17 (DRAM_CTL17).....944
20.11.19 DRAM CTL Register 18 (DRAM_CTL18).....945
20.11.20 DRAM CTL Register 19 (DRAM_CTL19).....946
20.11.21 DRAM CTL Register 20 (DRAM_CTL20).....947
20.11.22 DRAM CTL Register 21 (DRAM_CTL21).....948
20.11.23 DRAM CTL Register 22 (DRAM_CTL22).....949
20.11.24 DRAM CTL Register 23 (DRAM_CTL23).....950
20.11.25 DRAM CTL Register 24 (DRAM_CTL24).....951
20.11.26 DRAM CTL Register 25 (DRAM_CTL25).....952
20.11.27 DRAM CTL Register 26 (DRAM_CTL26).....952
20.11.28 DRAM CTL Register 27 (DRAM_CTL27).....953
20.11.29 DRAM CTL Register 28 (DRAM_CTL28).....954
20.11.30 DRAM CTL Register 29 (DRAM_CTL29).....955
20.11.31 DRAM CTL Register 30 (DRAM_CTL30).....955
20.11.32 DRAM CTL Register 31 (DRAM_CTL31).....956
20.11.33 DRAM CTL Register 32 (DRAM_CTL32).....956
20.11.34 DRAM CTL Register 33 (DRAM_CTL33).....957
20.11.35 DRAM CTL Register 34 (DRAM_CTL34).....958
20.11.36 DRAM CTL Register 35 (DRAM_CTL35).....959
20.11.37 DRAM CTL Register 36 (DRAM_CTL36).....960
20.11.38 DRAM CTL Register 37 (DRAM_CTL37).....961
20.11.39 DRAM CTL Register 38 (DRAM_CTL38).....963
20.11.40 DRAM CTL Register 39 (DRAM_CTL39).....964
20.11.41 DRAM CTL Register 40 (DRAM_CTL40).....965
20.11.42 DRAM CTL Register 41 (DRAM_CTL41).....967

20.11.43 DRAM CTL Register 42 (DRAM_CTL42)....968
20.11.44 DRAM CTL Register 43 (DRAM_CTL43)....969
20.11.45 DRAM CTL Register 44 (DRAM_CTL44)....969
20.11.46 DRAM CTL Register 45 (DRAM_CTL45)....970
20.11.47 DRAM CTL Register 46 (DRAM_CTL46)....970
20.11.48 DRAM CTL Register 47 (DRAM_CTL47)....971
20.11.49 DRAM CTL Register 48 (DRAM_CTL48)....971
20.11.50 DRAM CTL Register 49 (DRAM_CTL49)....972
20.11.51 DRAM CTL Register 50 (DRAM_CTL50)....973
20.11.52 DRAM CTL Register 51 (DRAM_CTL51)....974
20.11.53 DRAM CTL Register 52 (DRAM_CTL52)....975
20.11.54 DRAM CTL Register 53 (DRAM_CTL53)....976
20.11.55 DRAM CTL Register 54 (DRAM_CTL54)....977
20.11.56 DRAM CTL Register 55 (DRAM_CTL55)....977
20.11.57 DRAM CTL Register 56 (DRAM_CTL56)....978
20.11.58 DRAM CTL Register 57 (DRAM_CTL57)....979
20.11.59 DRAM CTL Register 58 (DRAM_CTL58)....980
20.11.60 DRAM CTL Register 59 (DRAM_CTL59)....981
20.11.61 DRAM CTL Register 60 (DRAM_CTL60)....982
20.11.62 DRAM CTL Register 61 (DRAM_CTL61)....983
20.11.63 DRAM CTL Register 62 (DRAM_CTL62)....984
20.11.64 DRAM CTL Register 63 (DRAM_CTL63)....985
20.11.65 DRAM CTL Register 64 (DRAM_CTL64)....986
20.11.66 DRAM CTL Register 65 (DRAM_CTL65)....987
20.11.67 DRAM CTL Register 66 (DRAM_CTL66)....988
20.11.68 DRAM CTL Register 67 (DRAM_CTL67)....988
20.11.69 DRAM CTL Register 68 (DRAM_CTL68)....989
20.11.70 DRAM CTL Register 69 (DRAM_CTL69)....989
20.11.71 DRAM CTL Register 70 (DRAM_CTL70)....990

20.11.72 DRAM CTL Register 71 (DRAM_CTL71)....991
20.11.73 DRAM CTL Register 72 (DRAM_CTL72)....992
20.11.74 DRAM CTL Register 73 (DRAM_CTL73)....993
20.11.75 DRAM CTL Register 74 (DRAM_CTL74)....994
20.11.76 DRAM CTL Register 75 (DRAM_CTL75)....995
20.11.77 DRAM CTL Register 76 (DRAM_CTL76)....995
20.11.78 DRAM CTL Register 77 (DRAM_CTL77)....996
20.11.79 DRAM CTL Register 78 (DRAM_CTL78)....996
20.11.80 DRAM CTL Register 79 (DRAM_CTL79)....997
20.11.81 DRAM CTL Register 80 (DRAM_CTL80)....998
20.11.82 DRAM CTL Register 81 (DRAM_CTL81)....998
20.11.83 DRAM CTL Register 82 (DRAM_CTL82)....998
20.11.84 DRAM CTL Register 83 (DRAM_CTL83)....999
20.11.85 DRAM CTL Register 84 (DRAM_CTL84)....999
20.11.86 DRAM CTL Register 85 (DRAM_CTL85)....1000
20.11.87 DRAM CTL Register 86 (DRAM_CTL86)....1000
20.11.88 DRAM PHY Register 00 (DRAM_PHY00)....1001
20.11.89 DRAM PHY Register 01 (DRAM_PHY01)....1001
20.11.90 DRAM PHY Register 02 (DRAM_PHY02)....1002
20.11.91 DRAM PHY Register 03 (DRAM_PHY03)....1004
20.11.92 DRAM PHY Register 04 (DRAM_PHY04)....1006
20.11.93 DRAM PHY Register 05 (DRAM_PHY05)....1006
20.11.94 DRAM PHY Register 06 (DRAM_PHY06)....1006
20.11.95 DRAM PHY Register 07 (DRAM_PHY07)....1007
20.11.96 DRAM PHY Register 08 (DRAM_PHY08)....1007
20.11.97 DRAM PHY Register 09 (DRAM_PHY09)....1008
20.11.98 DRAM PHY Register 10 (DRAM_PHY10)....1008
20.11.99 DRAM PHY Register 11 (DRAM_PHY11)....1008
20.11.100 DRAM PHY Register 12 (DRAM_PHY12)....1009

20.11.101 DRAM PHY Register 13 (DRAM_PHY13)....1009
20.11.102 DRAM PHY Register 14 (DRAM_PHY14)....1010
20.11.103 DRAM PHY Register 15 (DRAM_PHY15)....1011
20.11.104 DRAM PHY Register 16 (DRAM_PHY16)....1012
20.11.105 DRAM PHY Register 17 (DRAM_PHY17)....1012
20.11.106 DRAM PHY Register 18 (DRAM_PHY18)....1013
20.11.107 DRAM PHY Register 19 (DRAM_PHY19)....1013
20.11.108 DRAM PHY Register 20 (DRAM_PHY20)....1014
20.11.109 DRAM PHY Register 21 (DRAM_PHY21)....1014
20.11.110 DRAM PHY Register 22 (DRAM_PHY22)....1014
20.11.111 DRAM PHY Register 23 (DRAM_PHY23)....1015
20.11.112 DRAM PHY Register 24 (DRAM_PHY24)....1015
20.11.113 DRAM PHY Register 25 (DRAM_PHY25)....1016
20.11.114 DRAM PHY Register 26 (DRAM_PHY26)....1017
20.11.115 DRAM PHY Register 27 (DRAM_PHY27)....1017
20.11.116 DRAM PHY Register 28 (DRAM_PHY28)....1018
20.11.117 DRAM PHY Register 29 (DRAM_PHY29)....1018
20.11.118 DRAM PHY Register 30 (DRAM_PHY30)....1018
20.11.119 DRAM PHY Register 31 (DRAM_PHY31)....1019
20.11.120 DRAM PHY Register 32 (DRAM_PHY32)....1019
20.11.121 DRAM PHY Register 33 (DRAM_PHY33)....1020
20.11.122 DRAM PHY Register 34 (DRAM_PHY34)....1020
20.11.123 DRAM PHY Register 35 (DRAM_PHY35)....1020
20.11.124 DRAM PHY Register 36 (DRAM_PHY36)....1021
20.11.125 DRAM PHY Register 37 (DRAM_PHY37)....1021
20.11.126 DRAM PHY Register 38 (DRAM_PHY38)....1022

Chapter 21
Dynamic Voltage and Frequency Scaling Core (DVFSC)

21.1 Introduction 1023
21.1.1 Overview....1023
21.1.2 Features....1024
21.2 Functional Description of DVFS Load Tracking....1025
21.3 Component Blocks Description....1025
21.3.1 dvfs_stdb_smpl Block....1025
21.3.2 dvfs_sig_wt Block....1025
21.3.3 dvfs_pre_avg Block....1026
21.3.4 dvfs_ld_add Block....1029
21.3.5 dvfs_ema_avg Block....1029
21.3.6 dvfs_thres_cmp Block....1033
21.3.7 dvfs_thresh_count Block....1034
21.3.8 Load Tracking Buffer Register....1035
21.3.9 Frequency Pattern Generator....1036
21.4 DVFS Output Event/interrupt Configuration....1037
21.4.1 Interrupts....1037
21.5 Initialization Information....1037
21.6 Programmable Registers....1038
21.6.1 DVFSC Thresholds (DVFSC_THRS)....1039
21.6.2 DVFSC Counters thresholds (DVFSC_COUN)....1039
21.6.3 DVFSC general purpose bits weight (DVFSC_SIG1)....1040
21.6.4 DVFSC general purpose bits weight (DVFSC_SIG0)....1041
21.6.5 DVFSC general purpose bit 0 weight counter (DVFSC_GPC0)....1042
21.6.6 DVFSC general purpose bit 1 weight counter (DVFSC_GPC1)....1043
21.6.7 DVFSC general purpose bits enables (DVFSC_GPBT)....1044
21.6.8 DVFSC EMAC settings (DVFSC_EMAC)....1045
21.6.9 DVFSC Control (DVFSC_CNTR)....1045

21.6.10 DVFSC Load Tracking Register 0, portion 0 (DVFSC_LTR0_0)....1048
21.6.11 DVFSC Load Tracking Register 0, portion 1 (DVFSC_LTR0_1)....1049
21.6.12 DVFSC Load Tracking Register 1, portion 0 (DVFSC_LTR1_0)....1050
21.6.13 DVFS Load Tracking Register 3, portion 1 (DVFSC_LTR1_1)....1051
21.6.14 DVFSC pattern 0 length (DVFSC_PT0)....1051
21.6.15 DVFSC pattern 1 length (DVFSC_PT1)....1052
21.6.16 DVFSC pattern 2 length (DVFSC_PT2)....1053
21.6.17 DVFSC pattern 3 length (DVFSC_PT3)....1053

Chapter 22
Enhanced Configurable SPI (ECSPI)

22.1 Overview....1055
22.1.1 Features....1056
22.1.2 Modes and Operations....1056
22.2 External Signals....1057
22.3 Functional Description....1058
22.3.1 Master Mode....1059
22.3.2 Slave Mode....1059
22.3.3 Hardware Trigger (HT) Mode....1060
22.3.4 Low Power Modes....1060
22.3.5 Operations....1060
22.3.5.1 Typical Master Mode....1060
22.3.5.1.1 Master Mode with SPI_RDY....1061
22.3.5.1.2 Master Mode with Wait States....1063
22.3.5.1.3 Master Mode with SS_CTL[3:0] Control....1063
22.3.5.1.4 Master Mode with Phase Control....1064
22.3.5.2 Typical Slave Mode....1065
22.3.6 Clocks....1066
22.3.7 Reset....1066
22.3.8 Interrupts....1067

22.3.9 DMA 1068
22.3.10 Byte Order....1069
22.4 Initialization....1069
22.5 Applications....1070
22.6 Programmable Registers....1071
22.6.1 Receive Data Register (ECSPI*x*_RXDATA)....1072
22.6.2 Transmit Data Register (ECSPI*x*_TXDATA)....1073
22.6.3 Control Register (ECSPI*x*_CONREG)....1074
22.6.4 Config Register (ECSPI*x*_CONFIGREG)....1076
22.6.5 Interrupt Control Register (ECSPI*x*_INTREG)....1078
22.6.6 DMA Control Register (ECSPI*x*_DMAREG)....1079
22.6.7 Status Register (ECSPI*x*_STATREG)....1081
22.6.8 Sample Period Control Register (ECSPI*x*_PERIODREG)....1082
22.6.9 Test Control Register (ECSPI*x*_TESTREG)....1083
22.6.10 Message Data Register (ECSPI*x*_MSGDATA)....1084

Chapter 23
External Interface Module (EIM)

23.1 Overview....1086
23.2 Features....1087
23.3 Modes of Operation....1087
23.3.1 Asynchronous Mode....1088
23.3.2 Asynchronous Page Read Mode....1088
23.3.3 Multiplexed Address/Data Mode....1088
23.3.4 Burst Clock Mode....1089
23.3.5 Low Power Modes....1090
23.3.6 Boot Mode....1090
23.4 External Signal Description....1090
23.4.1 Signals Overview....1090
23.4.2 Detailed Signal Descriptions....1091

23.4.3 Other Important Block I/O Signals Internal to the SoC....1092
23.5 Chip Select Memory Map....1093
23.6 Functional Description....1093
23.6.1 Clocks....1093
23.6.2 Bus Sizing Configuration....1094
23.6.2.1 8 BIT PORT SUPPORT....1094
23.6.2.1.1 MOTOROLA 68000....1094
23.6.2.1.2 INTEL 386....1095
23.6.3 EIM Operational Modes....1095
23.6.4 Burst Mode (Synchronous) Memory Operation....1095
23.6.5 Burst Clock Divisor (BCD)....1096
23.6.6 Burst Clock Start (BCS)....1097
23.6.7 Multiplexed Address/Data Mode Support....1097
23.6.8 Mixed Master/Memory Burst Modes Support....1097
23.6.9 AXI (Master) Bus Cycles Support....1098
23.6.10 WAIT_B Signal, RWSC and WWSC bit fields Usage....1100
23.6.11 IPS Register Interface....1100
23.6.12 MRS Set for PSRAM....1101
23.6.13 EIM Access Termination....1101
23.6.14 Error Conditions....1101
23.6.15 DTACK Mode....1102
23.6.16 RDY_INT Signal as Interrupt....1102
23.6.17 RDY_INT Signal as Ready After Reset Indication....1103
23.6.18 EIM_GRANT / EIM_BUSY Handshake Description....1103
23.6.19 LPMD / LPACK Handshake Description....1103
23.6.20 Endianness....1104
23.6.21 Strobe Signal Use....1105
23.7 Initialization Information....1105
23.7.1 Active Chip Selects and Address Space Configuration....1105

23.7.2 Booting from EIM....1106
23.8 Application Note....1107
23.8.1 Access to AMD Flash....1107
23.8.1.1 AMD Flash Asynchronous Mode Configuration....1107
23.8.1.2 AMD Flash Utility....1108
23.8.2 Access to Intel Sibley Flash....1108
23.8.2.1 Intel Sibley Flash Asynchronous Mode Configuration....1109
23.8.2.2 Intel Sibley Flash Synchronous Mode Configuration....1109
23.8.2.3 Intel Sibley Flash Utility....1109
23.8.3 Access to MDOC Device....1110
23.8.3.1 MDOC Device Boot....1110
23.8.3.2 MDOC Device Asynchronous Mode Configuration....1110
23.8.3.3 MDOC Device Utility....1110
23.8.4 Access to Micron PSRAM....1110
23.8.4.1 Micron PSRAM Asynchronous Mode Configuration....1110
23.8.4.2 Micron PSRAM Synchronous Mode Configuration....1111
23.8.5 Access to Samsung OneNAND....1111
23.8.5.1 Samsung OneNAND Boot....1111
23.8.5.2 Samsung OneNAND Asynchronous Mode Configuration....1112
23.8.5.3 Samsung OneNAND Synchronous Mode Configuration....1112
23.8.5.4 Samsung OneNAND Utility....1112
23.8.6 Access to Samsung UtRAM....1113
23.8.6.1 Samsung UtRAM Asynchronous Mode Configuration....1113
23.8.6.2 Samsung UtRAM Synchronous Mode Configuration....1113
23.8.7 Access to Spansion Flash....1113
23.8.7.1 Spansion Flash Asynchronous Mode Configuration....1113
23.8.7.2 Spansion Flash Synchronous Mode Configuration....1114
23.8.7.3 Spansion Flash Utility....1114
23.8.8 8 bit support....1115

23.9 Booting from OneNAND and NOR Flash devices....1116
23.9.1 Asynchronous Read Memory Accesses Timing Diagram....1116
23.9.2 Asynchronous Write Memory Accesses Timing Diagram....1117
23.9.3 Asynchronous Read/Write Memory Accesses Timing Diagram....1118
23.9.4 Asynchronous Read/Write Using RAL, WAL and CSREC....1120
23.9.5 Consecutive Asynchronous Write Memory Accesses Timing Diagram....1121
23.9.6 Consecutive Asynchronous Read Memory Accesses Timing Diagram....1124
23.9.7 Async. Page Mode Access....1126
23.9.8 DTACK Mode - AXI Single Access....1127
23.9.9 DTACK Mode - AXI Single Write Access....1130
23.9.10 DTACK Mode - AXI Burst Access....1131
23.10 Programmable Registers....1133
23.10.1 EIM Memory Map/Register Definition....1133
23.101.1 Chip Select n General Configuration Register 1 (EIM_CS*n*GCR1)....1135
23.101.2 Chip Select n General Configuration Register 2 (EIM_CS*n*GCR2)....1139
23.101.3 Chip Select n Read Configuration Register 1 (EIM_CS*n*RCR1)....1141
23.101.4 Chip Select n Read Configuration Register 2 (EIM_CS*n*RCR2)....1144
23.101.5 Chip Select n Write Configuration Register 1 (EIM_CS*n*WCR1)....1145
23.101.6 Chip Select n Write Configuration Register 2 (EIM_CS*n*WCR2)....1148
23.101.7 EIM Configuration Register (EIM_WCR)....1149
23.101.8 EIM IP Access Register (EIM_WIAR)....1150
23.101.9 Error Address Register (EIM_EAR)....1151

Chapter 24
Electrophoretic Display Controller (EPDC)

24.1 Overview....1153
24.2 Block Diagram and Overview....1154
24.3 Programming Model....1155
24.3.1 Assumptions....1155
24.3.2 Register Space (Write/Set/Clear/Toggle)....1156

24.3.3 Interrupts....1156
24.3.3.1 Interrupt Sources....1156
24.3.3.2 Enabling/Masking Interrupts....1157
24.3.3.3 Handling/Clearing Interrupts....1157
24.3.4 Controller Setup....1157
24.3.4.1 Memory Requirements....1158
24.3.4.2 Panel Architecture Configuration....1158
24.3.4.3 TFT Panel Timing Configuration....1161
24.3.4.4 Source-Driver and Pixel-Clock Configuration....1167
24.3.4.5 Initializing the Display....1169
24.3.4.5.1 Reset/Clocks and Buffer Preparation....1169
24.3.4.5.2 Performing an Initialization Display Update....1170
24.3.5 Dual-Scan Configuration....1170
24.3.6 Display Update Programming....1173
24.3.6.1 Initiating a Display Update....1173
24.3.6.2 Update Processing and Collisions....1174
24.3.6.3 Multiple Update Flow....1178
24.3.7 Architectural Clock Gating (Low Power Mode)....1181
24.3.8 Performance Tuning and Considerations....1183
24.3.8.1 Memory and Bus Bandwidth Requirements....1183
24.3.8.2 Pixel Latency FIFOs....1184
24.3.8.3 Basic Watermarking Control....1184
24.3.8.4 Update/Refresh Tuning (VSCAN_HOLDOFF)....1185
24.3.8.5 System-Level Arbitration Control....1185
24.4 Programmable Registers....1187
24.4.1 EPDC Control Register (EPDC_CTRL*n*)....1193
24.4.2 EPDC Waveform Address Pointer (EPDC_WVADDR)....1194
24.4.3 EPDC Working Buffer Address (EPDC_WB_ADDR)....1194
24.4.4 EPDC Screen Resolution (EPDC_RES)....1195

24.4.5 EPDC Format Control Register (EPDC_FORMAT*n*)....1196
24.4.6 EPDC FIFO Control Register (EPDC_FIFOCTRL*n*)....1197
24.4.7 EPDC Update Region Address (EPDC_UPD_ADDR)....1198
24.4.8 EPDC Update Command Co-ordinate (EPDC_UPD_CORD)....1198
24.4.9 EPDC Update Command Size (EPDC_UPD_SIZE)....1199
24.4.10 EPDC Update Command Control (EPDC_UPD_CTRL*n*)....1200
24.4.11 EPDC Update Fixed Pixel Control (EPDC_UPD_FIXED*n*)....1201
24.4.12 EPDC Temperature Register (EPDC_EPDC_TEMP)....1201
24.4.13 EPDC Timing Control Engine Control Register (EPDC_EPDC_TCE_CTRL*n*)....1202
24.4.14 EPDC Timing Control Engine Source-Driver Config Register (EPDC_TCE_SDCFG*n*)....1204
24.4.15 EPDC Timing Control Engine Gate-Driver Config Register (EPDC_TCE_GDCFG*n*)....1205
24.4.16 EPDC Timing Control Engine Horizontal Timing Register 1 (EPDC_TCE_HSCAN1*n*)....1206
24.4.17 EPDC Timing Control Engine Horizontal Timing Register 2 (EPDC_TCE_HSCAN2*n*)....1207
24.4.18 EPDC Timing Control Engine Vertical Timing Register (EPDC_TCE_VSCAN*n*)....1207
24.4.19 EPDC Timing Control Engine OE timing control Register (EPDC_TCE_OE*n*)....1208
24.4.20 EPDC Timing Control Engine Driver Polarity Register (EPDC_TCE_POLARITY*n*)....1209
24.4.21 EPDC Timing Control Engine Timing Register 1 (EPDC_TCE_TIMING1*n*)....1210
24.4.22 EPDC Timing Control Engine Timing Register 2 (EPDC_TCE_TIMING2*n*)....1211
24.4.23 EPDC Timing Control Engine Timing Register 3 (EPDC_TCE_TIMING3*n*)....1212
24.4.24 EPDC IRQ Mask Register (EPDC_IRQ_MASK*n*)....1213
24.4.25 EPDC Interrupt Register (EPDC_IRQ*n*)....1215
24.4.26 EPDC Status Register - LUTs (EPDC_EPDC_STATUS_LUTS*n*)....1217
24.4.27 EPDC Status Register - Next Available LUT (EPDC_STATUS_NEXTLUT)....1219
24.4.28 EPDC LUT Collision Status (EPDC_STATUS_COL*n*)....1220
24.4.29 EPDC General Status Register (EPDC_STATUS*n*)....1222
24.4.30 EPDC Debug register (EPDC_DEBUG*n*)....1223
24.4.31 EPDC LUTn Debug Information register (EPDC_DEBUG_LUT*n*)....1224
24.4.32 EPDC General Purpose I/O Debug register (EPDC_GPIO*n*)....1225
24.4.33 EPDC Version Register (EPDC_VERSION)....1225

Chapter 25
Enhanced Periodic Interrupt Timer (EPIT)

25.1 Overview....1228
25.1.1 Features....1228
25.1.2 Modes and Operations....1229
25.2 External Signals....1229
25.3 Functional Description....1229
25.3.1 Operating Modes....1229
25.3.1.1 Set-and-Forget Mode....1229
25.3.1.2 Free-Running Mode....1230
25.3.2 Operations....1230
25.3.3 Clocks....1231
25.3.4 Compare Event....1232
25.3.4.1 Counter Value Overwrite....1232
25.3.4.2 Low-Power Mode Behavior....1233
25.3.4.3 Debug Mode Behavior....1233
25.4 Initialization/ Application Information....1233
25.4.1 Change of Clock Source....1233
25.5 Programmable Registers....1234
25.5.1 Control register (EPIT_EPITCR)....1234
25.5.2 Status register (EPIT_EPITSR)....1237
25.5.3 Load register (EPIT_EPITLR)....1238
25.5.4 Compare register (EPIT_EPITCMPR)....1238
25.5.5 Counter register (EPIT_EPITCNR)....1239

Chapter 26
Enhanced Secured Digital Host Controller (eSDHCv2)

26.1 Overview....1241
26.1.1 Features....1243

26.1.2 Modes and Operations....1244
26.1.2.1 Data transfer Modes....1244
26.2 External Signals....1244
26.2.1 Signals Overview....1245
26.2.2 Ports Table....1245
26.3 Functional Description....1246
26.3.1 Data Buffer....1246
26.3.1.1 Write Operation Sequence....1249
26.3.1.2 Read Operation Sequence....1249
26.3.1.3 Data Buffer and Block Size....1250
26.3.1.4 Dividing Large Data Transfer....1251
26.3.1.5 External DMA Request....1252
26.3.2 DMA AHB Interface....1253
26.3.2.1 Internal DMA Request....1254
26.3.2.2 DMA Burst Length....1254
26.3.2.3 AHB Master Interface....1255
26.3.2.4 ADMA Engine....1255
26.3.2.4.1 ADMA Concept and Descriptor Format....1256
26.3.2.4.2 ADMA Interrupt....1259
26.3.2.4.3 ADMA Error-DMA....1259
26.3.3 Register Bank with IP Bus Interface....1259
26.3.4 SD Protocol Unit....1260
26.3.4.1 SD Transceiver....1261
26.3.4.2 SD Clock & Monitor....1261
26.3.4.3 Command Agent....1261
26.3.4.4 Data Agent....1262
26.3.5 Clock & Reset Manager....1262
26.3.6 Clock Generator....1263

26.3.7 SDIO Card Interrupt....1263
26.3.7.1 Interrupts in 1-bit Mode....1263
26.3.7.2 Interrupt in 4-bit Mode....1263
26.3.7.3 Card Interrupt Handling....1264
26.3.8 Card Insertion and Removal Detection....1265
26.3.9 Power Management and Wake Up Events....1266
26.3.9.1 Setting Wake Up Events....1267
26.3.10 MMC Fast Boot....1267
26.3.10.1 Boot Operation....1267
26.3.10.2 Alternative Boot Operation....1268
26.4 Initialization/Application of ESDHC....1269
26.4.1 Command Send & Response Receive Basic Operation....1269
26.4.2 Card Identification Mode....1270
26.4.2.1 Card Detect....1270
26.4.2.2 Reset....1272
26.4.2.3 Voltage Validation....1273
26.4.2.4 Card Registry....1274
26.4.3 Card Access....1275
26.4.3.1 Block Write....1276
26.4.3.1.1 Normal Write....1276
26.4.3.1.2 Write with Pause....1277
26.4.3.2 Block Read....1278
26.4.3.2.1 Normal Read....1278
26.4.3.2.2 Read with Pause....1279
26.4.3.3 Suspend Resume....1280
26.4.3.3.1 Resume....1281
26.4.3.4 ADMA1 Usage....1281
26.4.3.5 Transfer Error....1282
26.4.3.5.1 CRC Error....1282

26.4.3.5.2 Internal DMA Error....1282
26.4.3.5.3 ADMA Error-Card Access....1283
26.4.3.5.4 Auto CMD12 Error....1283
26.4.3.6 Card Interrupt....1284
26.4.4 Switch Function....1284
26.4.4.1 Query, Enable and Disable SDIO High Speed Mode....1285
26.4.4.2 Query, Enable and Disable SD High Speed Mode....1285
26.4.4.3 Query, Enable and Disable MMC High Speed Mode....1286
26.4.4.4 Set MMC Bus Width....1286
26.4.5 ADMA Operation....1286
26.4.5.1 ADMA1 Operation....1286
26.4.5.2 ADMA2 Operation....1287
26.4.6 Fast Boot Operation....1287
26.4.6.1 Normal fast boot flow....1287
26.4.6.2 Alternative fast boot flow....1288
26.4.6.3 Fast boot application case (in DMA mode)....1289
26.5 Commands for MMC/SD/SDIO....1291
26.6 Software Restrictions....1296
26.6.1 Initialization Active....1296
26.6.2 Softeware Polling Procedure....1297
26.6.3 Suspend Operation....1297
26.6.4 Data Length Setting....1297
26.6.5 (A)DMA Address Setting....1297
26.6.6 Data Port Access....1297
26.6.7 Change Clock Frequency....1298
26.6.8 Multi-block Read....1298
26.7 Programmable Registers....1298
26.7.1 DMA System Address (ESDHCV2*x*_DSADDR)....1302
26.7.2 Block Attributes (ESDHCV2*x*_BLKATTR)....1303

26.7.3 Command Argument (ESDHCV2x_CMDARG)....1304
26.7.4 Command Transfer Type (ESDHCV2x_XFERTYP)....1305
26.7.5 Command Response 0 (ESDHCV2x_CMDRSP0)....1309
26.7.6 Command Response 1 (ESDHCV2x_CMDRSP1)....1310
26.7.7 Command Response 2 (ESDHCV2x_CMDRSP2)....1310
26.7.8 Command Response 3 (ESDHCV2x_CMDRSP3)....1310
26.7.9 Data Buffer Access Port (ESDHCV2x_DATPORT)....1312
26.7.10 Present State (ESDHCV2x_PRSSTAT)....1313
26.7.11 Protocol Control (ESDHCV2x_PROCTL)....1318
26.7.12 System Control (ESDHCV2x_SYSCTL)....1322
26.7.13 Interrupt Status (ESDHCV2x_IRQSTAT)....1326
26.7.14 Interrupt Status Enable (ESDHCV2x_IRQSTATEN)....1331
26.7.15 Interrupt Signal Enable (ESDHCV2x_IRQSIGEN)....1334
26.7.16 Auto CMD12 Status (ESDHCV2x_AUTOC12ERR)....1336
26.7.17 Host Controller Capabilities (ESDHCV2x_HOSTCAPBLT)....1339
26.7.18 Watermark Level (ESDHCV2x_WML)....1341
26.7.19 Force Event (ESDHCV2x_FEVT)....1342
26.7.20 ADMA Error Status Register (ESDHCV2x_ADMAES)....1344
26.7.21 ADMA System Address (ESDHCV2x_ADSADDR)....1346
26.7.22 Vendor Specific Register (ESDHCV2x_VENDOR)....1347
26.7.23 MMC Boot Register (ESDHCV2x_MMCBOOT)....1348
26.7.24 Host Controller Version (ESDHCV2x_HOSTVER)....1349

Chapter 27
Enhanced Secured Digital Host Controller (eSDHCv3)

27.1 Overview....1351
27.1.1 Features....1353
27.1.2 Modes and Operations....1354
27.1.2.1 Data transfer Modes....1354

27.2 External Signals....1355
27.2.1 Signals Overview....1355
27.2.2 Ports Table....1355
27.3 Functional Description....1356
27.3.1 Data Buffer....1356
27.3.1.1 Write Operation Sequence....1359
27.3.1.2 Read Operation Sequence....1360
27.3.1.3 Data Buffer and Block Size....1360
27.3.1.4 Dividing Large Data Transfer....1361
27.3.1.5 External DMA Request....1362
27.3.2 DMA AHB Interface....1363
27.3.2.1 Internal DMA Request....1364
27.3.2.2 DMA Burst Length....1364
27.3.2.3 AHB Master Interface....1365
27.3.2.4 ADMA Engine....1365
27.3.2.4.1 ADMA Concept and Descriptor Format....1366
27.3.2.4.2 ADMA Interrupt....1369
27.3.2.4.3 ADMA Error-DMA....1369
27.3.3 Register Bank with IP Bus Interface....1369
27.3.4 SD Protocol Unit....1370
27.3.4.1 SD Transceiver....1371
27.3.4.2 SD Clock & Monitor....1371
27.3.4.3 Command Agent....1371
27.3.4.4 Data Agent....1372
27.3.5 Clock & Reset Manager....1372
27.3.6 Clock Generator....1373
27.3.7 SDIO Card Interrupt....1373
27.3.7.1 Interrupts in 1-bit Mode....1373
27.3.7.2 Interrupt in 4-bit Mode....1373

27.3.7.3 Card Interrupt Handling....1374
27.3.8 Card Insertion and Removal Detection....1375
27.3.9 Power Management and Wake Up Events....1376
27.3.9.1 Setting Wake Up Events....1377
27.3.10 MMC Fast Boot....1377
27.3.10.1 Boot Operation....1377
27.3.10.2 Alternative Boot Operation....1378
27.4 Initialization/Application of ESDHC....1379
27.4.1 Command Send & Response Receive Basic Operation....1379
27.4.2 Card Identification Mode....1380
27.4.2.1 Card Detect....1380
27.4.2.2 Reset....1382
27.4.2.3 Voltage Validation....1383
27.4.2.4 Card Registry....1384
27.4.3 Card Access....1385
27.4.3.1 Block Write....1386
27.4.3.1.1 Normal Write....1386
27.4.3.1.2 DDR Write....1387
27.4.3.1.3 Write with Pause....1387
27.4.3.2 Block Read....1389
27.4.3.2.1 Normal Read....1389
27.4.3.2.2 DDR Read....1390
27.4.3.2.3 Read with Pause....1390
27.4.3.2.4 DLL (Delay Line) in Read Path....1391
27.4.3.3 Suspend Resume....1392
27.4.3.3.1 Resume....1393
27.4.3.4 ADMA1 Usage....1393
27.4.3.5 Transfer Error....1394
27.4.3.5.1 CRC Error....1394

27.4.3.5.2 Internal DMA Error....1394
27.4.3.5.3 ADMA Error-Card Access....1395
27.4.3.5.4 Auto CMD12 Error....1395
27.4.3.6 Card Interrupt....1396
27.4.4 Switch Function....1396
27.4.4.1 Query, Enable and Disable SDIO High Speed Mode....1397
27.4.4.2 Query, Enable and Disable SD High Speed Mode....1397
27.4.4.3 Query, Enable and Disable MMC High Speed Mode....1398
27.4.4.4 Set MMC Bus Width....1398
27.4.5 ADMA Operation....1398
27.4.5.1 ADMA1 Operation....1398
27.4.5.2 ADMA2 Operation....1399
27.4.6 Fast Boot Operation....1399
27.4.6.1 Normal fast boot flow....1399
27.4.6.2 Alternative fast boot flow....1400
27.4.6.3 Fast boot application case (in DMA mode)....1401
27.5 Commands for MMC/SD/SDIO....1403
27.6 Software Restrictions....1408
27.6.1 Initialization Active....1409
27.6.2 Softeware Polling Procedure....1409
27.6.3 Suspend Operation....1409
27.6.4 Data Length Setting....1409
27.6.5 (A)DMA Address Setting....1409
27.6.6 Data Port Access....1410
27.6.7 Change Clock Frequency....1410
27.6.8 Multi-block Read....1410
27.7 Programmable Registers....1411
27.7.1 DMA System Address (ESDHCV3*x*_DSADDR)....1412
27.7.2 Block Attributes (ESDHCV3*x*_BLKATTR)....1413

27.7.3 Command Argument (ESDHCV3x_CMDARG)....1414
27.7.4 Command Transfer Type (ESDHCV3x_XFERTYP)....1415
27.7.5 Command Response n (ESDHCV3x_CMDRSPn)....1419
27.7.6 Data Buffer Access Port (ESDHCV3x_DATPORT)....1421
27.7.7 Present State (ESDHCV3x_PRSSTAT)....1421
27.7.8 Protocol Control (ESDHCV3x_PROCTL)....1426
27.7.9 System Control (ESDHCV3x_SYSCTL)....1430
27.7.10 Interrupt Status (ESDHCV3x_IRQSTAT)....1434
27.7.11 Interrupt Status Enable (ESDHCV3x_IRQSTATEN)....1439
27.7.12 Interrupt Signal Enable (ESDHCV3x_IRQSIGEN)....1442
27.7.13 Auto CMD12 Status (ESDHCV3x_AUTOC12ERR)....1444
27.7.14 Host Controller Capabilities (ESDHCV3x_HOSTCAPBLT)....1447
27.7.15 Watermark Level (ESDHCV3x_WML)....1449
27.7.16 Force Event (ESDHCV3x_FEVT)....1450
27.7.17 ADMA Error Status Register (ESDHCV3x_ADMAES)....1452
27.7.18 ADMA System Address (ESDHCV3x_ADSADDR)....1454
27.7.19 DLL (Delay Line) Control (ESDHCV3x_DLLCTRL)....1455
27.7.20 DLL Status (ESDHCV3x_DLLSTS)....1456
27.7.21 Vendor Specific Register (ESDHCV3x_VENDOR)....1457
27.7.22 MMC Boot Register (ESDHCV3x_MMCBOOT)....1458
27.7.23 Host Controller Version (ESDHCV3x_HOSTVER)....1459

Chapter 28
Fast Ethernet Controller (FEC)

28.1 Overview....1461
28.1.1 Features....1463
28.2 Modes of Operation....1464
28.2.1 Full- and Half-Duplex Operation....1464
28.2.2 Interface Options....1464
28.2.2.1 10-Mbps and 100-Mbps Media Independent Interface (MII)....1464

28.2.2.2 10 Mbps and 100 Mbps RMII Interface....1465
28.2.2.3 10-Mbps 7-Wire Interface Operation....1465
28.2.3 Address Recognition Options....1465
28.2.4 Internal Loopback....1465
28.3 Functional Description....1466
28.3.1 Network Interface Options....1466
28.3.2 FEC Frame Transmission....1467
28.3.2.1 Transmit Inter-Packet Gap (IPG) Time....1468
28.3.2.2 Collision Handling....1468
28.3.2.3 Transmission Error Handling....1469
28.3.2.3.1 Transmitter Underrun....1469
28.3.2.3.2 Retransmission Attempts Limit Expired....1469
28.3.2.3.3 Late Collision....1469
28.3.2.3.4 Heartbeat....1470
28.3.3 FEC Frame Reception....1470
28.3.3.1 Receive Inter-Packet Gap (IPG) Time....1471
28.3.3.2 Ethernet Address Recognition....1471
28.3.3.2.1 Hash Algorithm....1474
28.3.3.3 Reception Error Handling....1477
28.3.3.3.1 Overrun....1477
28.3.3.3.2 Non-Octet (Dribbling Bits)....1477
28.3.3.3.3 CRC....1478
28.3.3.3.4 Frame Length Violation....1478
28.3.3.3.5 Truncation....1478
28.3.4 Full-Duplex Flow Control....1478
28.3.5 Internal and External Loopback....1480
28.4 Initialization/Application Information....1480
28.4.1 Initialization Sequence....1480
28.4.1.1 Hardware Controlled Initialization....1480

28.4.1.2 User Initialization (Prior to Asserting FEC_ECR[ETHER_EN])....1481
28.4.1.3 Microcontroller Initialization....1482
28.4.1.4 User Initialization (after asserting FEC_ECR[ETHER_EN])....1482
28.4.2 Buffer Descriptors....1483
28.4.2.1 Driver/DMA Operation with Buffer Descriptors....1483
28.4.2.2 Ethernet Transmit Buffer Descriptor (TxBD)....1484
28.4.2.2.1 Driver/DMA Operation with Transmit Buffer Descriptors....1485
28.4.2.2.1.1 Transmit Frame in Multiple Buffers....1485
28.4.2.3 Ethernet Receive Buffer Descriptor (RxBD)....1486
28.4.2.3.1 Driver/DMA Operation with Receive Buffer Descriptors....1488
28.5 Programmable Registers....1489
28.5.1 Top Level Block Memory Map....1489
28.5.2 Message Information Block (MIB) Counters Memory Map....1489
28.5.3 MIIGSK Registers Memory Map....1492
28.5.4 Ethernet interrupt event register (FEC_EIR)....1494
28.5.5 Ethernet interrupt mask register (FEC_EIMR)....1496
28.5.6 Receive descriptor active register (FEC_RDAR)....1498
28.5.7 Transmit descriptor active register (FEC_TDAR)....1499
28.5.8 Ethernet control register (FEC_ECR)....1500
28.5.9 MII management frame register (FEC_MMFR)....1501
28.5.10 MII speed control register (FEC_MSCR)....1503
28.5.11 MIB control register (FEC_MIBC)....1505
28.5.12 Receive control register (FEC_RCR)....1506
28.5.13 Transmit control register (FEC_TCR)....1507
28.5.14 Physical address low register (FEC_PALR)....1508
28.5.15 Physical address upper register (FEC_PAUR)....1509
28.5.16 Opcode and pause duration register (FEC_OPDR)....1510
28.5.17 Descriptor individual address upper register (FEC_IAUR)....1510
28.5.18 Descriptor individual address lower register (FEC_IALR)....1511

28.5.19 Descriptor group address upper register (FEC_GAUR)....1511
28.5.20 Descriptor group address lower register (FEC_GALR)....1512
28.5.21 Transmit FIFO watermark register (FEC_TFWR)....1512
28.5.22 FIFO receive bound register (FEC_FRBR)....1513
28.5.23 FIFO receive FIFO start registers (FEC_FRSR)....1513
28.5.24 Receive buffer descriptor ring start register (FEC_ERDSR)....1514
28.5.25 Transmit buffer descriptor ring start register (FEC_ETDSR)....1515
28.5.26 Maximum receive buffer size register (FEC_EMRBR)....1515

Chapter 29
General Power Controller (GPC)

29.1 Introduction....1517
29.1.1 Overview....1517
29.1.2 Features....1518
29.2 Functional Description....1518
29.2.1 DVFS - Dynamic Voltage & Frequency Scaling....1519
29.2.2 DVFS Change Request Sequence Diagrams....1520
29.2.3 Frequency / Voltage Change Controller Description....1522
29.2.3.1 GPC Controller Description....1522
29.2.3.2 Clock Control Module Frequency Update Controller Description....1524
29.2.4 State Retention Power Gating (SRPG)....1526
29.2.5 PMIC Interface Requirements for APM Support....1526
29.3 Programmable Registers....1530
29.3.1 Interface Control Register (GPC_CNTR)....1530
29.3.2 Voltage Counter Register (GPC_VCR)....1532
29.3.3 NEON register (GPC_NEON)....1533

Chapter 30
General Purpose Input/Output (GPIO)

30.1 Overview....1535
30.1.1 Features....1537

30.2 GPIO Functional Description....1537
30.2.1 GPIO Function....1537
30.2.2 GPIO Programming....1538
30.2.2.1 GPIO Read Mode....1538
30.2.2.2 GPIO Write Mode....1538
30.2.3 Interrupt Control Unit....1539
30.3 Programmable Registers....1539
30.3.1 GPIO data register (GPIO*x*_GPIO_DR)....1542
30.3.2 GPIO direction register (GPIO*x*_GPIO_GDIR)....1543
30.3.3 GPIO pad status register (GPIO*x*_GPIO_PSR)....1544
30.3.4 GPIO interrupt configuration register1 (GPIO*x*_GPIO_ICR1)....1544
30.3.5 GPIO interrupt configuration register2 (GPIO*x*_GPIO_ICR2)....1545
30.3.6 GPIO interrupt mask register (GPIO*x*_GPIO_IMR)....1546
30.3.7 GPIO interrupt status register (GPIO*x*_GPIO_ISR)....1547
30.3.8 GPIO edge select register (GPIO*x*_GPIO_EDGE_SEL)....1548

Chapter 31
General-Purpose Media Interface (GPMI)

31.1 Introduction....1549
31.2 Overview....1549
31.3 GPMI NAND Mode....1550
31.3.1 Multiple NAND Support....1551
31.3.2 GPMI NAND Timing and Clocking....1552
31.3.3 Basic NAND Timing....1552
31.3.3.1 NAND Asynchronous Timing....1552
31.3.3.2 NAND Asynchronous EDO Mode Timing....1554
31.3.3.3 NAND ONFI Source Synchronous Mode Timing....1557
31.3.3.4 NAND Toggle Mode Timing....1561
31.3.4 Hardware BCH Interface....1564
31.4 Behavior During Reset....1565

31.5 Programmable Registers....1565
31.5.1 GPMI Control Register 0 (GPMI_CTRL0*n*)....1567
31.5.2 GPMI Compare Register (GPMI_COMPARE)....1569
31.5.3 GPMI Integrated ECC Control Register (GPMI_ECCCTRL*n*)....1570
31.5.4 GPMI Integrated ECC Transfer Count Register (GPMI_ECCCOUNT)....1571
31.5.5 GPMI Payload Address Register (GPMI_PAYLOAD)....1572
31.5.6 GPMI Auxiliary Address Register (GPMI_AUXILIARY)....1572
31.5.7 GPMI Control Register 1 (GPMI_CTRL1*n*)....1573
31.5.8 GPMI Timing Register 0 (GPMI_TIMING0)....1576
31.5.9 GPMI Timing Register 1 (GPMI_TIMING1)....1577
31.5.10 GPMI Timing Register 2 (GPMI_TIMING2)....1577
31.5.11 GPMI DMA Data Transfer Register (GPMI_DATA)....1578
31.5.12 GPMI Status Register (GPMI_STAT)....1579
31.5.13 GPMI Debug Information Register (GPMI_DEBUG)....1581
31.5.14 GPMI Version Register (GPMI_VERSION)....1581
31.5.15 GPMI Debug2 Information Register (GPMI_DEBUG2)....1582
31.5.16 GPMI Debug3 Information Register (GPMI_DEBUG3)....1584
31.5.17 GPMI Double Rate Read DLL Control Register (GPMI_READ_DDR_DLL_CTRL)....1585
31.5.18 GPMI Double Rate Write DLL Control Register (GPMI_WRITE_DDR_DLL_CTRL)....1586
31.5.19 GPMI Double Rate Read DLL Status Register (GPMI_READ_DDR_DLL_STS)....1587
31.5.20 GPMI Double Rate Write DLL Status Register (GPMI_WRITE_DDR_DLL_STS)....1588

Chapter 32
General Purpose Timer (GPT)

32.1 Overview....1591
32.1.1 Features....1593
32.1.2 Modes and Operation....1593
32.2 External Signals....1594
32.2.1 External Clock Input: CLKIN....1594
32.2.2 Input Capture Trigger Signals: CAPIN1, CAPIN2....1594

32.2.3 Output Compare Signals: DO_CMPOUT1, DO_CMPOUT2, DO_CMPOUT3....1595
32.3 Functional Description....1595
32.3.1 Operating Modes....1595
32.3.1.1 Restart Mode....1595
32.3.1.2 Free-Run Mode....1595
32.3.2 Operation....1596
32.3.2.1 Clocks....1596
32.3.2.2 Input Capture....1598
32.3.2.3 Output Compare....1599
32.3.2.4 Interrupts....1600
32.3.2.5 Low Power Mode Behavior....1601
32.3.2.6 Debug Mode Behavior....1601
32.4 Programmable Registers....1601
32.4.1 GPT Control Register (GPT_CR)....1603
32.4.2 GPT Prescaler Register (GPT_PR)....1606
32.4.3 GPT Status Register (GPT_SR)....1607
32.4.4 GPT Interrupt Register (GPT_IR)....1608
32.4.5 GPT Output Compare Register 1 (GPT_OCR1)....1609
32.4.6 GPT Output Compare Register 2 (GPT_OCR2)....1610
32.4.7 GPT Output Compare Register 3 (GPT_OCR3)....1610
32.4.8 GPT Input Capture Register 1 (GPT_ICR1)....1611
32.4.9 GPT Input Capture Register 2 (GPT_ICR2)....1611
32.4.10 GPT Counter Register (GPT_CNT)....1612

Chapter 33
2D Graphics Processing Unit (GPU2D)

33.1 Overview....1613
33.2 GPU2D Feature List....1613
33.2.1 Frame Buffer....1613
33.2.2 2D Bitmap Graphics (Separate 2D Unit)....1614

33.2.3 Vector Graphics....1615
33.3 GPU2D Block Diagram....1616
33.4 GPU SoC Interface....1616
33.4.1 GPU2D Top Level Diagram....1616
33.4.2 SoC Bus Connection....1617
33.5 Other Signals Connection....1618
33.6 Clocking Architecture....1618
33.7 Power Management....1618
33.8 Modes of Operation....1619
33.9 Reset....1619
33.10 Interrupts....1620
33.11 DMA....1620
33.12 Memory Map....1620
33.12.1 AHB Slave Interface....1620
33.12.2 AXI Master Memory Interface (EXTMC Port)....1621

Chapter 34
I2C Controller (I2C)

34.1 Overview....1623
34.1.1 Features....1625
34.1.2 Modes and Operations....1626
34.1.2.1 Standard Mode....1626
34.1.2.2 Fast Mode....1626
34.2 External Signals....1626
34.3 Functional Description....1627
34.3.1 I2C System Configuration....1627
34.3.2 I2C Protocol....1627
34.3.2.1 START Signal....1628
34.3.2.2 Slave Address Transmission....1628
34.3.2.3 Data Transfer....1628

34.3.2.4 STOP Signal 1629
34.3.2.5 Repeat Start....1629
34.3.3 Arbitration Procedure....1630
34.3.4 Clock Synchronization....1630
34.3.5 Handshaking....1631
34.3.6 Clock Stretching....1631
34.3.7 Peripheral Bus Accesses....1632
34.3.8 Generation of Transfer Error on IP Bus....1632
34.3.9 Clocks....1632
34.3.10 Reset....1632
34.3.11 Interrupts....1632
34.3.12 Byte Order....1633
34.4 Initialization....1633
34.4.1 Initialization Sequence....1633
34.4.2 Generation of START....1633
34.4.3 Post-Transfer Software Response....1634
34.4.4 Generation of STOP....1634
34.4.5 Generation of Repeated START....1635
34.4.6 Slave Mode....1635
34.4.7 Arbitration Lost....1635
34.5 Software Restriction....1644
34.6 Programmable Registers....1644
34.6.1 I2C Memory Map/Register Definition....1644
34.61.1 I2C Address Register (I2C*x*_IADR)....1645
34.61.2 I2C Frequency Divider Register (I2C*x*_IFDR)....1646
34.61.3 I2C Control Register (I2C*x*_I2CR)....1647
34.61.4 I2C Status Register (I2C*x*_I2SR)....1649
34.61.5 I2C Data I/O Register (I2C*x*_I2DR)....1650

Chapter 35
IOMUXC

35.1 Overview....1653
35.1.1 Features....1654
35.1.2 Modes of Operation....1655
35.2 External Signal Description....1655
35.3 Functional Description....1655
35.3.1 ALT6 and ALT7 Extended Muxing Modes....1658
35.3.2 SW Loopback through SION Bit....1658
35.3.3 "Daisy Chain"-Multi Pads Driving Same Module Input Pin....1658
35.3.4 Interrupts....1660
35.4 Programmable Registers....1660
35.4.1 GPR0 (IOMUXC_GPR0)....1686
35.4.2 GPR1 (IOMUXC_GPR1)....1687
35.4.3 GPR2 (IOMUXC_GPR2)....1688
35.4.4 OBSERVE_MUX_0 (IOMUXC_OBSMUX0)....1689
35.4.5 OBSERVE_MUX_1 (IOMUXC_OBSMUX1)....1690
35.4.6 OBSERVE_MUX_2 (IOMUXC_OBSMUX2)....1691
35.4.7 OBSERVE_MUX_3 (IOMUXC_OBSMUX3)....1692
35.4.8 OBSERVE_MUX_4 (IOMUXC_OBSMUX4)....1693
35.4.9 SW_MUX_CTL_PAD_KEY_COL0 (IOMUXC_SMUXC_PKC0)....1695
35.4.10 SW_MUX_CTL_PAD_KEY_ROW0 (IOMUXC_SMUXC_PKR0)....1696
35.4.11 SW_MUX_CTL_PAD_KEY_COL1 (IOMUXC_SMUXC_PKC1)....1697
35.4.12 SW_MUX_CTL_PAD_KEY_ROW1 (IOMUXC_SMUXC_PKR1)....1698
35.4.13 SW_MUX_CTL_PAD_KEY_COL2 (IOMUXC_SMUXC_PKC2)....1699
35.4.14 SW_MUX_CTL_PAD_KEY_ROW2 (IOMUXC_SMUXC_PKR2)....1700
35.4.15 SW_MUX_CTL_PAD_KEY_COL3 (IOMUXC_SMUXC_PKC3)....1701
35.4.16 SW_MUX_CTL_PAD_KEY_ROW3 (IOMUXC_SMUXC_PKR3)....1702
35.4.17 SW_MUX_CTL_PAD_I2C1_SCL (IOMUXC_SMUXC_PI2C1_SCL)....1703

35.4.18 SW_MUX_CTL_PAD_I2C1_SDA (IOMUXC_SMUXC_PI2C1_SDA)....1704
35.4.19 SW_MUX_CTL_PAD_I2C2_SCL (IOMUXC_SMUXC_PI2C2_SCL)....1705
35.4.20 SW_MUX_CTL_PAD_I2C2_SDA (IOMUXC_SMUXC_PI2C2_SDA)....1706
35.4.21 SW_MUX_CTL_PAD_I2C3_SCL (IOMUXC_SMUXC_PI2C3_SCL)....1707
35.4.22 SW_MUX_CTL_PAD_I2C3_SDA (IOMUXC_SMUXC_PI2C3_SDA)....1708
35.4.23 SW_MUX_CTL_PAD_PWM1 (IOMUXC_SMUXC_PPWM1)....1709
35.4.24 SW_MUX_CTL_PAD_PWM2 (IOMUXC_SMUXC_PPWM2)....1710
35.4.25 SW_MUX_CTL_PAD_OWIRE (IOMUXC_SMUXC_POWIRE)....1711
35.4.26 SW_MUX_CTL_PAD_EPITO (IOMUXC_SMUXC_PEPITO)....1712
35.4.27 SW_MUX_CTL_PAD_WDOG (IOMUXC_SMUXC_PWDOG)....1713
35.4.28 SW_MUX_CTL_PAD_SSI_TXFS (IOMUXC_SMUXC_PSSI_TXFS)....1714
35.4.29 SW_MUX_CTL_PAD_SSI_TXC (IOMUXC_SMUXC_PSSI_TXC)....1715
35.4.30 SW_MUX_CTL_PAD_SSI_TXD (IOMUXC_SMUXC_PSSI_TXD)....1716
35.4.31 SW_MUX_CTL_PAD_SSI_RXD (IOMUXC_SMUXC_PSSI_RXD)....1717
35.4.32 SW_MUX_CTL_PAD_SSI_RXF (IOMUXC_SMUXC_PSSI_RXF)....1718
35.4.33 SW_MUX_CTL_PAD_SSI_RXC (IOMUXC_SMUXC_PSSI_RXC)....1719
35.4.34 SW_MUX_CTL_PAD_UART1_TXD (IOMUXC_SMUXC_PUART1_TXD)....1720
35.4.35 SW_MUX_CTL_PAD_UART1_RXD (IOMUXC_SMUXC_PUART1_RXD)....1721
35.4.36 SW_MUX_CTL_PAD_UART1_CTS (IOMUXC_SMUXC_PUART1_CTS)....1722
35.4.37 SW_MUX_CTL_PAD_UART1_RTS (IOMUXC_SMUXC_PUART1_RTS)....1723
35.4.38 SW_MUX_CTL_PAD_UART2_TXD (IOMUXC_SMUXC_PUART2_TXD)....1724
35.4.39 SW_MUX_CTL_PAD_UART2_RXD (IOMUXC_SMUXC_PUART2_RXD)....1725
35.4.40 SW_MUX_CTL_PAD_UART2_CTS (IOMUXC_SMUXC_PUART2_CTS)....1726
35.4.41 SW_MUX_CTL_PAD_UART2_RTS (IOMUXC_SMUXC_PUART2_RTS)....1727
35.4.42 SW_MUX_CTL_PAD_UART3_TXD (IOMUXC_SMUXC_PUART3_TXD)....1728
35.4.43 SW_MUX_CTL_PAD_UART3_RXD (IOMUXC_SMUXC_PUART3_RXD)....1730
35.4.44 SW_MUX_CTL_PAD_UART4_TXD (IOMUXC_SMUXC_PUART4_TXD)....1731
35.4.45 SW_MUX_CTL_PAD_UART4_RXD (IOMUXC_SMUXC_PUART4_RXD)....1732
35.4.46 SW_MUX_CTL_PAD_CSPI_SCLK (IOMUXC_SMUXC_PCSPI_SCLK)....1733

35.4.47 SW_MUX_CTL_PAD_CSPI_MOSI (IOMUXC_SMUXC_PCSPI_MOSI)....1734
35.4.48 SW_MUX_CTL_PAD_CSPI_MISO (IOMUXC_SMUXC_PCSPI_MISO)....1735
35.4.49 SW_MUX_CTL_PAD_CSPI_SS0 (IOMUXC_SMUXC_PCSPI_SS0)....1736
35.4.50 SW_MUX_CTL_PAD_ECSPI1_SCLK (IOMUXC_SMUXC_PECSPI1_SCLK)....1737
35.4.51 SW_MUX_CTL_PAD_ECSPI1_MOSI (IOMUXC_SMUXC_PECSPI1_MOSI)....1738
35.4.52 SW_MUX_CTL_PAD_ECSPI1_MISO (IOMUXC_SMUXC_PECSPI1_MISO)....1739
35.4.53 SW_MUX_CTL_PAD_ECSPI1_SS0 (IOMUXC_SMUXC_PECSPI1_SS0)....1740
35.4.54 SW_MUX_CTL_PAD_ECSPI2_SCLK (IOMUXC_SMUXC_PECSPI2_SCLK)....1741
35.4.55 SW_MUX_CTL_PAD_ECSPI2_MOSI (IOMUXC_SMUXC_PECSPI2_MOSI)....1742
35.4.56 SW_MUX_CTL_PAD_ECSPI2_MISO (IOMUXC_SMUXC_PECSPI2_MISO)....1743
35.4.57 SW_MUX_CTL_PAD_ECSPI2_SS0 (IOMUXC_SMUXC_PECSPI2_SS0)....1745
35.4.58 SW_MUX_CTL_PAD_SD1_CLK (IOMUXC_SMUXC_PSD1_CLK)....1746
35.4.59 SW_MUX_CTL_PAD_SD1_CMD (IOMUXC_SMUXC_PSD1_CMD)....1747
35.4.60 SW_MUX_CTL_PAD_SD1_D0 (IOMUXC_SMUXC_PSD1_D0)....1748
35.4.61 SW_MUX_CTL_PAD_SD1_D1 (IOMUXC_SMUXC_PSD1_D1)....1749
35.4.62 SW_MUX_CTL_PAD_SD1_D2 (IOMUXC_SMUXC_PSD1_D2)....1750
35.4.63 SW_MUX_CTL_PAD_SD1_D3 (IOMUXC_SMUXC_PSD1_D3)....1751
35.4.64 SW_MUX_CTL_PAD_SD2_CLK (IOMUXC_SMUXC_PSD2_CLK)....1752
35.4.65 SW_MUX_CTL_PAD_SD2_CMD (IOMUXC_SMUXC_PSD2_CMD)....1753
35.4.66 SW_MUX_CTL_PAD_SD2_D0 (IOMUXC_SMUXC_PSD2_D0)....1754
35.4.67 SW_MUX_CTL_PAD_SD2_D1 (IOMUXC_SMUXC_PSD2_D1)....1755
35.4.68 SW_MUX_CTL_PAD_SD2_D2 (IOMUXC_SMUXC_PSD2_D2)....1756
35.4.69 SW_MUX_CTL_PAD_SD2_D3 (IOMUXC_SMUXC_PSD2_D3)....1757
35.4.70 SW_MUX_CTL_PAD_SD2_D4 (IOMUXC_SMUXC_PSD2_D4)....1758
35.4.71 SW_MUX_CTL_PAD_SD2_D5 (IOMUXC_SMUXC_PSD2_D5)....1759
35.4.72 SW_MUX_CTL_PAD_SD2_D6 (IOMUXC_SMUXC_PSD2_D6)....1760
35.4.73 SW_MUX_CTL_PAD_SD2_D7 (IOMUXC_SMUXC_PSD2_D7)....1761
35.4.74 SW_MUX_CTL_PAD_SD2_WP (IOMUXC_SMUXC_PSD2_WP)....1762
35.4.75 SW_MUX_CTL_PAD_SD2_CD (IOMUXC_SMUXC_PSD2_CD)....1763

35.4.76 SW_MUX_CTL_PAD_DISP_D0 (IOMUXC_SMUXC_PDISP_D0)....1764
35.4.77 SW_MUX_CTL_PAD_DISP_D1 (IOMUXC_SMUXC_PDISP_D1)....1765
35.4.78 SW_MUX_CTL_PAD_DISP_D2 (IOMUXC_SMUXC_PDISP_D2)....1766
35.4.79 SW_MUX_CTL_PAD_DISP_D3 (IOMUXC_SMUXC_PDISP_D3)....1767
35.4.80 SW_MUX_CTL_PAD_DISP_D4 (IOMUXC_SMUXC_PDISP_D4)....1768
35.4.81 SW_MUX_CTL_PAD_DISP_D5 (IOMUXC_SMUXC_PDISP_D5)....1769
35.4.82 SW_MUX_CTL_PAD_DISP_D6 (IOMUXC_SMUXC_PDISP_D6)....1770
35.4.83 SW_MUX_CTL_PAD_DISP_D7 (IOMUXC_SMUXC_PDISP_D7)....1771
35.4.84 SW_MUX_CTL_PAD_DISP_WR (IOMUXC_SMUXC_PDISP_WR)....1772
35.4.85 SW_MUX_CTL_PAD_DISP_RD (IOMUXC_SMUXC_PDISP_RD)....1773
35.4.86 SW_MUX_CTL_PAD_DISP_RS (IOMUXC_SMUXC_PDISP_RS)....1774
35.4.87 SW_MUX_CTL_PAD_DISP_CS (IOMUXC_SMUXC_PDISP_CS)....1775
35.4.88 SW_MUX_CTL_PAD_DISP_BUSY (IOMUXC_SMUXC_PDISP_BUSY)....1776
35.4.89 SW_MUX_CTL_PAD_DISP_RESET (IOMUXC_SMUXC_PDISP_RESET)....1777

Chapter 36
Keypad Port (KPP)

36.1 Overview 2229
36.1.1 Features.....2230
36.1.2 Modes and Operations.....2231
36.2 External Signals.....2231
36.2.1 External Signals Overview.....2231
36.2.1.1 Input Pins.....2231
36.2.1.2 Output Pins.....2232
36.2.1.3 Generation of Transfer Error Signal on Peripheral Bus.....2232
36.3 Functional Description.....2233
36.3.1 Keypad Matrix Construction.....2233
36.3.2 Keypad Port Configuration.....2233

36.3.3 Keypad Matrix Scanning....2233
36.3.4 Keypad Standby....2234
36.3.5 Glitch Suppression on Keypad Inputs....2234
36.3.6 Multiple Key Closures....2236
36.3.6.1 Ghost Key Problem and Correction....2238
36.3.7 3-Point Contact Keys Support....2240
36.4 Initialization/Application Information....2241
36.4.1 Typical Keypad Configuration and Scanning Sequence....2241
36.4.2 Key Press Interrupt Scanning Sequence....2242
36.4.3 Additional Comments....2242
36.5 Programmable Registers....2243
36.5.1 Keypad Control Register (KPP_KPCR)....2243
36.5.2 Keypad Status Register (KPP_KPSR)....2244
36.5.3 Keypad Data Direction Register (KPP_KDDR)....2246
36.5.4 Keypad Data Register (KPP_KPDR)....2246

Chapter 37
Enhanced LCD Interface (eLCDIF)

37.1 Overview....2249
37.2 Operation....2249
37.2.1 Bus Interface Mechanisms....2250
37.2.1.1 Bus Master Operation in Write/Display Modes....2251
37.2.1.2 System Bus Master Performance....2251
37.2.1.3 DMA Operation in MPU Read Mode....2252
37.2.2 Write Data Path....2253
37.2.3 Read Data Path....2259
37.2.4 eLCDIF Interrupts....2264
37.2.5 Initializing the eLCDIF....2264
37.2.5.1 Write Modes....2264
37.2.5.2 MPU Read Mode....2265

37.2.6 MPU Interface....2266
37.2.6.1 Code Example to Initialize the eLCDIF in MPU Write Mode....2268
37.2.7 VSYNC Interface....2268
37.2.7.1 Code Example to Initialize eLCDIF in VSYNC Mode....2269
37.2.8 DOTCLK Interface....2270
37.2.8.1 Code Example....2272
37.2.9 ITU-R BT.656 Digital Video Interface (DVI)....2272
37.2.10 eLCDIF Pin Usage by Interface Mode....2273
37.3 Behavior During Reset....2277
37.4 Programmable Registers....2277
37.4.1 eLCDIF General Control Register (LCDIF_CTRL*n*)....2280
37.4.2 eLCDIF General Control1 Register (LCDIF_CTRL1*n*)....2283
37.4.3 eLCDIF General Control2 Register (LCDIF_CTRL2*n*)....2286
37.4.4 eLCDIF Horizontal and Vertical Valid Data Count Register (LCDIF_TRANSFER_COUNT)....2288
37.4.5 LCD Interface Current Buffer Address Register (LCDIF_CUR_BUF)....2288
37.4.6 LCD Interface Next Buffer Address Register (LCDIF_NEXT_BUF)....2289
37.4.7 LCD Interface Timing Register (LCDIF_TIMING)....2290
37.4.8 eLCDIF VSYNC Mode and Dotclk Mode Control Register0 (LCDIF_VDCTRL0*n*)....2290
37.4.9 eLCDIF VSYNC Mode and Dotclk Mode Control Register1 (LCDIF_VDCTRL1)....2292
37.4.10 LCDIF VSYNC Mode and Dotclk Mode Control Register2 (LCDIF_VDCTRL2)....2292
37.4.11 eLCDIF VSYNC Mode and Dotclk Mode Control Register3 (LCDIF_VDCTRL3)....2293
37.4.12 eLCDIF VSYNC Mode and Dotclk Mode Control Register4 (LCDIF_VDCTRL4)....2294
37.4.13 Digital Video Interface Control0 Register (LCDIF_DVICTRL0)....2295
37.4.14 Digital Video Interface Control1 Register (LCDIF_DVICTRL1)....2296
37.4.15 Digital Video Interface Control2 Register (LCDIF_DVICTRL2)....2297
37.4.16 Digital Video Interface Control3 Register (LCDIF_DVICTRL3)....2298
37.4.17 Digital Video Interface Control4 Register (LCDIF_DVICTRL4)....2299
37.4.18 RGB to YCbCr 4:2:2 CSC Coefficient0 Register (LCDIF_CSC_COEFF0)....2300
37.4.19 RGB to YCbCr 4:2:2 CSC Coefficient1 Register (LCDIF_CSC_COEFF1)....2301

37.4.20 RGB to YCbCr 4:2:2 CSC Coefficent2 Register (LCDIF_CSC_COEFF2)....2302
37.4.21 RGB to YCbCr 4:2:2 CSC Coefficient3 Register (LCDIF_CSC_COEFF3)....2303
37.4.22 RGB to YCbCr 4:2:2 CSC Coefficient4 Register (LCDIF_CSC_COEFF4)....2303
37.4.23 RGB to YCbCr 4:2:2 CSC Offset Register (LCDIF_CSC_OFFSET)....2304
37.4.24 RGB to YCbCr 4:2:2 CSC Limit Register (LCDIF_CSC_LIMIT)....2305
37.4.25 LCD Interface Data Register (LCDIF_DATA)....2306
37.4.26 Bus Master Error Status Register (LCDIF_BM_ERROR_STAT)....2306
37.4.27 CRC Status Register (LCDIF_CRC_STAT)....2307
37.4.28 LCD Interface Status Register (LCDIF_STAT)....2307
37.4.29 LCD Interface Version Register (LCDIF_VERSION)....2309
37.4.30 LCD Interface Debug0 Register (LCDIF_DEBUG0)....2309
37.4.31 LCD Interface Debug1 Register (LCDIF_DEBUG1)....2311
37.4.32 LCD Interface Debug2 Register (LCDIF_DEBUG2)....2312
37.4.33 eLCDIF Threshold Register (LCDIF_THRES)....2312

Chapter 38
On-Chip OTP (OCOTP) Controller

38.1 Introduction....2315
38.2 Overview of On-Chip OTP APB Slave (OCOTP)....2315
38.3 Top-Level Symbol and Functional Overview....2316
38.3.1 Operation....2316
38.3.1.1 Fuse and Shadow Register Reads....2317
38.3.1.2 Fuse and Shadow Register Writes....2318
38.3.1.3 Write Postamble....2319
38.3.2 Fuse Shadow Memory Footprint....2319
38.3.3 OTP Read/Write Timing Parameters....2320
38.3.4 Hardware Visible Fuses....2322
38.3.5 Behavior During Reset....2322
38.4 OCOTP Memory Map/Register Definition....2323
38.4.1 OTP Controller Control Register (OCOTP_CTRL*n*)....2325

38.4.2 OTP Controller Timing Register (OCOTP_TIMING).....2327
38.4.3 OTP Controller Write Data Register (OCOTP_DATA).....2328
38.4.4 Value of OTP Bank0 Word0 (Lock controls) (OCOTP_LOCK).....2328
38.4.5 Value of OTP Bank0 Word1 (Configuration and Manufacturing Info.) (OCOTP_CFG0).....2330
38.4.6 Value of OTP Bank0 Word2 (Configuration and Manufacturing Info.) (OCOTP_CFG1).....2331
38.4.7 Value of OTP Bank0 Word3 (Configuration and Manufacturing Info.) (OCOTP_CFG2).....2331
38.4.8 Value of OTP Bank0 Word4 (Configuration and Manufacturing Info.) (OCOTP_CFG3).....2332
38.4.9 Value of OTP Bank0 Word5 (Configuration and Manufacturing Info.) (OCOTP_CFG4).....2332
38.4.10 Value of OTP Bank0 Word6 (Configuration and Manufacturing Info.) (OCOTP_CFG5).....2333
38.4.11 Value of OTP Bank0 Word7 (Configuration and Manufacturing Info.) (OCOTP_CFG6).....2333
38.4.12 Value of OTP Bank1 Word0 (Memory Related Info.) (OCOTP_MEM0).....2334
38.4.13 Value of OTP Bank1 Word1 (Memory Related Info.) (OCOTP_MEM1).....2334
38.4.14 Value of OTP Bank1 Word2 (Memory Related Info.) (OCOTP_MEM2).....2335
38.4.15 Value of OTP Bank1 Word3 (Memory Related Info.) (OCOTP_MEM3).....2335
38.4.16 Value of OTP Bank1 Word4 (Memory Related Info.) (OCOTP_MEM4).....2336
38.4.17 Value of OTP Bank1 Word5 (Memory Related Info.) (OCOTP_MEM5).....2336
38.4.18 Value of OTP Bank1 Word6 (General Purpose Customer Defined Info.) (OCOTP_GP0).....2337
38.4.19 Value of OTP Bank1 Word7 (General Purpose Customer Defined Info.) (OCOTP_GP1).....2337
38.4.20 Shadow Register for OTP Bank2 Word0 (SCC and CRYPTO Key) (OCOTP_SCC0).....2338
38.4.21 Shadow Register for OTP Bank2 Word1 (SCC and CRYPTO Key) (OCOTP_SCC1).....2338
38.4.22 Shadow Register for OTP Bank2 Word2 (SCC and CRYPTO Key) (OCOTP_SCC2).....2339
38.4.23 Shadow Register for OTP Bank2 Word3 (SCC and CRYPTO Key) (OCOTP_SCC3).....2339
38.4.24 Shadow Register for OTP Bank2 Word4 (SCC Key) (OCOTP_SCC4).....2340
38.4.25 Shadow Register for OTP Bank2 Word5 (SCC Key) (OCOTP_SCC5).....2340
38.4.26 Shadow Register for OTP Bank2 Word6 (SCC Key) (OCOTP_SCC6).....2341
38.4.27 Shadow Register for OTP Bank2 Word7 (SCC Key) (OCOTP_SCC7).....2341
38.4.28 Shadow Register for OTP Bank3 Word0 (SRK Hash) (OCOTP_SRK0).....2342
38.4.29 Shadow Register for OTP Bank3 Word1 (SRK Hash) (OCOTP_SRK1).....2342
38.4.30 Shadow Register for OTP Bank3 Word2 (SRK Hash) (OCOTP_SRK2).....2343

38.4.31 Shadow Register for OTP Bank3 Word3 (SRK Hash) (OCOTP_SRK3).....2343
38.4.32 Shadow Register for OTP Bank3 Word4 (SRK Hash) (OCOTP_SRK4).....2344
38.4.33 Shadow Register for OTP Bank3 Word5 (SRK Hash) (OCOTP_SRK5).....2344
38.4.34 Shadow Register for OTP Bank3 Word6 (SRK Hash) (OCOTP_SRK6).....2345
38.4.35 Shadow Register for OTP Bank3 Word7 (SRK Hash) (OCOTP_SRK7).....2345
38.4.36 Value of OTP Bank4 Word0 (Secure JTAG Response Field) (OCOTP_SJC_RESP0).....2346
38.4.37 Value of OTP Bank4 Word1 (Secure JTAG Response Field) (OCOTP_SJC_RESP1).....2346
38.4.38 Value of OTP Bank4 Word2 (MAC Address) (OCOTP_MAC0).....2347
38.4.39 Value of OTP Bank4 Word3 (MAC Address) (OCOTP_MAC1).....2347
38.4.40 Value of OTP Bank4 Word4 (HW Capabilities) (OCOTP_HWCAP0).....2348
38.4.41 Value of OTP Bank4 Word5 (HW Capabilities) (OCOTP_HWCAP1).....2348
38.4.42 Value of OTP Bank4 Word6 (HW Capabilities) (OCOTP_HWCAP2).....2349
38.4.43 Value of OTP Bank4 Word7 (SW Capabilities) (OCOTP_SWCAP).....2349
38.4.44 Software Controllable Signals Register (OCOTP_SCS*n*).....2350
38.4.45 OTP Controller Version Register (OCOTP_VERSION).....2350

Chapter 39
On-Chip RAM (OCRAM)

39.1 Overview.....2353
39.1.1 Memory Map.....2354
39.1.2 Read/Write Arbitration.....2355
39.2 Advanced Features.....2355
39.2.1 Read Data Wait State.....2355
39.2.2 Read Address Pipeline.....2355
39.2.3 Write Data Pipeline.....2356
39.2.4 Write Address Pipeline.....2356
39.3 Programmable Registers.....2356

Chapter 40
1-Wire Block (OWIRE)

40.1 Overview....2357
40.1.1 Features....2357
40.1.2 Modes of Operation....2358
40.2 External Signals....2358
40.3 Functional Description....2358
40.3.1 Normal Operating Modes....2359
40.3.1.1 Reset/Presence-detect Pulse....2359
40.3.1.2 Bit Transfers....2359
40.3.1.2.1 Write-0 Sequence....2359
40.3.1.2.2 Write-1 / Read Sequence....2360
40.3.1.3 Byte Transfers....2360
40.3.1.4 Search ROM Accelerator Mode....2361
40.3.2 Low Power Mode....2361
40.3.3 Clocks....2361
40.3.4 Reset....2362
40.3.4.1 Hardware Reset....2362
40.3.4.2 Software Reset....2362
40.3.5 Interrupts....2362
40.4 Programmable Registers....2363
40.4.1 Control register (OWIRE_CONTROL)....2364
40.4.2 Time Divider register (OWIRE_TIME_DIVIDER)....2365
40.4.3 Reset register (OWIRE_RESET)....2365
40.4.4 Command Register (OWIRE_COMMAND)....2366
40.4.5 Transmit/Receive Register (OWIRE_TX/RX)....2367
40.4.6 Interrupt Register (OWIRE_INTERRUPT)....2367
40.4.7 Interrupt Enable Register (OWIRE_INTERRUPT_EN)....2369

Chapter 41
Performance Monitor (PerfMon)

41.1 Introduction....2371
41.2 Overview....2371
41.3 Operation....2372
41.4 Programmable Registers....2373
41.4.1 PerfMon Control Register (PERFMON_CTRL*n*)....2374
41.4.2 PerfMon Master Enable Register (PERFMON_MASTER_EN)....2376
41.4.3 PerfMon Trap Range Low Address Register (PERFMON_TRAP_ADDR_LOW)....2377
41.4.4 PerfMon Trap Range High Address Register (PERFMON_TRAP_ADDR_HIGH)....2378
41.4.5 PerfMon Latency Threshold Register (PERFMON_LAT_THRESHOLD)....2379
41.4.6 PerfMon AXI Active Cycle Count Register (PERFMON_ACTIVE_CYCLE)....2379
41.4.7 PerfMon Transfer Count Register (PERFMON_TRANSFER_COUNT)....2380
41.4.8 PerfMon Total Latency Count Register (PERFMON_TOTAL_LATENCY)....2380
41.4.9 PerfMon Total Data Count Register (PERFMON_DATA_COUNT)....2381
41.4.10 PerfMon Maximum Latency Register (PERFMON_MAX_LATENCY)....2381
41.4.11 PerfMon Debug Register (PERFMON_DEBUG)....2382
41.4.12 PerfMon Version Register (PERFMON_VERSION)....2383

Chapter 42
Pulse Width Modulation (PWM)

42.1 Overview....2385
42.2 Signal Description....2387
42.2.1 External Signals....2387
42.3 Functional Description....2387
42.3.1 Operation....2387
42.3.1.1 Clocks....2388
42.3.1.2 FIFO....2388
42.3.1.3 Rollover and Compare Event....2389
42.3.1.4 Low Power Mode Behavior....2389

42.3.1.5 Debug Mode Behavior....2390
42.4 Programmable Registers....2390
42.4.1 PWM Control Register (PWM*x*_PWMCR)....2391
42.4.2 PWM Status Register (PWM*x*_PWMSR)....2393
42.4.3 PWM Interrupt Register (PWM*x*_PWMIR)....2394
42.4.4 PWM Sample Register (PWM*x*_PWMSAR)....2395
42.4.5 PWM Period Register (PWM*x*_PWMPR)....2396
42.4.6 PWM Counter Register (PWM*x*_PWMCNR)....2396

Chapter 43
Enhanced Pixel Pipeline (ePXP)

43.1 Overview....2399
43.1.1 Image Support....2400
43.1.2 Block Size Selection....2401
43.1.3 ePXP Limitations/Issues....2401
43.2 Operation....2402
43.2.1 Pixel Handling....2403
43.2.2 S0 Cropping/Masking....2404
43.2.3 Scaling....2407
43.2.3.1 Bilinear Image Scaling Filter....2408
43.2.3.2 YUV 4:2:2 Image Scaling....2410
43.2.3.3 YUV 4:2:0 Image Scaling....2411
43.2.4 Color Space Conversion (CSC)....2411
43.2.4.1 CSC1 Operation....2412
43.2.4.2 YUV versus YCbCr Support....2413
43.2.4.3 CSC2 Operation....2413
43.2.5 Overlays....2414
43.2.6 Alpha Blending....2415
43.2.7 Color Key....2416
43.2.8 Raster Operations (ROPs)....2417

43.2.9 Lookup Table (LUT) Memory....2418
43.2.10 Histogram....2419
43.2.11 Rotation....2419
43.2.12 In-place Rendering....2423
43.2.13 Interlaced Video Support....2423
43.2.14 eLCDIF Interlock....2423
43.2.15 Queueing Frame Operations....2425
43.3 Examples....2427
43.3.1 Basic QVGA Example....2427
43.3.2 Basic QVGA with Overlays....2428
43.3.3 Cropped QVGA Example....2431
43.3.4 Upscale QVGA to VGA with Overlays....2433
43.3.5 Downscale VGA to WQVGA (480x272) to fill screen....2435
43.3.6 Downscale VGA to QVGA with Overlapping Overlays....2437
43.4 Programmable Registers....2440
43.4.1 ePXP Control Register 0 (ePXP_CTRL*n*)....2444
43.4.2 ePXP Status Register (ePXP_STAT*n*)....2448
43.4.3 Output Frame Buffer Pointer (ePXP_OUTBUF)....2449
43.4.4 Output Frame Buffer Pointer #2 (ePXP_OUTBUF2)....2449
43.4.5 ePXP Output Buffer Size (ePXP_OUTSIZE)....2450
43.4.6 ePXP Source 0 (video) Input Buffer Pointer (ePXP_S0BUF)....2451
43.4.7 Source 0 U/Cb or 2 Plane UV Input Buffer Pointer (ePXP_S0UBUF)....2451
43.4.8 Source 0 V/Cr Input Buffer Pointer (ePXP_S0VBUF)....2452
43.4.9 ePXP Source 0 (video) Buffer Parameters (ePXP_S0PARAM)....2452
43.4.10 Source 0 Background Color (ePXP_S0BACKGROUND)....2453
43.4.11 Source 0 Cropping Register (ePXP_S0CROP)....2454
43.4.12 Source 0 Scale Factor Register (ePXP_S0SCALE)....2455
43.4.13 Source 0 Scale Offset Register (ePXP_S0OFFSET)....2456
43.4.14 Color Space Conversion Coefficient Register 0 (ePXP_CSCCOEF0)....2457

43.4.15 Color Space Conversion Coefficient Register 1 (ePXP_CSCCOEF1).....2458
43.4.16 Color Space Conversion Coefficient Register 2 (ePXP_CSCCOEF2).....2459
43.4.17 ePXP Next Frame Pointer (ePXP_NEXT*n*).....2460
43.4.18 ePXP S0 Color Key Low (ePXP_S0COLORKEYLOW).....2462
43.4.19 ePXP S0 Color Key High (ePXP_S0COLORKEYHIGH).....2462
43.4.20 ePXP Overlay Color Key Low (ePXP_OLCOLORKEYLOW).....2463
43.4.21 ePXP Overlay Color Key High (ePXP_OLCOLORKEYHIGH).....2464
43.4.22 ePXP Debug Register (ePXP_DEBUG).....2464
43.4.23 ePXP Overlay n Buffer Pointer (ePXP_OL*n*).....2465
43.4.24 ePXP Overlay n Size (ePXP_OL__SIZE*n*).....2465
43.4.25 ePXP Overlay n Parameters (ePXP_OL__PARAM*n*).....2466
43.4.26 Color Space Conversion Control Register. (ePXP_CSC2CTRL).....2468
43.4.27 Color Space Conversion Coefficient Register 0 (ePXP_CSC2COEF0).....2469
43.4.28 Color Space Conversion Coefficient Register 1 (ePXP_CSC2COEF1).....2470
43.4.29 Color Space Conversion Coefficient Register 2 (ePXP_CSC2COEF2).....2470
43.4.30 Color Space Conversion Coefficient Register 3 (ePXP_CSC2COEF3).....2471
43.4.31 Color Space Conversion Coefficient Register 4 (ePXP_CSC2COEF4).....2471
43.4.32 Color Space Conversion Coefficient Register 5 (ePXP_CSC2COEF5).....2472
43.4.33 Lookup Table Control Register. (ePXP_LUT_CTRL).....2473
43.4.34 Lookup Table Data Register. (ePXP_LUT).....2473
43.4.35 Histogram Control Register. (ePXP_HIST_CTRL).....2474
43.4.36 2-level Histogram Parameter Register. (ePXP_HIST2_PARAM).....2475
43.4.37 4-level Histogram Parameter Register. (ePXP_HIST4_PARAM).....2476
43.4.38 8-level Histogram Parameter 0 Register. (ePXP_HIST8_PARAM0).....2477
43.4.39 8-level Histogram Parameter 1 Register. (ePXP_HIST8_PARAM1).....2478
43.4.40 16-level Histogram Parameter 0 Register. (ePXP_HIST16_PARAM0).....2479
43.4.41 16-level Histogram Parameter Register. (ePXP_HIST16_PARAM1).....2480
43.4.42 16-level Histogram Parameter Register. (ePXP_HIST16_PARAM2).....2481
43.4.43 16-level Histogram Parameter Register. (ePXP_HIST16_PARAM3).....2482

Chapter 44
Quality of Service Controller (QoSC)

44.1 Introduction....2483

44.2 Overview of Quality of Service Controller APB Slave (QoSC)....2483

44.3 Top-Level Symbol and Functional Overview....2483

44.4 APB Slave....2486

44.5 Master Side Signal Control....2487

44.6 Slave Side Signal Control....2487

44.6.1 Passthrough Priority Mode....2488

44.6.2 Manual Priority Mode....2488

44.7 Boost Functionality....2489

44.8 AXI Fabric Master Port Disable....2489

44.9 Programmable Registers....2490

44.9.1 QOS Control Register (QOS_CTRL*n*)....2491

44.9.2 AXI QOS Register (QOS_AXI_QOS0*n*)....2493

44.9.3 AXI QOS Register (QOS_AXI_QOS1*n*)....2495

44.9.4 AXI QOS Register (QOS_AXI_QOS2*n*)....2496

44.9.5 EMI priority Registers (QOS_EMI_PRIORITY0*n*)....2498

44.9.6 EMI priority Registers (QOS_EMI_PRIORITY1*n*)....2500

44.9.7 EMI priority Registers (QOS_EMI_PRIORITY2*n*)....2502

44.9.8 AXI Master Disble Register (QOS_DISABLE*n*)....2504

44.9.9 QOS Version Register (QOS_VERSION)....2506

Chapter 45
Read Only Memory Controller Patch (ROMCP)

45.1 Introduction....2507

45.1.1 Overview....2507

45.1.2 Features....2508

45.1.3 Modes of Operation....2508

45.1.3.1 Normal Operating Modes....2509

45.1.3.2 Low Power Modes....2509
45.2 Functional Description....2509
45.2.1 ROM Controller (ROMC) Functional Description....2509
45.2.1.1 Functionality Overview....2509
45.2.1.2 ROMC Architecture Diagram....2510
45.2.1.3 AHB-Lite Interface....2510
45.2.2 ROMPATCH Functional Description....2511
45.2.2.1 ROMPATCH Disabling....2511
45.2.2.2 ROMPATCH Event Priority....2511
45.2.2.3 Data Fixing....2511
45.2.2.4 Opcode Patching....2512
45.2.2.4.1 Typical Software Response to Opcode Patch....2513
45.2.2.5 Alternate Masters and ROMPATCH....2514
45.3 Programmable Registers....2514
45.3.1 ROMPATCH Data Registers (ROMCP_ROMPATCHD*n*)....2517
45.3.2 ROMPATCH Control Register (ROMCP_ROMPATCHCNTL)....2518
45.3.3 ROMPATCH Enable Registers Low (ROMCP_ROMPATCHENL)....2519
45.3.4 ROMPATCH Address Registers (ROMCP_ROMPATCHA*n*)....2520
45.3.5 ROMPATCH Status Register (ROMCP_ROMPATCHSR)....2521

Chapter 46
Smart Direct Memory Access Controller (SDMA)

46.1 Introduction....2523
46.1.1 Overview....2523
46.1.2 Features....2525
46.2 Functional Description....2527
46.3 SDMA Core....2529
46.3.1 SDMA Core Structure....2529
46.3.2 Program Control Unit (PCU)....2532
46.3.2.1 Instruction Types....2532

46.3.2.2 PCU States....2533
46.3.3 SDMA Core Memory....2536
46.4 Scheduler....2536
46.4.1 Primary Functions....2536
46.4.2 Channels and DMA Requests....2537
46.4.2.1 Channels....2537
46.4.2.2 DMA Requests....2537
46.4.2.3 Mapping from DMA Requests to Channels and Priorities....2537
46.4.3 Scheduler Functional Description....2537
46.4.3.1 Scheduler Overview....2537
46.4.3.2 DMA Requests Scanning....2539
46.4.3.3 Mapping DMA Requests to Pending Channels....2539
46.4.3.4 Channel Overflow....2543
46.4.3.5 Runnable Channels Evaluation....2543
46.4.3.6 Next Channel Decision Tree....2545
46.4.3.7 Scheduler State Diagram....2547
46.4.3.8 Scheduler Pipeline Timing Diagram....2549
46.4.3.9 Channel-DMA Request Mapping....2549
46.4.3.10 Examples: How to Start a Channel....2549
46.4.4 Context Switching....2550
46.4.4.1 Context Switch Modes....2551
46.4.4.2 Context Switch Procedure....2552
46.4.4.3 Context Map in Memory....2553
46.5 Functional Units....2553
46.5.1 CRC Calculation Unit....2553
46.5.1.1 CRC Structure....2554
46.5.1.2 CRC Data Processing....2554
46.5.1.3 CRC Registers....2555
46.5.1.4 CRC Summary....2555

46.5.2 Burst DMA Unit....2556
46.5.2.1 Burst DMA Structure....2557
46.5.2.2 Burst DMA Registers....2558
46.5.2.3 Burst DMA Data Transfers....2559
46.5.2.3.1 Data Retrieval from the ARM platform Memory....2559
46.5.2.3.2 Storing Data Into the ARM platform Memory....2560
46.5.2.3.3 Transferring Data Between Two ARM platform Memory Locations-Burst DMA Unit....2560
46.5.3 Peripheral DMA Unit....2560
46.5.3.1 Peripheral DMA Structure....2561
46.5.3.2 Peripheral DMA Registers....2562
46.5.3.3 Peripheral DMA Data Transfers....2563
46.5.3.3.1 Data Retrieval from the ARM platform Memory or Peripheral....2563
46.5.3.3.2 Storing Data into the ARM platform Memory or Peripheral....2563
46.5.3.3.3 Transferring Data Between Two ARM platform Memory Locations-Peripheral DMA Unit....2564
46.6 SDMA Security Support....2564
46.6.1 Locked Mode....2564
46.7 OnCE and PCU Debug States....2565
46.8 SDMA Clocks and Low Power Modes....2567
46.8.1 Clock Gating and Low Power Modes....2568
46.8.1.1 Coarse Clock Gating....2568
46.8.1.2 Refined Clock Gating....2569
46.8.1.3 Low Power Modes and User Control....2569
46.8.1.3.1 SLEEP Mode....2570
46.8.1.3.2 RUN Mode....2570
46.8.1.3.3 DEBUG Mode....2571
46.8.1.4 Stop Mode Response....2571
46.8.2 Reset....2571

46.9 Software Interface....2571
46.10 Initialization Information....2572
46.10.1 Hardware Reset....2572
46.10.2 Channel Script Execution....2573
46.10.3 Initialization and Script Execution Setup Sequence....2573
46.11 SDMA Programming Model....2574
46.11.1 State and Registers Per Channel....2575
46.11.2 General Purpose Registers....2575
46.11.3 Functional Unit State....2575
46.11.3.1 Program Counter Register (PC)....2575
46.11.3.2 Flags....2575
46.11.3.3 Return Program Counter (RPC)....2576
46.11.3.4 Loop Mode Start Program Counter (SPC)....2577
46.11.3.5 Loop Mode End Program Counter (EPC)....2577
46.11.4 Context Switching-Programming....2577
46.11.5 Address Space....2578
46.11.5.1 Instruction Memory Map....2579
46.11.5.2 Data Memory Map....2579
46.12 SDMA Initialization....2581
46.12.1 Hardware Reset-SDMA....2581
46.12.2 Standard Boot Sequence....2582
46.12.3 User-Defined Boot Sequence....2582
46.12.4 Script Loading and Context Initialization....2583
46.13 Instruction Description....2583
46.13.1 Scheduling Instructions....2583
46.13.2 Conditional Branch Instructions....2584
46.13.3 Unconditional Jump Instructions....2584
46.13.4 Subroutine Return Instructions....2585
46.13.5 Loop Instruction....2585

46.13.6 Miscellaneous Instructions....2585
46.13.7 Logic Instructions....2585
46.13.8 Arithmetic Instructions....2586
46.13.9 Compare Instructions....2586
46.13.10 Test Instructions....2587
46.13.11 Byte Permutation Instructions....2587
46.13.12 Bit Shift Instructions....2587
46.13.13 Bit Manipulation Instructions....2587
46.13.14 SDMA Memory Access Instructions....2588
46.13.15 Functional Unit Instructions....2588
46.13.16 Illegal Instructions....2588
46.13.17 Debug Instructions....2589
46.14 Functional Units Programming Model....2589
46.14.1 Burst DMA Unit Programming....2590
46.14.1.1 Memory Source Address Register (MSA)....2591
46.14.1.2 Memory Destination Address Register (MDA)....2591
46.14.1.3 Memory Data Buffer Register (MD)....2592
46.14.1.4 State Register (MS)....2592
46.14.1.5 Burst DMA Write (stf)....2594
46.14.1.6 Burst DMA Read (ldf)....2597
46.14.1.7 Prefetch/Flush and Auto-Flush Management-Burst DMA Unit....2598
46.14.1.8 Data Alignment and Endianness-Burst DMA Unit....2600
46.14.1.8.1 Burst DMA in Read Mode....2600
46.14.1.8.2 Burst DMA in Write Mode....2601
46.14.1.8.3 Endianness-Burst DMA Unit....2603
46.14.1.9 Burst DMA Unit Copy Mode....2603
46.14.1.10 Burst DMA Unit Error Management....2604
46.14.1.11 Conditional Yielding-Burst DMA Unit....2606

46.14.2 Peripheral DMA Unit Programming....2607
46.14.2.1 Peripheral Source Address Register (PSA)....2608
46.14.2.2 Peripheral Destination Address Register (PDA)....2609
46.14.2.3 Peripheral Data Register (PD)....2609
46.14.2.4 Peripheral State Register (PS)....2610
46.14.2.5 Peripheral DMA Write (stf)-Write Mode....2611
46.14.2.6 Peripheral DMA Read (ldf)-Read Mode....2614
46.14.2.7 Peripheral DMA Unit Copy Mode....2615
46.14.2.8 Error Management....2615
46.14.2.8.1 Immediate Errors....2616
46.14.2.8.2 Data Transfer Errors....2616
46.14.2.8.3 Read Error (First Phase)....2617
46.14.2.8.4 Write Error and Read Error (Second Phase)....2617
46.14.2.8.5 Copy Mode Errors....2618
46.14.2.8.6 Error Check Example....2618
46.14.2.9 Peripheral DMA Unit Prefetch/Flush Management....2619
46.14.3 CRC Unit....2619
46.14.3.1 Polynomial Register (CA)....2619
46.14.3.2 Accumulator Register (CS)....2620
46.14.3.3 Write Instruction (stf)....2621
46.14.3.4 Read Instruction (ldf)....2621
46.14.3.5 Operating Mode....2622
46.14.4 OnCE and Real-Time Debug....2623
46.14.4.1 Memory and Register Access....2623
46.14.4.2 Hardware Breakpoints....2623
46.14.4.3 Watchpoints....2623
46.14.4.4 Software Breakpoints....2624
46.14.4.5 Core Control....2624

46.15 The OnCE Controller....2624
46.15.1 OnCE Commands....2624
46.15.2 Sending Commands to the OnCE Controller....2625
46.15.2.1 Using the JTAG Interface....2625
46.15.2.2 Using the ARM platform....2626
46.15.2.3 Conflicts Between the JTAG and the ARM platform Accesses....2627
46.15.3 Executing a Command from the OnCE....2628
46.15.3.1 Nature of the Commands....2628
46.15.3.2 Execution Request....2628
46.15.3.3 Command Execution....2629
46.15.4 Registers Descriptions....2631
46.15.4.1 Event Cell Counter Register (ECOUNT)....2631
46.15.4.2 Event Cell Address Registers (EAA or EAB)....2631
46.15.4.3 Event Cell Address Mask Register (EAM)....2632
46.15.4.4 Event Cell Data Register (ED)....2632
46.15.4.5 Event Cell Data Mask Register (EDM)....2632
46.15.4.6 Real Time Buffer Register (RTB)....2632
46.15.4.7 Event Control Register (ECTL)....2633
46.15.4.8 Trace Buffer (TB)....2633
46.15.4.9 OnCE Status Register (OSTAT)....2633
46.15.5 JTAG Interface Requirements....2634
46.15.5.1 TCK Speed Limitation....2634
46.15.5.2 Synchronization Implementation....2634
46.15.5.3 JTAG Controller Start-Up Recommended Procedure....2636
46.16 Using the OnCE....2636
46.16.1 Activating Clocks in Debug Mode....2636
46.16.2 Getting the Current Status....2637
46.16.3 Methods of Entering Debug Mode....2637
46.16.3.1 External Debug Request During Reset....2637

46.16.3.2 Debug Request During Normal Activity....2638
46.16.3.3 Software Breakpoint Instruction....2638
46.16.3.4 Event Detection Unit Matching Condition....2638
46.16.4 Executing Instructions in Debug Mode....2638
46.16.5 Command Sequences Examples....2639
46.16.5.1 Getting the SDMA Status....2639
46.16.5.2 Saving the Context....2640
46.16.5.3 Restoring the Context....2641
46.16.5.4 Accessing the Memory....2642
46.16.5.5 Resuming Program Execution....2642
46.16.5.6 Single Stepping in RAM....2643
46.16.5.7 Single Stepping in ROM....2643
46.16.6 OnCE Event Detection Unit....2644
46.16.7 Clock Gating and Reset....2645
46.16.7.1 Clocks....2645
46.16.7.2 Resets....2646
46.16.8 Real Time Features....2646
46.16.8.1 Trace Buffer....2646
46.16.8.2 Real Time Buffer....2648
46.16.8.3 Emulation Pin....2648
46.16.8.4 Real-Time Debug Outputs....2648
46.17 Instruction Set....2652
46.17.1 Instruction Encoding....2652
46.17.2 SDMA Instruction Set....2654
46.17.2.1 ADD (Addition)....2657
46.17.2.2 ADDI (Add with Immediate Value)....2658
46.17.2.3 AND (Logical AND)....2659
46.17.2.4 ANDI (Logical AND with Immediate Value)....2660
46.17.2.5 ANDN (Logical AND NOT)....2661

46.17.2.6 ANDNI (Logical AND with Negated Immediate Value).....2662
46.17.2.7 ASR1 (Arithmetic Shift Right by 1 Bit).....2663
46.17.2.8 BCLRI1 (Bit Clear Immediate).....2663
46.17.2.9 BDF (Conditional Branch if Destination Fault).....2664
46.17.2.10 BF (Conditional Branch if False).....2665
46.17.2.11 BSETI (Bit Set Immediate).....2667
46.17.2.12 BSF (Conditional Branch if Source Fault).....2668
46.17.2.13 BT (Conditional Branch if True).....2669
46.17.2.14 BTSTI (Bit Test immediate).....2670
46.17.2.15 CLRF (Clear ARM platform flags).....2671
46.17.2.16 CMPEQ (Compare for Equal).....2671
46.17.2.17 CMPEQI (Compare with Immediate for Equal).....2672
46.17.2.18 CMPHS (Compare for Higher or Same).....2673
46.17.2.19 CMPLT (Compare for Less Than).....2674
46.17.2.20 cpShReg (Update Context of PCU Registers and Flag).....2675
46.17.2.21 DONE (DONE, Yield) 2675
46.17.2.22 ILLEGAL (ILLEGAL Instruction).....2677
46.17.2.23 JMP (Unconditional Jump Immediate).....2678
46.17.2.24 JMPR (Unconditional Jump).....2679
46.17.2.25 JSR (Unconditional Jump to Subroutine Immediate).....2679
46.17.2.26 JSRR (Unconditional Jump to Subroutine).....2680
46.17.2.27 LD (Load Register).....2681
46.17.2.28 LDF (Load Register from Functional Unit).....2682
46.17.2.29 LDI (Load Register with Immediate Value).....2684
46.17.2.30 LDRPC (Load from RPC to Register).....2685
46.17.2.31 LOOP (Hardware Loop).....2686
46.17.2.32 LSL1 (Logical Shift Left by 1 Bit).....2689
46.17.2.33 LSR1 (Logical Shift Right by 1 Bit).....2689
46.17.2.34 MOV (Logical Move).....2690

46.17.2.35 NOTIFY (Notify to ARM platform)....2691
46.17.2.36 OR (Logical OR)....2692
46.17.2.37 ORI (Logical OR with Immediate Value)....2693
46.17.2.38 RET (Return from Subroutine)....2694
46.17.2.39 REVB (Reverse Byte Order)....2695
46.17.2.40 Reverse Low Order Bytes(REVBLO)....2696
46.17.2.41 ROR1 (Rotate Right by 1 Bit)....2696
46.17.2.42 RORB (Rotate Right by 1 Byte)....2697
46.17.2.43 SOFTBKPT (Software Breakpoint)....2698
46.17.2.44 ST (Store Register)....2698
46.17.2.45 STF (Store Register in Functional Unit)....2700
46.17.2.46 SUB (Subtract)....2703
46.17.2.47 SUBI (Subtract with Immediate)....2704
46.17.2.48 TST (Test with Zero)....2705
46.17.2.49 TSTI (Test Immediate)....2706
46.17.2.50 XOR (Logical Exclusive OR)....2707
46.17.2.51 XORI (Exclusive OR with Immediate)....2708
46.17.2.52 YIELD, YIELDGE (DONE, Yield)....2709
46.18 Software Restrictions....2709
46.18.1 Unsupported Burst DMA Access Sequence....2709
46.19 Application Notes....2710
46.19.1 Data Structures for Boot Code and Channel Scripts....2710
46.19.1.1 Buffer Descriptor Format....2711
46.19.1.2 Buffer Descriptor Commands for Bootload scripts....2714
46.19.1.3 Example of Buffer Descriptors for Channel 0....2716
46.19.1.4 Channel Context....2719
46.19.2 Typical Data Transfer Supported by SDMA DMA Units....2721
46.19.2.1 External Memory to External Memory....2722

46.19.2.2 Peripheral to Peripheral Transfer....2723
46.19.2.2.1 Source and Destination Target Have the Same Data Path Width....2723
46.19.2.2.2 Source and Destination Target Have a Different Data Path Width....2724
46.19.2.3 Transfer Between Peripheral and External Memory....2725
46.19.2.3.1 Peripheral to External Memory Transfer....2725
46.19.2.3.2 External Memory to Peripheral Transfer....2727
46.19.2.4 Transfer Between External Memory and Internal Memory....2728
46.19.2.4.1 Internal Memory to Internal Memory....2728
46.19.2.4.2 Transfer Between Peripheral and Internal Memory....2728
46.20 ARM Platform Memory Map and Control Register Definitions....2729
46.20.1 ARM platform Channel 0 Pointer (SDMAARM_MC0PTR)....2734
46.20.2 Channel Interrupts (SDMAARM_INTR)....2735
46.20.3 Channel Stop/Channel Status (SDMAARM_STOP_STAT)....2735
46.20.4 Channel Start (SDMAARM_HSTART)....2735
46.20.5 Channel Event Override (SDMAARM_EVTOVR)....2736
46.20.6 Channel BP Override (SDMAARM_DSPOVR)....2736
46.20.7 Channel ARM platform Override (SDMAARM_HOSTOVR)....2737
46.20.8 Channel Event Pending (SDMAARM_EVTPEND)....2737
46.20.9 Reset Register (SDMAARM_RESET)....2738
46.20.10 DMA Request Error Register (SDMAARM_EVTERR)....2738
46.20.11 Channel ARM platform Interrupt Mask (SDMAARM_INTRMASK)....2739
46.20.12 Schedule Status (SDMAARM_PSW)....2739
46.20.13 DMA Request Error Register (SDMAARM_EVTERRDBG)....2740
46.20.14 Configuration Register (SDMAARM_CONFIG)....2741
46.20.15 SDMA LOCK (SDMAARM_SDMA_LOCK)....2742
46.20.16 OnCE Enable (SDMAARM_ONCE_ENB)....2743
46.20.17 OnCE Data Register (SDMAARM_ONCE_DATA)....2743
46.20.18 OnCE Instruction Register (SDMAARM_ONCE_INSTR)....2744
46.20.19 OnCE Status Register (SDMAARM_ONCE_STAT)....2744

46.20.20 OnCE Command Register (SDMAARM_ONCE_CMD).....2746
46.20.21 Illegal Instruction Trap Address (SDMAARM_ILLINSTADDR).....2746
46.20.22 Channel 0 Boot Address (SDMAARM_CHN0ADDR).....2747
46.20.23 DMA Requests (SDMAARM_EVT_MIRROR).....2748
46.20.24 DMA Requests 2 (SDMAARM_EVT_MIRROR2).....2748
46.20.25 Cross-Trigger Events Configuration Register 1 (SDMAARM_XTRIG_CONF1).....2749
46.20.26 Cross-Trigger Events Configuration Register 2 (SDMAARM_XTRIG_CONF2).....2750
46.20.27 Channel Priority Registers (SDMAARM_SDMA_CHNPRI*n*).....2751
46.20.28 Channel Enable RAM (SDMAARM_SDMA.CHNENBL*n*).....2752
46.21 BP Memory Map and Control Register Definitions.....2752
46.21.1 Channel 0 Pointer (SDMABP_DC0PTR).....2753
46.21.2 Channel Interrupts (SDMABP_INTR).....2753
46.21.3 Channel Stop/Channel Status (SDMABP_STOP_STAT).....2754
46.21.4 Channel Start (SDMABP_DSTART).....2754
46.21.5 DMA Request Error Register (SDMABP_EVTERR).....2755
46.21.6 Channel DSP Interrupt Mask (SDMABP_INTRMASK).....2755
46.21.7 DMA Request Error Register (SDMABP_EVTERRDBG).....2756
46.22 SDMA Internal (Core) Memory Map and Internal Register Definitions.....2756
46.22.1 ARM platform Channel 0 Pointer (SDMACORE_MC0PTR).....2757
46.22.2 Current Channel Pointer (SDMACORE_CCPTR).....2758
46.22.3 Current Channel Register (SDMACORE_CCR).....2758
46.22.4 Highest Pending Channel Register (SDMACORE_NCR).....2759
46.22.5 External DMA Requests Mirror (SDMACORE_EVENTS).....2760
46.22.6 Current Channel Priority (SDMACORE_CCPRI).....2761
46.22.7 Next Channel Priority (SDMACORE_NCPRI).....2761
46.22.8 OnCE Event Cell Counter (SDMACORE_ECOUNT).....2762
46.22.9 OnCE Event Cell Control Register (SDMACORE_ECTL).....2762
46.22.10 OnCE Event Address Register A (SDMACORE_EAA).....2764
46.22.11 OnCE Event Cell Address Register B (SDMACORE_EAB).....2764

46.22.12 OnCE Event Cell Address Mask (SDMACORE_EAM)....2765
46.22.13 OnCE Event Cell Data Register (SDMACORE_ED)....2765
46.22.14 OnCE Event Cell Data Mask (SDMACORE_EDM)....2765
46.22.15 OnCE Real-Time Buffer (SDMACORE_RTB)....2766
46.22.16 OnCE Trace Buffer (SDMACORE_TB)....2766
46.22.17 OnCE Status (SDMACORE_OSTAT)....2767
46.22.18 Channel 0 Boot Address (SDMACORE_MCHN0ADDR)....2769
46.22.19 ENDIAN Status Register (SDMACORE_ENDIANNESS)....2770
46.22.20 Lock Status Register (SDMACORE_SDMA_LOCK)....2771
46.22.21 External DMA Requests Mirror #2 (SDMACORE_EVENTS2)....2771
46.23 SDMA Peripheral Registers....2772

Chapter 47
System JTAG Controller (SJC)

47.1 Introduction....2773
47.1.1 Overview....2774
47.2 Modes of Operation....2775
47.3 TAP Selection Block (TSB)....2777
47.3.1 Select Mode Using Software....2777
47.4 External Signal Description....2778
47.4.1 External Signal Overview....2778
47.4.2 TAP Controller....2780
47.4.3 Accessing ExtraDebug Registers....2782
47.5 Boundary Scan Register (BSR)....2785
47.6 SoC JTAG Instruction Register (SJIR)....2785
47.6.1 ID_CODE Instruction (IDCODE)....2786
47.6.2 SAMPLE/PRELOAD Instruction....2787
47.6.3 EXTEST Instruction....2788
47.6.4 HIGHZ Instruction....2788
47.6.5 BYPASS Instruction....2789

47.6.6 ENABLE_ExtraDebug Instruction....2789
47.6.7 ENTER_DEBUG instruction....2789
47.6.8 TAP Select Instruction....2790
47.7 Security....2791
47.7.1 JTAG Security Modes....2791
47.7.1.1 Mode 1: No Debug - Maximum Security....2791
47.7.1.2 Mode 2: Secure JTAG - High Security....2792
47.7.1.2.1 Challenge/Response Mechanism in System JTAG Mode....2792
47.7.1.3 Mode 3: JTAG Enabled - Low Security....2793
47.7.2 Software Enabled JTAG....2793
47.7.3 Kill Trace....2794
47.7.4 SJC Disable Fuse....2794
47.8 Functional Description....2795
47.8.1 Static Core Debug....2795
47.8.2 Reset Mechanism....2795
47.9 Initialization/Application Information....2796
47.10 Programmable Registers....2797
47.10.1 General Purpose Unsecured Status Register 1 (SJC_GPUSR1)....2798
47.10.2 General Purpose Unsecured Status Register 2 (SJC_GPUSR2)....2799
47.10.3 General Purpose Unsecured Status Register 3 (SJC_GPUSR3)....2800
47.10.4 General Purpose Secured Status Register (SJC_GPSSR)....2800
47.10.5 Debug Control Register (SJC_DCR)....2801
47.10.6 Security Status Register (SJC_SSR)....2802
47.10.7 General Purpose Clocks Control Register (SJC_GPCCR)....2804
47.10.8 General Purpose Unsecured Control Register n (SJC_GPUCR)....2805
47.10.9 General Purpose Secured Control Register (SJC_GPSCR)....2805

Chapter 48
Shared Peripheral Bus Arbiter (SPBA)

48.1 Introduction....2807

48.2 General Overview....2809
48.3 Features....2809
48.4 Modes of Operation....2809
48.5 Functional Description....2810
48.5.1 Masters Arbitration....2810
48.6 Resource Ownership Control....2813
48.6.1 Access Control....2813
48.6.1.1 Peripheral Access....2813
48.6.1.2 Peripheral Right Register Access....2814
48.6.2 Owner Election....2815
48.6.3 Ending Ownership....2815
48.6.3.1 Software Controlled Ownership Ending....2815
48.6.4 The Un-owned State....2816
48.7 Memory Map/Register Definition....2816
48.7.1 SPBA Register Definition....2817
48.7.1.1 Peripheral Right Register (SPBA_PRRn)....2820

Chapter 49
System Reset Controller (SRC)

49.1 Introduction....2823
49.1.1 Overview....2823
49.1.2 Features....2824
49.2 Functional Description....2824
49.2.1 Reset Control....2825
49.2.1.1 Reset Inputs and Outputs....2825
49.2.1.2 Reset Handling....2828
49.2.1.2.1 Reset Qualification....2828
49.2.1.2.2 Reset Sequence and De-Assertion....2828
49.2.1.2.2.1 IPP_RESET_B(POR)....2829
49.2.1.2.2.2 COLD RESET....2829

49.2.1.2.2.3 WARM RESET....2830
49.2.1.2.2.4 WARM BOOT....2831
49.2.1.2.3 SMS Sub Module....2835
49.2.1.2.4 SRTC_RST_B generation....2838
49.2.2 SJC_POR_RST_B Generation....2838
49.2.3 Parallel Reset Requests....2838
49.2.4 DFT Mux on Reset Outputs....2839
49.2.5 Boot Mode Control....2840
49.2.5.1 BOOT_MODE Pin Latching....2841
49.2.5.2 Correspondence between SRC SBMR Bit/Signal Names and Fuse Names....2842
49.2.5.3 Output Boot Signals....2844
49.3 Programmable Registers....2845
49.3.1 SRC Control Register (SRC_SCR)....2846
49.3.2 SRC Boot Mode Register (SRC_SBMR)....2847
49.3.3 SRC Reset Status Register (SRC_SRSR)....2848
49.3.4 SRC Interrupt Status Register (SRC_SISR)....2850
49.3.5 SRC Interrupt Mask Register (SRC_SIMR)....2851

Chapter 50
State Retention Power Gating Controller (SRPGC)

50.1 Introduction....2853
50.1.1 Features....2853
50.1.2 Modes of Operation....2853
50.1.2.1 Functional Mode....2853
50.1.2.2 Debug Mode....2854
50.2 Power Gating Cells....2854
50.2.1 Power Supply Switch Cells....2854
50.2.2 Power Supply Shorting Cells....2855
50.2.3 State Retention Power Gating (SRPG) Cell....2857

50.3 SRPGC Interface....2860
50.3.1 Power-Down Sequence (SRPG Entry Sequence)....2860
50.3.1.1 Power-Down Sequence Timing Waveforms....2861
50.3.2 Power-Up Sequence (SRPG Exit Sequence)....2862
50.3.2.1 Power-up Sequence Timing Waveforms....2862
50.4 Programmable Registers....2863
50.4.1 SPRGC Control Register (SRPGC_SRPGCR)....2864
50.4.2 Power-up Sequence Control Register (SRPGC_PUPSCR)....2864
50.4.3 Power-down Sequence Control Register (SRPGC_PDNSCR)....2865
50.4.4 SPRGC Status Register (SRPGC_SRPGSR)....2866
50.4.5 SPRGC Debug Register (SRPGC_SRPGDR)....2867

Chapter 51
Secure Real Time Clock (SRTC)

51.1 Overview....2869
51.1.1 Low Power SRTC (SRTC LP) Overview....2869
51.1.2 High Power SRTC (SRTC HP) Overview....2870
51.1.3 Features....2872
51.1.4 Modes of Operations....2873
51.2 External Signal Description....2873
51.3 Functional Description....2874
51.3.1 Power and Clock Source....2874
51.3.1.1 Clocks....2875
51.3.2 High Power SRTC (SRTC HP) Description....2875
51.3.2.1 SRTC HP nonsecured Counter....2875
51.3.2.1.1 SRTC HP Counter Calibration....2876
51.3.2.2 SRTC HP nonsecured Counter Alarm....2876
51.3.2.3 SRTC HP Periodic Alarm....2877
51.3.3 Low Power SRTC (SRTC LP) Description....2878
51.3.3.1 SRTC LP Behavior during System Power Down and POR....2878

51.3.3.2 SRTC LP Secured Counter....2879
51.3.3.2.1 SRTC LP Counter Calibration....2879
51.3.3.3 SRTC LP Secured Counter Alarm....2880
51.3.3.4 Monotonic Counter....2880
51.3.3.4.1 Monotonic Counter Roll-Over Protection Mechanism....2881
51.3.3.5 General Purpose Always-Powered Registers....2884
51.3.3.6 SRTC LP Monitor....2884
51.3.3.6.1 SRTC State Machine....2884
51.3.3.6.2 Power Supply Glitch Detector (PGD)....2885
51.3.3.6.3 Clock Tampering Detector (CTD)....2886
51.3.3.6.4 Voltage Level Tampering Detector....2887
51.3.3.6.5 Power Fail Detector (PFD)....2887
51.4 SRTC Reset and System Power-Up....2888
51.5 SRTC Interrupts and Alarms....2888
51.6 Initialization Information/Application Information....2889
51.6.1 Flow Chart of SRTC LP Operation....2889
51.6.2 Flow Chart of SRTC HP Operation....2890
51.7 Software Restrictions....2891
51.8 Programmable Registers....2892
51.8.1 LP Secure Counter MSB Register (SRTC_LPSCMR)....2894
51.8.2 LP Secure Counter LSB Register (SRTC_LPSCLR)....2894
51.8.3 LP Secure Alarm Register (SRTC_LPSAR)....2895
51.8.4 LP Secure Monotonic Counter Register (SRTC_LPSMCR)....2895
51.8.5 LP Control Register (SRTC_LPCR)....2896
51.8.6 LP Status Register (SRTC_LPSR)....2899
51.8.7 LP Power Supply Glitch Detector Register (SRTC_LPPDR)....2902
51.8.8 LP General Purpose Register (SRTC_LPGR)....2902
51.8.9 HP Counter MSB Register (SRTC_HPCMR)....2903
51.8.10 HP Counter LSB Register (SRTC_HPCLR)....2904

51.8.11 HP Alarm MSB Register (SRTC_HPAMR)....2904
51.8.12 HP Alarm LSB Register (SRTC_HPALR)....2905
51.8.13 HP Control Register (SRTC_HPCR)....2905
51.8.14 HP Interrupt Status Register (SRTC_HPISR)....2907
51.8.15 HP Interrupt Enable Register (SRTC_HPIENR)....2910

Chapter 52
Synchronous Serial Interface (SSI)

52.1 Overview....2913
52.1.1 Features....2914
52.1.2 Modes of Operation....2915
52.2 External Signal Description....2915
52.2.1 Signals Overview....2915
52.3 SSI Transmit FIFO 0 & 1 Registers....2919
52.4 SSI Transmit Shift Register (TXSR)....2919
52.5 SSI Receive FIFO 0 and 1 Registers....2922
52.6 SSI Receive Shift Register (RXSR)....2922
52.7 Functional Description....2924
52.7.1 Operating Modes....2924
52.7.1.1 Normal Mode....2926
52.7.1.1.1 Normal Mode Transmit....2926
52.7.1.1.2 Normal Mode Receive....2927
52.7.1.2 Network Mode....2929
52.7.1.2.1 Network Mode Transmit....2930
52.7.1.2.2 Network Mode Receive....2931
52.7.1.3 Gated Clock Mode....2933
52.7.1.4 I2S Mode....2936
52.7.1.5 AC97 Mode....2938
52.7.1.5.1 AC97 Fixed Mode (SSI.SACNT[1]=0)....2940
52.7.1.5.2 AC97 Variable Mode (SSI.SACNT[1]=1)....2940

52.7.2 External Frame and Clock Operation....2941
52.7.2.1 Data Alignment Formats Supported....2941
52.7.3 SSI Architecture....2942
52.7.4 SSI Clocking....2943
52.7.4.1 SSI Clock and Frame Sync Generation....2944
52.7.4.2 DIV2, PSR and PM Bit Description....2945
52.7.5 Receive Interrupt Enable Bit Description....2947
52.7.6 Transmit Interrupt Enable Bit Description....2948
52.7.7 Internal Frame and Clock Shutdown....2949
52.7.8 Peripheral Bus Interface....2951
52.7.8.1 Transfer Lengths Supported....2951
52.7.8.2 Transfer Bus Errors....2951
52.7.8.3 Clock Rate....2952
52.7.9 Reset....2952
52.8 Programmable Registers....2952
52.8.1 SSI Transmit Data Register n (SSI*x*_SSI_STX*n*)....2955
52.8.2 SSI Receive Data Register n (SSI*x*_SSI_SRX*n*)....2955
52.8.3 SSI Control Register (SSI*x*_SSI_SCR)....2956
52.8.4 SSI Interrupt Status Register (SSI*x*_SSI_SISR)....2958
52.8.5 SSI Interrupt Enable Register (SSI*x*_SIER)....2963
52.8.6 SSI Transmit Configuration Register (SSI*x*_SSI_STCR)....2965
52.8.7 SSI Receive Configuration Register (SSI*x*_SSI_SRCR)....2967
52.8.8 SSI Transmit Clock Control Register (SSI*x*_SSI_STCCR)....2969
52.8.9 SSI Receive Clock Control Register (SSI*x*_SRCCR)....2971
52.8.10 SSI FIFO Control/Status Register (SSI*x*_SSI_SFCSR)....2972
52.8.11 SSI AC97 Control Register (SSI*x*_SSI_SACNT)....2976
52.8.12 SSI AC97 Command Address Register (SSI*x*_SSI_SACADD)....2977
52.8.13 SSI AC97 Command Data Register (SSI*x*_SSI_SACDAT)....2978
52.8.14 SSI AC97 Tag Register (SSI*x*_SATAG)....2978

52.8.15 SSI Transmit Time Slot Mask Register (SSI*x*_SSI_STMSK)....2979
52.8.16 SSI Receive Time Slot Mask Register (SSI*x*_SSI_SRMSK)....2979
52.8.17 SSI AC97 Channel Status Register (SSI*x*_SSI_SACCST)....2980
52.8.18 SSI AC97 Channel Enable Register (SSI*x*_SSI_SACCEN)....2980
52.8.19 SSI AC97 Channel Disable Register (SSI*x*_SSI_SACCDIS)....2981

Chapter 53
Temperature Sensor (TempSensor)

53.1 Introduction....2983
53.2 Overview....2983
53.3 Features....2984
53.4 Digital-Count-to-Temperature Conversion Algorithm....2984
53.5 TempSensor Memory Map/Register Definition....2984
53.5.1 TempSensor Control Register (TEMPSENSOR_ANADIG_CTRL*n*)....2985

Chapter 54
Interrupt Controller (TZIC)

54.1 Overview....2987
54.2 Features....2988
54.3 External Signal Description....2989
54.4 Functional Description....2989
54.4.1 Security Configurability....2989
54.4.1.1 Interrupt Priority....2989
54.4.2 AXI Interface....2989
54.4.3 Interrupt Engine....2990
54.4.4 Auto-Vectored Interrupt Handling....2991
54.4.5 Reset....2992
54.5 Initialization Information....2992
54.6 Programmable Registers....2993
54.6.1 Control Register (TZIC_INTCTRL)....2997
54.6.2 Interrupt Controller Type Register (TZIC_INTTYPE)....2998

54.6.3 Priority Mask Register (TZIC_PRIOMASK)....2999
54.6.4 Synchronizer Control (TZIC_SYNCCTRL)....3000
54.6.5 DSM Interrupt Holdoff (TZIC_DSMINT)....3001
54.6.6 Interrupt Security (FIQ) Register: Irq 0 to 31 (TZIC_INTSEC*n*)....3002
54.6.7 Enable Set Register: Irq 0 to 31 (TZIC_ENSET*n*)....3003
54.6.8 Enable Clear Register: Irq 0 to 31 (TZIC_ENCLEAR*n*)....3004
54.6.9 Source Set Register: Irq 0 to 31 (TZIC_SRCSET*n*)....3005
54.6.10 Source Clear Register: Irq 0 to 31 (TZIC_SRCCLEAR*n*)....3006
54.6.11 Priority Register: Irq 0 to 3 (TZIC_PRIORITY*n*)....3006
54.6.12 Pending Register: Irq 0 to 31 (TZIC_PND*n*)....3008
54.6.13 High Priority Pending Register: Irq 0 to 31 (TZIC_HIPND*n*)....3008
54.6.14 Wakeup Config Register: Irq 0 to 31 (TZIC_WAKEUP*n*)....3009
54.6.15 Software Interrupt Trigger Register (TZIC_SWINT)....3010

Chapter 55
Universal Asynchronous Receiver/Transmitter (UART)

55.1 Overview....3013
55.1.1 Features....3014
55.1.2 Modes of Operation....3015
55.2 External Signals....3015
55.2.1 Detailed Signal Descriptions....3016
55.2.1.1 Serial/IrDA Signals....3016
55.2.1.1.1 RXD - Data Receive....3016
55.2.1.1.2 TXD - Data Transmit....3016
55.2.1.2 Modem Control Signals....3017
55.2.1.2.1 CTS - Clear To Send....3017
55.2.1.2.2 RTS - Request To Send....3017
55.2.1.2.3 DSR - Data Set Ready....3017
55.2.1.2.4 DCD - Data Carrier Detected....3017
55.2.1.2.5 DTR - Data Terminal Ready....3017

55.2.1.2.6 RI - Ring Indicator....3017
55.2.1.3 Interrupt Signals....3017
55.2.1.3.1 interrupt_uart - UART Interrupt....3018
55.2.1.4 DMA Request Signals....3018
55.2.1.4.1 dma_req_rx - Receiver DMA Request....3018
55.2.1.4.2 dma_req_tx - Transmitter DMA Request....3018
55.2.1.5 Clock Signals....3018
55.2.1.5.1 peripheral_clock - Peripheral Clock....3018
55.2.1.5.2 module_clock - Module Clock....3018
55.2.1.6 Special Signals....3018
55.2.1.6.1 stop_req - Stop Mode....3018
55.2.1.6.2 doze_req - Doze Mode....3018
55.2.1.6.3 debug_req - Debug Mode....3019
55.3 Functional Description....3019
55.3.1 Interrupts and DMA Requests....3019
55.3.2 Clocks....3020
55.3.2.1 Clock requirements....3020
55.3.2.2 Maximum Baud Rate....3021
55.3.2.3 Clocking in Low-Power Modes....3021
55.3.3 General UART Definitions....3022
55.3.3.1 RTS - UART Request To Send....3023
55.3.3.2 RTS Edge Triggered Interrupt....3023
55.3.3.3 DTR - Data Terminal Ready....3024
55.3.3.4 DSR - Data Set Ready....3024
55.3.3.5 DTR/DSR Edge Triggered Interrupt....3025
55.3.3.6 DCD - Data Carrier Detect....3025
55.3.3.7 RI - Ring Indicator....3026
55.3.3.8 CTS - Clear To Send....3026
55.3.3.9 Programmable CTS Deassertion....3026

55.3.3.10 TXD - UART Transmit....3026
55.3.3.11 RXD - UART Receive....3027
55.3.4 Transmitter....3028
55.3.4.1 Transmitter FIFO Empty Interrupt Suppression....3029
55.3.4.2 Transmitting a Break Condition....3031
55.3.5 Receiver....3031
55.3.5.1 Idle Line Detect....3032
55.3.5.2 Aging Character Detect....3033
55.3.5.3 Receiver Wake....3034
55.3.5.4 Receiving a BREAK Condition....3035
55.3.5.5 Vote Logic....3035
55.3.5.6 Baud Rate Automatic Detection Logic....3037
55.3.5.6.1 Baud Rate Automatic Detection Protocol....3038
55.3.5.6.2 New Baud Rate Determination....3038
55.3.5.6.2.1 New Autobaud Counter Stopped bit and Interrupt....3039
55.3.6 Escape Sequence Detection....3039
55.4 Binary Rate Multiplier (BRM)....3041
55.5 Infrared Interface....3043
55.5.1 Generalities-Infrared....3043
55.5.2 Inverted Transmission and Reception bits (INVT & INVR)....3044
55.5.3 InfraRed Special Case (IRSC) Bit....3044
55.5.4 IrDA interrupt....3045
55.5.5 Conclusion about IrDA....3046
55.5.6 Programming IrDA Interface....3047
55.5.6.1 High Speed....3047
55.5.6.2 Low Speed....3047
55.6 Low Power Modes....3048
55.6.1 UART Operation in System Doze Mode....3049
55.6.2 UART Operation in System Stop Mode....3049

55.6.3 Power Saving Method in UART....3049
55.7 UART Operation in System Debug State....3050
55.8 Reset....3050
55.8.1 Hardware reset....3050
55.8.2 Software reset....3051
55.9 Transfer Error....3051
55.10 Functional Timing....3051
55.10.1 IrDA Mode....3051
55.11 Initialization....3052
55.11.1 Programming the UART in RS-232 mode....3052
55.12 References....3054
55.13 Programmable Registers....3054
55.13.1 UART Receiver Register (UART*x*_URXD)....3059
55.13.2 UART Transmitter Register (UART*x*_UTXD)....3061
55.13.3 UART Control Register 1 (UART*x*_UCR1)....3062
55.13.4 UART Control Register 2 (UART*x*_UCR2)....3064
55.13.5 UART Control Register 3 (UART*x*_UCR3)....3067
55.13.6 UART Control Register 4 (UART*x*_UCR4)....3069
55.13.7 UART FIFO Control Register (UART*x*_UFCR)....3071
55.13.8 UART Status Register 1 (UART*x*_USR1)....3073
55.13.9 UART Status Register 2 (UART*x*_USR2)....3075
55.13.10 UART Escape Character Register (UART*x*_UESC)....3078
55.13.11 UART Escape Timer Register (UART*x*_UTIM)....3078
55.13.12 UART BRM Incremental Register (UART*x*_UBIR)....3079
55.13.13 UART BRM Modulator Register (UART*x*_UBMR)....3079
55.13.14 UART Baud Rate Count Register (UART*x*_UBRC)....3080
55.13.15 UART One Millisecond Register (UART*x*_ONEMS)....3081
55.13.16 UART Test Register (UART*x*_UTS)....3082

Chapter 56
Universal Serial Bus OTG HOST1 (USBOH1)

56.1 Introduction....3085
56.1.1 Overview....3086
56.1.2 Features....3086
56.1.3 Modes of Operation....3086
56.1.3.1 Operational Modes....3086
56.1.3.1.1 Normal Mode....3086
56.1.3.1.2 Low Power Mode....3087
56.2 External Signal Description....3087
56.2.1 External Signal Overview....3087
56.2.2 Detailed Signal Descriptions....3091
56.3 Functional Description....3092
56.3.1 USB HOST Controller 1....3092
56.3.2 USB OTG Controller....3092
56.3.2.1 Host Mode....3092
56.3.2.2 Peripheral (Device) Mode....3092
56.3.3 USB Power Control Module....3092
56.3.3.1 Entering Suspend Mode....3093
56.3.3.2 Wake-up Events....3093
56.3.3.2.1 Host Mode Events....3093
56.3.3.2.2 Device Mode Events....3094
56.3.4 USB Interrupts....3094
56.3.4.1 USB Core Interrupts....3094
56.3.4.2 USB Wake-up Interrupts....3094
56.4 Initialization/Application Information....3095
56.4.1 Software Model....3095
56.4.1.1 Device Data Structure....3096
56.4.1.2 Host Data Structure....3097

56.4.2 Register Interface....3098
56.4.2.1 Configuration, Control and Status register set....3099
56.4.2.2 Summary of register layouts....3102
56.4.2.3 Identification Registers....3105
56.4.2.4 Device/Host Capability Registers....3105
56.4.2.5 Device/Host Timer Registers (Non-EHCI)....3105
56.4.2.6 Device/Host Operational Registers....3105
56.4.2.7 OTG Operations....3105
56.4.2.7.1 Register Bits....3105
56.4.2.7.2 Hardware Assist....3106
56.4.2.7.2.1 Auto-Reset....3107
56.4.2.7.2.2 Data-Pulse....3107
56.4.2.7.2.3 B-Disconnect to A-Connect....3107
56.4.3 Host Data Structures....3108
56.4.3.1 Periodic Frame List....3109
56.4.3.2 Asynchronous List Queue Head Pointer....3110
56.4.3.3 Isochronous (High-Speed) Transfer Descriptor (iTD)....3111
56.4.3.3.1 iTD Next Link Pointer....3113
56.4.3.3.2 iTD Transaction Status and Control List....3114
56.4.3.3.3 iTD Buffer Page Pointer List (Plus)....3115
56.4.3.4 Split Transaction Isochronous Transfer Descriptor (siTD)....3116
56.4.3.4.1 siTD Next Link Pointer....3118
56.4.3.4.2 siTD Endpoint Capabilities/Characteristics....3118
56.4.3.4.3 siTD Transfer State....3119
56.4.3.4.4 siTD Buffer Pointer List (plus)....3120
56.4.3.4.5 siTD Back Link Pointer....3121
56.4.3.5 Queue Element Transfer Descriptor (qTD)....3121
56.4.3.5.1 Next qTD Pointer....3123
56.4.3.5.2 Alternate Next qTD Pointer....3123

56.4.3.5.3 qTD Token....3123
56.4.3.5.4 qTD Buffer Page Pointer List....3126
56.4.3.6 Queue Head....3127
56.4.3.6.1 Queue Head Endpoint Capabilities/Characteristics....3129
56.4.3.6.2 Queue Head Transfer Overlay....3131
56.4.3.7 Periodic Frame Span Traversal Node (FSTN) 3132
56.4.3.7.1 FSTN Normal Path Pointer 3133
56.4.3.7.2 FSTN Back Path Link Pointer 3133
56.4.4 Host Operational Model 3134
56.4.4.1 Host Controller Initialization 3134
56.4.4.2 Port Routing and Control 3136
56.4.4.2.1 Port Routing Control via EHCI Configured (CF) Bit 3137
56.4.4.2.2 Port Routing Control via PortOwner and Disconnect Event 3138
56.4.4.2.3 Example Port Routing State Machine 3140
56.4.4.2.3.1 EHCI HC Owner 3140
56.4.4.2.3.2 Companion HC Owner 3141
56.4.4.2.4 Port Power 3141
56.4.4.2.5 Port Reporting Over-Current 3142
56.4.4.3 Host Operational Model Suspend/Resume 3143
56.4.4.3.1 Port Suspend/Resume 3144
56.4.4.4 Schedule Traversal Rules 3146
56.4.4.4.1 Example - Preserving Micro-Frame Integrity 3148
56.4.4.4.1.1 Transaction Fit - A Best-Fit Approximation Algorithm 3149
56.4.4.5 Periodic Schedule Frame Boundaries vs Bus Frame Boundaries 3151
56.4.4.6 Periodic Schedule 3154
56.4.4.7 Managing Isochronous Transfers Using iTDs 3155
56.4.4.7.1 Host Controller Operational Model for iTDs 3156
56.4.4.7.2 Software Operational Model for iTDs 3158
56.4.4.7.2.1 Periodic Scheduling Threshold....3160

56.4.4.8 Asynchronous Schedule 3161
56.4.4.8.1 Adding Queue Heads to Asynchronous Schedule....3162
56.4.4.8.2 Removing Queue Heads from Asynchronous Schedule 3163
56.4.4.8.3 Empty Asynchronous Schedule Detection 3165
56.4.4.8.4 Restarting Asynchronous Schedule Before EOF 3166
56.4.4.8.4.1 Example Method for Restarting Asynchronous Schedule Traversal 3167
56.4.4.8.4.2 Async Sched Not Active 3168
56.4.4.8.4.3 Async Sched Active 3168
56.4.4.8.4.4 Async Sched Sleeping 3169
56.4.4.8.4.5 Example Derivation for AsyncSchedSleepTime....3169
56.4.4.8.5 Asynchronous Schedule Traversal : Start Event....3169
56.4.4.8.6 Reclamation Status Bit (USBSTS Register) 3170
56.4.4.9 Operational Model for Nak Counter....3170
56.4.4.9.1 Nak Count Reload Control 3172
56.4.4.9.1.1 Wait for List Head 3173
56.4.4.9.1.2 Do Reload 3173
56.4.4.9.1.3 Wait for Start Event 3173
56.4.4.10 Managing Control/Bulk/Interrupt Transfers via Queue Heads....3174
56.4.4.10.1 Fetch Queue Head 3176
56.4.4.10.2 Advance Queue 3176
56.4.4.10.3 Execute Transaction 3177
56.4.4.10.3.1 Interrupt Transfer Pre-condition Criteria 3178
56.4.4.10.3.2 Asynchronous Transfer Pre-operations and Pre-condition Criteria 3178
56.4.4.10.3.3 Transfer Type Independent Pre-operations....3178
56.4.4.10.3.4 Halting a Queue Head 3181
56.4.4.10.3.5 Asynchronous Schedule Park Mode 3182
56.4.4.10.4 Write Back qTD 3184

56.4.4.10.5 Follow Queue Head Horizontal Pointer 3184
56.4.4.10.6 Buffer Pointer List Use for Data Streaming with qTDs 3184
56.4.4.10.7 Adding Interrupt Queue Heads to the Periodic Schedule 3187
56.4.4.10.8 Managing Transfer Complete Interrupts from Queue Heads 3187
56.4.4.11 Ping Control 3188
56.4.4.12 Split Transactions 3189
56.4.4.12.1 Split Transactions for Asynchronous Transfers 3189
56.4.4.12.1.1 Asynchronous-Do Start Split.....3190
56.4.4.12.1.2 Asynchronous-Do Complete Split 3191
56.4.4.12.2 Split Transaction Interrupt 3192
56.4.4.12.2.1 Split Transaction Scheduling Mechanisms for Interrupt 3192
56.4.4.12.2.2 Host Controller Operational Model for FSTNs 3195
56.4.4.12.2.3 Software Operational Model for FSTNs.....3198
56.4.4.12.2.4 Tracking Split Transaction Progress for Interrupt Transfers ...3198
56.4.4.12.2.5 Split Transaction Execution State Machine for Interrupt 3199
56.4.4.12.2.6 Periodic Interrupt-Do Start Split 3201
56.4.4.12.2.7 Periodic Interrupt- Do Complete Split 3202
56.4.4.12.2.8 Managing QH.FrameTag Field 3205
56.4.4.12.2.9 Rebalancing the Periodic Schedule 3206
56.4.4.12.3 Split Transaction Isochronous 3207

Chapter 1
Introduction

1.1 About This Document

This reference manual describes the functionality of the i.MX50 multimedia applications processor, Freescale Semiconductor's latest addition to a growing family of multimedia-focused products offering high performance processing optimized for lowest power consumption. The i.MX50 is a system on a chip (SoC) which integrates on one circuit a complete microcomputer platform, and features Freescale's advanced implementation of the ARM®Cortex™-A8 core.

1.1.1 Audience

This manual is intended for use by board-level product designers and product software developers. Readers should have a background in computer engineering and/or software engineering, and understand concepts of digital system design, microprocessor architecture, input/output (I/O) devices, and industry standard communication and device interface protocols.

1.1.2 Organization

The manual is parced in to two main sections titled "Book I" and "Book II".

Book I examines the chip at a system level and provides an architectural overview. Topics you'll find include the system memory map, system-level interrupt events, external pins and pin multiplexing, external memory, system debug, system boot, multimedia subsystem, power management, and system security.

Book II describes the ARM Platform, ARM Platform debug, and an array of internal functional blocks.

1.1.3 Conventions

This document uses the following notational conventions:

Table 1-1. Notational Conventions

Convention	Description
cleared / set	When a bit takes the value zero, it is said to be cleared; when it takes a value of one, it is said to be set.
mnemonics	Instruction mnemonics are shown in lowercase bold.
italics	Italics indicate variable command parameters, for example, **bcctr***x* Book titles in text are set in italics.
15	An integer in decimal
0x	Prefix to denote hexadecimal number
0b	Prefix to denote binary number. Binary 0 and 1 are written without the prefix.
n'H4000CA00	n-bit hexadecimal number
BLK_REG_NAME	Register names are all uppercase. The block mnemonic is prepended with an underscore delimiter (_).
BLK_REG[FIELD]	Fields within registers appear in brackets. For example, ESR[RLS] refers to the Receive Last Slot field of the ESAI Status Register.
BLK_REG[*n*]	Bit number *n* within register BLK.REG. Bit numbering is little endian.
BLK_REG[*l:r*]	Register bit ranges. Ranges are indicated by the left-most bit number *l* and the right-most bit number *r* separated by a colon (:). For example, ESR[15:0] refers to the lower half word in the ESAI Status Register.
x, U	In some contexts, such as signal encodings, an unitalicized x indicates a don't care or uninitialized. The binary value could be 1 or 0.
x	An italicized *x* indicates an alphanumeric variable.
n, m	Italicized *n or m* represent integer variables.
!	Binary logic operator NOT
&&	Binary logic operator AND
||	Binary logic operator OR
^ or <O+>	Binary logic operator XOR
|	Bit-wise OR. For example, 0b0001 | 0b1000 yields the value 0b1001.
&	Bit-wise AND. For example, 0b0001 & 0b1000 yields the value 0b0000.

Table continues on the next page...

Table 1-1. Notational Conventions (continued)

Convention	Description
{A,B}	Concatenation, where the *n*-bit value A is prepended to the *m*-bit value B to form an (*n*+*m*)-bit value. For example, {0, REG*m* [14:0]} yeilds a 16-bit value with 0 in the most significant bit.
- or grey fill	Indicates a reserved bit field in an register. Although these bits can be written to as ones or zeros, they are always read as zeros.
>>	Shift right logical one position
<<	Shift left logical one position
= <left arrow>	Assignment
==	Compare equal
!=	Compare not equal
>	Greater than
<	Less than

The following signal conventions are also used:

Table 1-2. Signal Conventions

Convention	Description
_b, _B	When appended to a signal name, this indicates that a signal is active-low.
$\overline{\text{NEG\_ACTIVE}}$	Overbar also denotes a negative active signal.
UPPERCASE	Package pin names, Block I/O signals
lowercase	Lowercase is used to indicate internal signals.

1.1.4 Register Access

1.1.4.1 Register Diagram Field Access Type Legend

The following figure provides an interpretation of the notation which is used in register diagrams for a number of common field access types.

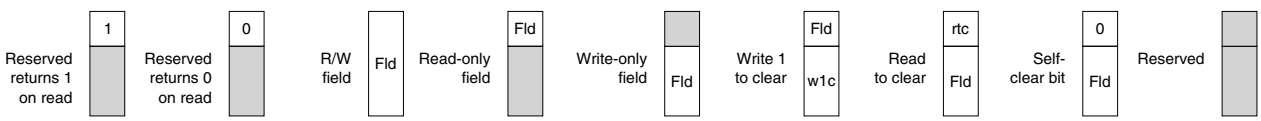

Figure 1-1. Register Field Conventions

NOTE

For reserved register fields, software should mask off the data in the field after read (software can't rely on the contents of data read from a reserved field) and always write all zeros.

1.1.4.2 Register Macro Usage

A common operation is to update one field without disturbing the contents of the remaining fields in the register. Normally, this requires a read-modify-write (RMW) operation, where the CPU reads the register, modifies the target field, then writes the results back to the register. This is an expensive operation in terms of CPU cycles, because of the initial register read.

To address this issue, some hardware registers are implemented as a group, including registers that can be used to either set, clear, or toggle (SCT) individual bits of the primary register. When writing to an SCT register, all bits set to 1 perform the associated operation on the primary register, while all bits set to 0 are not affected. The SCT registers always read back 0, and should be considered write-only. The SCT registers are not implemented if the primary register is read-only.

With this architecture, it is possible to update one or more fields using only register writes. First, all bits of the target fields are cleared by a write to the associated clear register, then the desired value of the target fields is written to the set register. This sequence of two writes is referred to as a clear-set (CS) operation.

A CS operation does have one potential drawback. Whenever a field is modified, the hardware sees a value of 0 before the final value is written. For most fields, passing through the 0 state is not a problem. Nonetheless, this behavior is something to consider when using a CS operation.

Also, a CS operation is not required for fields that are one bit wide. While the CS operation works in this case, it is more efficient to simply set or clear the target bit (that is, one write instead of two). A simple set or clear operation is also atomic, while a CS operation is not.

Note that not all macros for set, clear, or toggle (SCT) are atomic. For registers that do not provide hardware support for this functionality, these macros are implemented as a sequence of read/modify/write operations. When atomic operation is required, the developer should pay attention to this detail, because unexpected behavior might result if an interrupt occurs in the middle of the critical section comprising the update sequence.

1.1.5 Acronyms and Abbreviations

The following acronyms and abbreviations are used in this document:

Table 1-3. Acronyms and Abbreviated Terms

Term	Meaning
BIST	Built-in self test
DDR	Double data rate (of Dynamic RAM)
FIFO	First In / First Out (of a queue)
DMA	Direct memory access
DPLL	Digital phase-locked loop
DRAM	Dynamic random access memory
EHCI	Enhanced host controller interface
EPROM	Erasable programmable read-only memory
GPIO	General-purpose I/O
GPR	General-purpose register
GPU	Graphicd Processing Unit
I2C or I2C	Inter-integrated circuit
IEEE	Institute of Electrical and Electronics Engineers
IrDA	Infrared Data Association
JTAG	Joint Test Action Group (a serial bus protocol usually used for test purposes)
LIFO	Last-in-first-out
LRU	Least recently used
LSB	Least-significant byte
lsb	Least-significant bit
MSB	Most-significant byte
msb	Most-significant bit
PCMCIA	Personal Computer Memory Card International Association
PIC	Programmable interrupt controller
POR	Power-on reset
RISC	Reduced instruction set computing
RTOS	Real-time operating system
Rx	Receive
SDLC	Synchronous data link control
SDMA	Serial DMA
SPDIF	Sony Phillips Digital Interface
SPI	Serial peripheral interface
SRAM	Static random access memory

Table continues on the next page...

Table 1-3. Acronyms and Abbreviated Terms (continued)

Term	Meaning
Tx	Transmit
UART	Universal asynchronous receiver/transmitter
USB	Universal serial bus

1.2 Target Applications

The i.MX50 processor provides designers with the power and flexibility necessary to support a wide variety of system designs including:

- eReaders
- Smartphones
- Gaming consoles
- PDAs
- Portable media players (PMPs)
- Web tablets
- Other media devices

1.3 Features

The i.MX50 Application Processor (AP) is based on the ARM Cortex A8™ platform, which has the following features:

- Memory Management Unit (MMU), L1 Instruction Cache, and L1 Data Cache
- Unified L2 cache
- 800 MHz target frequency of the core (including Neon, VFP Version 3, and L1 cache)
- Neon coprocessor (SIMD Media Processing Architecture) and Vector Floating Point (VFP-Lite) coprocessor supporting VFPv3

The memory system consists of the following components:

- Level 1 Cache:
  - Instruction (32 Kbyte)
  - Data (32 Kbyte)
- Level 2 Cache:
  - Unified instruction and data (256 Kbyte)
- Level 2 (internal) memory:

    - Boot ROM, including High Assurance Boot (96 Kbyte)
    - Internal multimedia/shared, fast access RAM (128 Kbyte)
- External memory interfaces:
    - 16/32-bit DDR2-533, LPDDR2-533, or LPDDR1-400 up to a total of 2 Gbyte
    - 8-bit NAND SLC/MLC Flash, up to 100 MHz, with up to 32-bit hardware ECC with up to 1 Kbyte block size.
    - 16/32-bit NOR Flash, with a dedicated 16-bit muxed-mode interface. I/O muxing logic selects EIM port as primary muxing at boot.
    - 16-bit PSRAM, Cellular RAM
    - Managed NAND including eMMC up to rev 4.4

The i.MX50 introduces a next generation system bus fabric architecture which aggregates various subsystem buses and masters for access to system peripherals and memories. The various bus systems and components are as follows:

- 64-bit AXI Fabric (266 MHz)—This bus fabric is the SoC's central bus aggregation point.
    - Provides access to all slave targets in the SoC:
        - ROM (ROMCP)
        - On-chip RAM (OCRAM)
        - DRAM Memory Controller (DRAMMC)
        - External static RAM (EIM)
        - Interrupt controller (TZIC)
        - Decode into the AHB MAX crossbar second level AHB fabric.
    - Provides arbitration to the following masters in the system:
        - ARM platform complex
        - Pixel processing pipeline (ePXP)
        - Electrophoretic display controller (EPDC)
        - LCD display controller (eLCDIF)
        - Data Co-processor (DCP) Crypto engine
        - Error Correcting Accelerator (BCH)
        - 2D GPU
        - Smart Direct Memory Access (SDMA)
        - USB On the Go and host controller complex (USB)
        - Fast Ethernet controller (FEC)
- MAX AHB crossbar (133 MHz)—This connects the various AHB bus sub-segments in the system and provides decode into the following slaves:
    - IP-Bus 1 (66 MHz)—This bus segment contains peripherals accessible by the ARM core and without DMA capability

    - IP-Bus 2 (66 MHz)—This bus segment contains peripherals accessible by the ARM core and without DMA capability
    - APBH DMA bridge (133 MHz)—The APBH DMA bridge is a master to the MAX for its memory-side DMA operations. The APBH bus is an AMBA APB slave bus providing peripheral access to many of the high-speed IP blocks on the i.MX50.
- IP-Bus 3 (66 MHz): This third peripheral bus segment contains peripherals accessible by the ARM core and SDMA and as such houses peripherals with DMA capability. The IP-Bus 3 can be accessed by the ARM platform through IP-Bus 1 and SPBA.
- Quality of Service Controller (QoSC): This provides both soft and dynamic arbitration/priority control. The QoSC works in conjunction with the critical display modules such as the eLCDIF and EPDC to provide dynamic priority control, based on real-time metrics.

The i.MX50 makes use of dedicated hardware accelerators to achieve state-of-the-art multimedia performance. The use of hardware accelerators provides both high performance and low power consumption, while freeing up the ARM core for other tasks.

The i.MX50 incorporates the following hardware accelerators:

- GPU2D —2D Graphics accelerator, OpenVG 1.1, version 1, 200 Mpix/s performance
- ePXP—enhanced PiXel Processing Pipeline off loading key pixel processing operations required to support both LCD and EPD display applications.

The i.MX50 includes the following interfaces to external devices:

NOTE

Not all the interfaces are available simultaneously depending on I/O multiplexer configuration.

- Displays:
    - EPDC—Supporting direct-driver TFT backplanes beyond 2048 × 1536 at 106 Hz refresh (or 4096 × 4096 at 20 Hz)
    - eLCDIF—Supporting beyond SXGA + (1400 × 1050) at 60 Hz resolutions with up to a 32-bit display interface
    - Both displays can be active simultaneously. If both displays are active, the eLCDIF only provides a 16-bit interface due to pin multiplexing.
- Expansion cards:
    - Four SD/MMC cards
- USB:

    - One High Speed (HS) USB 2.0 OTG-capable port with integrated HS USB PHY
    - One High Speed (HS) USB 2.0 host port with integrated HS USB PHY
- Miscellaneous interfaces:
    - One-Wire (OWIRE) port
    - Two internal I2S/SSI/AC97 ports, supporting up to 1.4 Mbps each connected to the Digital Audio Multiplexer (AUDMUX) with four external ports
    - Five UART RS232 ports, up to 4.0 Mbps each.
    - Two eCSPI (Enhanced CSPI) ports, up to 66 Mbps each plus a CSPI port, up to 16.6 Mbps
    - Three I^2C ports, supporting 400 kbps
    - Fast Ethernet controller IEEE 802.3, 10/100 Mbps
    - Sony Memory Stick Pro Host Controller
    - Key Pad Port (KPP)
    - Two Pulse Width Modulators (PWM)
    - GPIO with interrupt capabilities
    - System JTAG Controller (SJC)

The system supports efficient and smart power control and clocking:

- Suppors DVFS techniques for low power modes, including autos-low from the STMP architecture
- Power gating-SRPG (State Retention Power Gating) for ARM core and Neon
- Support for various levels of system power modes
- Flexible clock gating control scheme
- On-chip temperature monitor
- On-chip 32 KHz and 24 MHz oscillators
- A total of four PLLs with the fourth PLL providing up to eight independently controllable outputs, improving the ease of clocking control especially for display and connectivity modules

Security functions are enabled and accelerated by the following hardware:

- System JTAG Controller (SJC)—Protecting JTAG from debug port attacks by regulating or blocking the access to the system debug features
- Secure Real-Time Clock (SRTC)—Tamper resistant RTC with dedicated power domain and mechanism to detect voltage and clock glitches
- Advanced High Assurance Boot (A-HAB)—HAB with the next embedded enhancements: SHA-256, 2048-bit RSA key, version control mechanism, warm boot, CSU, and TZ initialization

1.4 Architectural Overview

This section contains a simplified block diagram of the i.MX50.

1.4.1 Block Diagram

Figure 1-2 shows a high-level block diagram of the i.MX50, providing a view of the major subsystems (processor domains, shared peripherals domain, memories, and so on) and logical connectivity.

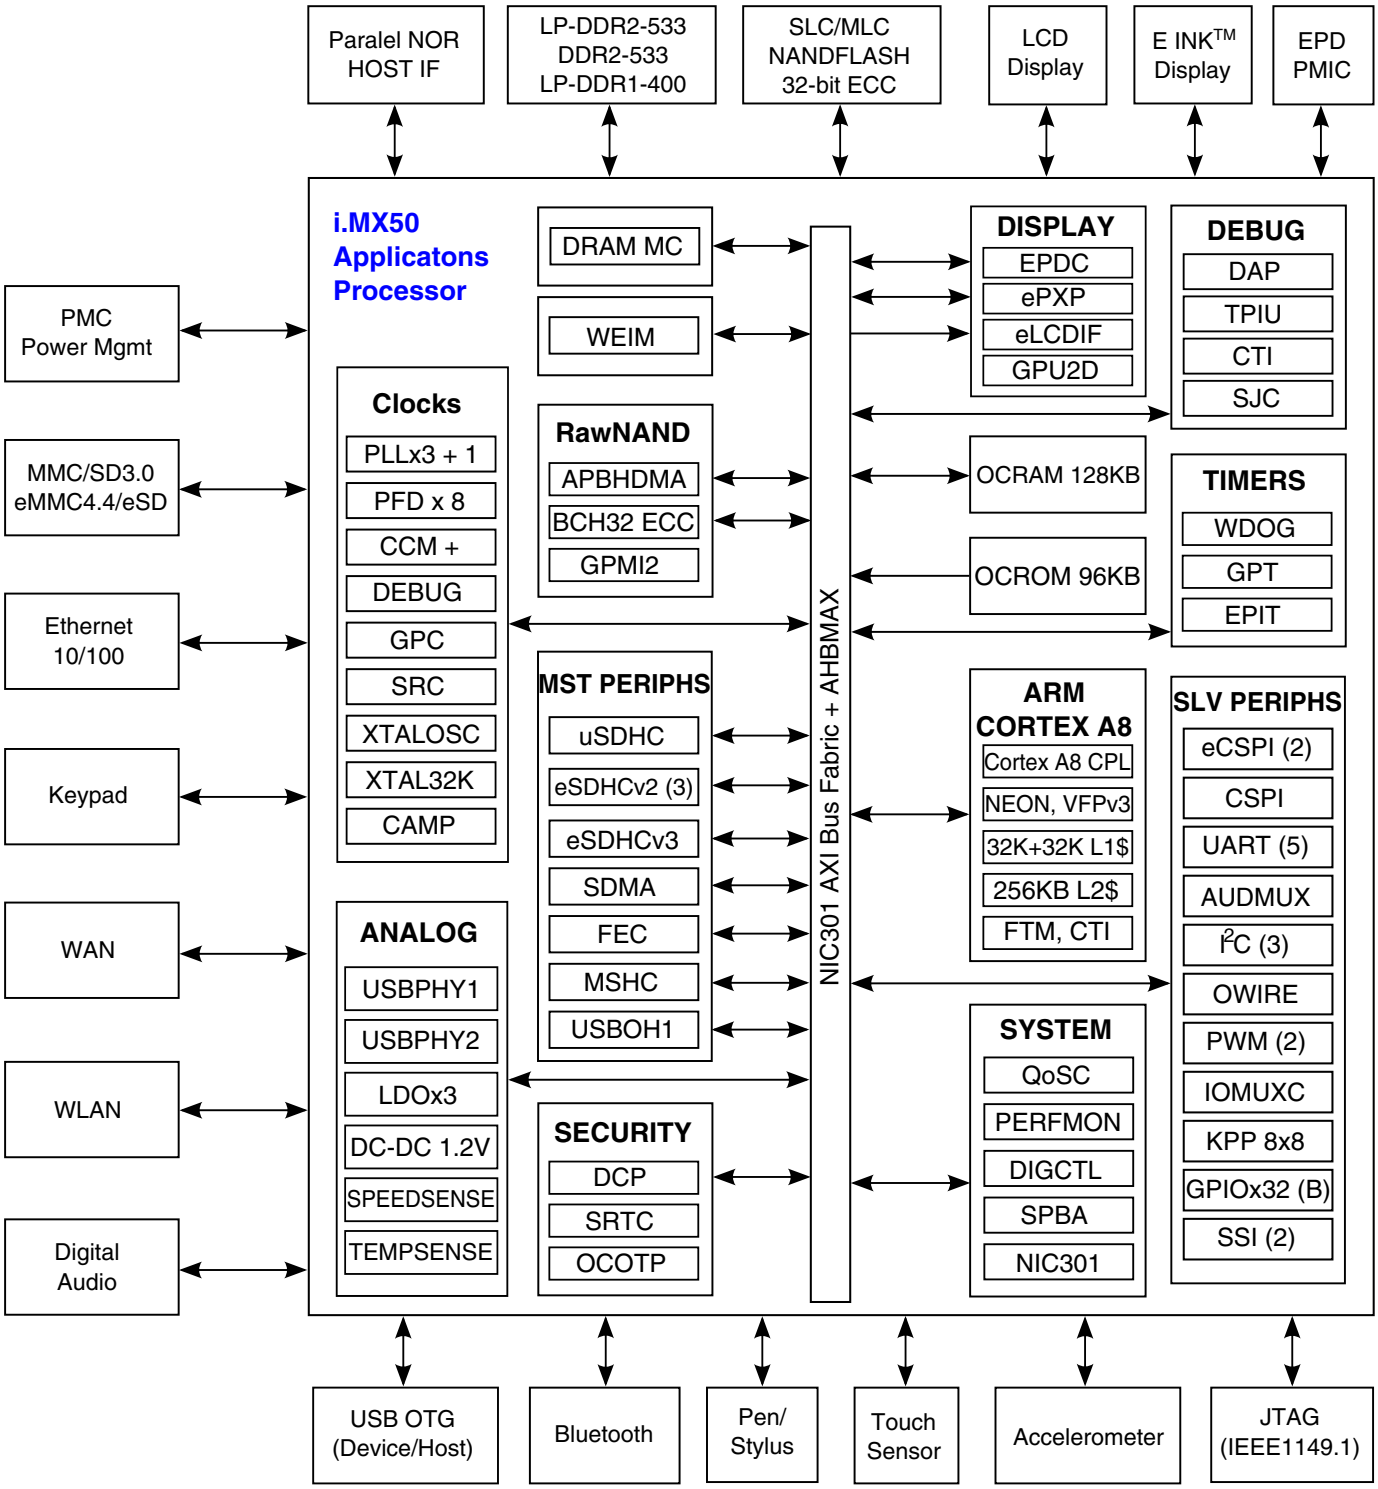

Figure 1-2. i.MX50 System Block Diagram

1.4.2 Major Subsystems

The i.MX50 consists of the following major subsystems:

- Core (ARM Cortex A8™) Platform, L1/L2 memories
- SDMA controller and the shared peripheral domain
- System Control—Boot Flow control, Clocks distribution, **Reset** control and Low Power logic
- Multimedia
  - Video Processor
  - TV-Encoder (TVe-) for PAL/NTSC output
  - Image Processor
  - Graphics Processors
  - Audio—connectivity interfaces in hardware, while codecs are performed in SW by ARM core.
- Security
- Connectivity peripherals
- External Memory Interface

1.4.3 Architectural Partitioning

This paragraph defines how architecture supports the processing intensive tasks:

- ARM Cortex A8™ Platform is responsible for:
  - Operating System
  - User applications (including control over hardware accelerators and non-accelerated functions)
- Smart DMA enables data transfer between non-mastering peripherals and external or internal memories
- System Control is supported through:
  - Clock Control Block (CCM)
  - Three (3×) PLLs
  - XTALOSC—Crystal oscillator source support
  - Frequency Pre-multiplier (FPM)
  - System Reset Controller (SRC)
  - Global Power Controller (GPC)
  - Two (2×) CAMPs—Clock Amplifier modules on the CKIH1 and CKIH2 inputs
- Multimedia is supported with:
  - LCD Interface (eLCDIF) ,
    - Pixel processing pipeline (ePXP), supports
- YUV bi-linear scaling, upto 8 overlays, rotation function, in-place rendering, and high resolutions upto 2048x2048.
- Electrophoretic Display Controller (EPDC)
- Graphics Processing Unit (GPU2D), 2D graphics processing
- Audio

    - Audio codecs are provided by software, which runs on ARM core
    - 2 × SSIs
    - Audio Mux
- Security is supported by:
    - High Assurance Boot (HAB) System
    - On-Chip OTP Controller (OCOTP) for the One-Time programmable electrical fuse array (E-Fusebox)
    - Data co-processor (DCP)
    - SJC—System JTAG controller
    - Secure Real Time Clock (SRTC)
    - Tamper Detection
- Connectivity peripherals, timers, and External Memory Interface (EMI)
    - Low-level communication protocols
    - Embedded DMAs
    - 3.3-V IO voltage for seamless integration
    - USB 2.0 with integrated PHY/Transceiver
    - DDR, Nand Flash (MLC 4/8-bit ECC) memory interface
    - Timers: 2 × EPIT, GPT, and Watch Dog timer (WDOG)
    - Miscellaneous connectivity support—I2C, SPI, UART, PWM, and Keypad interface

1.5 i.MX50 Modules List

Table 1-4 lists the modules used by the various subsystems of the i.MX50.

Table 1-4. i.MX50 Digital and Analog Modules

Block Mnemonic	Block Name	Subsystem	Brief Description
ARM Cortex A8™	ARM Cortex A8™ Platform	ARM	The ARM Cortex A8™ Core Platform consists of the ARM Cortex A8™ processor and its essential sub-blocks. It contains the 32 Kbyte L1 instruction cache, 32 Kbyte L1 data cache, Level 2 cache controller and a 256 Kbyte L2 cache. The platform also contains an event monitor and debug modules. It also has a NEON co-processor with SIMD media processing architecture, register file with 32 × 64-bit general-purpose registers, an Integer execute pipeline (ALU, Shift, MAC), dual, single-precision floating point execute pipeline (FADD, FMUL), load/store and permute pipeline, and a non-pipelined vector floating point (VFP Lite) co-processor supporting VFPv3.

Table 1-4. i.MX50 Digital and Analog Modules (continued)

Block Mnemonic	Block Name	Subsystem	Brief Description
EPDC	Electrophoretic Display Controller	Display	The EPDC is a feature-rich, low power, and high-performance direct-drive active matrix EPD controller. It is specifically designed to drive E-INK™ EPD panels supporting a wide variety of TFT backplanes. The goal of the EPDC is to provide an efficient SoC integration of this functionality.
ePXP	enhanced PiXel Processing Pipeline	Display	A high-performance pixel processor is capable of 1 pixel/clock performance for combined operations such as color-space conversion, alpha blending, gamma-mapping, and rotation. The ePXP is enhanced with features specifically for grayscale applications. In addition, the ePXP supports traditional pixel/frame processing paths for still-image and video processing applications allowing it to interface with the integrated LCD controller (eLCDIF).
eLCDIF	enhanced LCD Interface	Display	The eLCDIF is a high-performance LCD controller interface supporting a rich set of modes allowing inter operability with a wide variety of LCD panels (including smart-panels, DOTCK/RGB, and so on). The module also supports a synchronous operation with the ePXP to allow the processed frames to be passed from the ePXP to the eLCDIF through an on-chip SRAM buffer. The eLCDIF can support up to 32-bit interfaces.
AUDMUX	Digital Audio Mux	Multimedia Peripherals	The AUDMUX is a programmable interconnect for voice, audio, and synchronous data routing between host serial interfaces (for example, SSI1, SSI2) and peripheral serial interfaces (audio and voice codecs). The AUDMUX has seven ports (three internal and four external) with identical functionality and programming models. A desired connectivity is achieved by configuring two or more AUDMUX ports.
CAMP-1	Clock Amplifier	Clocks, Resets, and Power Control	Clock Amplifier
CCM GPC SRC	Clock Control Module General Power Controller System Reset Controller	Clocks, Resets, and Power Control	These modules are responsible for clock and reset distribution in the system, and also for system power management. The system includes four PLLs.
CSPI eCSPI-1 eCSPI-2	Configurable SPI, Enhanced CSPI	Connectivity Peripherals	Full-duplex enhanced synchronous serial interface, with data rate up to 66.5 Mbit/s (for eCSPI, master mode). It is configurable to support Master/Slave modes, four chip selects to support multiple peripherals.

Table continues on the next page...

Table 1-4. i.MX50 Digital and Analog Modules (continued)

Block Mnemonic	Block Name	Subsystem	Brief Description
Debug System	Debug System	System Control	The Debug System provides real-time trace debug capability of both instructions and data. It supports a trace protocol that is an integral part of the ARM Real Time Debug solution (RealView). Real-time tracing is controlled by specifying a set of triggering and filtering resources, which include address and data comparators, three cross-system triggers (CTI), counters, and sequencers. Debug Access Port (DAP)—The DAP provides real-time access for the debugger without halting the core to System memory and peripheral registers. All debug configuration registers and Debugger access to JTAG scan chains.
DRAM MC	DRAM Memory Controller	Connectivity Peripherals	The DRAM Memory Controller multiple external memory types, including: Standard 1.8V DDR2, 1.8V Mobile DDR1 (LPDDR1), 1.2V Mobile DDR2 (LPDDR2).
EIM	Wireless External Interface Module (EIM)	Connectivity Peripherals	The Wireless External Interface Module (EIM) handles the interface to devices external to the chip, including generation of chip selects, clock and control for external peripherals and memory. It provides asynchronous access to devices with SRAM-like interface and synchronous access to devices with Nor-Flash like or PSRAM like interface.
BCH32/GPMI	Raw NAND System with ECC	Connectivity Peripherals	The General Purpose Media Interface(GPMI) is a flexible interface to up to eight NAND flash with configurable address and command behavior, providing support for ONFI2.1 standard and Samsung Toggle-DDR NAND devices. A hardware BCH ECC engine is built in allowing for up to 32-bit correction with programmable NAND page layout.
APBHDMA	AHB-to-APBH Bridge with DMA	System Control Peripherals	The AHB-to-APBH bridge includes the AHB-to-APB PIO bridge for memory-mapped I/O to the APB devices, as well as a central DMA facility for devices on this bus and a vectored interrupt controller for the ARM core.
DCP	Data Co-Processor	Security	It includes sections on memory copy functionality, Advanced Encryption Standard (AES), hashing, and arbitration
System Fabric and QoS	System Fabric and QoS	System	The Quality of Service Controller APB Slave provides the following features: • Provide software programmability of the master ports of the AXI fabric(NIC301). • Provide translation and pass through of AXI QOS values to the AWPRIORITY and ARPRIORITY sideband signals of the DRAM Memory Controller (DRAM MC). Alternatively allow independent programmability of the DRAM MC priority sideband signals. • Automatic qos/priority boost for eEPDC and eLCDIF masters. • Per port disabling of AXI master port traffic.

Table continues on the next page...

Table 1-4. i.MX50 Digital and Analog Modules (continued)

Block Mnemonic	Block Name	Subsystem	Brief Description
EPIT	Enhanced Periodic Interrupt Timer	Timer Peripherals	Each EPIT is a 32-bit set and forget timer that starts counting after the EPIT is enabled by software. It is capable of providing precise interrupts at regular intervals with minimal processor intervention. It has a 12-bit prescaler for division of input clock frequency to get the required time setting for the interrupts to occur, and counter values can be programmed on the fly.
eSDHCv3-3 (eMMC 4.4)	Ultra-High- Speed Multi-Media Card/ Secure Digital card host controller, ver. 3	Connectivity Peripherals	Ultra High-Speed eSDHC, enhanced to support eMMC 4.4 standard specification, for 832 MBps. Port 3 is specifically enhanced to support eMMC 4.4 specification, for double data rate (832 Mbps, 8-bit port). eSDHCv3 is backward compatible to eSDHCv2 IP and supports all the features of eSDHCv2 as described below.
eSDHCv2-1 eSDHCv2-2 eSDHCv2-4	Enhanced Multi-Media Card/ Secure Digital Host Controller, ver. 2		Enhanced Multi-Media Card/Secure Digital Host Controller: Ports 1, 2, and 4 are compatible with the MMC System Specification version 4.3, full support Port 4 supports up to 8-bit data width, ports 1 and 2 are limited to 4-bit data width interface The generic features of the eSDHCv2 module, when serving as SD/MMC host, include the following: Can be configured either as SD/MMC controller Supports eSD and eMMC standard, for SD/MMC embedded type cards Conforms to *SD Host Controller Standard Specification* version 2.0, full support. Compatible with the SD Memory Card Specification version 1.1 Compatible with the SDIO Card Specification version 1.2 Designed to work with SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, MMC and MMC RS cards Configurable to work in one of the following modes: - SD/SDIO 1-bit, 4-bit - MMC 1-bit, 4-bit, 8-bit (8-bit supported only on port 4) Full/High speed mode Host clock frequency variable between 32 kHz to 52 MHz Up to 200 Mbps data transfer for SD/SDIO cards using four parallel data lines Up to 416 Mbps data transfer for MMC cards using eight parallel data lines (port 4)

Table continues on the next page...

Table 1-4. i.MX50 Digital and Analog Modules (continued)

Block Mnemonic	Block Name	Subsystem	Brief Description
FEC	Fast Ethernet Controller	Connectivity Peripherals	The Ethernet Media Access Controller (MAC) is designed to support both 10 Mbps and 100 Mbps Ethernet/IEEE Std 802.3™ networks. An external transceiver interface and transceiver function are required to complete the interface to the media.
GPIO-1 GPIO-2 GPIO-3 GPIO-4 GPIO-5 GPIO-6	General Purpose I/O Modules	System Control Peripherals	These modules are used for general purpose input/output to external ICs. Each GPIO module supports up to 32 bits of I/O.
GPT	General Purpose Timer	Timer Peripherals	Each GPT is a 32-bit *free-running* or *set* and *forget* mode timer with a programmable prescaler and compare and capture register. A timer counter value can be captured using an external event, and can be configured to trigger a capture event on either the leading or trailing edges of an input pulse. When the timer is configured to operate in "set and forget" mode, it is capable of providing precise interrupts at regular intervals with minimal processor intervention. The counter has output compare logic to provide the status and interrupt at comparison. This timer can be configured to run either on an external clock or on an internal clock.
GPU2Dv1	Graphics Processing Unit-2D, ver. 1	Multimedia Peripherals	The GPU2Dv1 provides hardware acceleration for 2D graphic algorithms with sufficient processor power to run desk-top quality interactive graphics applications on displays up to HD1080 resolution.
I^2C-1 I^2C-2 I^2C-3	I^2C Interface	Connectivity Peripherals	I^2C provides serial interface for controlling peripheral devices. Data rates of up to 400 kbps are supported.
OCOTP	On-chip OTP controller	Security	The on-chip one-time -programmable (OCOTP) ROM serves the functions of hardware and software capability bits, Freescale operations and unique-ID, the customer-programmable cryptography key, and storage of various ROM configuration bits.
IOMUXC	IOMUX Control	System Control Peripherals	This module enables flexible I/O multiplexing. Each I/O pad has default as well as several alternate functions. The alternate functions are software configurable.
KPP	Keypad Port	Connectivity Peripherals	The KPP supports an 8 × 8 external keypad matrix. The KPP features are as follows: Open drain design Glitch suppression circuit design Multiple keys detection Standby key press detection

Table continues on the next page...

Table 1-4. i.MX50 Digital and Analog Modules (continued)

Block Mnemonic	Block Name	Subsystem	Brief Description
OWIRE	One-Wire Interface	Connectivity Peripherals	One-Wire support provided for interfacing with an on-board EEPROM, and smart battery interfaces, for example, Dallas DS2502.
PWM-1 PWM-2	Pulse Width Modulation	Connectivity Peripherals	The pulse-width modulator (PWM) has a 16-bit counter and is optimized to generate sound from stored sample audio images. It can also generate tones. The PWM uses 16-bit resolution and a 4 x 16 data FIFO to generate sound.
OC RAM 128 Kbytes	On-Chip RAM	Internal Memory	Internal RAM The On-Chip Memory controller (OCRAM) module, is an interface between the system's AXI bus, to the internal (on-chip) SRAM memory module. It is used for controlling the 128 Kbyte multimedia RAM, through a 64-bit AXI bus.
OC ROM 96 Kbytes	On-Chip ROM	Internal Memory	Supports secure and regular Boot Modes. The On-Chip ROM Controller supports ROM Patching.
SDMA	Smart Direct Memory Access	System Control Peripherals	The SDMA is multi-channel flexible DMA engine. It helps in maximizing system performance by offloading various cores in dynamic data routing. The SDMA features list is as follows: Powered by a 16-bit instruction-set micro-RISC engine Multi-channel DMA supports up to 32 time-division multiplexed DMA channels 48 events with total flexibility to trigger any combination of channels Memory accesses including linear, FIFO, and 2D addressing Shared peripherals between ARM Cortex A8™ and SDMA Very fast context-switching with two-level priority-based preemptive multi-tasking DMA units with auto-flush and prefetch capability Flexible address management for DMA transfers (increment, decrement, and no address changes on source and destination address) DMA ports can handle uni-directional and bi-directional flows (copy mode) Up to 8-word buffer for configurable burst transfers for PL301 Support of byte-swapping and CRC calculations A library of scripts and API is available

Table continues on the next page...

Table 1-4. i.MX50 Digital and Analog Modules (continued)

Block Mnemonic	Block Name	Subsystem	Brief Description
SJC	System JTAG Interface	System Control Peripherals	The System JTAG controller provides a mechanism for regulating JTAG access, preventing unauthorized JTAG usage while allowing JTAG access for manufacturing tests and software debugging. The i.MX50 JTAG port provides debug access to several hardware blocks including the ARM processor and the system bus, therefore, it must be accessible for initial laboratory bring-up,manufacturing tests and troubleshooting, and for software debugging by authorized entities. However, if the JTAG port is left unsecured it provides a method for executing unauthorized program code, getting control over secure applications, and running code in privileged modes. The System JTAG controller provides three different security modes that can be selected through an e-fuse configuration to prevent unauthorized JTAG access.
SPBA	Shared Peripheral Bus Arbiter	System Control Peripherals	SPBA (Shared Peripheral Bus Arbiter) is a two-to-one IP bus interface (IP bus) arbiter.
SRTC	Secure Real Time Clock	Security	The SRTC incorporates a special System State Retention Register (SSRR) that stores system parameters during system shutdown modes. This register and all SRTC counters are powered by dedicated supply rail NVCC_SRTC_POW. The NVCC_SRTC_POW can be energized separately even if all other supply rails are shut down. This register is helpful for storing warm boot parameters. The SSRR also stores the system security state. In case of a security violation, the SSRR marks the event (security violation indication).
SSI-1 SSI-2	I2S/SSI/AC97 Interface	Connectivity Peripherals	The SSI is a full-duplex synchronous interface used on the i.MX50 processor to provide connectivity with off-chip audio peripherals. The SSI interfaces connect internally to the AUDMUX for mapping to external ports. The SSI supports a wide variety of protocols (SSI normal, SSI network, I2S, and AC-97), bit depths (up to 24 bits per word), and clock/frame sync options. Each SSI has two pairs of 15 x 24 FIFOs and hardware support for an external DMA controller in order to minimize its impact on system performance. The second pair of FIFOs provides hardware interleaving of a second audio stream, which reduces ARM platform overhead in use cases where two time slots are being used simultaneously.
Temperature Monitor	(Part of SATA IP)	System Control Peripherals	The temperature sensor is an internal module to the i.MX50 that monitors the die temperature. The monitor is capable of generating a SW interrupt, or triggering the CCM, to reduce the core operating frequency.

Table 1-4. i.MX50 Digital and Analog Modules (continued)

Block Mnemonic	Block Name	Subsystem	Brief Description
UART-1 UART-2 UART-3 UART-4 UART-5	UART Interface, ver. 2	Connectivity Peripherals	Each of the UARTv2 modules supports the following serial data transmit/receive protocols and configurations: 7 or 8-bit data words, 1 or 2 stop bits, programmable parity (even, odd, or none) Programmable bit-rates up to 4 Mbps. This is a higher max baud rate relative to the 1.875 Mbps, which is specified by the TIA/EIA-232-F standard. 32-byte FIFO on Tx and 32 half-word FIFO on Rx supporting auto-baud IrDA 1.0 support (up to SIR speed of 115200 bps) Option to operate as 8-pins full UART, DCE, or DTE
USB-OH-1	USB 2.0 High-Speed OTG-capable and Host ports	Connectivity Peripherals	USB-OH-1 supports USB2.0 HS/FS/LS, and contains: One high-speed OTG-capable module with integrated HS USB PHY One high-speed Host module with integrated HS USB PHY.
WDOG-1	Watch Dog	Timer Peripherals	The Watchdog (WDOG) timer module protects against system failures by providing a method of escaping from unexpected events or programming errors. The WDOG Timer supports two comparison points during each counting period. Each of the comparison points is configurable to invoke an interrupt to the ARM core, and a second point invokes an external event on the WDOG line.
XTALOSC	Crystal Oscillator I/F	Clocking	The XTALOSC module allows connectivity to an external crystal.

Chapter 2
Memory Map

2.1 Introduction

This chapter introduces the memory architecture of the i.MX50 device. The system memory high-level partition is defined below:

- Level 1 Cache
  - Instruction (32 Kbyte)
  - Data (32 Kbyte)
- Level 2 Cache
  - Unified instruction and data (256 Kbyte)
- Level 2 (internal) Memory
  - Boot ROM, including HAB (96 Kbyte)
  - Internal multimedia/shared, fast access RAM (128 Kbyte).
- External memory interfaces
  - 16/32-bit DDR2-533, LP-DDR2-533, or LP-DDR1-400 up to a total of 2 Gbyte
  - 8-bit NAND SLC/MLC Flash, up to 100 MHz, with up to 32-bit hardware ECC with up to 1 Kbyte block size.
  - 16/32-bit NOR Flash, with a dedicated 16-bit muxed-mode interface. I/O muxing logic selects EIM port as primary muxing at system boot.
  - 16-bit PSRAM, Cellular RAM
  - Managed NAND including eMMC up to rev 4.4

2.2 ARM Platform Memory Map

SPBA Registers	0xF000	4 Kbyte	-

NOTE

User should not address reserved memory regions. Access to reserved memory regions can cause unpredictable behavior.

Chapter 3
Interrupts and DMA Events

3.1 Overview

The Interrupts and DMA Events chapter provides information on the assigments of interrupts of the AP domain in AP Interrupts and of the DMA events in SDMA Event Mapping.

3.2 AP Interrupts

The Interrupt Controller (TZIC) collects up to 128 interrupt requests from all i.MX50 sources and provides interface to the core. Software force registers and software priority masking are also supported. Table 3-1 details the ARM interrupt sources.

Table 3-1. ARM Domain Interrupt Summary

IRQ	Interrupt Source	Interrupt Description
0	Reserved	Reserved
1	eSDHC1	Enhanced SDHC1 Interrupt Request
2	eSDHC2	Enhanced SDHC2 Interrupt Request
3	eSDHC3	Enhanced SDHC3 Interrupt Request
4	uSDHC	Enhanced SDHC4 Interrupt Request
5	DAP	DAP Interrupt Request
6	SDMA	"AND" of all 48 interrupts from all the channels
7	IOMUX	External Interrupt Request, usually used as POWER FAIL interrupt
8	Reserved	Reserved
9	Reserved	Reserved
10	Reserved	Reserved
11	Reserved	Reserved
12	Reserved	Reserved

30	Reserved	-
31	Reserved	-
32	Reserved	-
33	Reserved	-
34	Reserved	-
35	Reserved	-
36	Reserved	-
37	Reserved	-
38	CSPI	CSPI DMA Rx request
39	CSPI	CSPI DMA Tx request
40	Reserved	-
41	Reserved	-
42	UART3	UART3 Rx request
43	UART3	UART3 Tx request
44	Reserved	-
45	Reserved	-
46	Reserved	-
47	Reserved	-

As shown in the table, some of the events are an output of a mux of two signals or triggers. The select of this mux is controlled by general purpose register in IOMUXC.

For other shared connectivity peripherals that do not have dedicated DMA request signals, the AP interrupt service routines have the option to program the SDMA to move data between the peripheral and memory.

Chapter 4
External Signals and Pin Multiplexing

4.1 Introduction

The i.MX50 IC contains a limited number of pins, therefore, most pins have multiple signal options. The input-output multiplexer (IOMUX) controls the pin multiplexing. The IOMUX also configures other pin characteristics, such as voltage level, drive strength, and hysteresis.

4.2 External Signals

- Table 4-1 shows the chip's external signals.
- Table 4-2 shows an additional view of the muxing of external signals. It presents the muxing options per module/instance.
- Table 4-3 shows the IOMUX daisy chain.

Chapter 5
Clock Controller Module (CCM)

5.1 Introduction

The Clock Controller Module (CCM) controls the clocks for i.MX50 blocks. This block uses the available clock sources to generate the root clocks. Figure 5-1 shows a high level CCM clock tree diagram.

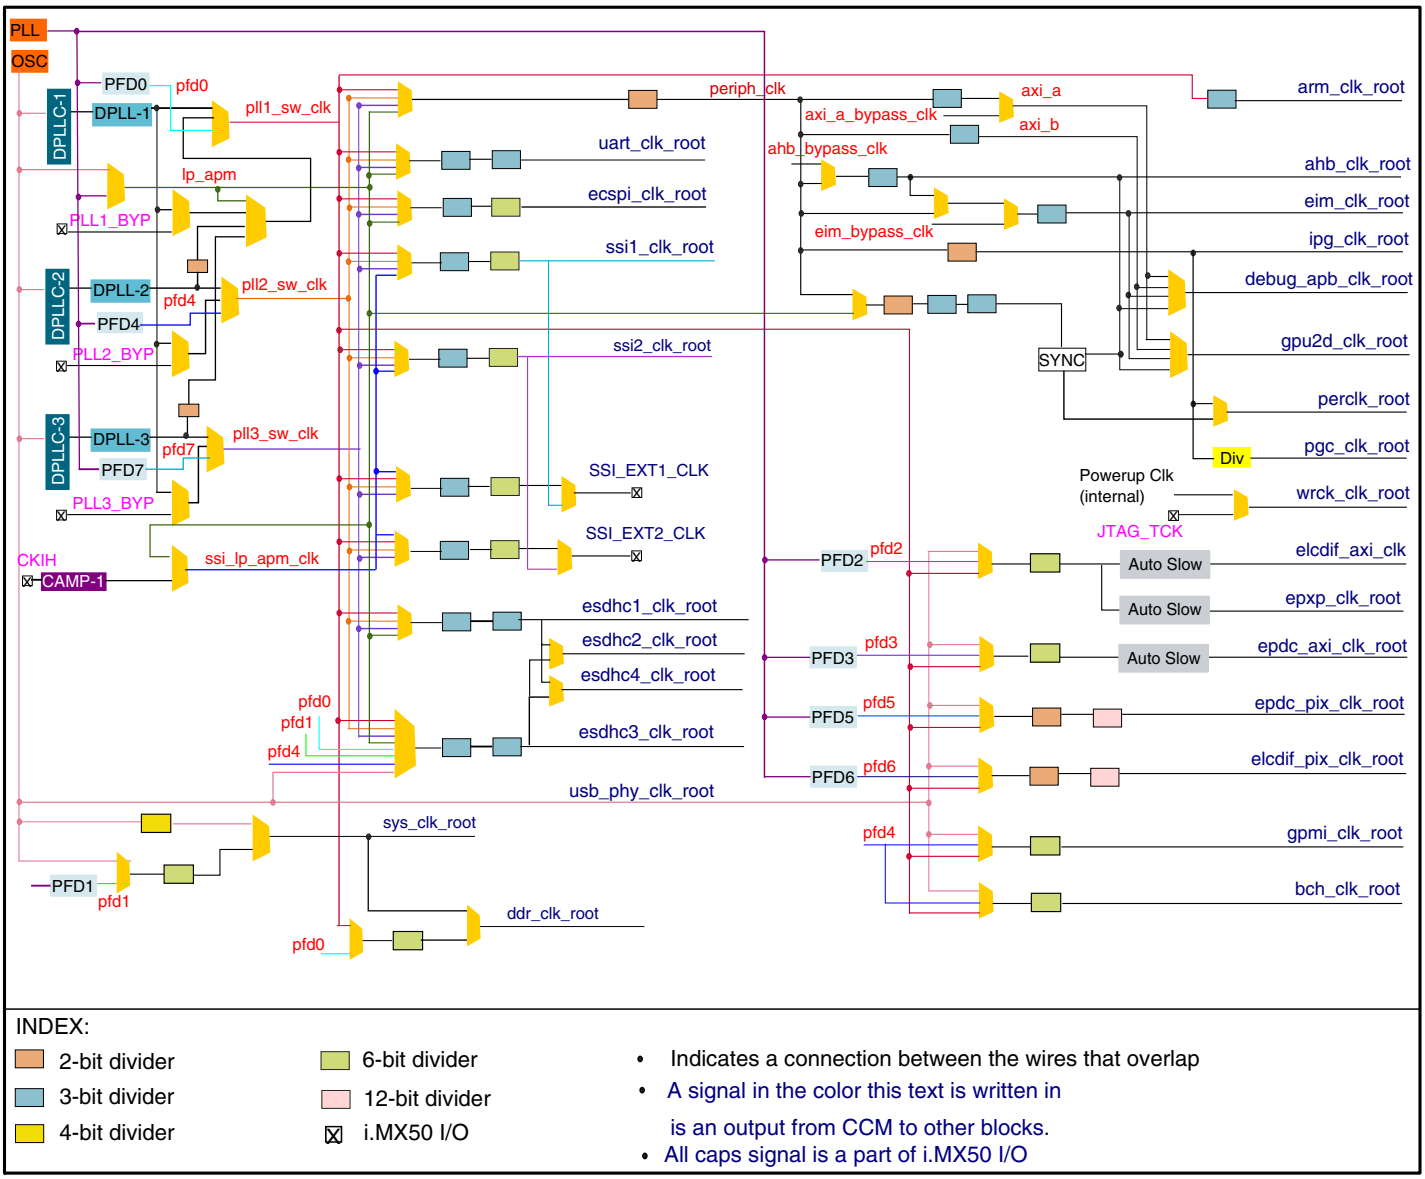

Figure 5-1. High Level Clock Tree Diagram

5.1.1 Overview

The Clock Controller Module controls the following functions in i.MX50:

- Uses the available clock sources to generate root clocks for various parts of the chip.
- Uses programmable bits to control frequencies of the clock roots.
- Controls the low power mechanism.
- Provides control signals to LPCG sub-block for gating clocks.
- Provides handshake with SRC for reset performance.
- Provides handshake with GPC for support of DVFS, DPTC and power gating operations.

5.1.2 Features

The CCM includes the following features:

- Clock switcher module to generate three switcher source clocks based on four PLLs.
- Root clocks generation—provides root clocks to i.MX50's modules based on three switcher source clocks.
- ARM core root clock generated from dedicated switcher source clock.
- Includes separate dividers to control generation of core and bus root clocks .
- Includes separate dividers and clock source selectors for each serial root clock.
- Option for external clocks to bypass PLL clocks.
- Selects clock signals to output on CLKO and CKOH on to the pads for observability.
- Controllable registers are accessible through IP bus.
- Manages the Low Power Modes, namely RUN, WAIT, and STOP. The peripheral clock gating is programmable in RUN and WAIT modes.
- Manages frequency scaling procedure for ARM core clock by shifting between PLL sources, without loss of clocks.
- Manages frequency scaling procedure for peripheral clock roots by programable divider. The dividing is done on the fly without loss of clocks.
- DFT feature support.
- Interface for the following IPs
    - PLLC—PLL Controller interfaces for each PLL on the IC.
    - LPCG—Low Power Clock Gating unit
    - SRC —System reset Controller
    - GPC—General Power Controller

5.1.3 CCM Block Diagram

CCM includes the following submodules:

CCM_CLK_IGNITION

Manages the ignition process. This sub-block starts its functionality once CCM comes out of reset. It manages the process that begins with starting the CAMPs, PLLs and finishes with creation of stable output root clocks after reset.

CCM_CLK_SWITCHER

This sub-block receives the clock outputs of the three PLLs, together with the bypass clocks for three PLLs , and generates three switcher clock outputs (pll1_sw_clk, pll2_sw_clk, pll3_sw_clk) for the ccm_clk_root_gen sub-block.

CCM_CLK_ROOT_GEN

This sub-block receives the three switcher clocks and generates the output root clocks.

CCM_CLK_LOGIC

This sub-block generates the clock enables based on information from CCM_LPM and CCM_IP. The clock enables are used by LPCG to turn off and on the split-ed clocks.

CCM_LPM

This sub-block manages the low power modes of the IC.

CCM_REG

This sub-block manages the memory map of CCM. It holds the programmable registers and the connectivity to the IP bus. This module is connected to all the sub-blocks that need definition of programmable bits. Note that in the diagram below it appears to be connected only to the ccm_clk_logic sub-block.

CCM_HND_SK

This sub-block manages the handshake when changing root clock dividers that require handshake, and manages the frequency change in case of DVFS scenario.

CCM_CLK_PUSM

This sub-block manages the powerup clock and asynchronous chip_reset_n for the CCM and OCOTPC block

Figure 5-2 describes the CCM boundary.

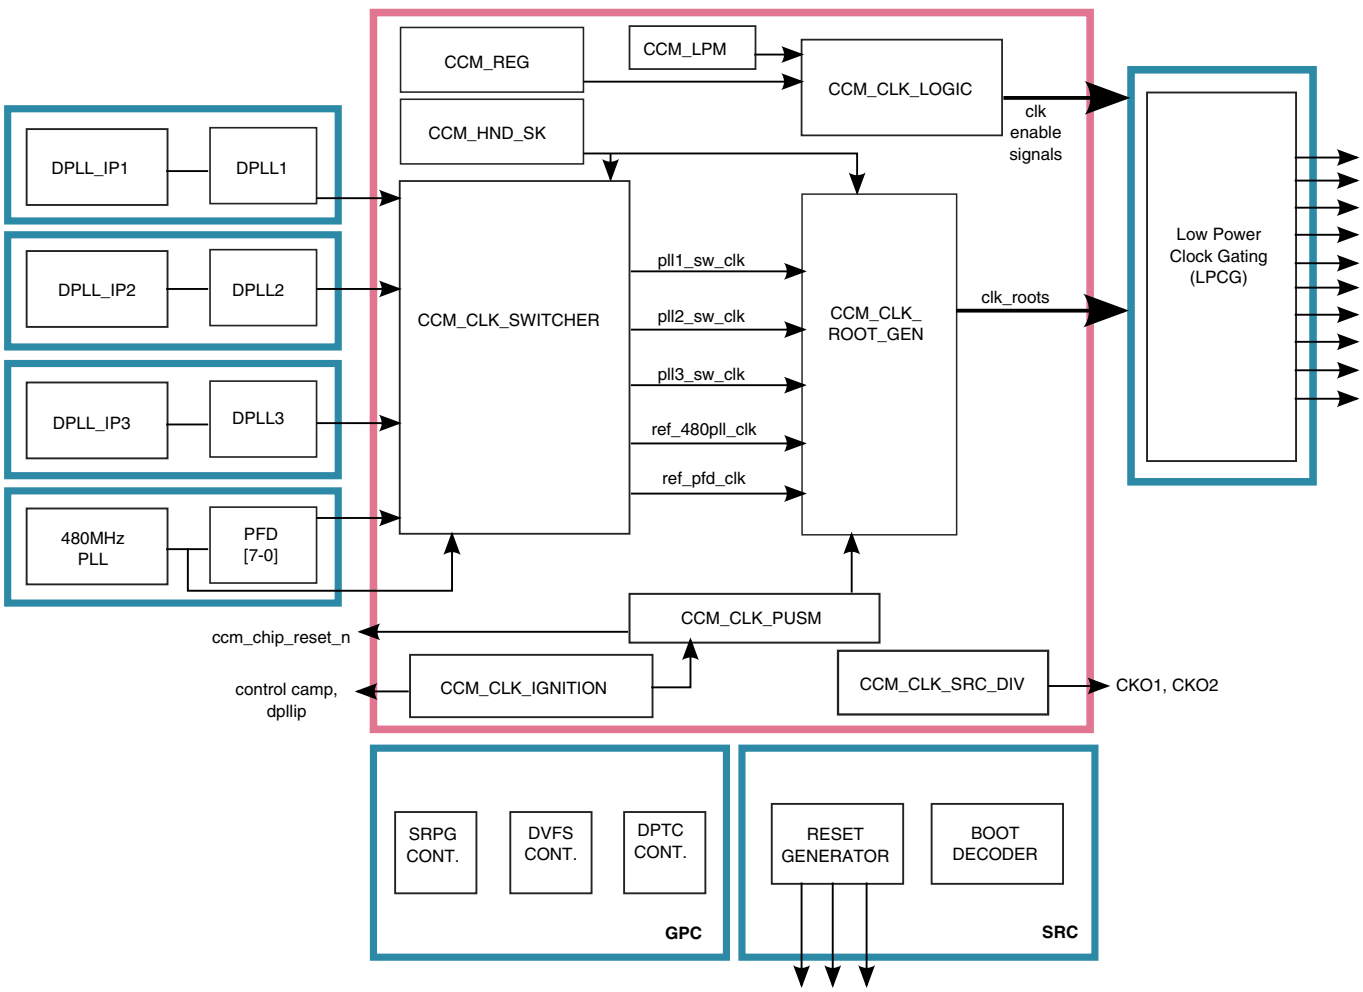

Figure 5-2. Block Diagram

5.2 CCM External Signals Description

Table 5-1 describes the input / output signals of CCM module:

Table 5-1. Signal Descriptions

Signal	I/O	Description
init_ahb_podf	I	SJC PODF values for AHB
init_ipg_podf	I	SJC PODF values for IPG
init_axi_a_podf	I	SJC PODF values for AXI_A

Table continues on the next page...

Table 5-1. Signal Descriptions (continued)

Signal	I/O	Description
init_axi_b_podf	I	SJC PODF values for AXI_B
init_weim_podf	I	SJC PODF values for EIM
init_perclk_pred2	I	SJC PODF values for PERCLK
init_perclk_podf	I	SJC PODF values for PERCLK
init_pll1_sw_sel	I	SJC values for PLL1 mux select
init_periph_clk_sel	I	SJC values for PERIPH mux select
init_ssi_apm_clk_sel	I	SJC values for SSI_APM mux select
osc_clk	I	24MHz clock input
ahb_bypass_clk	I	Bypass clock for ahb root clock
axi_a_bypass	I	Bypass select for AXI A root clock
axi_a_bypass_clk	I	Bypass clock for AXI A root clock
weim_bypass	I	bypass of input of eim clock divider
weim_bypass_clk	I	clock for bypass of input of eim clock divider
shd_current_state [1:0]	O	clock shutdown state machine current state
arm_debug_clk_enable	O	lpcg clkgate enable for debug_apb_clk_root
debug_apb_clk_root	O	DEBUG APB root clock
ecspi_clk_root	O	ECSPI root clock
gpu2d_clk_root	O	GPU2D root clock
display_axi_clk_root	O	root clock
sys_clk_root	O	root clock
gpmi_clk_root	O	root clock
bch_clk_root	O	root clock

5.3 Functional Description

5.3.1 Clock Generation

Clock frequency selection for some domains can be a function of multiple reference clock sources and divide parameters that are set in the CCM control registers. The most extreme case is using a PLL or PFD source, a multiplexer that selects either the osc_clk (24 MHz xtal), PLL or PFD clock as a source to drive the clock divider, and the divide value for the clock divider itself. When programming a selected frequency, the sequence

of events to achieve a given frequency must maintain the integrity of the system as a whole. During a clock system context switch, intermediate clock frequencies for selected domains cannot be faster than the sub system or I/O interface it is designed to support.

5.3.1.1 External Low Frequency Clock—CKIL

The i.MX50 can use either a 32 kHz, 32.768 kHz or a 38.4 kHz crystal as the external low frequency source. Throughout this chapter, the low frequency crystal is referred to as the 32 kHz crystal. CMOS input buffer with Schmitt trigger feature is used as receiver of 32 kHz clock. This clock source should be active all the time the i.MX50 is powered on. The 32 kHz entering the CCM is referred as CKIL. It is synchronized to ipg_clk and supplied to blocks that require it.

5.3.1.2 External High Frequency Clock—CKIH and Internal Oscillator

The i.MX50 uses an internal oscillator (OSC) to generate the reference clock. The internal oscillator will be connected to an external crystal. The oscillator generates frequencies in the range of 24 MHz.

Moreover, i.MX50 uses a CKIH input pin to generate special serial clock demands (like eLCDIF, ePDC, SSI1 and so on) as a backup to the PLL clocks.

5.3.1.3 DPLL Reference Clock

There are three DPLLs in i.MX50 project named:

- PLL1 (typical functional frequency 800 MHz)
- PLL2 (typical functional frequency 400 MHz)
- PLL3 (typical functional frequency 216 MHz)

Each DPLL is controlled by a DPLLC interface block. Each DPLLC uses the 24 MHz osc_clk as a reference.

5.3.1.4 Analog PLL Reference Clock

There is a fixed 480 MHz PLL that feeds eight independent Phase Fractional Dividers (PFDs). The PFDs allow multiple fractional clocks to be generated from one PLL without the trouble of relocking the PLL each time. There is a specific startup sequence that must be performed when powering up the PLL.

1. The TZIC_DSMINT[DSM] bit must be set before powering up the PLL.

2. After the 50us lock counter indicates lock, the DSM bit is then cleared and at least 10us extra time must be waited before using the output of the PLL.

After the fixed 480 MHz PLL has been enabled and locked after 50us counter indicates pll lock, each PFD can be programmed to a target frequency of f (MHz) = (480 × 18) / N; where N = PFD*X*_FRAC with a range from 18 to 35.

The control registers for the fixed 480 MHz PLL and 8 PFDs are located in the analog digital control module. For programming convenience to setup the clocks, the register descriptions for the 480 MHz PLL and 8 PFDs are shown in CCM_ANALOG.

5.3.1.5 CCM Internal Clock Generation

The clock generation is comprised of three submodules:

- CCM_CLK_SWITCHER
- CCM_CLK_IGNITION
- CCM_CLK_ROOT_GEN

5.3.1.5.1 CCM_CLK_SWITCHER

CCM_CLK_SWITCHER sub module receives the pll output clocks and the pll bypass clocks. It generates 3 main switcher clocks to be delivered for CCM_CLK_ROOT_GEN:

- pll1_sw_clk (typical functional frequency 800 MHz—used to supply ARM platform)
- pll2_sw_clk (typical functional frequency 400 MHz—used to supply AXI/AHB/IP buse clocks)
- pll3_sw_clk (typical functional frequency 216 MHz—used to supply serial clocks like USB, SSI, and so on)

Figure 5-3 describes the generation of the three switcher clocks. The figure also includes Frequency Switch Control sub-block that is responsible for frequency change during DVFS scenario.

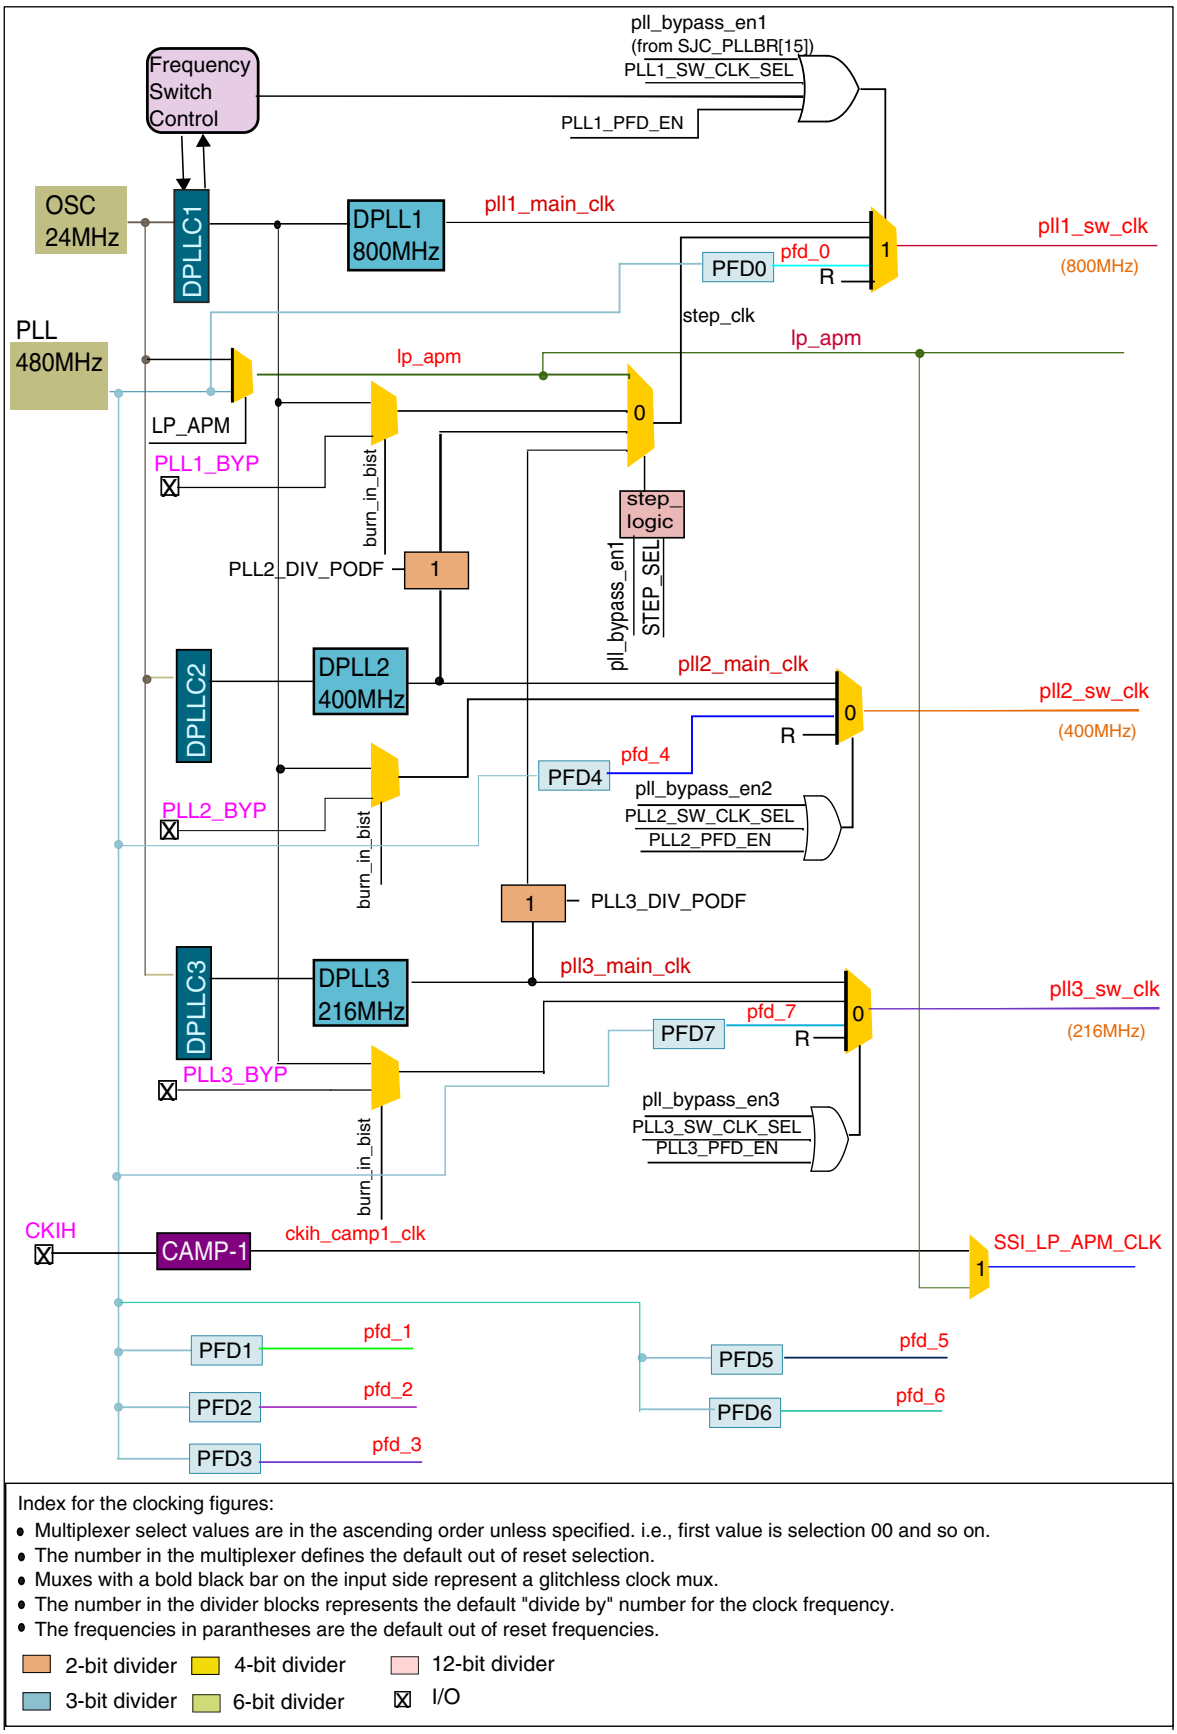

Figure 5-3. Switcher Clock Generation

5.3.1.5.2 PLL Bypass Procedure

CCM_CLK_SWITCHER sub-block includes the capability for each of the pll*x*_main_clk's to be bypassed with an external bypass clock to supply the pll*x*_sw_clk outputs an external bypass clock. In burn_in_bist mode the PLL bypass clocks for all PLLs will be supplied from pll1_ref_clk (the output of DPLLC1).

The decision to shift from pll_main_clk to pll_bypass_clk is done either by programable bits in CCSR or by pll_bypass_en signals which are driven from the jtag module. Since the switch between the clocks are done by a glitch less multiplexer, then both pll_main_clk and pll_bypass_clk should be running to complete the shift without a glitch. In case the selection is programmed in reset by jtag, then both clocks do not need to be active.

There are 4 bypass clock options for pll1_sw_clk. Since the pll1_sw_clk bypass clock is selected from a standard cell mux, changing the CCSR[STEP_SEL] selection should only be done when the glitch less clock multiplexer is selecting the PLL1 reference clock via CCSR[PLL1_SE_CLK_SEL].

5.3.1.5.3 DPLLC Reference Clock Connectivity

For all four DPLLCs:

- The clock2 input port is connected to the 24 MHz osc_clk.
- The input init_dp_ctl_dpllip [8] is connected to gnd.
- The input init_dp_ctl_dpllip [9] is connected to vcc.

The above connections allows DPLLC to choose the 24 MHz osc_clk as the default reference clock to the DPLL. Out of reset, software may select the clock0 input, CKIH, as an alternate reference clock source.

NOTE

clock1 and clock3 are unconnected for the i.MX50.

5.3.1.5.4 PLL Clock Change

The following sequence should be followed when changing the PLL source, frequency or DPLL reference clock for downstream dividers:

1. All active downstream dividers should either be gated off or moved to an alternate PLL source via glitchless clock multiplexers.
2. Reprogram the respective DPLLC:
   a. Configure DPLLC-n_CONFIG[1] to auto restart the PLL on the next update of the reference clock.

b. Configure DPLLC-n_CTL[8:9] to change the reference clock multiplexer.
c. Configure the DPLL divide values.

3. After the DPLLC is reprogrammed, the DPLLC will generate a sticky signal DPLLCx_CTL[LRF] (pll lock) to the CCM. Based on the CCM_CIMR[2:0] settings, the PLL lock may generate a software interrupt.
4. If needed, reprogram downstream dividers to handle the new PLL frequency.
5. Switch downstream dividers back to the updated PLL and if needed, enable the downstream divider clocks.

5.3.1.5.5 CCM_CLK_IGNITION

The responsibility of the ccm_clk_ignition sub-block is to manage the wake up after reset of the on chip oscillator, CAMP1, DPLLC and DPLL blocks. Its task starts with de-assertion of early_reset from the Reset controller (SRC). Its task finishes with assertion of signal that notifies the reset controller that the root clocks are ready.

Figure 5-4 describes the connectivity of ccm_clk_ignition sub module.

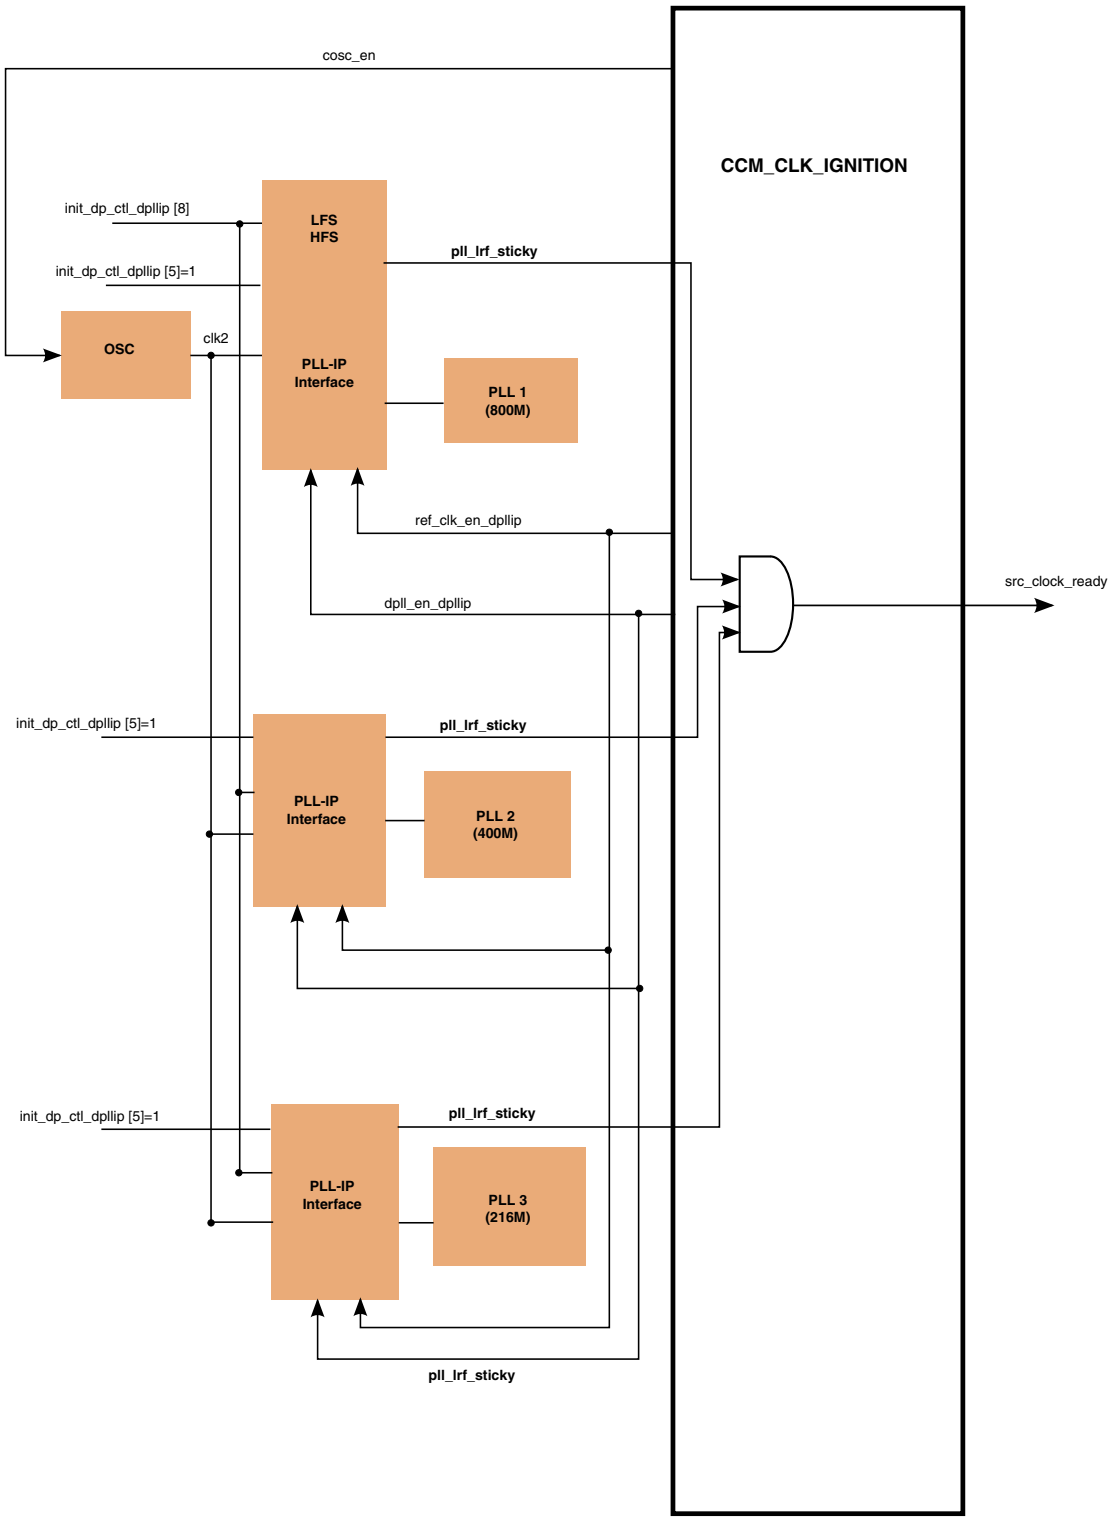

Figure 5-4. Connectivity of ccm_clk_ignition Sub Module

The 24 MHz oscillator will be used as the default reference for all of the system PLLs in the design.

Out of reset, the CCM_CCR[COSC_EN] signal will be asserted and CCM_CLPCR[COSC_POWERDOWN] will remain deasserted to start the on board oscillator. The external oscillator and camps will also be enabled during the ignition process: CCM_CCR[CAMP1_EN] = 1 and CCM_CSR[REF_EN_B] = 0 so that the ckih_camp1 clock will be started. Next ccm_clk_ignition will count the number of 32 kHz CKIL cycles defined by CCM_CCR[OSCNT] bit field. Once the counter has elapsed, it is assumed that the 24 MHz osc_clk and the ckih_camp1 clock are both ready. In this stage CCM will assert the CCM_CSR[COSC_READY] and CCM_CSR[CAMP1_READY] bits. At this time, the ccm_clk_ignition will also assert the start_pusm bit to the powerup state machine in the CCM.

With the PLL's disabled out of reset, the ccm_clk_ignition will generate the src_clock_ready signal after the assertion of COSC_READY to indicate to the SRC module that the oscillator clocks are ready.

Upon arrival of src_clock_ready signal to reset controller, the reset sequence will continue. In parallel with the memory repair mode of the SRC, the CCM's clk_pusm sub-block will execute it's startup sequence, see CCM_CLK_PUSM Reset Sequence. Following the completion of the clk_pusm sequence the SRC reset sequence will run to completion. Review SRC spec for details on this sequence.

5.3.1.5.6 CCM_CLK_PUSM Reset Sequence

A unique aspect is that the system reset clock is shared with the system scan clock. All registers throughout the design see a clock at 6 MHz during power up and system reset. A state sequence begins when the start_pusm bit goes active. The state sequence is as follows:

1. chip_reset_n deassert, functional clock select disabled to select system wide synchronous 6 MHz clock. Functional clock sources are gated off.
2. Propagate 32 power-up clock cycles to propagate reset through the system.
3. Disable the 6 MHz system reset clock generator.
4. Wait # number of xtal clock cycles.
5. De-assert the asynchronous reset, chip_reset_n
6. Wait # number of xtal clock cycles
7. With the reset clock low, reset inactive and functional clock sources gated off (logic low0, switch the multiplexor to select functional clock sources (which are still gated low also).
8. Wait # number of xtal clock cycles.

9. De-assert the clock gate which allows the functional clocks to start at the selected frequency.
10. Continue SRC reset sequence.

5.3.1.5.7 Reset Values for DPLLC

Reset values which are hard coded into the dpll-ip are:

- PLL1—initial value = 208 MHz
- PLL2—initial value = 208 MHz
- PLL3—initial value = 182 Mhz

These frequencies correspond to reference clock source of the 24 MHz on chip oscillator as the source of the DPLL.

5.3.1.5.8 Analog 480 PLL and PFD

The CCM has the ability to use the analog fixed 480 MHz PLL and eight independently programmable PFDs as reference clock sources. The frequency of the PFD can be calculated as follows:

- Freq = (480 × 18) / N; where N = 18 – 35.

5.3.1.5.9 CCM_CLK_ROOT_GEN

CCM_CLK_ROOT_GEN sub-block generates the root clocks to be delivered to LPCG.

The following is a list of the root clocks generated by this module. The clocks are supposed to be asynchronous unless mentioned differently:

- ARM_CLK_ROOT — Generated from pll1_sw_clk.
- WEIM_CLK_ROOT
- AHB_CLK_ROOT
- IPG_CLK_ROOT — Divide by 2 of the AHB_CLK_ROOT. This clock is edge-aligned and balanced with the AHB_CLK_ROOT.
- PERCLK_ROOT — This clock is synchronized and balanced to AHB_CLK_ROOT. For the synchronization process , perclk predivider and podf should generate a clock frequency 2.5 times slower than the AHB clock. In peripheral DVFS scenario, when AHB's frequency is reduced, perclk frequency should be configured to be remain 2.5 times slower than the minimum value of ahb_clk (the DVFS value of ahb_clk).
- PGC_CLK_ROOT—Generated as a division of ipg_clk and balanced to it.
- CKIL_SYNC_CLK_ROOT—When not in stop mode, the ckil clock is synchronized to the IPG_CLK_ROOT and balanced with it. In stop mode, the synchronizer is bypassed and ckil_sync_clk_root is driven by the raw ckil clock.

- DDR_CLK
- ESDHC1_CLK_ROOT
- ESDHC2_CLK_ROOT
- ESDHC3_CLK_ROOT
- UART_CLK_ROOT
- SSI1_CLK_ROOT
- SSI2_CLK_ROOT
- SSI_EXT1_CLK—Connected to external pad
- SSI_EXT2_CLK—Connected to external pad
- USB_PHY_CLK_ROOT
- ECSPI_CLK_ROOT
- WRCK_CLK_ROOT
- EPDC_PIX_CLK_ROOT
- ELCDIF_PIX_CLK_ROOT
- EPDC_AXI_CLK_ROOT
- DISPLAY_AXI_CLK_ROOT
- SYS_CLK
- GPMI_CLK_ROOT

Figure 5-5 and Figure 5-6 describe the above clocks generation. The frequencies in parentheses are the default typical frequencies.

NOTE

Muxes with a bold black bar on the input side represent a glitchless clock multiplexer.

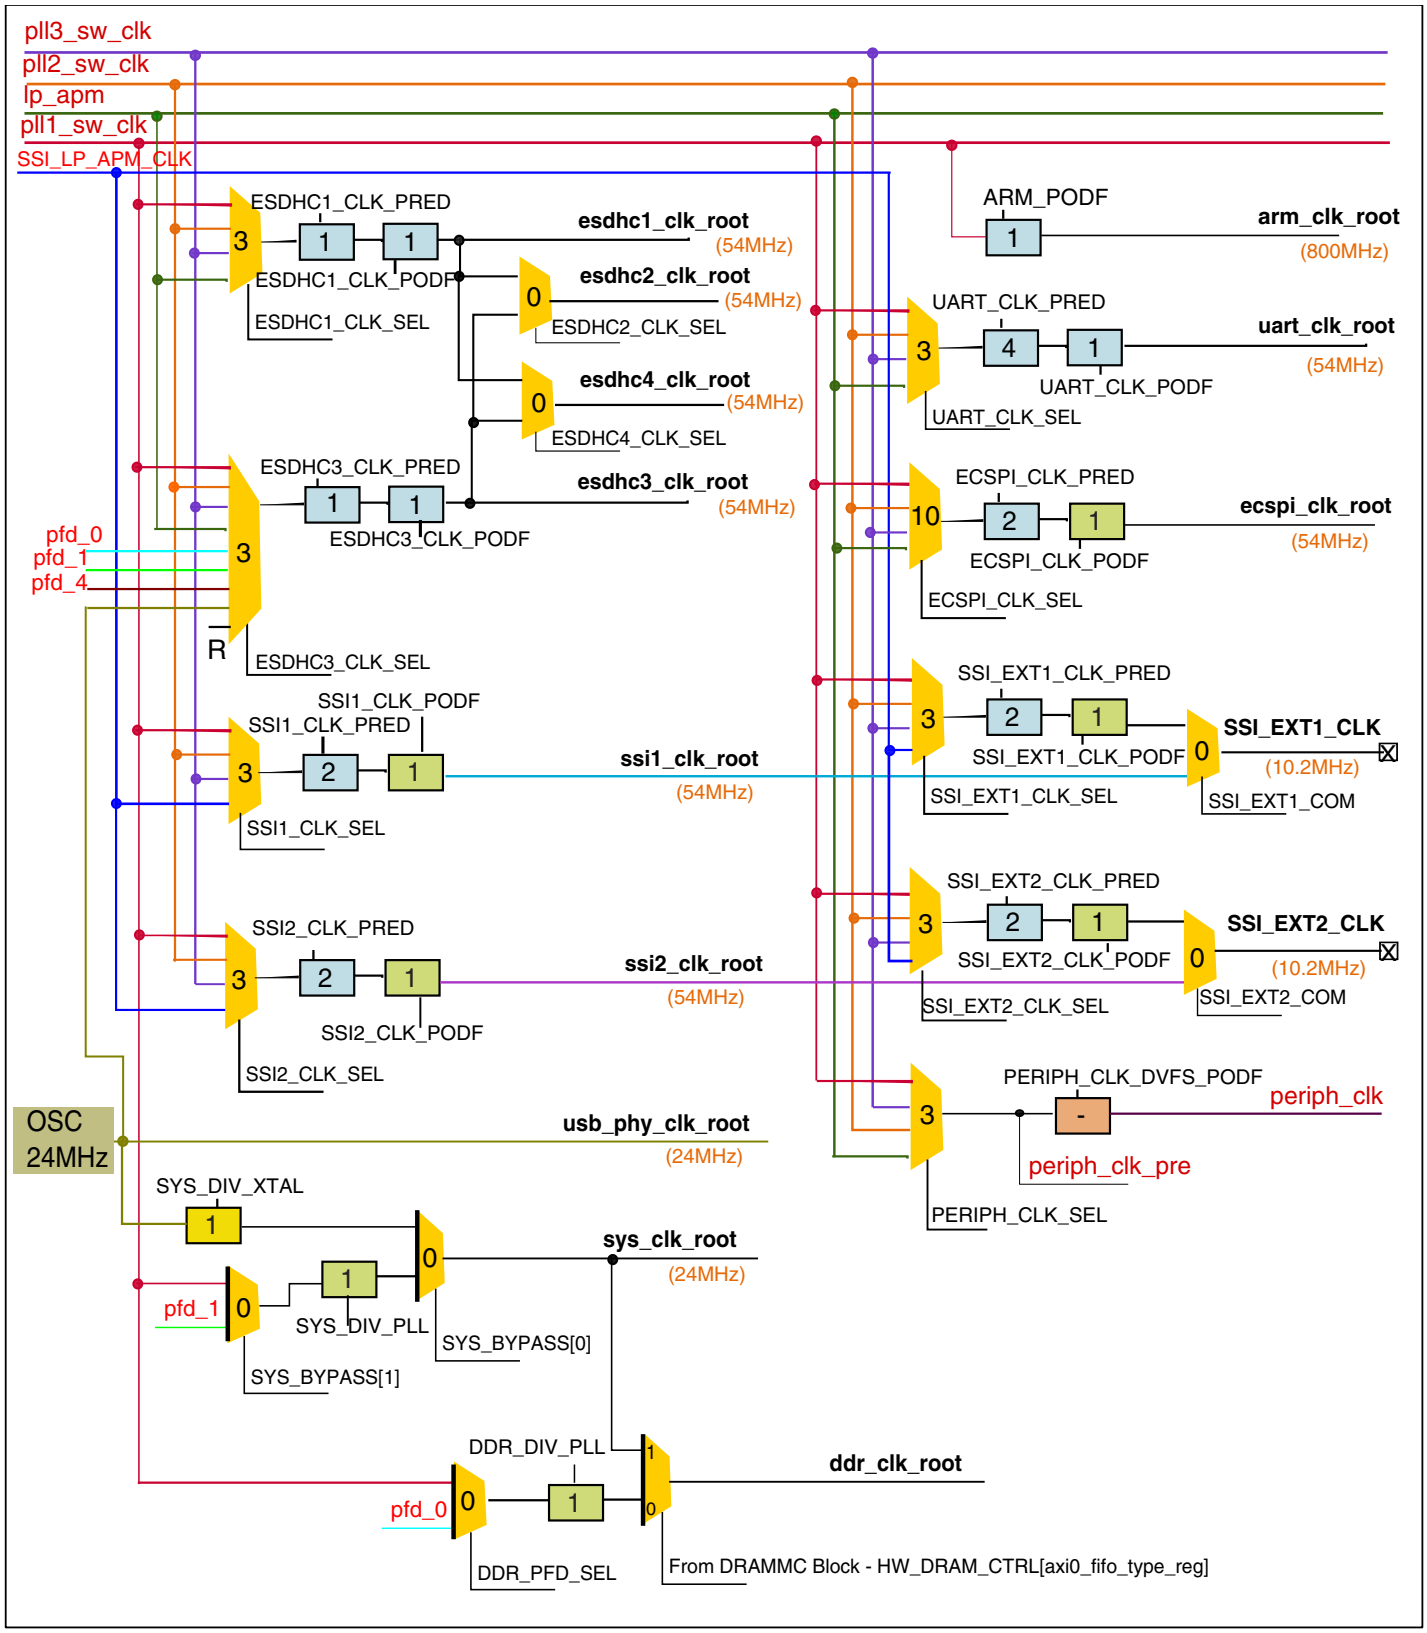

Figure 5-5. Root Clock Generation

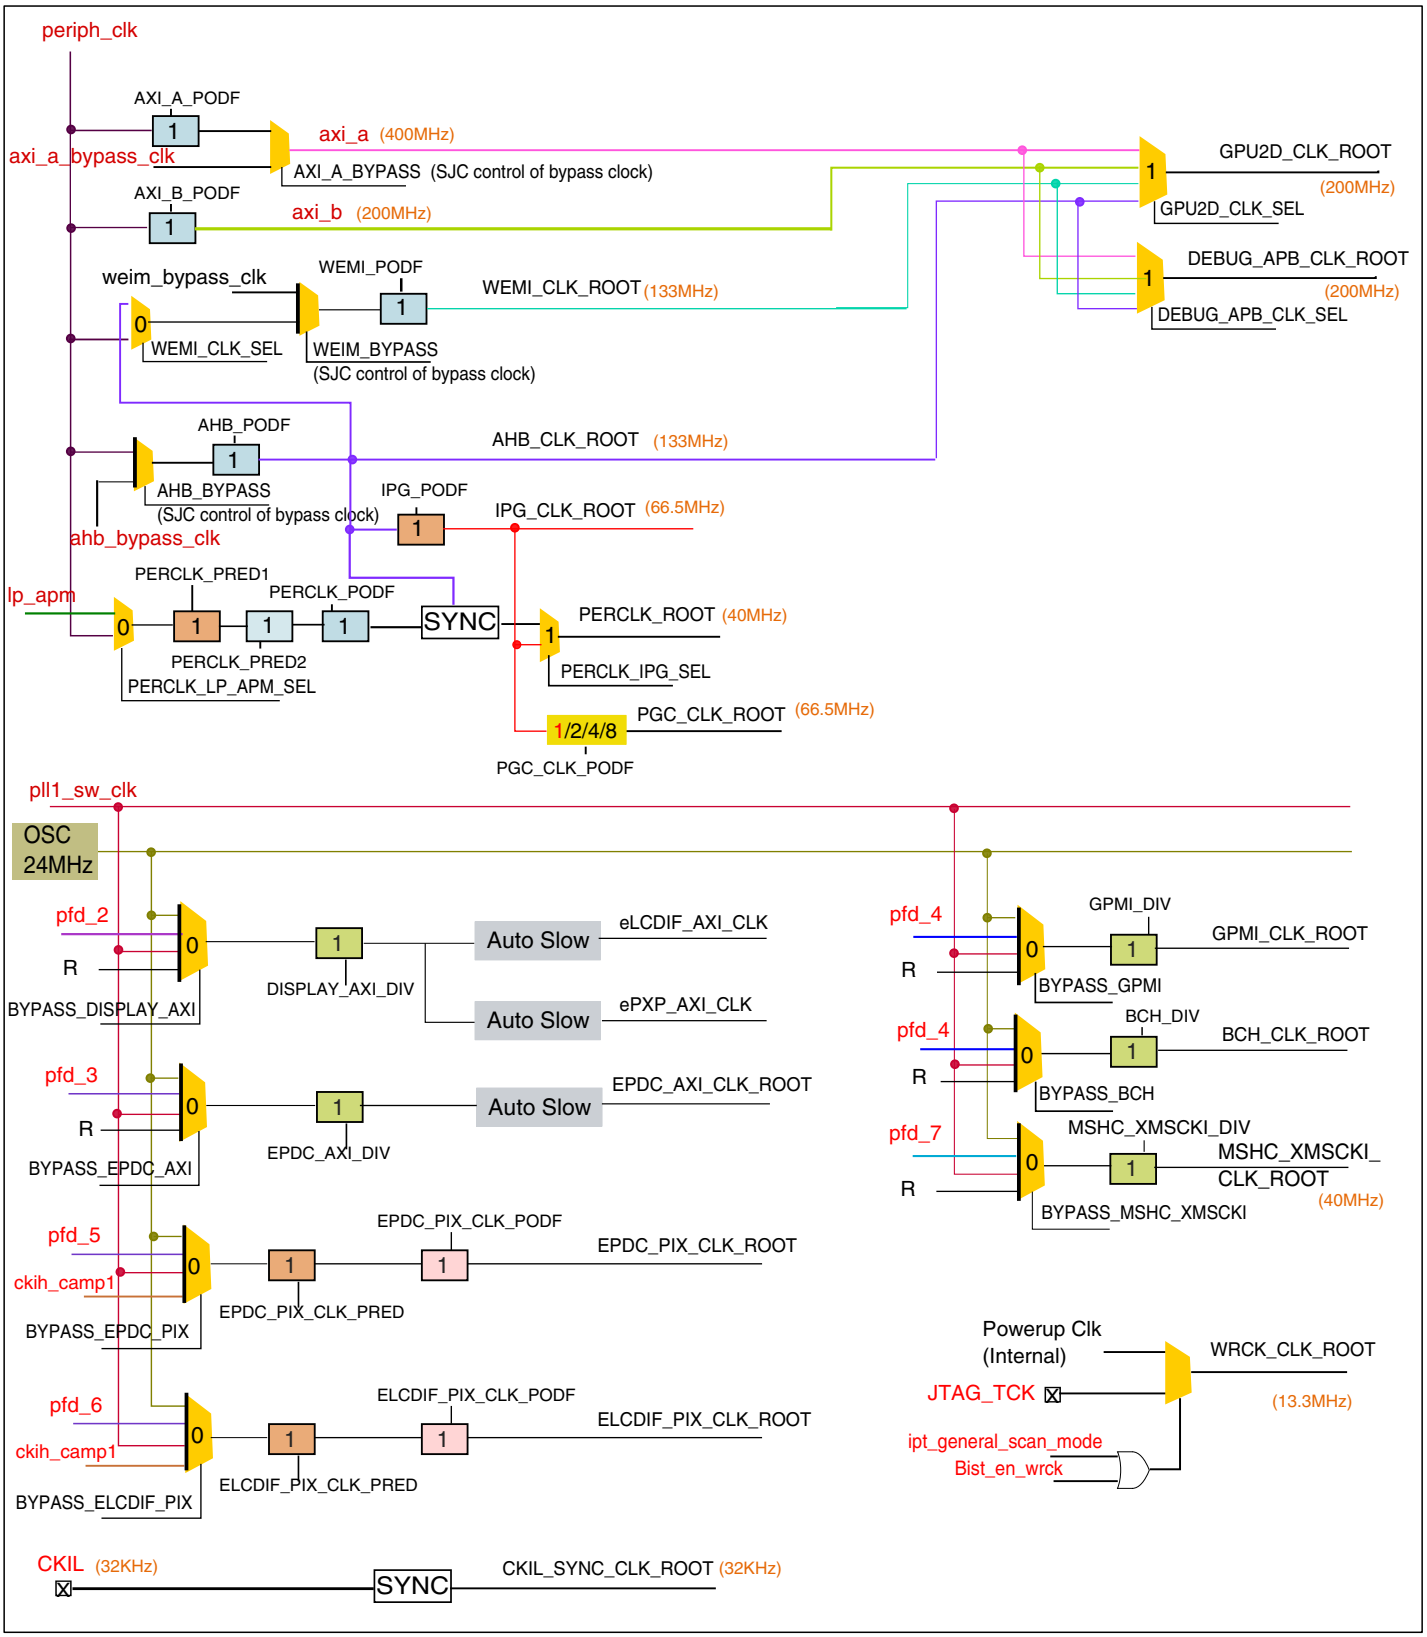

Figure 5-6. Root Clock Generation (cont)

NOTE

The following pre dividers should use divider values larger than '1'. The option '000' is not allowed for them: SSI1_CLK_PRED, SSI2_CLK_PRED, SSI_EXT1_CLK_PRED, SSI_EXT2_CLK_PRED, ECSPI_CLK_PRED.

5.3.1.5.10 Initial Reset Values Controlled by SJC

The control register reset values of the following dividers and muxes are controlled by the jtag module (SJC). These reset values are programmable. In normal operation, the SJC will drive the reset values stated in the CCM register memory map. If the SJC is programmed to change those values, then the "programmed" values will be applied to the control registers during system reset. Table 5-2 shows the control signals and the dividers/muxes.

Table 5-2. SJC Init Control

init Signal	Control Reset Value for Divider or mux
init_perclk_pred[1:0]	perclk_pred1 divider
init_perclk_pred2[2:0]	perclk_pred2 divider
init_perclk_podf[2:0]	perclk_podf divider
init_ipg_podf[1:0]	ipg_podf divider
init_ahb_podf[2:0]	ahb_podf divider
init_axi_a_podf[2:0]	axi_a_podf divider
init_axi_b_podf[2:0]	axi_b_podf divider
init_weim_podf[2:0]	weim_podf divider
init_pll1_sw_sel	pll1_sw_sel mux
init_periph_clk_sel[1:0]	periph_clk_sel mux
init_ssi_apm_clk_sel[1:0]	ssi_apm_clk_sel mux

5.3.1.5.11 Divider Change Handshake

For the i.MX50, the hardware modules the CCM handshaked with on the previous i.MX designs were removed. To maintain compatability with the previous designs, the state machine has been retained, but the acknowledge from the modules have been replaced with a single cycle wait state.

Divider	Handshake with Module	Comment
weim_podf	—	NA

Table continues on the next page...

Divider	Handshake with Module	Comment
axi_a_podf	—	NA
axi_b_podf	—	NA
ahb_podf	—	NA

Once the CCM_CBCDR register is updated, CCM will check which of the above dividers was updated. For the updated dividers, CCM will perform the frequency change. The signal, periph_dvfs_sw_ack, is held for two clock cycles of ipg_clk on each divider change.

Since there are no blocks to handshake with, a write to the respective divider will commence immediately after the CCM_CBCDR register is updated.

Interrupts can be generated for each of the above divider changes. Refer to CCM_CISR register for details on those interrupts.

In addition, the CCM has divider handshake in process register (CCM_CDHIPR). This register has status bits for each of the above dividers that are involved in the handshake process. When the respective bit is asserted, it means that the divider is being updated. During the update, software should not attempt to write to this divider until the respective CCM_CDHIPR bit is de-asserted. Any reads of the divide value during the update will reflect the new value being applied to the divider. To guarantee that software reads the actual dividers value, reads should be performed after the respective CCM_CDHIPR bit is de-sasserted.

NOTE

When DVFS is enabled (through GPC), software should not "manually" change the control register divide value because this might corrupt the handshake process. The frequency of the system should be setup prior to enabling the DVFS.

Dividers without hardware handshake:

For dividers with non-glitchless clock muxes, software needs to ensure that and downstream clocks are gated off before changing multiplexer settings because there is no hardware handshake for changing multiplexer settings to prevent glitching the clock.

Likewise, the multiplexers of the AXI buses that are controlled by CCM_CBCDR register are not glitchless clock muxes, the reference clock should not be switched on the fly. Software should make sure that any downstream clock branches are gated off before changing the multiplexer configuration.

5.3.1.5.12 CKIL Synchronizing to ipg_clk

CKIL is synchronized to ipg_clk when system is in functional mode. When system is in stop mode, that is, when there is no ipg_clk, the CKIL synchronizer will be bypassed, and raw ckil will be supplied to the system.

5.3.1.6 DPLL's Disabling/Enabling

PLL disabling and enabling is done via DPLLC block. Software should first move all the clocks generated from a specific PLL to another PLL, before disabling the PLL through DPLLC. This move of clocks can be done via glitch less multiplexer for clocks which are critical to the system, that is, bus clocks. For serial clocks, software should first disable the downstream modules and gate off the respective clock branch. Next, switch the mux controlling the source of the clocks to another PLL, and finally start back the module and its clocks. Only when the PLL is not being used as a reference clock source is it safe to disable the PLL.

5.3.1.7 Observability Output Signals

CCM has three mux's to generate critical signals to the IO PADS for observability. The three MUX outputs are connected to the three CCM outputs named obs_output_0, obs_output_1, obs_output_2. The three MUX's are controlled via CCM_CTOR register.

It is possible to generate also the obs_input_0, obs_input_1, obs_input_2, obs_input_3, obs_input_4 and obs_input_5 to the external pads through the MUX's controlled by CCM_CTOR. This allows to observe the signals connected to those 6 CCM input pins. Below list describes the signals connected for observability to those input pins:

- obs_input_0 connect to DPLLC1 : dpllip_cpen
- obs_input_1 connect to DPLLC1 : dpllip_cpres
- obs_input_2 connect to DPLLC1 : dpllip_crstrt
- obs_input_3 connect to DPLLC1 : dpllip_load_req
- obs_input_4 connect to DPLLC2 : dpllip_cpen
- obs_input_5 connect to DPLLC3 : dpllip_cpen

5.3.1.8 Low Power Clock Gating Module (LPCG)

The LPCG sub-block receives the root clocks and splits them to clock branches for each block. The clock branches are gated clocks. The enables for those gates can come from six sources:

1. Clock enable signal from CCM—this signal is generated by configuration of the CCGR bits in CCM control register map.
2. Clock enable signal from the module—this signal is generated by the module based on internal logic of the module. For clock enable signals from the module that are used, the CCM will generate an override signal based on a CCM CMEOR control register bit.
3. Clock enable signal from Reset controller (SRC)—this signal will enable the clock during the reset procedure. Please refer to SRC spec for details on the clock enable signal during reset procedure.
4. Hard coded enable from fuse box.
5. Enable or disable clock on bist mode, based on bist_en signal. This will be applicable for clocks that are not functional and needed only on memory repair or bist sequence (like sms_clk's and wrck).
6. Auto-slow mode enable from CCM.

The enable sources are AND'ed to generate the enable signal for the gating cell.

In order to prevent glitches on the gated clock, the enable signal for the gating cell is synchronized with the clock it needs to gate.

Feedback signals are generated for the CCM, to indicate when to gate on/off the clock roots. All feedback signals that correspond to the same clock root will be OR'ed to generate one notification signal to CCM for clock root gating.

Figure 5-7 describes the implementation for each gating cell.

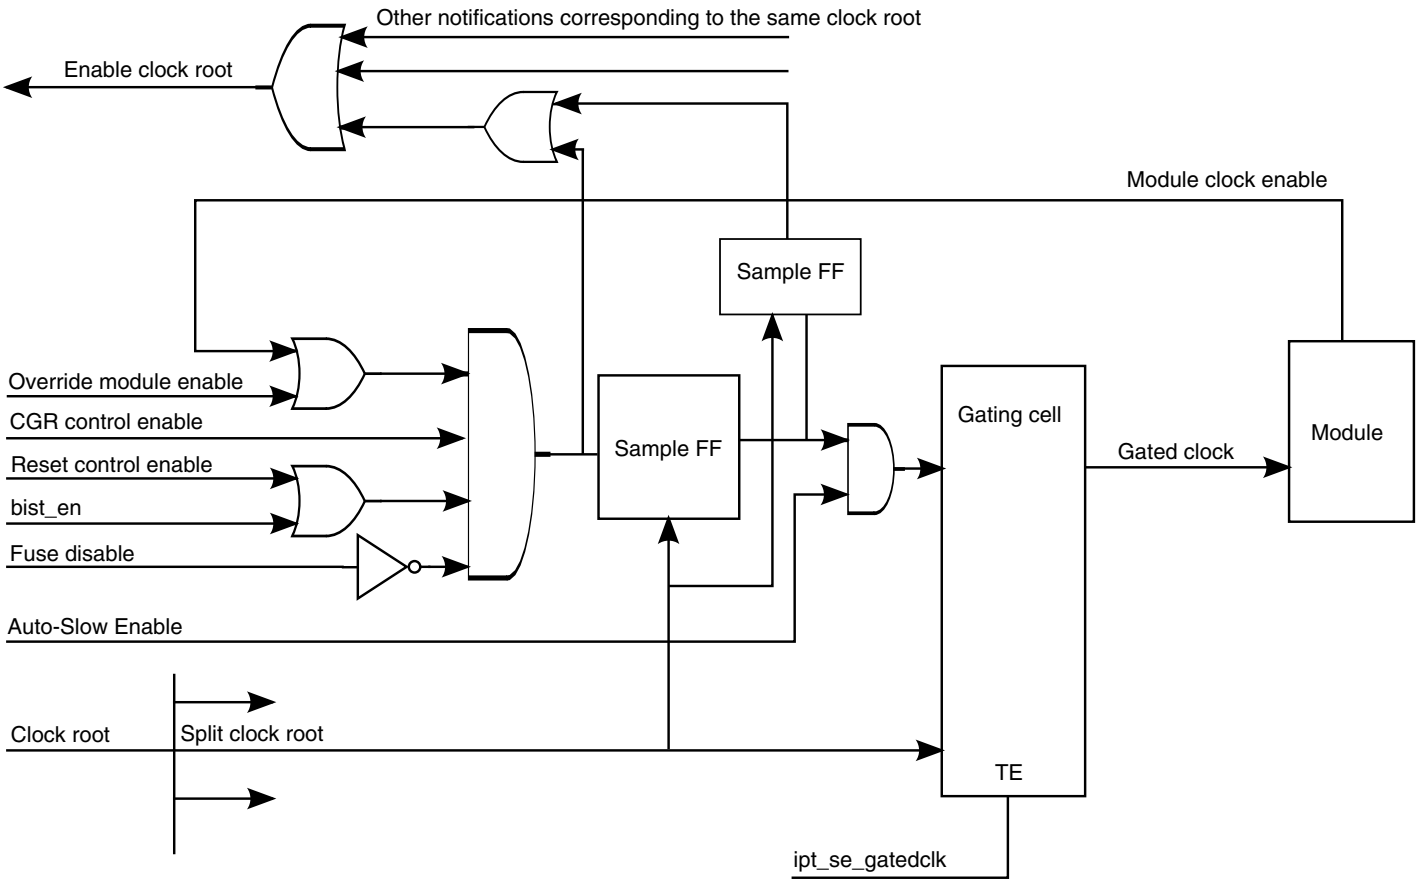

Figure 5-7. Implementaion of Gating Cell

Figure 5-8 describes the clock split inside LPCG sub-block. It describes the case of 2 blocks, one block without an enable signal and one with an enable signal. (SRC enable signals and sync FF's are omitted from this figure).

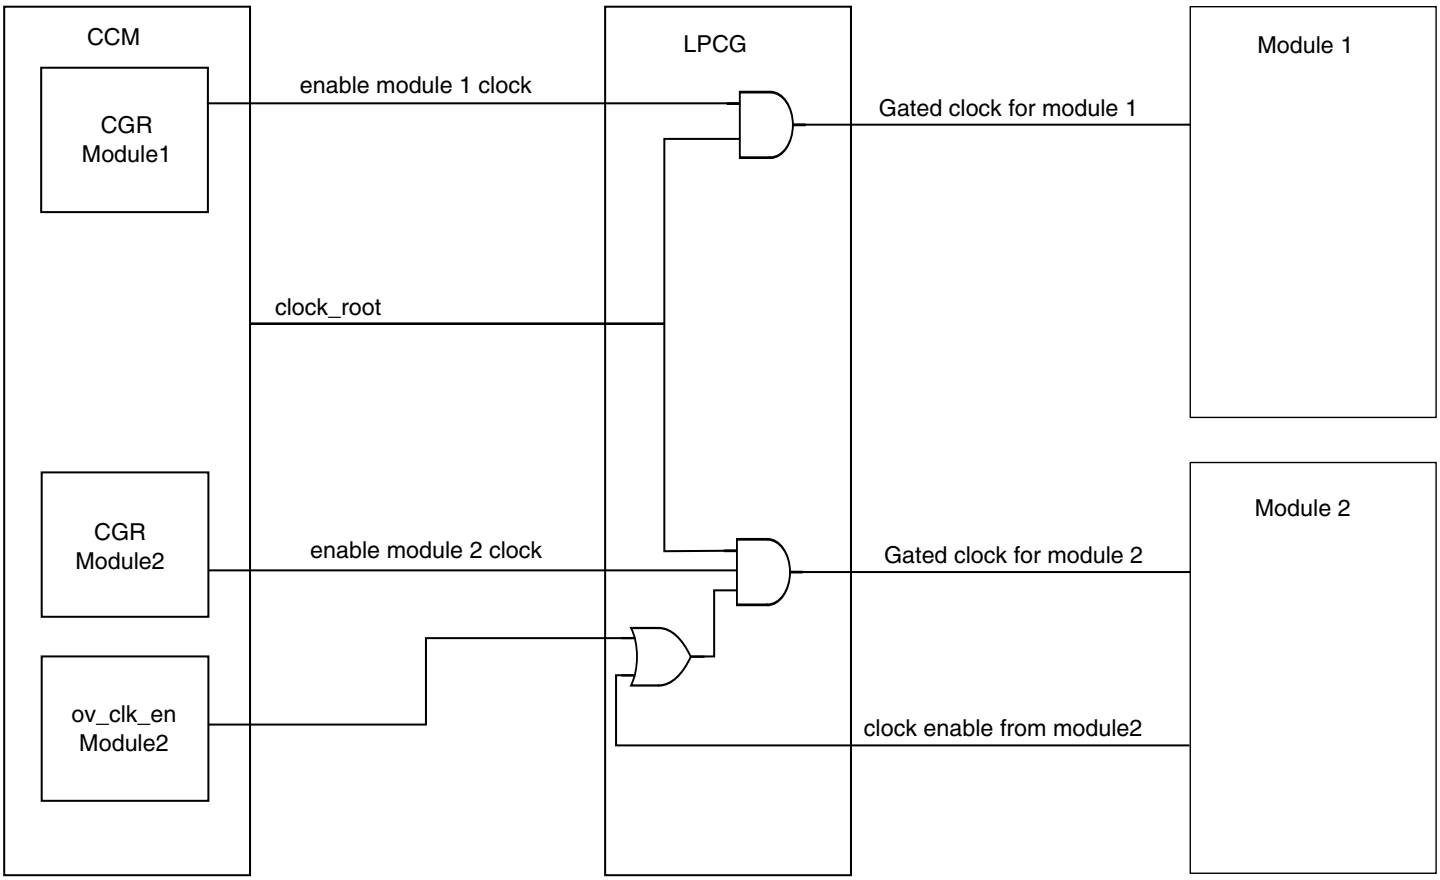

Figure 5-8. Clock Split in LPCG

5.3.2 DVFS Support

Dynamic frequency changing in the i.MX50 can be done on two domains:

1. ARM clock domain frequency change
2. Peripherals clock domain frequency change (including buses)

The General Power Controller (GPC) will initiate the DVFS procedure. It will initiate only one frequency change at a time. There is not an option to commence both of the DVFS domains simultaneously. The GPC will be aided by SDMA and CCM to execute the frequency change.

5.3.2.1 ARM Clock Domain Frequency Change

The SDMA can request an ARM frequency change by dividers, or by PLL1 re-lock.

The following steps will be configured by SDMA:

1. SDMA can request ARM frequency change by dividers, or by PLL1 relock. This request will be written to CCM_CDCR[ARM_FREQ_SHIFT_DIVIDER] bit:
   a. ARM_FREQ_SHIFT_DIVIDER = 0: PLL1 relock shift is requested.
   b. ARM_FREQ_SHIFT_DIVIDER = 1: ARM_PODF divider shift is requested. In this case any new writes to ARM_PODF will be held until arm_clk_switch_req signal is asserted. The CCM holds a status bit to notify that the arm_podf divider being updated. Software should wait until the write finishes before writing any new value to arm_podf. Pease refer to CCM_CDHIPR register for details on the status bit. The CCM can also generate an interrupt once the actual arm_podf has been written in the DVFS scenario. Please refer to CCM_CISR register for details.

      SDMA will continue with next steps only if (ARM_FREQ_SHIFT_DIVIDER = 0: PLL1 relock shift is requested).
2. Check which frequency mode is active in DPLLIP1, HFS or LFS: DPLLIP bit HFSM of DP_CTL register.
3. Configure the non active frequency mode (HFS or LFS) of DPLLIP1, with the new frequency needed for PLL1 to relock on: DPLLIP1 registers DP_OP, DP_MFD, DP_MFN, DP_HFS_OP, DP_HFS_MFD, DP_HFS_MFN.
4. Configure the step frequency divider: CCM CCSR register, bit pll2_div_podf or pll3_div_podf (depending on the decision in the step mux in step 5).
5. Configure the step frequency mux: CCM bit step_sel of CCM_CNT register.

Once the configuration is completed, the SDMA will notify the GPC to continue with the frequency change procedure.

The actual frequency change will start by the assertion of the arm_clk_switch_req signal from the GPC to the CCM.

The CCM will start the following steps when the arm_clk_switch_req signal is asserted:

If ARM_FREQ_SHIFT_DIVIDER = 1 dividers shift is requested):

1. Load the ARM domain new divider values.
2. After loading the divider (all counters in 0), assert clk_switch_ack for 2 ipg cycles as an acknowledge to the GPC that the frequency has been updated.

If ARM_FREQ_SHIFT_DIVIDER = 0 (PLL1 relock shift is requested):

1. Switch to the step frequency by a glitchless clock mux.
2. After the glitchless clock mux has changed to the step frequency, invert pll_lvs signal to DPLLC-1 so that PLL1 will lock on the new frequency.
3. When the pll_lrf_sticky1 is asserted switch back to DPLL1 with the glitchless mux.

4. After the glitchless clock mux has switched, assert clk_switch_ack for 2 ipg cycle as an acknowledge to the GPC that frequency has been updated.

When the clk_switch_ack is asserted, the GPC will de-assert the arm_clk_switch_req signals.

At this point, the ARM has changed frequency and system is ready for a new frequency switch procedure.

Figure 5-9 shows the ARM DVFS Connectivity.

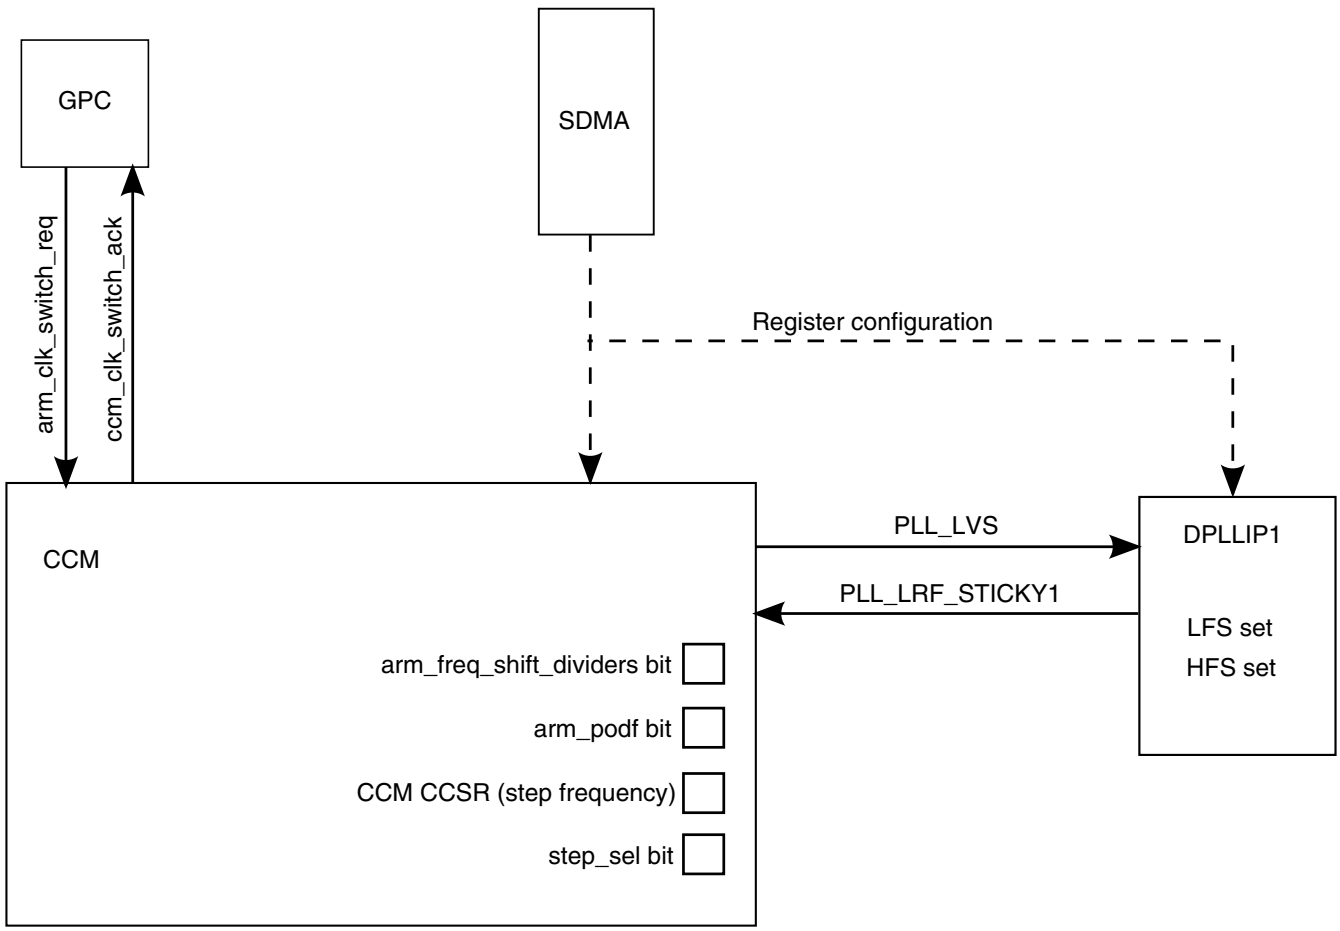

Figure 5-9. ARM DVFS Connectivity

5.3.2.2 Peripheral Clock Domain Frequency Change

The CCM includes the capability to slow the peripheral bus clock by divide down by 2/3/4. This will affect the root of bus clocks: ahb, axi, ipg, weim_clk. The actual division factor is defined by bits in CCM_CDCR[1:0]. The software is expected to set those bits

prior to enabling DVFS operation. The value written to the DVFS register divider (CCM_CDCR[1:0]) will not be loaded immediately to the divider, but will wait until the peripheral DVFS procedure commences.

While in the DVFS scenario, the root clocks which are not affected by DVFS divider should be generated from a low frequency pll. This frequency should not be higher than 240 MHz. Software can use pll3 with a frequency of 216 MHz for this operation. Note: Prior to the DVFS clock change, some modules with a root clock that will be slowed down, may need to be re-configured with new control register values for proper operation.

Divide by 2/3/4 procedure (lowering frequency):

1. In the CCM control register, write the new peripheral divide value.
2. Enable peripheral DVFS.
3. The GPC will assert the periph_clk_div_req signal to the CCM.
4. The CCM will switch to the new peripheral divide value as long as the GPC asserts the periph_clk_div_req.
5. When the GPC de-asserts the periph_clk_div_req, the periph divider will switch back to divide by

NOTE

The DVFS operation can also start by software controlling the sw_periph_clk_div_req. In this case, the GPC control will be ignored and the ccm_clk_switch_ack will not be asserted.

There is no need to synchronize the 4 dividers for the DVFS change since they work on asynchronous clock domains.

5.3.2.3 Peripherals Restrictions in DVFS Scenario

In the DVFS scenario for peripherals, ipg and ahb clocks are divided from their nominal frequency.

The serial dividers in the low voltage case, should use a low frequency PLL input (below 300 MHz) to work correctly.

Table 5-4 describes restrictions that need to be followed to support the DVFS frequency shift:

Table 5-4. DVFS Restrictions

Module	Support	Restriction
R—Modules that will work with restriction		

Table continues on the next page...

Table 5-4. DVFS Restrictions (continued)

Module	Support	Restriction
UART	R	Need to configure uart rate to be low_frequency_ipg_clk/16. Hence rates of 1.875 M and 4 M cannot be reached in DVFS scenario.
ESDHC	R	Need to configure the AHB clock to be faster than the SD Card clock.
SSI	R	Master clock should be generated from ssi_ext1 and ssi_ext2 pads.
CSPI	R	Need to configure spi rate to be low_ipg_clk/4.
N—Modules that will not work		
USB_PHY	N	Needs ipg_clk>60 MHz. Hence will not work under DVFS scenario
FEC	N	Needs ipg_clk>50 MHz. Hence will not work under DVFS scenario

5.3.3 Auto-Slow Mode

The output of the Auto-Slow Mode logic will be referred to as the clk_asm clock domain. The reference clock will be referred to as the int_ref_clk. The clk_asm branches of the int_ref_clk domain is gated by an instantiated ICG that uses a counter in the int_ref_clk domian to enable/disable the clk_asm branch based on a divide value programmed in the clk_asm fast divide register. This is the mechanism that provides the desired frequency on the clk_asm domain with respect to the int_ref_clk domain.

A dynamic power management mechanism that further divides the clk_asm branch is also provided and throttled based on system activity. An asm_enable value of 0 disables this feature and the clk_asm frequency will be as programmed in the clk_asm divide register. When the asm_enable register is not 0, then this feature is enabled.

When a system component is busy and needs full throughput on the clk_asm branch, its busy signal is asserted. The clk_asm branch will then assume the clock rate indicated by the clk_asm divide register. When the system component is not busy, it will deactivate its busy signal.

5.3.4 Power Modes

The i.MX50 supports 3 low power modes: RUN mode, WAIT mode and STOP mode.

5.3.4.1 Run Mode

This is the normal/functional operating mode. In this mode the ARM runs in its normal operational mode. The frequency and voltage can be changed upon dvfs scenario as described in DVFS Support. Clocks to the modules can be gated by configuring the corresponding CCM_CCGR bits.

5.3.4.2 Wait Mode

In this mode the ARM clock is gated. All other clocks are functional and can be gated by programing their CCGR bits. Power gating can be done on the ARM platform.

5.3.4.2.1 Wait Mode Procedure

The wait mode procedure is as follows:

1. The ARM will write to CCM_CLPCR[LPM] bit to set it for WAIT mode.
2. The ARM will write to DSM_INT_HOLDOFF bit in TZIC.
3. The TZIC_DSMINT[DSM] (DSM Interrupt Hold off) assertion forces the interrupt controller to stop the synchronizer clock for incoming interrupts. Any interrupts that had previously been synchronized by the interrupt controller will remain asserted.
4. If a wakeup event occurred or an interrupt was serviced or is pending, the ARM platform may abort the DSM sequence by exiting the main shutdown code sequence and returning to the desired security mode.
5. If not the software should execute the Wait For Interrupt (WFI) instruction.
6. Upon execution, the WFI instruction will cause the ARM to drain its write buffers and enter a quiescent state. At this point the ARM will assert the STANDBYWFI signal.
7. The ARM platform will then wait until the L2 cache controller has become inactive. Once the L2 is inactive and the ARM platform's STANDBYWFI output is asserted, the ARM platform will assert the ARM_DSM_REQUEST signal to the CCM.
8. The CCM will continuously synchronize both the ARM_DSM_REQUEST and the TZIC_DSM_WAKEUP inputs into the clock domain used by its internal state machine.
9. If the TZIC_DSM_WAKEUP is negated and the ARM_DSM_REQUEST is asserted, the CCM will begin the WAIT shutdown sequence:
10. The CCM will stop the ARM clock. (soc_mxclk input to the ARM will be gated only if the respective CCM_CCGR defines to gate it in WAIT mode).
11. Stop of the ARM clock will take place only if CCM_CLPCR[5]=1 and debug_arm_clk_off_on_lpm=0 (connected to sjc register SJC_GPUCR3[15]). If either CLPCR[5]=0 or debug_arm_clk_off_on_lpm=1 then the ARM clocks will not be gated off and the CCM will continue to next step.

12. The CCM will generate the ccm_ipg_wait to indicate that it has started the wait procedure.
13. The CCM will request an acknowledge to close clocks of SDMA, RNGP and AHBMAX if their CCM_CCGR bits indicate to close their clocks in wait mode and if their clocks were not already closed in run mode. The request will be issued if the handshake is not bypassed by programing the CCM_CLPCR[23:16]. If the corresponding bits are set, then the request signal will not be issued to the corresponding module and the CCM will not wait for its acknowledge in the process of entering low power mode. The requests will commence via the following signals:
    - SDMA,RNGB: sdma_ipg_stop_req and rngb_ipg_stop_req
    - EIM: weim_lpmd - this request will be asserted based on the definition of CCM_CCGRs.

NOTE

Since EIM needs the aclk_fast (eim clock) to be running for it to answer with weim_lpmd, then software should make sure to turn on the aclk_fast (weim_clk) before entering any low power mode that requests the weim_lpmd.

    - AHBMAX: ahbmax_halt_req
    - Once the above modules finish their operation and are ready to enter low power mode, they acknowledge the CCM that its safe to turn of their clocks. The acknowledge signals are as follows:
    - SDMA,RNGB: sdma_ipg_stop_ack and rngb_ipg_stop_ack
    - EIM: weim_lpack
    - AHBMAX: ahbmax_halt_ack
14. The requests will be generated by the CCM in stages. CCM will continue from stage to stage once all the acknowledges of a present stages were received. The stages are the following:
    - Stage 1: SDMA
    - Stage 2: AHBMAX
15. Once the CCM receives all the acknowledge signals needed, and if at least 8 ipg_clk cycles have elapsed since the assertion of ccm_ipg_wait signal, then it will enter wait mode and do the following:
    - Close the clocks to the blocks which were defined to be shut at WAIT mode in the CCM_CCGR bits.
    - Assert system_in_wait_mode signal. This signal is connected to the IO pads for observability, to indicate wait mode is active.

Once the CCM is in WAIT mode, it will check if the TZIC_DSM_WAKEUP signal has been asserted or if the ARM_DSM_REQUEST has been negated during the process of entering wait mode. If this has occurred, then the CCM will exit wait mode.

If the TZIC_DSM_WAKEUP is not asserted and ARM_DSM_REQUEST is still asserted, then the CCM will move to the state SRPG_ARM and generate a request to the GPC to power down the ARM platform and GPU2D by asserting signals ccm_pdn_4arm_req and ccm_pdn_4all_req. If those modules are defined to be powered down on wait mode in the GPC, then the GPC will commence powering them down. Please refer to the Figure 5-10 diagram. The GPC will send a pdn_ack at the end of the power down sequence.

The CCM's low power state machine will remain in the state "SRPG_ARM" until the wait mode is exited.

5.3.4.2.2 Exiting Wait Mode

As soon as the synchronized TZIC_DSM_WAKEUP signal is asserted or the ARM_DSM_REQUEST is negated, the CCM will begin the process of exiting WAIT mode.

1. Enable GPU2D clocks only.
2. CCM will request the GPC to restore power. The CCM will assert the ccm_pup_req to request to the GPC to power up the ARM platform if it was powered down on the entrance to wait mode.
3. The GPC will notify the CCM by asserting the signal PUP_ACK to indicate power to the ARM is restored, and its safe to exit from WAIT mode. Only then will the CCM do the following:
4. Once the SRC has asserted the src_power_gating_reset_done to indicate completion of reset to the power gated modules, negate the low power request signals to all modules and enable all modules clocks including the ARM clocks and return to run mode based on their CCGR values.
5. Once the system is in run mode, the CCM will negate the ccm_ipg_wait and system_in_wait_mode.
6. Once the interrupt propagates through all the synchronization logic, the ARM platform will recognize and service it. This will force the negation of the ARM_DSM_REQUEST output. Prior to this point, both the ARM_DSM_REQUEST and TZIC_DSM_WAKEUP were asserted. Since the TZIC_DSM_WAKEUP has top priority, the system is able to wake up.

Before the ARM exits the ISR, it will clear the interrupt source. This will cause the TZIC_DSM_WAKEUP signal to be negated. At this point, the two low power control signals (TZIC_DSM_WAKEUP and ARM_DSM_REQUEST) are negated, and the WAIT sequence can be repeated at any time.

5.3.4.3 Stop Mode

In this mode all system clocks are stopped, the PLL's are stopped and power gating can be done on the ARM platform.

5.3.4.3.1 Entering Stop Mode

The Stop mode is entered by the following procedure:

1. The ARM will write to the CCM_CLPCR[LPM] bit to set it for stop mode.
2. The ARM will write to the TZIC_DSMINT[DSM] (DSM interrupt hold off) bit.
3. The DSM assertion forces the interrupt controller to stop the synchronizer clock for incoming interrupts. Any interrupts that had previously been synchronized by the interrupt controller will remain asserted.
4. If a wakeup event occurred or an interrupt was serviced or is pending, the ARM platform may abort the DSM sequence by exiting the main shutdown code sequence and returning to the desired security mode. If not the software should execute the Wait For Interrupt (WFI) instruction.
5. Upon execution, the WFI instruction will cause the ARM to drain its write buffers and enter a quiescent state. At this point the ARM will assert the STANDBYWFI signal.
6. The ARM platform will then wait until the L2 cache controller has become inactive. Once the L2 is inactive and the ARM platform's STANDBYWFI output is asserted, the ARM platform will assert the ARM_DSM_REQUEST signal to the CCM.
7. The CCM will continuously synchronize both the ARM_DSM_REQUEST and the TZIC_DSM_WAKEUP inputs into the clock domain used by its internal state machine.The only time those signals will not be synchronized is when the pll's will be disabled. In this case exiting from stop mode will be done asynchronously (please refer to the section below describing the exit from stop mode).

If the TZIC_DSM_WAKEUP is negated and the ARM_DSM_REQUEST is asserted, the CCM will begin the STOP shutdown sequence:

1. The CCM will stop the ARM clock.
2. The CCM will generate the ccm_ipg_stop to indicate that it has started the stop procedure.
3. The CCM will request an acknowledge to gate off the SDMA, RNGB and AHBMAX clocks if their clocks were not already gated off in run mode. The stop request to these modules will be issued if the handshake is not bypassed by programing the CCM_CLPCR[23:16]. If the corresponding bits are set, then the request signal will not be issued to the corresponding module and CCM will not wait for its acknowledge in the process of entering low power mode. The requests will commence via the following signals:

- SDMA,RNGB: sdma_ipg_stop_req and rngb_ipg_stop_req
- EIM: weim_lpmd

NOTE

Since EIM needs the aclk_fast (weim clock) to be running for it to answer with weim_lpmd, then software should make sure to turn on the aclk_fast (weim_clk) before entering any low power mode that requests the weim_lpmd.

- AHBMAX: ahbmax_halt_req
- Once the above modules finished their operation and are ready to enter low power mode, they acknowledge CCM that its safe to turn of their clocks. The acknowledge signals are as follows:
- SDMA,RNGB : sdma_ipg_stop_ack and rngb_ipg_stop_ack
- EIM: weim_lpack
- AHBMAX: ahbmax_halt_ack

The requests will be generated by CCM in stages. CCM will continue from stage to stage once all the acknowledges of a present stages were received. The stages are the following:

- Stage 1: SDMA, RNGB
- Stage 2: AHBMAX

Once CCM receives all the acknowledge signals needed, and if at least 8 ipg_clk cycles have elapsed since the assertion of the ccm_ipg_stop signal, then it will enter stop mode and do the following tasks in the order they are written below:

- Gate off the system block clocks, not including pgc_clk. The clock gating will include the ckil_sync clocks of Megamix (all blocks except ARM, DPLL and GPU) only if the indication from GPC is that Megamix is about to be powered down (by megamix_power_down indication). The gating signal output for the CKIL sync gating cell is gate_ckil_sync.
- Assert the system_in_stop_mode signal. This signal is connected to the IO pads for observability, to indicate stop mode is active.

Once the CCM is in STOP mode, it will check if the TZIC_DSM_WAKEUP signal has asserted or if the ARM_DSM_REQUEST has negated during the process of entering stop mode. If this has occurred, then the CCM will exit stop mode.

If the TZIC_DSM_WAKEUP is not asserted and the ARM_DSM_REQUEST is still asserted, then the CCM will move to state STOP_GPC and generate a request to the GPC to power down the ARM platform and the GPU2D by asserting the signals ccm_pdn_4arm_req and ccm_pdn_4all_req. If those modules are defined to be powered down on stop mode in the GPC, then the GPC will commence powering them down.

After powering down the modules, the GPC will send the pdn_ack signal and the following will take place:

- Shut down the PLLs and DPLLCs by de-asserting dpll_en_dpllip and ref_clk_en_dpllip.
- After de-assertion of the lock ready flag from the PLL's, close the CAMP by de-asserting ccm_camp1_en.
- If the CCM_CLPCR[SBYOS] bit was set, then de-assert the CCM_CSR[REF_EN_B] signal to close the external oscillator and assert the CCM_CLPCR[COSC_POWERDOWN] to put on the board oscillator in power down mode. (if they were not already closed by software. If one of them was already closed by software then discard the SBYOS operation for it and perform the SBYOS operation only on the one that is working. If both of them were closed in run mode , then discard SBYOS operation for both of them).
- If the CCM_CLPCR[VSTBY] bit was set, then assert the pmic_vstby_req signal, to indicate to the power management IC to shift the voltage to standby voltage.

The CCM's low power state machine will remain in the state "STOP_GPC" until the stop mode is exited.

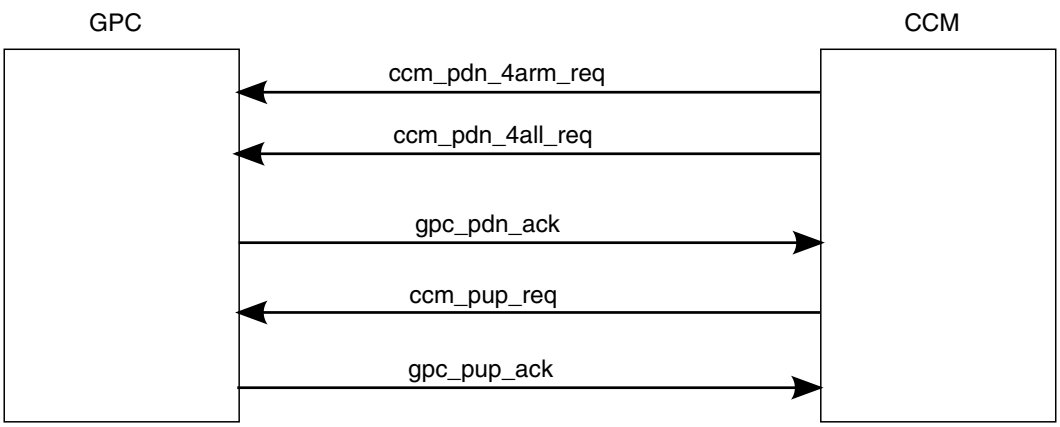

Figure 5-10. CCM-GPC Connectivity

5.3.4.3.2 Exiting Stop Mode

As soon as the unsynchronized TZIC_DSM_WAKEUP signal is asserted or the ARM_DSM_REQUEST is de-asserted, the CCM will begin the process of exiting the STOP mode.

The following steps will take place:

- If the CCM_CLPCR[VSTBY] bit was set, de-assert the pmic_vstby_req to notify the power management IC to change the voltage from standby voltage to functional voltage.
- If the CCM_CLPCR[SBYOS] was set, and the CCM closed either the external oscillator or the on board oscillator, then the CCM will start the external oscillator and the on board oscillator by asserting the CCM_CSR[REF_EN_B] signal and de-asserting the CCM_CLPCR[COSC_PWRDOWN] sigal respectively.
- After the amount of CKIL cycles defined in the CCM_CLPCR[STBY_COUNT] bits, wait until the pmic_vfunctional_ready signal is asserted. This is the notification from the power management IC that the functional voltage is ready. (Figure 5-13 describes the pmic signals connectivity.) Only after the functional voltage is ready will the CCM continues with the next steps:
  - Start the CAMP (based on definition of CCM_CCR[CAMP1_EN] bits)
  - If either the CAMP or on board oscillator were started, wait until the oscnt has finished counting to make sure that the external oscillator, camp1 and the on board oscillator are ready.
  - Start the PLLs. Only the PLLs that were configured to be on prior to the enterance to stop mode will be started.
  - Enable GPU2D clocks only.

The CCM will request the GPC to restore power by the GPC_PUP_REQ. If power was removed from the ARM platform or the GPU2D, the GPC will notify the CCM by asserting signal the GPC_PUP_ACK that power to the ARM and the GPU2D is back on, and its safe to exit from STOP mode. Only then will the CCM do the following:

- Once the SRC has asserted the src_power_gating_reset_done to indicate the reset to the power gated modules have completed, negate the low power request signals to all modules and enable all modules clocks based on their CCGR value including the ARM clocks and the ckil sync of the Megamix (if it was turned off), and return to run mode.
- Once the system is in run mode, negate the signals ccm_ipg_stop and system_in_stop_mode.

Once the interrupt propagates through all the synchronization logic, the ARM platform will recognize and service it. This will force the negation of the ARM_DSM_REQUEST output. Prior to this point, the ARM_DSM_REQUEST and TZIC_DSM_WAKEUP were both asserted. Since the TZIC_DSM_WAKEUP has top priority, the system is able to wake up.

Before the ARM exits the ISR, it will clear the interrupt source. This will cause the TZIC_DSM_WAKEUP signal to be negated. At this point, the two low power control signals are negated, and the STOP sequence can be repeated at any time.

Figure 5-11 describes the connectivity of the ARM, CCM and TZIC.

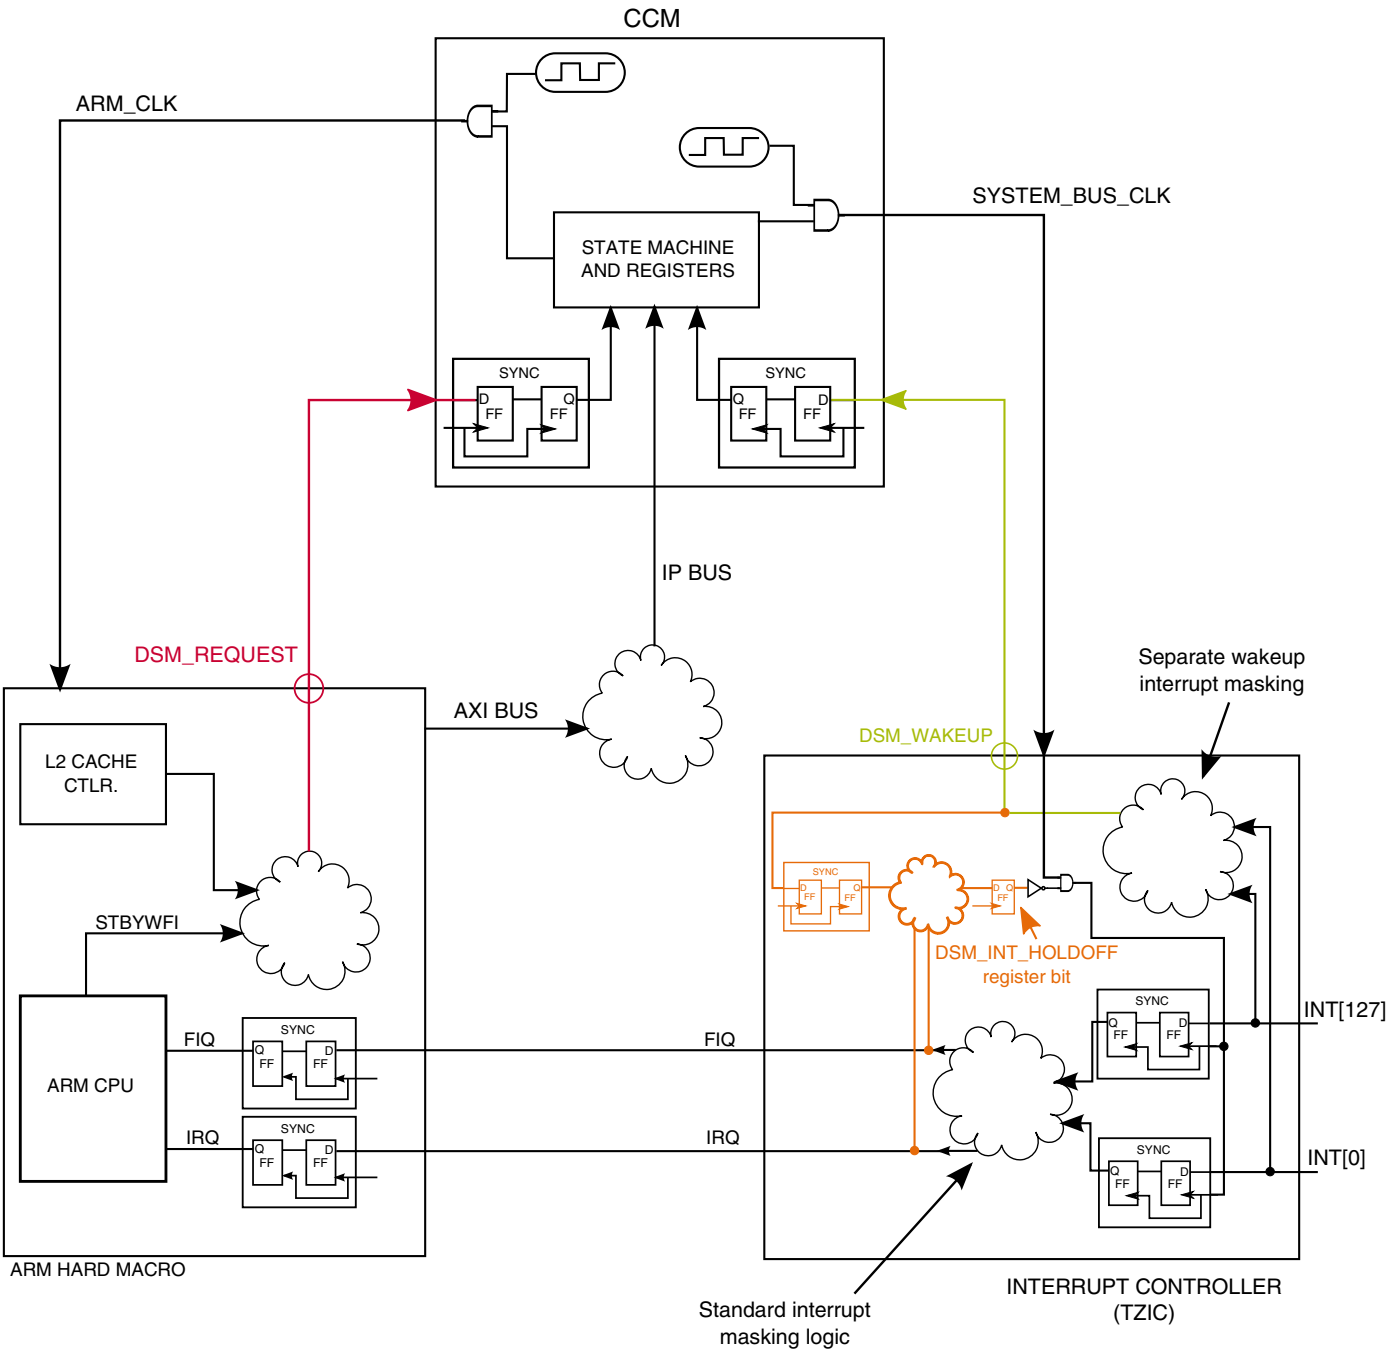

Figure 5-11. ARM Low Power Request

Figure 5-12 describes the CCM's Low Power State Machine.

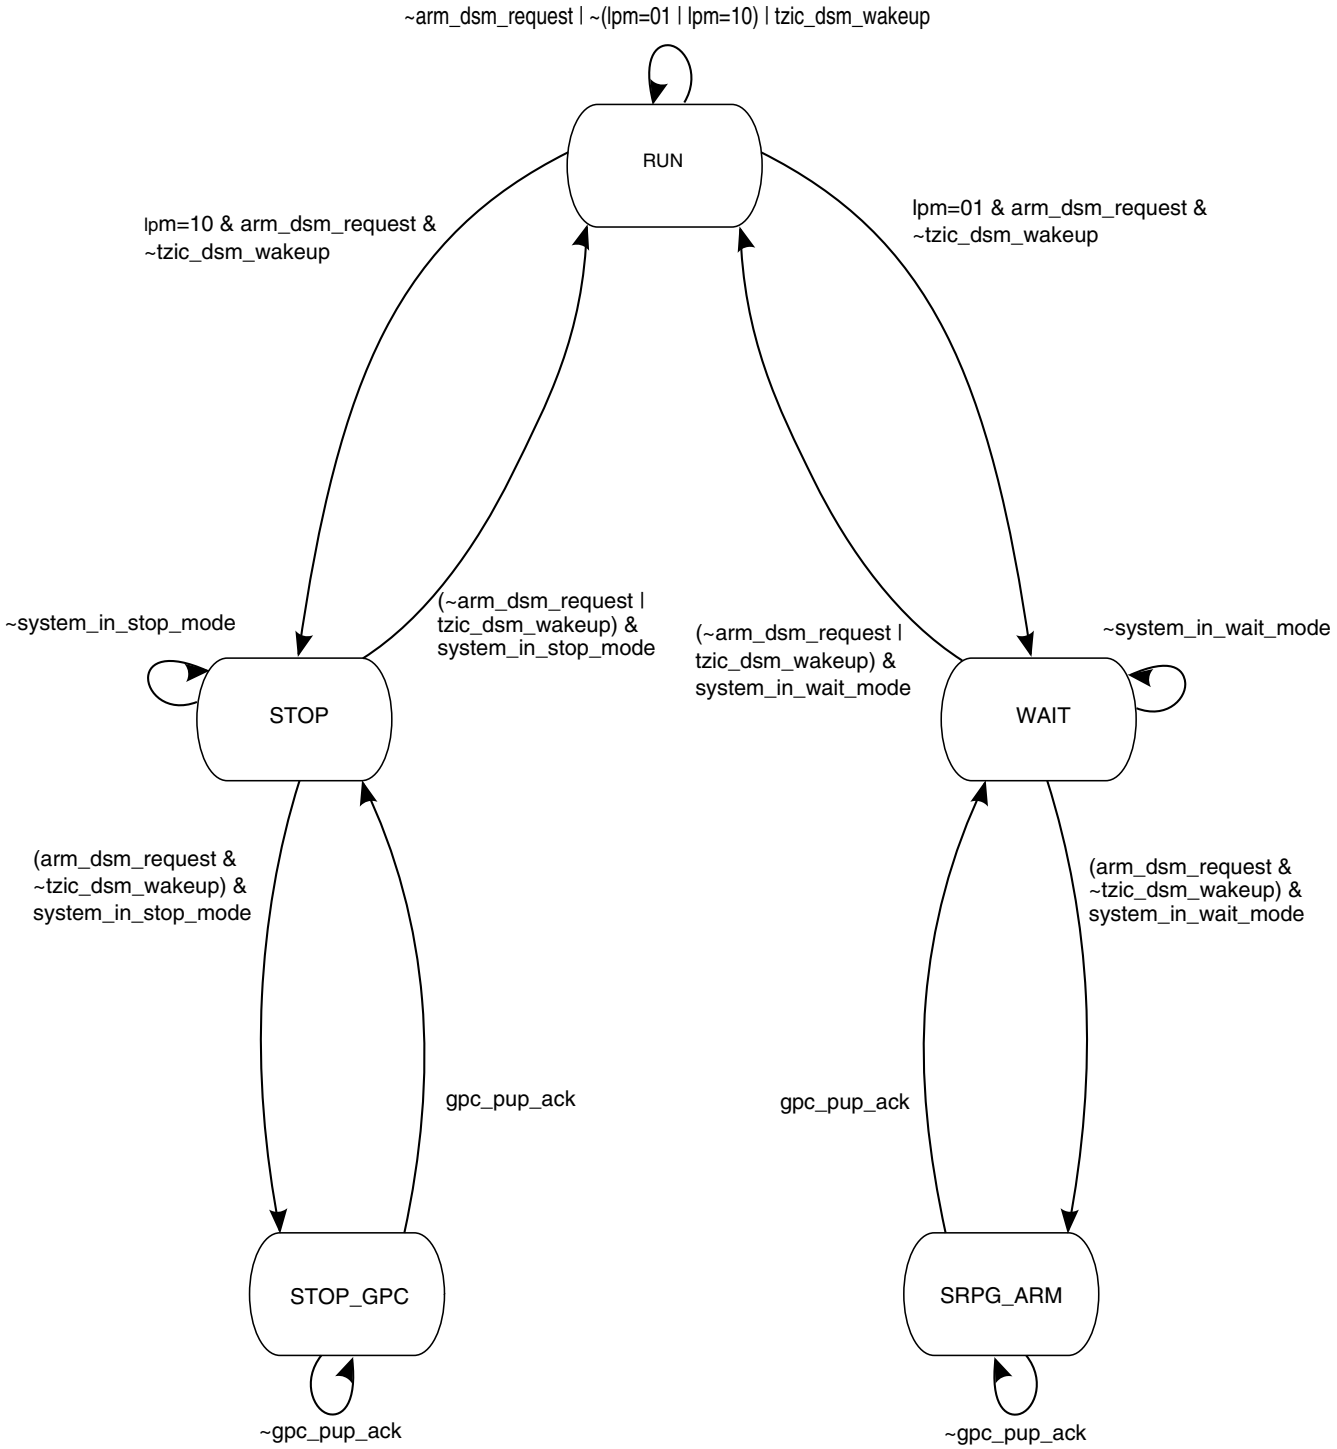

Figure 5-12. CCM Low Power State Machine

5.3.4.3.3 PMIC Signal Description

The CCM_CLPCR[STBY_COUNT] value should be larger than t1, which is the amount of time between the CCM's negation of pmic_vstby_req and the negation of pmic_vfuncional_ready (the signal coming back from PMIC to indicate that the voltage started to change).

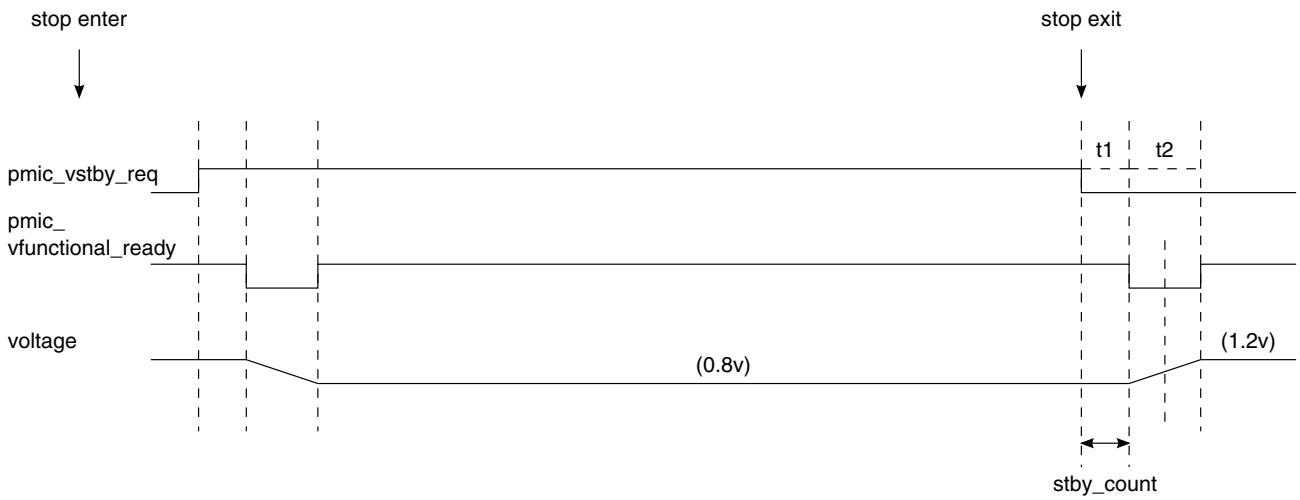

Figure 5-13. PMIC Signal Description

NOTE

Software should configure the IOMUXC so that pmic_vstby_req and pmic_vfuncional_ready will be operating in the correct ALT mode, so that they will be connected between CCM and the pads.

5.3.4.4 Low Power Audio Playback Mode (LP-APM)

Low Power Audio Playback mode (referred to as APM across this document) defines a special low power mode dedicated to the audio only playback mode. It involves PLL on/off and frequency settings, as well as voltage and clock gating aspects, to enable lowest possible power consumption.

This section covers APM, as well as assumptions, and Enter/Exit flows from the APM.

5.3.4.4.1 Low Power APM Mode Definition

Only one PLL of i.MX50 is running—ARM PLL. This PLL is set to the maximal frequency that the ARM can run at that lowest point while satisfying the ARM and bus system processing needs.

The peripherals will also work on low voltage (1.0 v). The peripherals will work at a frequency suitable for this low voltage (about a third of the nominal frequency).

For i.MX50 used as master on SSI clocks, the MCU PLL frequency must be set to an integer multiplication of SSI clock.

5.3.4.4.2 LP-APM Mode Restrictions

Entering and exiting LP-APM mode has an impact on the SSI clocks. If the chip is a master of the SSI clocks, audio playback will be interrupted during the switch, and therefore it is not recommended to switch modes during audio playback.

5.3.4.4.3 LP-APM Entry and Exit

Table 5-5 describes an example sequence for switching from a high power setting to LP-APM. Table 5-6 describes the corresponding sequence to exit from LP-APM. These entry and exit flows are valid for DDR types that support 24 MHz frequency.

Table 5-5. Stages of Entering LP-APM Mode

Stage	ARM Frequency (MHz)	ARM Voltage (V)	AHB Frequency (MHz)	DDR Frequency (MHz)	Vcc Voltage (V)	Comments
Initial State	Initial freq	Initial Voltage	Initial freq, sourced from PLL2	Initial freq, sourced from PLL1	Initial Voltage	ARM and DDR are sourced from PLL1 at initial frequency. AHB, AXI, etc. sourced from PLL2. ARM and Vcc at initial voltage.
DVFS on ARM	**Low freq**	**Low Voltage**	Initial freq, sourced from PLL2	Initial freq, sourced from PLL1	Initial Voltage	Use ARM_PODF to reduce ARM to low frequency.
Change DDR Frequency	**Low freq**	**Low Voltage**	Initial freq, sourced from PLL2	**Low freq, sourced from 24 MHz OSC**	Initial Voltage	Set DDR to be in Sync mode and source from 24 MHz OSC.
Change bus dividers	**Low freq**	**Low Voltage**	**Low freq, sourced from 24 MHz OSC**	**Low freq, sourced from 24 MHz OSC**	Initial Voltage	Change AHB, AXI dividers and source periph_clk from 24 MHz OXC. Relock PLL1 to low freq.
Reduce Peripheral Voltage (Vcc)	**Low freq**	**Low Voltage**	**Low freq, sourced from 24 MHz OSC**	**Low freq, sourced from 24 MHz OSC**	**Low Voltage**	Change Vcc.

NOTE

It is possible to source ARM from 24MHz OSC when the system enters WAIT mode in LPAPM state, so that all PLLs are OFF in LPAPM mode.

Table 5-6. Stages of Exiting LP-APM Mode

Stage	ARM Frequency (MHz)	ARM Voltage (V)	AHB Frequency (MHz)	DDR Frequency (MHz)	Vcc Voltage (V)	Comments
Initial State	**Low freq**	**Low Voltage**	**Low frequency, sourced from 24 MHz OSC**	**Low frequency, sourced from 24 MHz OSC**	**Low Voltage**	PLL1 locked at low frequency.
Relock PLL1	**Low freq**	**Low Voltage**	**Low frequency, sourced from 24 MHz OSC**	**Low frequency, sourced from 24 MHz OSC**	**Low Voltage**	PLL1 relocked at higher frequency.
Increase Peripheral Voltage (Vcc)	**Low freq**	**Low Voltage**	**Low frequency, sourced from 24 MHz OSC**	**Low frequency, sourced from 24 MHz OSC**	Normal Voltage	Change Vcc.
Change bus dividers	**Low freq**	**Low Voltage**	Normal frequency, sourced from PLL2	**Low frequency, sourced from 24 MHz OSC**	Normal Voltage	Change AHB, AXI dividers and source periph_clk from PLL2.
Change DDR Frequency	**Low freq**	**Low Voltage**	Normal frequency, sourced from PLL2	Normal frequency, sourced from PLL1	Normal Voltage	Set DDR to be in async mode and source from PLL1.
Raise ARM Frequency	Normal freq	Normal Voltage	Normal frequency, sourced from PLL2	Normal frequency, sourced from PLL1	Normal Voltage	Change ARM_PODF to increase ARM frequency (if needed).

Figure 5-14 and Figure 5-15 provide examples of the LP-APM entry flow using specific PLL frequencies and supply voltages:

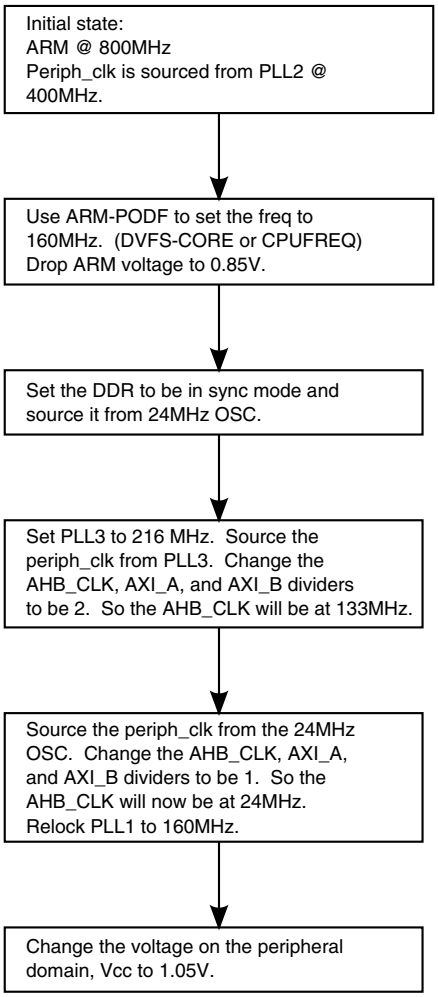

Figure 5-14. Flow of Entering Low Power APM on i.MX50

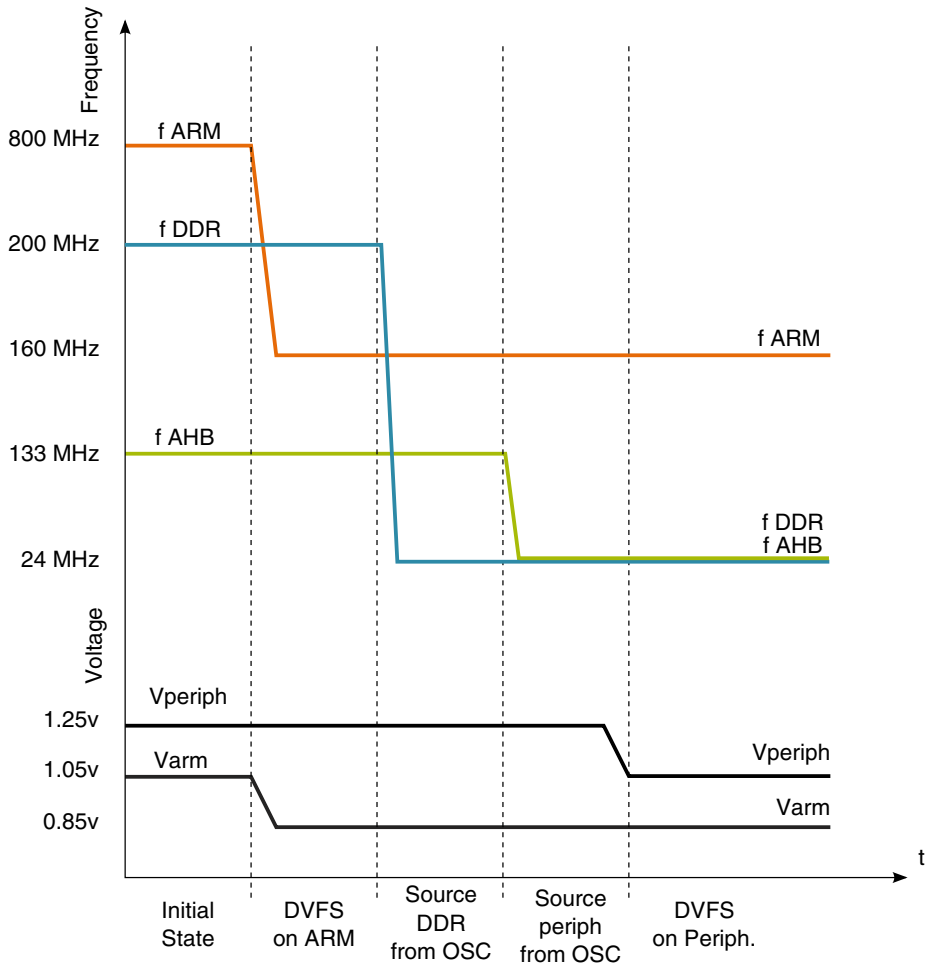

Figure 5-15. Frequency and Voltage Flow

5.3.4.5 Recomendations for Using Low Power Consumption from CCM

In addition to using APM mode for low power, here are recomendations of configuring CCM so that it will consume less power. Those recomendations should be followed when applicable:

- Using AHB clock source as the source of all AXI buses—in this case the power of the AXI dividers will be preserved.
- Working from one PLL or PFD and disabling the other PLLs.
- Generate SSI external clocks from SSI clock roots—in this case the SSI external clocks dividers' power will be preserved.

5.4 CCM Memory Map/Register Definition

CCM memory map

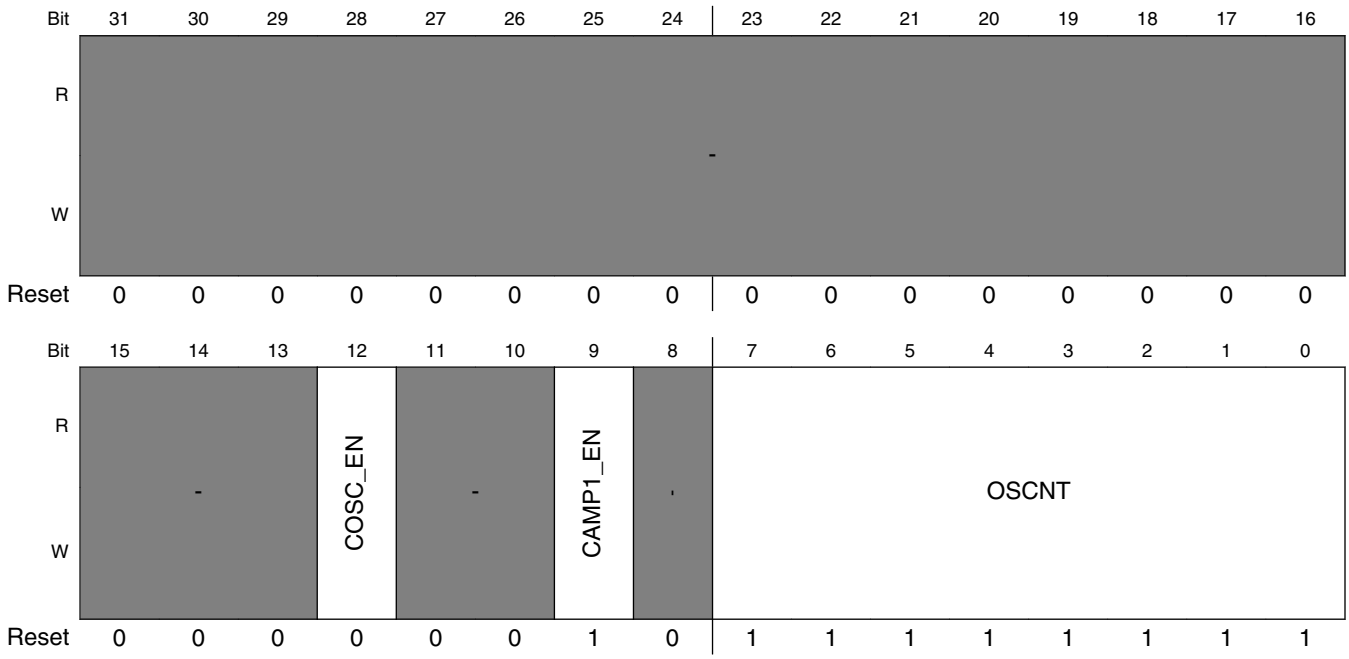
5.4.1 CCM Control Register (CCM_CCR)

The following figure represents the CCM Control Register (CCR), which contains bits to control general operation of CCM.

Address: CCM_CCR is 53FD_4000h base + 0h offset = 53FD_4000h



CCM_CCR field descriptions

Field	Description
31–13 -	Reserved
12 COSC_EN	On chip oscillator enable bit - this bit value is reflected on the output cosc_en. The system will start with on chip oscillator enabled to supply source for the PLL's. Software can change this bit if a transition to the bypass PLL clocks was performed for all the PLLs. In cases that this bit is changed from '0' to '1' then CCM will enable the on chip oscillator and after counting oscnt ckil clock cycles it will notify that on chip oscillator is ready by a interrupt cosc_ready and by status bit cosc_ready. The cosc_en bit should be changed only when on chip oscillator is not chosen as the clock source.0 disable on chip oscillator 0 disable on chip oscillator 1 enable on chip oscillator
11–10 -	Reserved
9 CAMP1_EN	CAMP1 Enable bit - the ignition process will always set this bit. In run mode, software can control camp1 enable/disable through this bit. If this bit is changed from '0' to '1' then CCM will enable the camp1 and after counting oscnt ckil's it will notify that camp1 is ready by a interrupt camp1_ready and by status bit camp1_ready. The camp1_en bit should be changed only when camp1 is not chosen as a clock source. **NOTE:** CCM has an output ccm_camp1_dis. this signal will be inverted from the camp1_en bit, that is, when camp1_en bit is '1' the ccm_camp1_dis signal is '0'.

Table continues on the next page...

CCM_CCR field descriptions (continued)

Field	Description
	0 disable camp1 1 enable camp1
8 -	Reserved
7–0 OSCNT	Oscillator ready counter value. These bits define value of 32KHz counter, that serve as counter for oscillator lock time. This is used for both the on chip oscillator lock time and the time that CAMP1 will be ready since the CAMP receives the external oscillator clock. Current estimation is ~5ms. This counter will be used in ignition sequence and in wake from stop sequence if sbyos bit (CCM Low Power Control Register) was defined, to notify that on chip oscillator output is ready for the DPLLC to use and only then the gate in DPLLC can be opened. 000000 count 1 ckil 111111 count 256 ckil's

5.4.2 CCM Control Divider Register (CCM_CCDR)

The following figure represents the CCM Control Divider Register (CCDR), which contains bits that control the loading of the dividers that need handshake with the modules they affect.

Address: CCM_CCDR is 53FD_4000h base + 4h offset = 53FD_4004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

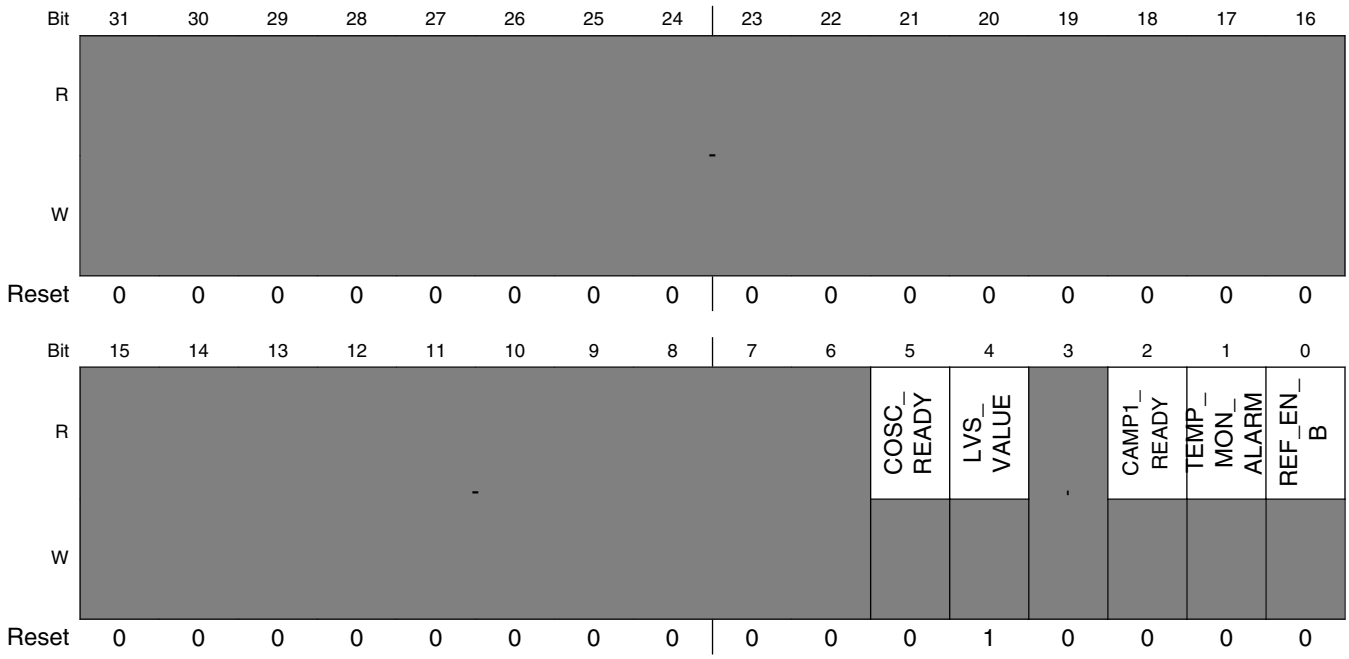
CCM_CCDR field descriptions

Field	Description
31–0 -	Reserved

5.4.3 CCM Status Register (CCM_CSR)

The following figure represents the CCM status Register (CSR). The status bits are read only bits.

Address: CCM_CSR is 53FD_4000h base + 8h offset = 53FD_4008h



CCM_CSR field descriptions

Field	Description
31–6 -	Reserved
5 COSC_READY	Status indication of on board oscillator. This bit will be asserted if on chip oscillator is enabled and on chip oscillator is not powered down, and if oscnt counter has finished counting. 0 on board oscillator is not ready. 1 on board oscillator is ready.
4 LVS_VALUE	Status of the value of pll_lvs control from the CCM to DPLLC 0 value of pll_lvs output is '0' 1 value of pll_lvs output is '1'
3 -	Reserved
2 CAMP1_READY	Status indication of camp1. This will be asserted if camp1 was enabled, and if oscnt counter has finished counting. 0 camp1 is not ready. 1 camp1 is ready.

Table continues on the next page...

CCM_CSR field descriptions (continued)

Field	Description
1 TEMP_MON_ALARM	Indicates the status of input "temp_mon_alarm" of the Temperature Monitor logic. 0 value of "temp_mon_alarm" is '0' 1 value of "temp_mon_alarm" is '1'
0 REF_EN_B	Status of the value of ref_en_b output of ccm 0 value of ref_en_b is '0' 1 value of ref_en_b is '1'

5.4.4 CCM Clock Switcher Register (CCM_CCSR)

The following figure represents the CCM Clock Switcher register (CCSR). The CCSR register contains bits to control the switcher sub module dividers and multiplexers.

Address: CCM_CCSR is 53FD_4000h base + Ch offset = 53FD_400Ch

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0	0

CCM_CCSR field descriptions

Field	Description
31–14 -	Reserved
13 PLL3_PFD_EN	PFD enable for pll3_sw_clk 0 select pll3_main_clk or pll3 bypass clock 1 select PFD source if PLL3 not in bypass mode. Refer to CCSR bit 0.

Table continues on the next page...

CCM_CCSR field descriptions (continued)

Field	Description
12 PLL2_PFD_EN	PFD enable for pll2_sw_clk 0 select pll2_main_clk or pll2 bypass clock 1 select PFD source if PLL2 not in bypass mode. Refer to CCSR bit 1.
11 PLL1_PFD_EN	PFD enable for pll1_sw_clk 0 select pll1_main_clk or pll1 step clock 1 select PFD source if PLL1 not in step clock mode. Refer to CCSR bit 2.
10 LP_APM	Selects the option to be chosen for the Low Power Audio Playback source clock. 0 Oscillator clock output 1 Fixed 480MHz PLL clock output
9 -	Reserved
8–7 STEP_SEL [1:0]	Selects the option to be chosen for the step frequency when shifting ARM frequency. this will control the step_clk. **NOTE:** This mux is allowed to be changed only if its output is not used, i.e. ARM uses the output of pll1. **NOTE:** To consume power, it is preferred to not set this mux to the pll2 and pll3 options when they are not needed - if they are not chosen then the path from pll2 and pll3 to this mux will be shut down and its power will be consumed. 00 clock source 4 - source for lp_apm. (Default) 01 pll1 bypass clock 10 divided pll2 clock 11 divided pll3 clock
6–5 PLL2_DIV_ PODF [1:0]	Divider for pll2 clock. **NOTE:** This podf is allowed to be changed only during period that its output is not used. 00 divide by 1 01 divide by 2 10 divide by 3 11 divide by 4
4–3 PLL3_DIV_ PODF [1:0]	Divider for pll3 clock. **NOTE:** This podf is allowed to be changed only during period that its output is not used. 00 divide by 1 01 divide by 2 10 divide by 3 11 divide by 4
2 PLL1_SW_CLK_ SEL	Selects source to generate pll1_sw_clk. **NOTE:** This bit will be ored with pll_bypass_en1 signal and dvfs_control signal. If one of the sources requests to move to step_clk (pll1_sw_clk=1 or pll_bypass_en1=1 or dvfs_control=1) then the pll1_sw_clk will be step_clk. Only if both sources request pll1_main_clk (pll1_sw_clk=0 and pll_bypass_en1=0 and dvfs_control=0) then the pll1_sw_clk will be pll1_main_clk.

Table continues on the next page...

CCM_CCSR field descriptions (continued)

Field	Description
	0 pll1_main_clk 1 step_clk (Default)
1 PLL2_SW_CLK_SEL	Selects source to generate pll2_sw_clk. This bit should only be used for testing purposes. **NOTE:** This bit will be ored with pll_bypass_en2 signal. If one of the sources requests to move to pll2 bypass clk (pll2_sw_clk=1 or pll_bypass_en2=1) then the pll2_sw_clk will be pll2 bypass clk. Only if both sources request pll2_main_clk (pll2_sw_clk=0 and pll_bypass_en2=0) then the pll2_sw_clk will be pll2_main_clk. 0 pll2_main_clk(Default) 1 pll2 bypass clock
0 PLL3_SW_CLK_SEL	Selects source to generate pll3_sw_clk. This bit should only be used for testing purposes. **NOTE:** This bit will be ored with pll_bypass_en3 signal. If one of the sources requests to move to pll3 bypass clk (pll3_sw_clk=1 or pll_bypass_en3=1) then the pll3_sw_clk will be pll3 bypass clk. Only if both sources request pll3_main_clk (pll3_sw_clk=0 and pll_bypass_en3=0) then the pll3_sw_clk will be pll3_main_clk. 0 pll3_main_clk(Default) 1 pll3 bypass clock

5.4.5 CCM ARM Clock Root Register (CCM_CACRR)

The following figure represents the CCM ARM Clock Root register (CACRR). The CACRR register contains bits to control the ARM clock root generation.

Address: CCM_CACRR is 53FD_4000h base + 10h offset = 53FD_4010h

5.4.7 CCM Bus Clock Multiplexer Register (CCM_CBCMR)

The following figure represents the CCM Bus Clock Multiplexer Register (CBCMR). The CBCMR register contains bits to control the multiplexers that generate the bus clocks.

NOTE

Any change to the above multiplexers must be done while the block whose clock is affected is not functional and the respective clock is gated in LPCG. If the change is made while the block is in the middle of an operation, it is not guaranteed that the module's operation will not be harmed.

When switching the divider from a slow clock source to a fast clock source, it is recommended to follow the steps below. The divider is not guaranteed to stop at the beginning of the divide sequence:

1. Change the divide value.
2. Enable the divider to allow the new divide to take effect.
3. Gate off divider, and switch to fast clock source.
4. Enable divider.

Address: CCM_CBCMR is 53FD_4000h base + 18h offset = 53FD_4018h

5.4.10 CCM Serial Clock Divider Register 1 (CCM_CSCDR1)

The following figure represents the CCM Serial Clock Divider Register 1 (CSCDR1). The CSCDR1 register contains bits to control the clock generation submodule dividers.

NOTE

Any change to the above multiplexers will have to be done while the block whose clock is affected is not functional and the respective clock is gated in LPCG. If the change is made while the block is in the middle of an operation, it is not guaranteed that the module's operation will not be harmed.

When switching the divider from a slow clock source to a fast clock source, it is recommended to follow the steps below. The divider is not guaranteed to stop at the beginning of the divide sequence:

1. Change the divide value.
2. Enable the divider to allow the new divide to take effect.
3. Gate off divider, and switch to fast clock source.
4. Enable divider.

Address: CCM_CSCDR1 is 53FD_4000h base + 24h offset = 53FD_4024h

5.4.17 CCM Serial Clock Divider Register 4 (CCM_CSCDR4)

The following figure represents the CCM Serial Clock Divider Register 4 (CSCDR4). The CSCDR4 register contains bits to control the clock generation submodule dividers.

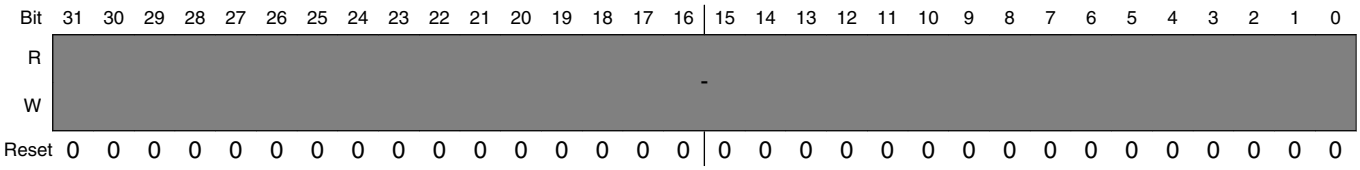
NOTE

Any change to the serial clock dividers (all dividers in the registers CSCDR1, CECDR, CSCDR2, CSCDR3 and CSCDR4) must be done while the block whose clock is affected is not functional. If the change is done while the block is in the middle of an operation, it is not guaranteed that the module's operation will not be harmed.

When switching the divider from a slow clock source to a fast clock source, these steps are recommended. The divider is not guaranteed to stop at the beginning of the divide sequence:

1. Change the divide value.
2. Enable the divider to allow the new divide to take effect.
3. Gate off divider, and switch to fast clock source.
4. Enable divider.

Address: CCM_CSCDR4 is 53FD_4000h base + 40h offset = 53FD_4040h



CCM_CSCDR4 field descriptions

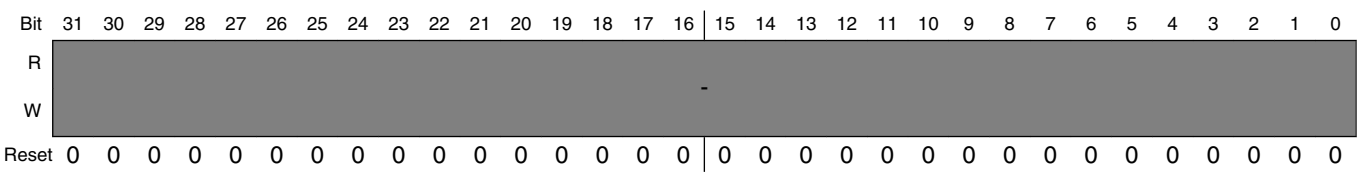
31–0 -	Reserved

5.4.18 CCM Wakeup Detector Register (CCM_CWDR)

The following figure represents the CCM Wakeup Detector Register (CWDR). The CWDR register contains bits to control the functionality of the wakeup detector.

Address: CCM_CWDR is 53FD_4000h base + 44h offset = 53FD_4044h



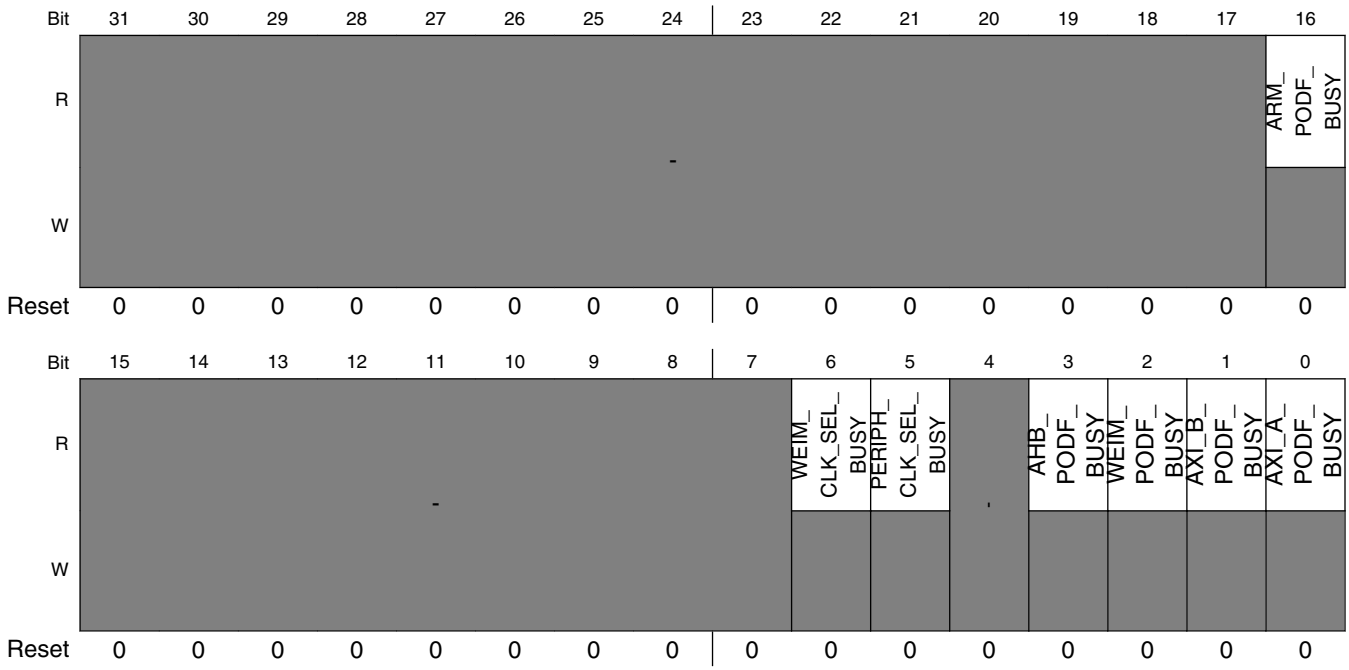
CCM_CWDR field descriptions

Field	Description
31–0 -	Reserved

5.4.19 CCM Divider Handshake In-Process Register (CCM_CDHIPR)

The following figure represents the CCM Divider Handshake In-Process Register (CDHIPR). The CDHIPR register contains read only bits that indicate that CCM is in process of updating dividers or muxes that might need handshake with modules.

Address: CCM_CDHIPR is 53FD_4000h base + 48h offset = 53FD_4048h



CCM_CDHIPR field descriptions

Field	Description
31–17 -	Reserved
16 ARM_PODF_BUSY	Busy indicator for arm_podf. This bit corresponds to the arm_podf divider only if ARM dvfs operation is done through arm_podf change (arm_freq_shift_divider = '1'). **NOTE:** Do not write arm_podf while arm_podf_busy is 1. This bit will not assert if arm_freq_shift_divider=0. **NOTE:** Transition from 1 to 0 can generate a ccm interrupt if not masked, refer to CIMR register description. 0 Divider is not busy and its value represents the actual division. 1 Divider is busy with handshake process. The value read in the divider represents the next value that the divider will hold after the handshake with gpc (after assertion of arm_clk_switch_req and the actual write to the divider).
15–7 -	Reserved

Table continues on the next page...

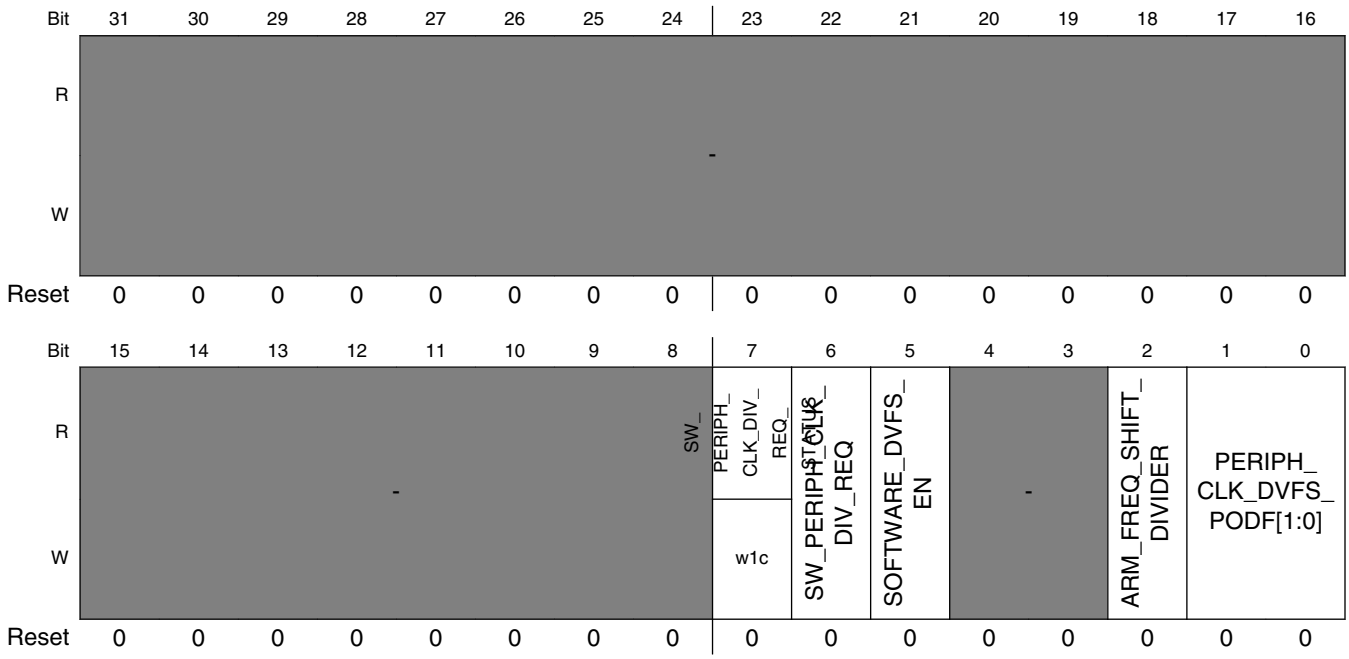
CCM_CDHIPR field descriptions (continued)

Field	Description
6 WEIM_CLK_ SEL_BUSY	Busy indicator for gcm weim_clk_sel. **NOTE:** Transition from 1 to 0 can generate a ccm interrupt if not masked, refer to CIMR register description. 0 mux is not busy. 1 mux is busy with handshake process.
5 PERIPH_CLK_ SEL_BUSY	Busy indicator for periph_clk_sel mux control. **NOTE:** Transition from 1 to 0 can generate a ccm interrupt if not masked, refer to CIMR register description. 0 mux is not busy . 1 mux is busy with handshake process.
4 -	Reserved
3 AHB_PODF_ BUSY	Busy indicator for ahb_podf. **NOTE:** Transition from 1 to 0 can generate a ccm interrupt if not masked, refer to CIMR register description. 0 divider is not busy and its value represents the actual division. 1 divider is busy with handshake process with module. The value read in the divider represents the next value that the divider will hold after the handshake.
2 WEIM_PODF_ BUSY	Busy indicator for weim_podf. **NOTE:** Transition from 1 to 0 can generate a ccm interrupt if not masked, refer to CIMR register description. 0 divider is not busy and its value represents the actual division. 1 divider is busy with handshake process with module. The value read in the divider represents the next value that the divider will hold after the handshake.
1 AXI_B_PODF_ BUSY	Busy indicator for axi_b_podf. **NOTE:** Transition from 1 to 0 can generate a ccm interrupt if not masked, refer to CIMR register description. 0 divider is not busy and its value represents the actual division. 1 divider is busy with handshake process with module. The value read in the divider represents the next value that the divider will hold after the handshake.
0 AXI_A_PODF_ BUSY	Busy indicator for axi_a_podf. **NOTE:** Transition from 1 to 0 can generate a ccm interrupt if not masked, refer to CIMR register description. 0 Divider is not busy and its value represents the actual division. 1 Divider is busy with handshake process with module. The value read in the divider represents the next value that the divider will hold after the handshake.

5.4.20 CCM DVFS Control Register (CCM_CDCR)

The following figure represents the CCM DVFS Control Register (CDCR). The CDCR register contains bits to control the DVFS operation.

Address: CCM_CDCR is 53FD_4000h base + 4Ch offset = 53FD_404Ch



CCM_CDCR field descriptions

Field	Description
31–8 -	Reserved
7 SW_PERIPH_CLK_DIV_REQ_STATUS	Status bit to define the operation of DVFS driver in case of software control of DVFS divider. this bit is write '1' to clear - after a DVFS divider switch request it will be asserted and software should write '1' to clear it and prepare it for the next DVFS divider switch request. 1 DVFS frequency switch operation finished. 0 DVFS frequency switch is not finished, or there is no frequency switch request.
6 SW_PERIPH_CLK_DIV_REQ	Start DVFS frequency division operation. This bit will affect the DVFS divider only if software_dvfs_en bit was set to '1'. 0 Remove DVFS divider operation-DVFS divider will divide by '1'. 1 enable DVFS divider operation. DVFS divider will divide by the PERIPH_CLK_DVFS_PODF settings.
5 SOFTWARE_DVFS_EN	Defines if the DVFS operation will comence by software bit or by GPC signal "periph_clk_div_req". 0 DVFS operation will start by GPC signal "periph_clk_div_req" 1 DVFS operation will start by software bit sw_periphe_clk_div_req
4–3 -	reserved

Table continues on the next page...

CCM_CDCR field descriptions (continued)

Field	Description
2 ARM_FREQ_ SHIFT_DIVIDER	Define if next DVFS of ARM domain will be through podf change or pll relock. 0 Next ARM DVFS operation is done through pll relock. The pll relock process will start once arm_clk_switch_req is asserted. (in this case any new writes to arm_podf will be commences immediately, without waiting for arm_clk_switch_req). 1 Next ARM DVFS operation is done through arm_podf change. CCM will hold updates to arm_podf until signal arm_clk_switch_req is asserted.
1–0 PERIPH_CLK_ DVFS_ PODF[1:0]	Divider value for next operation of peripheral DVFS. This defines the value of the dividers affecting main_bus_clk. This divider will take place only during DVFS operation. Refer to Peripheral Clock Domain Frequency Change for details. 00 restricted 01 divide by 2 10 divide by 3 11 divide by 4

5.4.21 CCM Testing Observability Register (CCM_CTOR)

The following figure represents the CCM Testing Observability Register (CTOR). CCM includes three muxes to mux between different critical signals for testing observability. The output of the three muxes is generated on the three output signals obs_output_0, obs_output_1 and obs_output_2. Those three output signals can be generated on the IC pads by configuring the IOMUXC. The CTOR register contains bits to control the data generated for observability on the three output signals above.

Address: CCM_CTOR is 53FD_4000h base + 50h offset = 53FD_4050h

Reset	0	0	0	0	0	0	0	0	0	1	1	0	0	0	0	1

CCM_CLPCR field descriptions

Field	Description
31–26 -	Reserved
25 BYPASS_MAX_LPM_HS	Bypass handshake with the ahbmax on next entrance to low power mode (wait or stop mode). CCM does not wait for the module's acknowledge. 0 handshake with max on next entrance to low power mode will be performed. 1 handshake with max on next entrance to low power mode will be bypassed.
24 BYPASS_SDMA_LPM_HS	Bypass handshake with sdma on next entrance to low power mode (wait or stop mode). CCM does not wait for the module's acknowledge. 0 handshake with sdma on next entrance to low power mode will be performed. 1 handshake with sdma on next entrance to low power mode will be bypassed.
23 BYPASS_RNGB_LPM_HS	Bypass handshake with rngb on next entrance to low power mode (wait or stop mode). CCM does not wait for the module's acknowledge. 0 handshake with rngb on next entrance to low power mode will be performed. 1 handshake with rngb on next entrance to low power mode will be bypassed.
22–20 -	Reserved
19 BYPASS_WEIM_LPM_HS	Bypass handshake with weimon next entrance to low power mode (wait or stop mode). CCM does not wait for the module's acknowledge. 0 handshake with sdma on next entrance to low power mode will be performed. 1 handshake with sdma on next entrance to low power mode will be bypassed.
18–12 -	Reserved
11 COSC_PWRDOWN	In run mode, software can manually control powering down of on chip oscillator, i.e. generating '1' on cosc_pwrdown signal. If software manually powered down the on chip oscillator, then sbyos functionality for on chip oscillator will be bypassed. The manual closing of onchip oscillator should be performed only in case the reference oscilator is not the source of all the clocks generation. 0 On chip oscillator will not be powered down, i.e. cosc_pwrdown = '0'. 1 On chip oscillator will be powered down, i.e. cosc_pwrdown = '1'.
10–9 STBY_COUNT	Standby counter definition. These two bits define, in the case of stop exit (if vstby bit was set), the amount of time CCM will wait between PMIC_VSTBY_REQ negation and the check of assertion of PMIC_VFUNCIONAL_READY. If bypass_pmic_vfunctional_ready is set, STBY_COUNT is the amount of time the CCM will wait between PMIC_VSTBY_REQ negation and exiting STOP mode. 00 CCM will wait 2 ckil clock cycles 01 CCM will wait 4 ckil clock cycles 10 CCM will wait 8 ckil clock cycles 11 CCM will wait 16 ckil clock cycles
8 VSTBY	Voltage standby request bit. This bit defines if PMIC_VSTBY_REQ pin, which notifies external power management IC to move from functional voltage to standby voltage, will be asserted in stop mode. **NOTE:** When returning from stop mode, the PMIC_VSTBY_REQ will be deasserted (if it was asserted when entering stop mode), and CCM will wait for indication that functional voltage is ready (by

CCM_CLPCR field descriptions (continued)

Field	Description
	sampling the assertion of pmic_vfuncional_ready) before continuing the process of exiting from stop mode. Please refer to stby_count bits. 0 voltage will not be changed to standby voltage after next entrance to stop mode. (PMIC_VSTBY_REQ will remain negated - '0') 1 voltage will be requested to change to standby voltage after next entrance to stop mode. (PMIC_VSTBY_REQ will be asserted - '1').
7 DIS_REF_OSC	dis_ref_osc - in run mode, software can manually control closing of external reference oscillator clock, i.e. generating '1' on ref_en_b signal. If software closed manually the external reference clock, then sbyos functionality will be bypassed. The manual closing of external reference oscilator should be performed only in case the reference oscilator is not the source of any clock generation. 0 external high frequency oscillator will be enabled, i.e. ref_en_b = '0'. 1 external high frequency oscillator will be disabled, i.e. ref_en_b = '1'
6 SBYOS	Standby clock oscillator bit. This bit defines if REF_EN_B pin, which disables external high frequency crystal, and cosc_pwrdown, which power down the on chip oscillator, will be asserted in stop mode. This bit is discarded if dis_ref_osc = '1' for external oscillator, and if cosc_pwrdown='1' for the on chip oscillator. 0 external high frequency oscillator will not be disabled and on chip oscillator will not be powered down, after next entrance to stop mode. (ref_en_b will remain asserted - '0' and cosc_pwrdown will remain de asserted - '0') 1 external high frequency oscillator will be disabled and on chip oscillator will be powered down, after next entrance to stop mode. (ref_en_b will be deasserted - '1' and cosc_pwrdown will be asserted - '1'). When returning from stop mode, external oscillator will be enabled again, on chip oscillator will return to oscillator mode , and after oscnt count ccm will continue with the exit from stop mode process.
5 ARM_CLK_DIS_ON_LPM	Define if ARM clocks (arm_clk, soc_mxclk, soc_pclk, soc_dbg_pclk, vl_wrck) will be disabled on wait mode. This is useful for debug mode, when the user still wants to simulate entering wait mode and still keep ARM clock functioning. **NOTE:** Software should not enable ARM power gating in wait mode if this bit is cleared. 0 ARM clock enabled on wait mode. 1 ARM clock disabled on wait mode.
4–3 -	Reserved
2 BYPASS_PMIC_VFUNCTIONAL_READY	By asserting this bit CCM will bypass waiting for pmic_vfunctional_ready signal when coming out of STOP mode. This should be used for PMIC's that don't support the pmic_vfunctional_ready signal. 0 Don't bypass the pmic_vfunctional_ready signal; CCM will wait for its assertion during exit of low power mode if standby voltage was enabled. 1 Bypass the pmic_vfunctional_ready signal; CCM will not wait for its assertion during exit of low power mode if standby voltage was enabled. Note that the CCM will wait for STBY_COUNT cycles after PMIC_VSTBY_REQ negation before exiting STOP mode.
1–0 LPM[1:0]	Setting the low power mode that system will enter on next assertion of dsm_request signal. 00 Remain in run mode 01 Transfer to wait mode

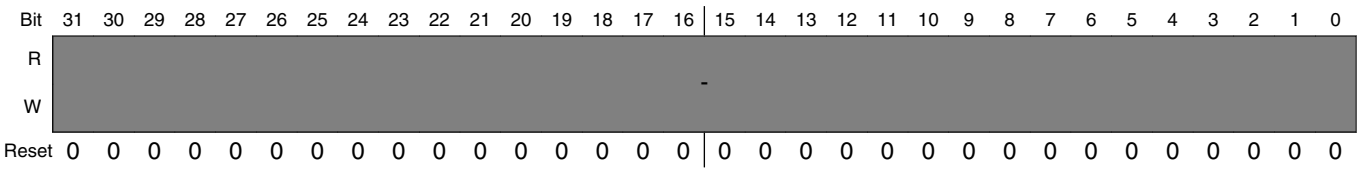
5.4.26 CCM General Purpose Register (CCM_CGPR)

The following figure represents the CCM General Purpose Register (CGPR). This is a regular read/write implemented register, which can serve for future possible usage. The respective bits are connected to cgpr_dout[31:0] output of CCM. Several bits are already in use, while other bits are free for future usage.

Address: CCM_CGPR is 53FD_4000h base + 64h offset = 53FD_4064h



CCM_CGPR field descriptions

Field	Description
31–0 -	Reserved for future use. Those bits are connected to ccm output cgpr_dout[31-0]

5.4.27 CCM Clock Gating Register 0 (CCM_CCGR0)

The following figure represents CCM Clock Gating Register 0 (CCGR0). The clock gating Registers define the clock gating for power reduction of each clock (CG(i) bits). There are eight CGR registers. The number of registers required corresponds to the number of peripherals in the system.

NOTE

Additional information about the bit fields of this register can be found in Table 5-55.

Address: CCM_CCGR0 is 53FD_4000h base + 68h offset = 53FD_4068h

5.4.34 CCM Clock Gating Register 7 (CCM_CCGR7)

The following figure represents CCM Clock Gating Register 7 (CCGR7). The clock gating Registers define the clock gating for power reduction of each clock (CG(i) bits). There are 8 CGR registers. The number of registers required corresponds to the number of peripherals in the system.

NOTE

Additional information about the bit fields of this register can be found in Table 5-62.

Address: CCM_CCGR7 is 53FD_4000h base + 84h offset = 53FD_4084h

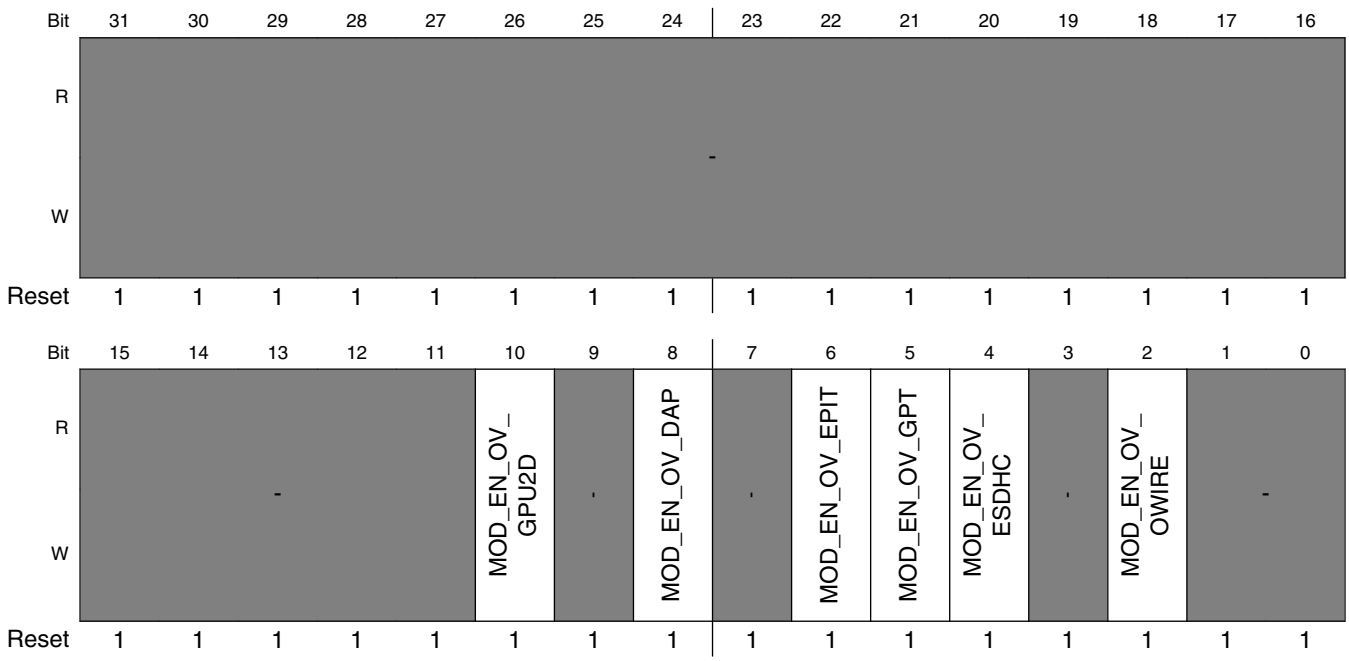
5.4.35 CCM Module Enable Override Register (CCM_CMEOR)

The following figure represents the CCM Module Enable Override Register (CMEOR). The CMEOR register contains bits to override the clock enable signal from the module. This should be used in case it is decided to bypass the clock enable signals from the modules. This bit will be applicable only for the modules for which a clock enable signal is used.

Address: CCM_CMEOR is 53FD_4000h base + 88h offset = 53FD_4088h



CCM_CMEOR field descriptions

Field	Description
31–11 -	Reserved
10 MOD_EN_OV_GPU2D	Overide clock enable signal from gpu2d - clock will not be gated based on gpu2d's signal 'gpu2d_busy' . 0 don't overide module enable signal 1 overide module enable signal
9 -	Reserved
8 MOD_EN_OV_DAP	Overide clock enable signal from dap- clock will not be gated based on dap's signal 'dap_dbgen' . 0 don't overide module enable signal 1 overide module enable signal
7 -	Reserved

Field	Description
6 MOD_EN_OV_EPIT	Overide clock enable signal from epit - clock will not be gated based on epit's signal 'ipg_enable_clk' . 0 don't overide module enable signal 1 overide module enable signal
5 MOD_EN_OV_GPT	Overide clock enable signal from gpt - clock will not be gated based on gpt's signal 'ipg_enable_clk' . 0 don't overide module enable signal 1 overide module enable signal
4 MOD_EN_OV_ESDHC	Overide clock enable signal from esdhc - clock will not be gated based on esdhc's signals 'hclk_en', 'ipg_clk_en' and 'ipg_per_clk_en'. 0 don't overide module enable signal 1 overide module enable signal
3 -	Reserved
2 MOD_EN_OV_OWIRE	Overide clock enable signal from owire - clock will not be gated based on owire's signal 'owire_clk_en'. 0 don't overide module enable signal 1 overide module enable signal
1–0 -	Reserved

5.4.36 CCM Control Status Register 2 (CCM_CSR2)

The following figure represents the CCM Control Status Register 2 (CSR2). The CSR2 register contains bits which check the status of various CCM divide and glitchless clock mux changes. When the busy bit for the respective clock divider is high, the divider change is being updated; subsequent updates to the divider should not be performed until the busy bit has cleared.

Address: CCM_CSR2 is 53FD_4000h base + 8Ch offset = 53FD_408Ch

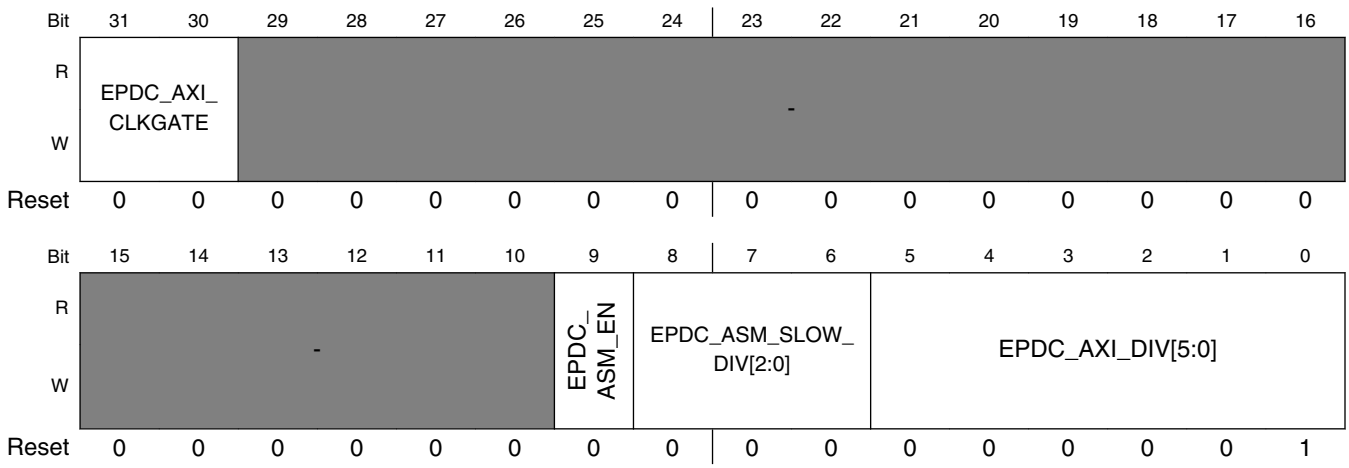
CCM_DISPLAY_AXI field descriptions (continued)

Field	Description
9 ELCDIF_ASM_EN	Enable Auto slow Mode for elcdif_axi clock 1 Enable Auto Slow Mode 0 Disable Auto Slow Mode
8–6 ELCDIF_ASM_SLOW_DIV[2:0]	Elcdif auto slow mode divide. The display_axi clock for the elcdif_axi branch is divided down when elcdif_asm_en and the elcdif is not busy. 000 Clock is not auto slowed 001 Clock is divided by 2 010 Clock is divided by 4 011 Clock is divided by 8 100 Clock is divided by 16 101 Clock is divided by 32 110 - 111 Reserved
5–0 DISPLAY_AXI_DIV[5:0]	Divider for display_axi clock. **NOTE:** The display_axi_clkgate will gate the clock off before the divider and should be used for maximum power savings instead of dividing by 0. 000 Clock is gated off 001 divide by 1 010 divide by 2 011 divide by 3 100 divide by 4 101 divide by 5 110 divide by 6 111 divide by 7 111111 divide by (2^6)-1

5.4.43 CCM EPDC_AXI Clock Divide Register (CCM_EPDC_AXI)

The following figure represents the CCM EPDC_AXI Clock Divide Register (EPDC_AXI). The EPDC_AXI register contains bits to control the clock generation submodule dividers.

Address: CCM_EPDC_AXI is 53FD_4000h base + A8h offset = 53FD_40A8h



CCM_EPDC_AXI field descriptions

Field	Description
31–30 EPDC_AXI_ CLKGATE	Enable/Disable asynchronous epdc_axi_clk source clock divider 00 Clock is gated off 01 Clock is on in run mode, but off in wait and stop modes 10 Clock is always on 11 Clock is on during all modes, except stop mode
29–10 -	Reserved
9 EPDC_ASM_EN	Enable Auto slow Mode for epdc_axi clock 1 Enable Auto Slow Mode 0 Disable Auto Slow Mode
8–6 EPDC_ASM_ SLOW_DIV[2:0]	Elcdif auto slow mode divide. The epdc_axi clock is divided down when epdc_asm_en and the epdc is not busy. 000 Clock is not auto slowed 001 Clock is divided by 2 010 Clock is divided by 4 011 Clock is divided by 8 100 Clock is divided by 16 101 Clock is divided by 32 110 - 111 Reserved

Table continues on the next page...

CCM_EPDC_AXI field descriptions (continued)

Field	Description
5–0 EPDC_AXI_ DIV[5:0]	Divider for epdc_axi clock. **NOTE:** The epdc_axi_clkgate will gate the clock off before the divider and should be used for maximum power savings instead of dividing by 0. 000 Clock is gated off 001 divide by 1 010 divide by 2 011 divide by 3 100 divide by 4 101 divide by 5 110 divide by 6 111 divide by 7 111111 divide by (2^6)-1

5.4.44 CCM GPMI Clock Divide Register (CCM_GPMI)

The following figure represents the CCM GPMI Clock Divide Register (GPMI). The GPMI register contains bits to control the clock generation submodule dividers.

Address: CCM_GPMI is 53FD_4000h base + ACh offset = 53FD_40ACh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	GPMI_ CLKGATE		-													
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	-										GPMI_DIV[5:0]					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

CCM_GPMI field descriptions

Field	Description
31–30 GPMI_ CLKGATE	Enable/Disable asynchronous gpmi_clk source clock divider 00 Clock is gated off 01 Clock is on in run mode, but off in wait and stop modes 10 Clock is always on 11 Clock is on during all modes, except stop mode
29–6 -	Reserved
5–0 GPMI_DIV[5:0]	Divider for gpmi clock.

Table continues on the next page...

CCM_GPMI field descriptions (continued)

Field	Description
	NOTE: The gpmi_clkgate will gate the clock off before the divider and should be used for maximum power savings instead of dividing by 0. 000 Clock is gated off 001 divide by 1 010 divide by 2 011 divide by 3 100 divide by 4 101 divide by 5 110 divide by 6 111 divide by 7 111111 divide by (2^6)-1

5.4.45 CCM BCH Clock Divide Register (CCM_BCH)

The following figure represents the CCM BCH Clock Divide Register (BCH). The BCH register contains bits to control the clock generation submodule dividers.

Address: CCM_BCH is 53FD_4000h base + B0h offset = 53FD_40B0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	BCH_ CLKGATE		-													
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	-										BCH_DIV[5:0]					
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

CCM_BCH field descriptions

Field	Description
31–30 BCH_CLKGATE	Enable/Disable asynchronous bch_clk source clock divider 00 Clock is gated off 01 Clock is on in run mode, but off in wait and stop modes 10 Clock is always on 11 Clock is on during all modes, except stop mode
29–6 -	Reserved
5–0 BCH_DIV[5:0]	Divider for bch clock. **NOTE:** The bch_clkgate will gate the clock off before the divider and should be used for maximum power savings instead of dividing by 0.

Table continues on the next page...

CCM_BCH field descriptions (continued)

Field	Description	
	000	Clock is gated off
	001	divide by 1
	010	divide by 2
	011	divide by 3
	100	divide by 4
	101	divide by 5
	110	divide by 6
	111	divide by 7
	111111	divide by (2^6)-1

5.4.46 CCM MSHC_XMSCKI Clock Divide Register (CCM_MSHC_XMSCKI)

The following figure represents the CCM MSHC_XMSCKI Clock Divide Register (MSHC_XMSCKI). The MSHC_XMSCKI register contains bits to control the clock generation submodule dividers.

NOTE

The CLK_SYS, CLK_DDR, ELCDIFPIX, EPDCPIX, DISPLAY_AXI, EPDC_AXI, GPMI, BCH and MSHC_XMSCKI dividers load new divide values on the fly without loss of clock cycles. The dividers should not be gated off when the divide value is updated; the new divide value will only take effect if the divider is active.

Address: CCM_MSHC_XMSCKI is 53FD_4000h base + B4h offset = 53FD_40B4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	MSHC_ XMSCKI_ CLKGATE		-

R	-										MSHC_XMSCKI_DIV[5:0]					
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

CCM_MSHC_XMSCKI field descriptions

Field	Description
31–30 MSHC_ XMSCKI_ CLKGATE	Enable/Disable asynchronous mshc_xmscki_clk source clock divider 00 Clock is gated off 01 Clock is on in run mode, but off in wait and stop modes 10 Clock is always on 11 Clock is on during all modes, except stop mode
29–6 -	Reserved
5–0 MSHC_ XMSCKI_ DIV[5:0]	Divider for mshc_xmscki clock. **NOTE:** The mshc_xmscki_clkgate will gate the clock off before the divider and should be used for maximum power savings instead of dividing by 0. 000 Clock is gated off 001 divide by 1 010 divide by 2 011 divide by 3 100 divide by 4 101 divide by 5 110 divide by 6 111 divide by 7 111111 divide by (2^6)-1

5.4.47 Clock Gating bits (CG(i))

These bits are used to turn on/off the clock to each module independently. Table 5-54 details the possible clock activity conditions for each module.

Table 5-54. Clock Gating Bits Description

CGR value	Clock Activity Description
00	Clock is off during all modes.
01	Clock is on in run mode, but off in wait and stop modes
10	Clock is always on
11	Clock is on during all modes, except stop mode.

NOTE

Module should be stopped before the CGR value is set to 00 because clocks to the module will be stopped immediately.

Table 5-55 through Table 5-62 show the register mappings for the gated clocks connected to each target module.

The CCM Root Clock in each table refers to the parent clock output shown in Figure 5-1.

Table 5-55. CCM_CCGR0 Gated Clock Mapping to Target Module

4101_807C	PLL Control Register (CCM_ANALOG_PLLCTRL_TOG)	32	R/W	00FF_0000h	5.5.4/411

5.5.1 Fractional Clock Control Register 0 (CCM_ANALOG_FRAC0*n*)

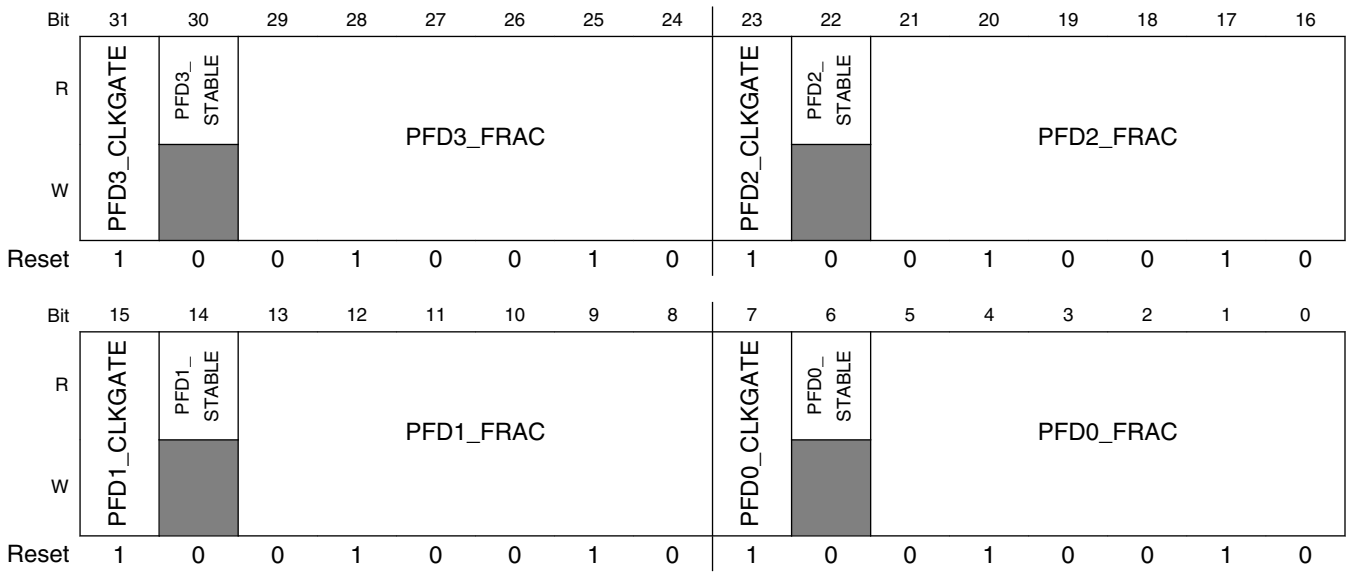
The FRAC0 control register provides control for PFD clock generation. This register controls the 4-phase fractional clock dividers. The fractional clock frequencies are a product of the values in these registers.

Addresses: CCM_ANALOG_FRAC0 is 4101_8000h base + 10h offset = 4101_8010h

CCM_ANALOG_FRAC0_SET is 4101_8000h base + 14h offset = 4101_8014h

CCM_ANALOG_FRAC0_CLR is 4101_8000h base + 18h offset = 4101_8018h

CCM_ANALOG_FRAC0_TOG is 4101_8000h base + 1Ch offset = 4101_801Ch



CCM_ANALOG_FRAC0*n* field descriptions

Field	Description
31 PFD3_ CLKGATE	IO Clock Gate. 0 **ref_pfd3 fractional divider clock is enabled** — 1 **The 3rd fractional divider clock (reference ref_pfd3) is off (power saving)** —
30 PFD3_STABLE	This read-only bitfield is for DIAGNOSTIC PURPOSES ONLY since the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bit inverts, the phase divider clock output is stable. **NOTE:** The value will not invert when the fractional divider is taken out of or placed into clock-gated state.
29–24 PFD3_FRAC	This field controls the IO clocks fractional divider. The resulting frequency shall be 480 * (18/ PFD3_FRAC) where PFD3_FRAC = 18-35.
23 PFD2_ CLKGATE	IO Clock Gate. 0 **ref_pfd2 fractional divider clock is enabled** — 1 **The 2nd fractional divider clock (reference ref_pfd2) is off (power saving)** —

22 PFD2_STABLE	This read-only bitfield is for DIAGNOSTIC PURPOSES ONLY since the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bit inverts, the phase divider clock output is stable. **NOTE:** The value will not invert when the fractional divider is taken out of or placed into clock-gated state.
21–16 PFD2_FRAC	This field controls the IO clocks fractional divider. The resulting frequency shall be 480 * (18/PFD2_FRAC) where PFD2_FRAC = 18-35.
15 PFD1_ CLKGATE	IO Clock Gate. 0 **ref_pfd1 fractional divider clock is enabled** — 1 **The 1st fractional divider clock (reference ref_pfd1) is off (power saving)** —
14 PFD1_STABLE	This read-only bitfield is for DIAGNOSTIC PURPOSES ONLY since the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bit inverts, the phase divider clock output is stable. **NOTE:** The value will not invert when the fractional divider is taken out of or placed into clock-gated state.
13–8 PFD1_FRAC	This field controls the IO clocks fractional divider. The resulting frequency shall be 480 * (18/PFD1_FRAC) where PFD1_FRAC = 18-35.
7 PFD0_ CLKGATE	IO Clock Gate. 0 **ref_pfd0 fractional divider clock is enabled** — 1 **The 0th fractional divider clock (reference ref_pfd0) is off (power saving)** —
6 PFD0_STABLE	This read-only bitfield is for DIAGNOSTIC PURPOSES ONLY since the fractional divider should become stable quickly enough that this field will never need to be used by either device driver or application code. The value inverts when the new programmed fractional divide value has taken effect. Read this bit, program the new value, and when this bit inverts, the phase divider clock output is stable. **NOTE:** The value will not invert when the fractional divider is taken out of or placed into clock-gated state.
5–0 PFD0_FRAC	This field controls the IO clocks fractional divider. The resulting frequency shall be 480 * (18/PFD0_FRAC) where PFD0_FRAC = 18-35.

5.5.2 Fractional Clock Control Register 1 (CCM_ANALOG_FRAC1*n*)

The FRAC1 control register provides control for PFD clock generation. This register controls the 4-phase fractional clock dividers. The fractional clock frequencies are a product of the values in these registers.

Addresses: CCM_ANALOG_FRAC1 is 4101_8000h base + 20h offset = 4101_8020h

CCM_ANALOG_FRAC1_SET is 4101_8000h base + 24h offset = 4101_8024h

CCM_ANALOG_FRAC1_CLR is 4101_8000h base + 28h offset = 4101_8028h

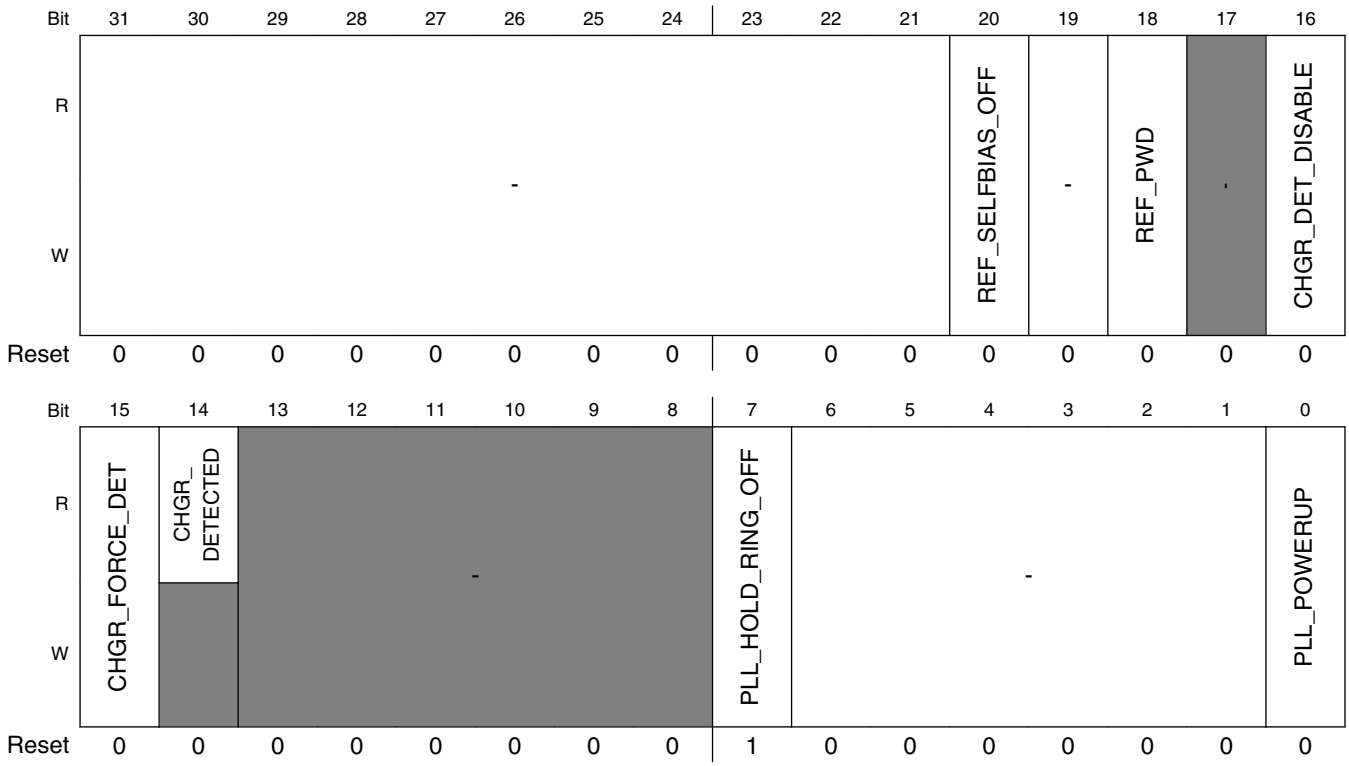
CCM_ANALOG_MISC_TOG is 4101_8000h base + 6Ch offset = 4101_806Ch



CCM_ANALOG_MISC*n* field descriptions

Field	Description
31–21 -	Reserved.
20 REF_ SELFBIAS_OFF	This bit controls the source of the reference bias currents. The bit needs to wait at least 10 us after bandgap is powered up before setting and needs to be set high by software or the tester very early in the flow. The bit needs to be cleared before the bandgap is powered down.
19 -	Reserved.
18 REF_PWD	Powers down the bandgap reference.
17 -	Reserved.
16 CHGR_DET_ DISABLE	This bit disables the charget detect function. The CHGR_FORCE_DET bit should be set if external open drain output needs to be kept asserted.

Table continues on the next page...

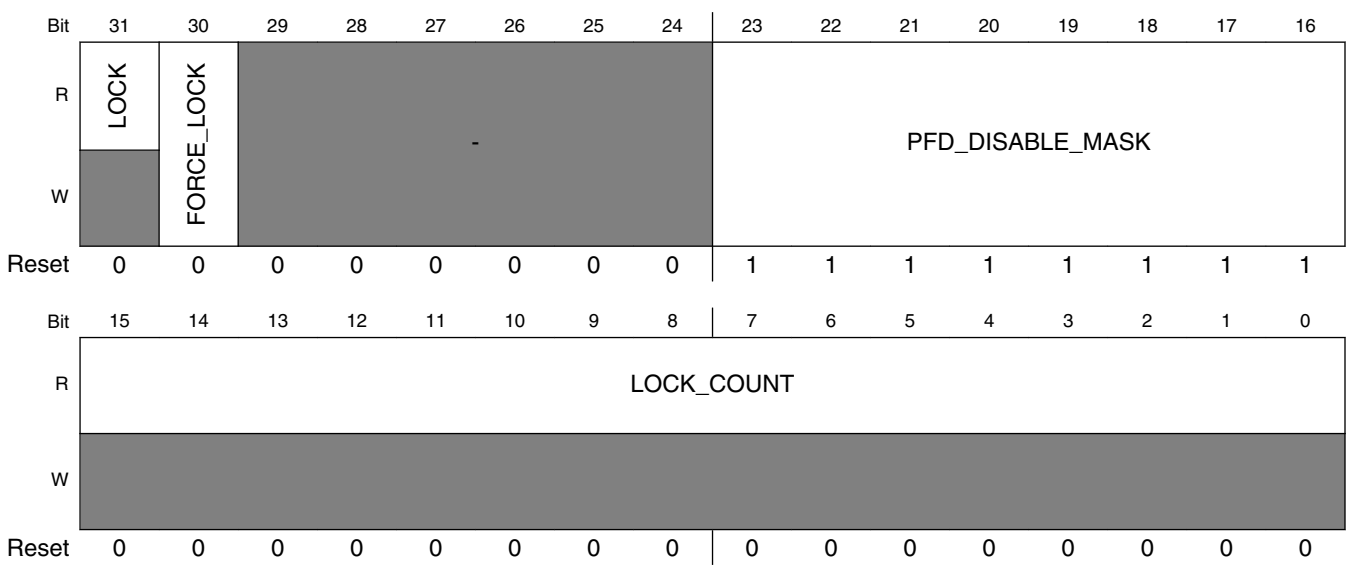
CCM_ANALOG_MISC*n* field descriptions (continued)

Field	Description
15 CHGR_FORCE_DET	This bit asserts the open drain CHGR_DET_B pin regardless of the detector output (enabled or disabled). **NOTE:** This function will not work unless the VBUS power for the OTG USB is present.
14 CHGR_DETECTED	Status bit reflecting the state CHGR_DET_B pin. 1 = asserted.
13–8 -	Reserved.
7 PLL_HOLD_RING_OFF	This hold ring off bit is essential when starting the APLL. This bit should initially be set before powering up the APLL and then cleared more than 10 us later. Additional 10 us wait should occur after clearing the bit before using the output clock either in the PFD's or elsewhere in the system.
6–1 -	Reserved.
0 PLL_POWERUP	PLL Power On. Allow 10 us after turning the PLL0 on before using the PLL0 as a clock source. This is the time the PLL0 takes to lock to 480 MHz. **NOTE:** The POWER bit must be set to on to ungate the reference xtal to all of the PLLs. 0 PLL Off. 1 PLL On.

5.5.4 PLL Control Register (CCM_ANALOG_PLLCTRL*n*)

PLL0 Lock Control Register

Addresses: CCM_ANALOG_PLLCTRL is 4101_8000h base + 70h offset = 4101_8070h
CCM_ANALOG_PLLCTRL_SET is 4101_8000h base + 74h offset = 4101_8074h
CCM_ANALOG_PLLCTRL_CLR is 4101_8000h base + 78h offset = 4101_8078h
CCM_ANALOG_PLLCTRL_TOG is 4101_8000h base + 7Ch offset = 4101_807Ch



CCM_ANALOG_PLLCTRL*n* field descriptions

Field	Description
31 LOCK	PLL0 Lock bit. 0 PLL0 Unlocked. 1 PLL0 Locked.
30 FORCE_LOCK	Force the PLL0 Lock sequence to start. 1= Enable Force Lock. This bit is not self clearing.
29–24 -	Reserved.
23–16 PFD_DISABLE_MASK	This mask determines which PFD's are disabled when the disable_pfds_n is asserted. A 1 indicates the PFD is disabled. The PLL will only be disabled when this mask is set to 0xFF.
15–0 LOCK_COUNT	Status of the PLL0 lock count. The PLL0 lock bit will assert when the count reaches 0x4B0. The lock count is driven off of xtal, so it should be asserted after 50us.

Chapter 6
System Boot

6.1 Introduction

The i.MX50 boot process begins at Power On Reset (POR) where the hardware reset logic forces the ARM core to begin execution starting from the on-chip boot ROM. The boot ROM logic reads hardware inputs such as the boot pins on the IC, OCOTP bits and/or GPIO settings to determine the boot flow behavior of the i.MX50.

The main features of the ROM include:

- Support for booting from various boot devices
- USB Downloader support Device Configuration Data (DCD)
- Digital signature based High Assurance Boot (HAB)

The i.MX50 boot ROM supports the following boot devices:

- Parallel NOR Flash
- NAND Flash
- ONFI 2.x BA-NAND
- Toggle-Mode High speed NAND
- OneNAND Flash
- SD/eSD/MMC/eMMC
- Serial ROM devices, including SPI NOR/EEPROM, I^2C EEPROM

The boot ROM is configured using a combination of external boot pins and OCOTP bits. For development purposes a few key OCOTP bits may be overridden using GPIO pin inputs. The combination of the boot pin and OCOTP bit (or GPIO pin) settings dictate the boot device from which the i.MX50 attempts to boot and the flow within the boot ROM.

The boot ROM logic also allows the downloading of programs to be run on the i.MX50. An example is a provisioning program that can make further use of the serial connection to provision a boot device with a new image. Typically the provisioning program is

downloaded to internal RAM which facilitates programming boot devices such as a NAND Flash. The ROM Serial Downloader uses a high speed USB in non-stream mode connection.

The Device Configuration Data (DCD) feature allows the ROM to obtain IC configuration data from an external Program Image residing on the boot device. As an example, DCD can be used to program the DRAM MC for optimal settings improving the boot performance. DCD is restricted to memory areas and peripheral addresses that are considered essential for boot purposes.

A key feature of the i.MX50 ROM is the ability to perform a secure or High Assurance Boot (HAB). This is supported by the HAB security library which is a subcomponent of the i.MX50 ROM. The HAB uses a combination of hardware and software together with a Public Key Infrastructure (PKI) protocol to protect the system from executing unauthorized programs. Before the HAB allows a user's image to execute, the image must be signed. The signing process is done during the image build process by the private key holder and the signatures are then included as part of the final Program Image. If configured to do so, the i.MX50 verifies the signatures using the public keys included in the Program Image. A secure boot with HAB can be performed on all boot devices supported on i.MX50 in addition to the Serial Downloader. The HAB library in the i.MX50 boot ROM also provides API functions, allowing additional boot chain components (bootloaders) to extend the secure boot chain. The out-of-fab setting for HAB is the open (engineering) configuration mode in which the ROM/HAB performs image authentication but all authentication errors are ignored and the image is still allowed to execute.

The remainder of this chapter provides the details on how to configure and use the boot features of the i.MX50.

6.2 Boot Modes

6.2.1 Boot Mode Pin Settings

The i.MX50 has four boot modes (one is reserved for FSL internal use) that are selected by the two boot mode pins on the IC package (BOOT_MODE[1:0]). The settings of these two pins are sampled out of reset and stored in the BOOT_MODE[1:0] field of the SRC Boot Mode Register (SBMR) in the SRC (System Reset Controller) module. The boot modes are: Internal, Reserved , Internal Boot - Fuses Only, and USB Downloader.

Table 6-1. Boot Mode Pin Settings

BOOT_MODE[1:0]	Boot Type
00	Internal Boot
01	Reserved
10	Internal Boot-Fuses Only
11	USB Downloader

6.2.2 High Level Boot Sequence

Figure 6-1 shows the High Level processor ROM code flow followed in the i.MX50.

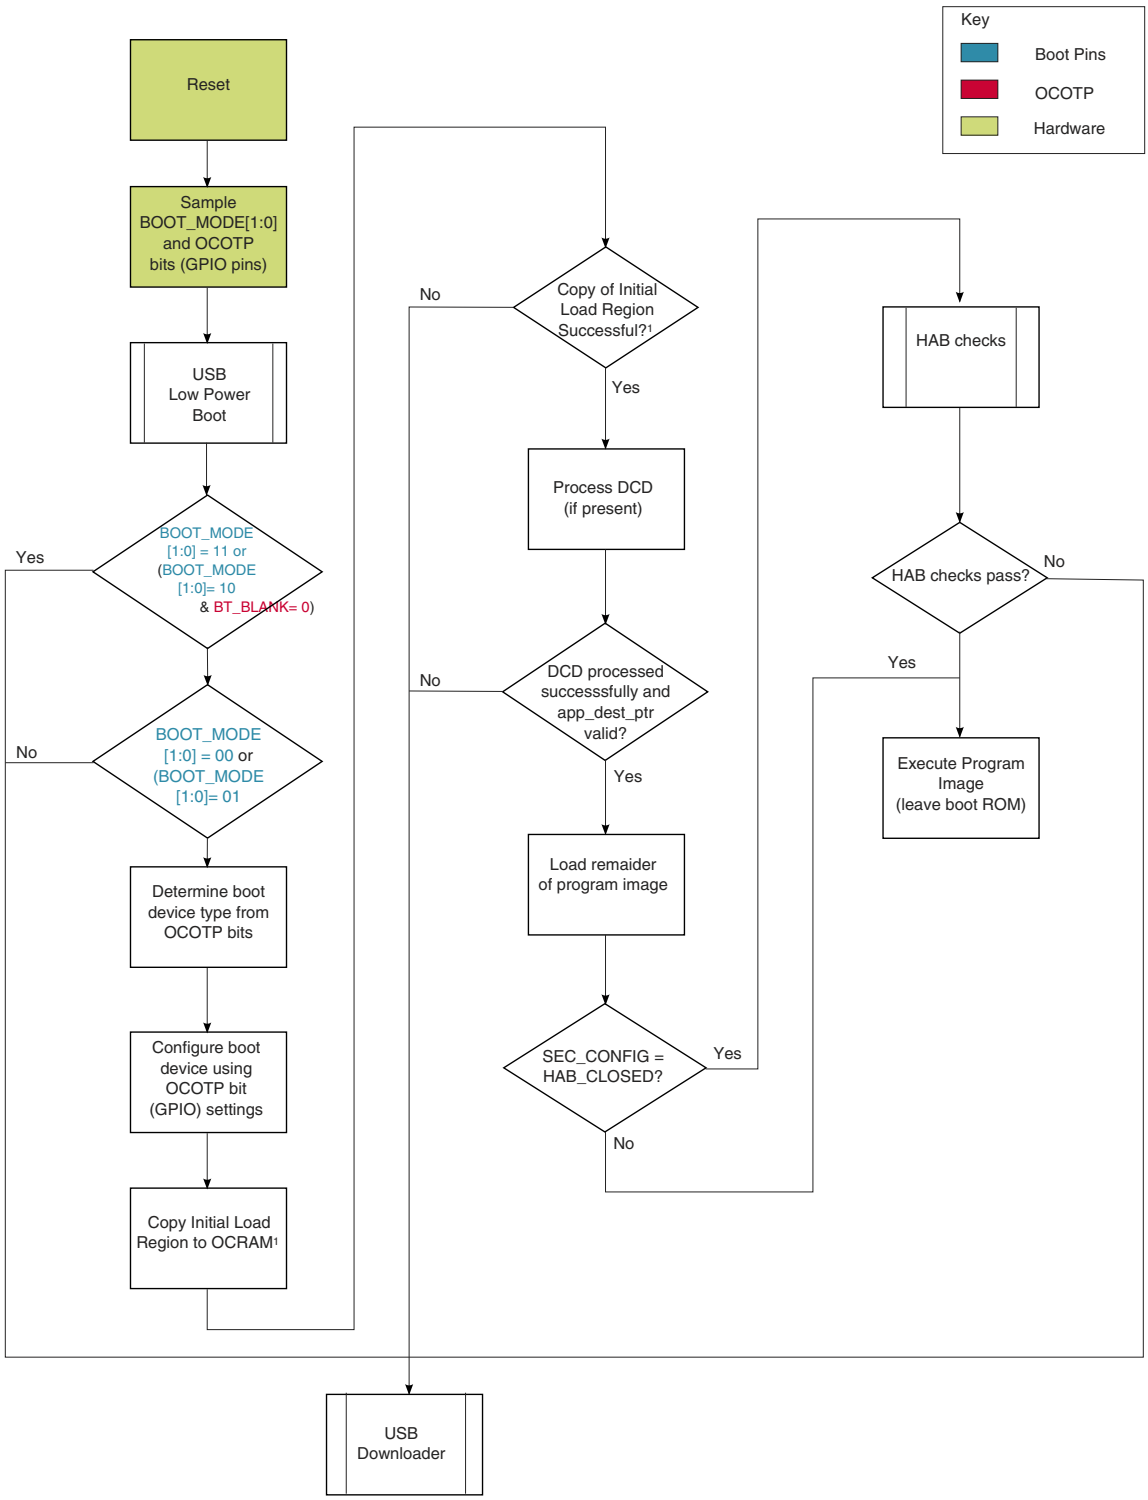


Figure 6-1. i.MX50 ROM Boot Flow

6.2.3 Overview of USB Low Power Boot

The i.MX50 supports a mode where a USB connection can be used to power the device when either the battery level is too low or a battery is not connected to the device. This USB Low Power Boot (LPB) mode feature is enabled by default and can be disabled by blowing the BT_DISABLE_LPB OCOTP bit field.

When a low battery condition is detected, the i.MX50 ROM minimizes the power consumption during the boot process by decreasing the ARM core frequency from 800 MHz/400 MHz to a much lower frequency to meet the power limit constraints of the USB connection. An additional OCOTP bit field BT_LPB_FREQ[1:0] allows users to define the ARM core frequency used in the LPB mode. The lower ARM core frequencies in LPB mode means that the i.MX50 boot times increase but this ensures the constraints of the USB power limits (100 mA) are met. See USB Low-Power Boot, for more details.

6.2.4 Internal Boot (BOOT_MODE [1:0] = 00)

Internal boot mode is selected by driving a value of 00 on the BOOT_MODE[1:0] pins at device power up. In this mode, the processor boots from internal ROM. The boot ROM code performs HW initialization, loads the program image from the chosen boot device, performs image validation using the HAB library (see Boot Security Settings), and then jumps to an address derived from the program image. If any error occurs during internal boot, the boot ROM code jumps to the USB Downloader (see USB Downloader (BOOT_MODE[1:0] = 11)). A secure boot using the HAB on the i.MX50 is possible in all the three boot modes (BOOT_MODE[1:0] = 00, BOOT_MODE[1:0] = 10, and BOOT_MODE[1:0] = 11).

When set to Internal Boot (BOOT_MODE[1:0] = 00) the boot flow may be controlled by a combination of OCOTP bit settings with an option of overriding the fuse setting using GPIO pins. Whether the ROM uses GPIO inputs for a select number of configuration parameters or OCOTP bits is determined by the GPIO Boot Select (BT_FUSE_SEL) OCOTP bit.

- If BT_FUSE_SEL = 1, all boot options are controlled by the OCOTP bits described in Table 6-2.
- If BT_FUSE_SEL = 0, a select number of boot configuration parameters may be set using GPIO pins rather than OCOTP bits. The fuses that can be overridden when in GPIO are indicated in the GPIO column of Table 6-2. Table 6-3 provides the details on the GPIO pins.

The use of GPIO overrides is intended for development since these pads are used for other purposes in deployed products. Freescale recommends controlling the boot configuration by OCOTP bits (BT_FUSE_SEL fuse blown) in deployed products and reserve the use of the GPIO mode (BT_FUSE_SEL fuse intact) for development and testing purposes only.

6.2.5 Internal Boot-Fuses Only (BOOT_MODE [1:0] = 10)

Internal boot-Fuses Only mode is selected by driving a value of 10 on the BOOT_MODE[1:0] pins at device power up. This mode is similar to the Internal boot BOOT_MODE[1:0]=00, with one difference being the GPIO boot override pins are ignored regardless of the BT_FUSE_SEL setting. The boot ROM code uses the boot OCOTP bit settings only. This mode also supports a secure boot using HAB.

If set to Internal Boot - Fuses Only mode, the boot flow is controlled by the BT_BLANK OCOTP bit value. If BT_BLANK = 0, indicating that the boot device (Flash, SD/MMC, and so on.) has not yet been programmed, the boot flow jumps directly to the Serial Downloader. If BT_BLANK = 1, then the normal boot flow is followed, where the ROM attempts to boot from the selected boot device.

The first time a board is used, the default OCOTP bits may be configured incorrectly for the hardware on the platform. In such a case, the ROM code may try to boot from a boot device that does not exist. This may cause an electrical/logic violation on some pads. Using Internal Mode-Fuses Only (BOOT_MODE[1:0] = 10) mode solves this problem. The first time the BT_BLANK OCOTP bit is encountered, it is not blown and forces the ROM to jump directly to the Serial Downloader. This allows a bootloader to be downloaded which can then provision the boot device with a Program Image and blow the BT_BLANK and the other boot configuration OCOTP bits. After a reset, the ROM determines that BT_BLANK is blown and the ROM code performs internal boot according to the new OCOTP bit settings. This allows a user to set BOOT_MODE[1:0]=10 on a production device and burn fuses on the same device (by forcing entry to the Serial Downloader), without changing the value of BOOT_MODE[1:0] or pull-ups/pull-downs on the boot pins.

6.2.6 USB Downloader (BOOT_MODE [1:0] = 11)

The USB Downloader is invoked if the external boot device is not programmed, when a failure is encountered during the boot flow process or any of the following conditions are met:

- BOOT_MODE[1:0] = 11 USB Downloader mode

- BOOT_MODE[1:0] = 10 Internal boot-Fuses Only and the OCOTP bit BT_BLANK = 0
- BOOT_MODE[1:0] = 00 Internal Boot or BOOT_MODE[1:0]=10 Internal Boot-Fuses Only and valid image is not found on the boot device
- Internal failure
- Runtime exception occurs
- Error returned by the HAB functions while SEC_CONFIG = HAB_CLOSED configuration. (Errors are ignored in SEC_CONFIG = HAB_OPENED configuration). See Boot Security Settings.

See USB Downloader (BOOT_MODE[1:0] = 11) for details on the USB Downloader.

6.2.7 Boot Security Settings

All internal boot modes use one of following two secure boot configurations:

- **SEC_CONFIG = HAB_CLOSED** This configuration is intended for use with shipping secure products. All HAB functions are executed and security hardware is initialized, DCD is processed if present, and software in the boot device or software downloaded to RAM is authenticated by HAB prior to its execution. The first error detected is logged, and the boot flow aborted with control passing to the USB Downloader. In this configuration execution does not leave the internal ROM unless the target Program Image has been successfully authenticated.
- **SEC_CONFIG = HAB_OPENED** (default). This configuration is intended for use in non-secure products or during the development phases of a secure product. All HAB functions are executed as for a SEC_CONFIG=HAB_CLOSED configuration: security hardware is initialized, DCD is processed if present, and a Program Image in a boot device or that has been downloaded through the USB Downloader to RAM is authenticated by HAB prior to its execution. The first failure detected is logged, but has no influence and the boot flow continues as if the failure did not occur.

See the SEC_CONFIG entry in Table 6-2 for the specific OCOTP bit field settings.

6.3 Device Configuration

This section describes the external inputs defined that control the behavior of the i.MX50 ROM. This includes boot device selection (NAND, NOR, MMC/SD, SPI, I2C,Toggle-mode NAND, OneNAND), boot device configuration (NAND address cycles), and so on.

In general, the source for this configuration comes from OCOTP bits embedded inside the i.MX50. However, select configuration parameters can be sourced from GPIO pins allowing further flexibility during the development process.

6.3.1 Boot OCOTP bit Descriptions

Table 6-2 shows a comprehensive list of the configuration parameters that the i.MX50 ROM uses.

Table 6-2. Boot OCOTP Bit Descriptions

Fuse	Config	Definition	GPIO[1]	Settings[2]
DIR_BT_DIS	OEM	Reserved FSL test mode disabled.	NA	0 -Reserved FSL test boot allowed 1 - Reserved FSL test boot not allowed
OSC_FREQ_SEL	OEM	CKIH Frequency Select. It is used by boot code for PLL configuration.	Yes	0 - 24Mhz fixed 1 - 26/19.2/27/24 Mhz auto calibration
BT_FUSE_SEL	OEM	GPIO Boot Select. Determines, whether the boot settings indicated by a Yes in the GPIO column are controlled by GPIO pins or OCOTP bit settings in the IIM: **NOTE:** This feature requires BOOT_MODE[1:0] = 00 to operate.	NA	If BOOT_MODE="00" (Development) 0=Boot mode configuration is taken from GPIOs. 1=Boot mode configuration is taken from fuses. If BOOT_MODE="10" (Production) 0 - Boot using Serila Loader (UART/USB) 1- Boot mode configuration is taken from fuses.
BT_BLANK	OEM	Indicates that the boot area has not yet been programmed. **NOTE:** This fuse is only read when BOOT_MODE[1:0]=1(	NA	0 BOOT area is not yet programmed. Boot flow jumps to serial downloader. 1 BOOT area is programmed. Regular boot flow is performed.

Table continues on the next page...

Table 6-2. Boot OCOTP Bit Descriptions (continued)

Fuse	Config	Definition	GPIO[1]	Settings[2]
SEC_CONFIG[1:0]	OEM	Security mode configurations. See Boot Security Settings, for definitions.	YES	00 - HAB_FAB Configuration, out of fab configuration. 01 - HAB_OPENED Configuration (allows any Program Image to be executed, even if it has no valid signature) Others - HAB_CLOSED Configuration (Program Images must have valid signatures)
SRK_HASH[255:0]	OEM	256-bit hash value of super root key (SRK_HASH).	NA	Settings vary - used by HAB
DIE-X-CORDINATE[7:0] DIE-Y-CORDINATE[7:0] WAFER_NO[4:0] LOT_NO_ENC[42:40] LOT_NO_ENC[39:32] LOT_NO_ENC[31:24] LOT_NO_ENC[23:16] LOT_NO_ENC[15:8] LOT_NO_ENC[7:0]	Freescale	Device Unique ID, 64-bit UID.	NA	Settings vary - used by HAB
BT_FREQ	OEM	OCOTP bit used to select ARM core frequency at normal boot mode	Yes	0 800Mhz 1 400Mhz
BT_LPB_FREQ[1:0]	OEM	ARM core frequency at Low-Power Boot Mode (LPB).	Yes	00 - 192 MHz (Default[3] - out of reset), 01 - 133 MHz 10 - 55.33 MHz 11 - 220 MHz
BT_MMU_DISABLE	OEM	MMU/D-Cache disable bit used by boot ROM to control HAB processing speed (faster with MMU/D-Cache enabled)	Yes	0 - MMU/D-Cache is enabled by ROM during the boot 1 - MMU/D-Cache is disabled by ROM during the boot
BT_DISABLE_LPB	OEM	Bit used to disable Low-Power Boot Mode (LPB).	No	0 LPB Enabled in default 1 LPB is disabled
BT_DEVICE_1.8V	OEM	OCOTP bit used to enable iomux configuration for 1.8v boot media devices	Yes	0 Boot device is 3.3v(default) 1 Boot device is 1.8v
BT_DISABLE_ROM_REDUNDANT_BOOT	OEM	Disable redundant boot functionality	YES	0 - Redundant boot enabled 1 - Redundant boot disabled

Table continues on the next page...

Table 6-2. Boot OCOTP Bit Descriptions (continued)

Fuse	Config	Definition	GPIO[1]	Settings[2]
AXI/DDR_FREQ	OEM	Select PLL2 frequency	YES	0 - PLL2 400 MHz 1 - PLL2 333 MHz
BT_USB_LEGACY	Freescale	Bit used to disable USB HID mode. If blown device will connect to usb host in legacy mode and host will need JUNGO USB driver installed on host machine to enumerate the device	No	0 Device enumerates on host as USB HID device 1 Device enumerates on host in legacy mode if JUNGO driver is installed on host machine
ENABLE_WDOG_TIMER_RESET	Freescale	Bit used to enable wdog timer reset in USB mode	No	0 In USB mode wdog reset timer is not used 1 In USB mode wdog reset timer is used.
DISABLE_WDOG_BOOT	Freescale	Bit used to disable wdog boot feature newly added into i.MX50 ROM	No	0 Watch dog boot enabled 1 Watch dog boot disabled
USB_VID	OEM	16 bits used for specifying USB vendor id	No	default value if not blown is 0x15A2
USB_PID	OEM	16 bits used for specifying USB product id	No	default value if not blown is 0x0052
DISABLE_MMC_FAST_BOOT_ACK at fuse BOOT_CFG3[6]	OEM	By default ROM will enable BOOT_ACK mode of MMC boot register for eSDHCv3. This fuse can be use to disable BOOT_ACK mode.	Yes	0 - ROM will set 1 to BOOT_ACK bit of MMC_BOOT_REGISTER 1 - ROM will set 0 to BOOT_ACK bit of MMC_BOOT_REGISTER
DISABLE_EMMC44_CMD0_RESET at BOOT_CFG3[26]	OEM	For fast boot, by default ROM will send CMD0+0xF0F0F0F0 to reset eMMC card. For earlier versions of eMMC like 4.3 this sequence is not supported so this fuse can be used to force ROM not to send reset cmd to the card.	Yes	0 - fast boot from eMMC4.4 card, CMD0+0xF0F0F0F0 will be sent before fast boot 1 - fast boot from eMMC4.3 card if blown, since (CMD0+F0F0F0F0) reset is not supported by eMMC4.3
ENABLE_MAX_DRIVE_STRENGTH at CFG6[16]	OEM	By default ROM will enable high drive strength for SD pins. If this fuse is set then ROM will set max drive strength for SD pins	No	0 - Not enabled (default to high strength) 1 - Enabled
DLL_SLAVE_OVERRIDE at CFG6[17]	OEM	If this bit is set then ROM will enable DLL SLAVE and DLL will not be enabled otherwise ROM will enable the DLL during eMMC init	No	0 - Use DLL SLAVE 1 - DLL OVERRIDE

Table continues on the next page...

Table 6-2. Boot OCOTP Bit Descriptions (continued)

Fuse	Config	Definition	GPIO[1]	Settings[2]
NUMBER_OF_NANDS at CFG6[15:13]	OEM	These fuse bits are used to indicate to the ROM number of NAND chip enables present on the device. This fuse value is useful when enabling internal pull-ups on NAND CE and RDY pins. If there are 8 chip selects then an external pull-up should be added on board. ROM can only enable internal pull-ups for 7 nand chip selects, this is due to a bug in ROM code.	No	000 - 1 001 - 1 010 - 2 011 - 3 100 - 4 101 - 5 110 - 6 111 - 7
ENABLE_INTERNAL_NAND_PULL_UP at CFG6[8]	OEM	If this bit is set then ROM will enable internal pull-ups for NAND chip-enable and ready-busy pins.	No	0 - Not enable internal pull-ups for NAND CE and RDY pins. 1- Enable internal pull-ups for NAND CE and RDY pins
DISABLE_LEVEL1_ICACHE at CFG6[4]	Freescale	By default ROM will enable ICache at startup and this fuse can be used to force ROM to not enable I-Cache.	No	0 - I-Cache will be enabled 1 - I-Cache will not be enabled

1. Setting can be overridden by GPIO settings when BT_FUSE_SEL fuse is intact. See Table 6-3 for corresponding GPIO pin.
2. 0 = intact otp bit and 1= blown fuse
3. For details refer to Clock Initialization.

6.3.2 GPIO Boot Overrides

Table 6-3 provides a list of GPIO boot overrides. These input pins are sampled at boot, and can be used to override corresponding OCOTP bit values, depending on the setting of the BT_FUSE_SEL fuse. The GPIO override feature is only available when BT_FUSE_SEL is 0 (fuse is unblown) and BOOT_MODE[1:0] = 00.

Table 6-3. GPIO Override Contact Assignments

Contact	Boot Configuration Bits	Details
BOOT_MODE0	BOOT_MODE[0]	
EIM_DA0	BOOT_CFG1[0]	BT_MMU_DISABLE
EIM_DA1	BOOT_CFG1[1]	BT_FREQ
EIM_DA2	BOOT_CFG1[2]	BT_1.8V_BOOT
EIM_DA3	BOOT_CFG1[3]	-
EIM_DA4	BOOT_CFG1[4]	-
EIM_DA5	BOOT_CFG1[5]	-

Table continues on the next page...

Table 6-3. GPIO Override Contact Assignments (continued)

Contact	Boot Configuration Bits	Details
EIM_DA6	BOOT_CFG1[6]	-
EIM_DA7	BOOT_CFG1[7]	-
EIM_DA8	BOOT_CFG2[0]	SEC_CONFG[0]
EIM_DA9	BOOT_CFG2[1]	SEC_CONFIG[1]
EIM_DA10	BOOT_CFG2[2]	DISABLE_REDUNDANT_BOOT
EIM_DA11	BOOT_CFG2[3]	OSC_FREQ_SEL
EIM_DA12	BOOT_CFG2[4]	BT_DDR_FREQ
SSI_TXFS	CFG4[10]	BT_LPB_FREQ[0]
SSI_TXC	CFG4[11]	BT_LPB_FREQ[1]

6.3.3 Device Configuration Data

See Device Configuration Data (DCD), for more details on Device Configuration Data.

6.4 Device Initialization

This section describes the details on the i.MX50 ROM and the provides initialization details. This includes details on:

- The OCROM Memory Map
- The OCRAM Memory Map
- On-chip modules that the ROM should make use of or change POR register default values
- Clock initialization
- Enabling the MMU/L2 cache
- Exception handling, error logging, and interrupt handling

6.4.1 Memory Map

Figure 6-2 shows the OCROM and OCRAM memory map for the i.MX50 Memory Map.

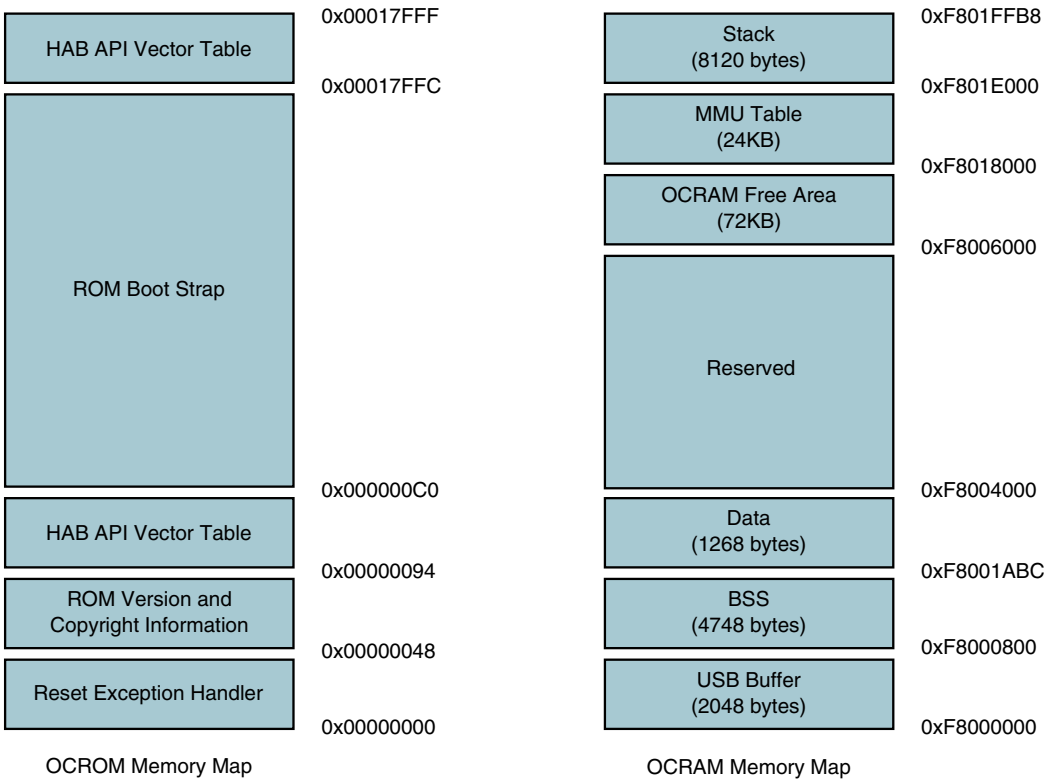

Figure 6-2. OCROM and OCRAM Memory Map

The OCRAM free space occupies the address from 0xF8006000~0xF8017FFF occupying a total of 72 Kbytes. The following 24 Kbytes of OCRAM is reserved for MMU page tables when the BT_MMU_DISABLE OCOTP bit is not blown. When the BT_MMU_DISABLE OCOTP bit is blown the OCRAM space from 0xF8006000-0xF801DFFF may be treated as OCRAM free space. See Enabling MMU/ Caches, for additional information on enabling the MMU.

NOTE

When the BT_MMU_DISABLE OCOTP bit is not blown, don't write any data to the MMU Page Table area in OCRAM. Doing so will cause the i.MX50 to fail boot.

6.4.2 Boot Module Activation

The i.MX50 boot ROM affects a number of different hardware modules which are activated and play a vital role in the boot flow. The i.MX50 ROM configures and uses the following modules (listed in alphabetical order) during the boot process. Note that the modules actually used depend on the boot mode and boot device selection:

- CCM-Clock Control Module

- CSPI/eCSPI-Configurable Serial Peripheral Interface and enhanced Configurable Serial Peripheral Interface
- DCP-Data Co-Processor
- DRAM MC(EIM)-DRAM Memory Controller. Only used for booting from an external memory device using the EIM.
- eSDHC/v3-enhanced Secure Digital Host Controller
- I2C-Inter IC
- IOMUX- I/O Multiplexor allows using the GPIO to override OCOTP bit boot settings.
- OCOTP-On Chip One Time Programming bits
- PLL- Phase Locked Loop. Also called Digital Phase Locked Loop (DPLL)
- SRC-System Reset Controller
- GPT-General Purpose Timer
- SRTC-Secure Real Time Clock
- USB-Used for serial download of a boot device provisioning program
- WDOG-Watchdog Timer
- BCH-32-bit error correction HW engine with AXI bus master and private connection to GPMI.
- GPMI-NAND controller pin interface.
- APBH_DMA-DMA engine to drive the GPMI module.

6.4.3 Clocks at Boot Time

The clocks that are enabled (and their frequencies) when ROM begins execution are shown in Table 6-5. This table also describes the peripheral clock sources.

6.4.4 Clock Initialization

On reset, the processor has access to all shared peripherals and by default all peripheral clocks are enabled and the boot ROM does not change any of the peripheral clock enables. The clocks are initialized depending on whether a normal boot or a USB low power boot is performed.

6.4.4.1 NORMAL Mode

In normal mode the following frequencies are available as input clock to PLL1-3 modules. Selection of these frequencies is accomplished as follows:

1. The CLKSS is read and if OSC is selected then further input clock selection is based on the OCOTP bit OSC_FREQ_SEL (Refer to Table 6-4).
2. If the CLKSS is FPM, then 32 kHz is selected as input to PLL1-3 module.

Table 6-4. OSC_FREQ_SEL Frequencies

OSC_FREQ_SEL	Oscillator Frequency	LPB Frequency BT_LPB_FREQ = 0
0	24 MHz	192 MHz
1	26/19.2/27/24 MHz Auto Calibration	208/153.2/216/192 MHz

NOTE: Although ROM code can calibrate the frequency of oscillator on board when OSC_FREQ_SEL is blown, it is not recommended to do so, because auto calibration of frequency will take 10ms to calculate, furthermore 24 MHz oscillator is recommended.

Table 6-5 shows PLL1-PLL3 with their associated frequencies.

Table 6-5. PLL Frequencies

Clock	Frequency (MHz)
PLL1	800/400
PLL2	400/333
PLL3	216

Table 6-6 shows the various clocks used and the clock sources used.

Table 6-6. Normal Clock Configuration

	CCM Signal	Source	Freq [MHz] Fuse AXI/DDR Freq = 0 and BT_FREQ=0	Freq [MHz] Fuse AXI/DDR Freq = 0 and BT_FREQ=1	Freq [MHz] Fuse AXI/DDR Freq = 1 and BT_FREQ=0	Freq [MHz] Fuse AXI/DDR Freq = 1 and BT_FREQ=1
ARM Core	arm_clk_root	PLL1	800	400	800	400
GPMI rawnand	gpmi_clk_root	OSC	24	24	24	24
GPMI Togglemode NAND	gpmi_clk_root	PFD0 or PLL1	33/40/66	33/40/66	33/40/66	33/40/66
DRAM MC slow	emi_slow_clk_root	PLL2	100	100	83.25	83.25
AHB	ahb_clk_root	PLL2	133	133	110	110
IPG	ipg_clk_root	PLL2	66.5	66.5	55	55
AXI_A	axi_a	PLL2	400	400	133	133
AXI_B	axi_b	PLL2	200	200	166.5	166.5

Table continues on the next page...

Table 6-6. Normal Clock Configuration (continued)

	CCM Signal	Source	Freq [MHz] Fuse AXI/DDR Freq = 0 and BT_FREQ=0	Freq [MHz] Fuse AXI/DDR Freq = 0 and BT_FREQ=1	Freq [MHz] Fuse AXI/DDR Freq = 1 and BT_FREQ=0	Freq [MHz] Fuse AXI/DDR Freq = 1 and BT_FREQ=1
eSDHC1	esdhc1_clk_root	PLL2	80	80	66.6	66.6
eSDHC2	esdhc2_clk_root	PLL2	80	80	66.6	66.6
eSDHC3	esdhc3_clk_root	PLL2	80	80	66.6	66.6
eSDHC4	esdhc4_clk_root	PLL2	80	80	66.6	66.6
eCSPI	eCSPI_clk_root	PLL3	54	54	54	54
CSPI	ipg_clk_root	IPG_CLK	66.5	66.5	55	55
I2C	per_clk_clk	PER_CLK	20	20	16.65	16.65
USBOH1_PHY	Oscillator	OSC	26/19.2/27/24 See Table 6-4	26/19.2/27/24 See Table 6-4	26/19.2/27/224 See Table 6-4	26/19.2/27/24 See Table 6-4

In addition to these clocks, the PERCLK_ROOT clock is generated by dividing PLL2 as a source to I^2C module and the CSPI_CLOCK_ROOT using IPG_ROOT (66.5 MHz).

6.4.4.2 USB Low-Power Boot Mode (LPB)

In MX50, LPB support is implemented by only decreasing the ARM core frequency, and the frequency of other modules will be the same with that of normal boot mode. The ROM code configures the ARM core frequency value based on the setting of the OCOTP bit BT_LPB_FREQ[1:0]. The LPB ARM core frequency defaults to 192 MHz out of reset. The LPB ARM core frequency can change based on the BT_LPB_FREQ[1:0] as shown in Table 6-7.

Table 6-7 lists the various LPB frequencies used by different clocks based on the value of BT_LPB_FREQ[1:0].

Table 6-7. ARM Frequency of Low Power Boot Mode

BT_LPB_FREQ[1:0]	00	01	10	11
PLL1	192	266	166	220
ARM core	192 Mhz	133 Mhz	55.3 Mhz	220 Mhz

6.4.5 Enabling MMU/Caches

Boot ROM includes a feature of enabling the MMU and caches to improve boot speed when performing image authentication using HAB library (High Assurance Boot (HAB). L1 instruction cache is enabled at the start of image download. L1 data cache, L2 cache and MMU are enabled during image authentication. The MMU and caches are enabled by default. If the BT_MMU_DISABLE fuse bit is blown, then MMU and caches are disabled during boot.

6.4.6 Error Logging

The HAB status is logged to a single 32-bit word. The value can be obtained in USB HID mode using the SDP command ERROR_STATUS. For details on HAB status codes please contact your local Freescale representative.

6.4.7 Exception Handling

The exception vectors located at the start of OCROM are used to map all the ARM exceptions (except the reset exception) to a duplicate exception vector table in internal RAM. Copying the exception vectors to OCRAM allows the vectors to be changed by later stages in the boot chain.

During the boot phase, the OCRAM vectors point to the USB Downloader in OCROM. After boot the OS loader can overwrite the vectors as required. The OCRAM exception table is filled with the address of the USB Downloader entry point such that any exception or interrupt results in execution of the USB Downloader. The code shown is used to map the ROM exception vector table to the duplicate one in OCRAM.

Mapping ROM Exception Vector Table

```
;; Define linker area for OCROM exception vector table
AREA IROM_VECTORS, CODE, READONLY

LDR   PC, Reset_Addr
LDR   PC, Undefined_Addr
LDR   PC, SWI_Addr
LDR   PC, Prefetch_Addr
LDR   PC, Abort_Addr
NOP         ; Reserved vector
LDR   PC, IRQ_Addr
LDR   PC, FIQ_Addr
LDR   PC, SW_monitor_addr

;; Define exception vector table
Reset_Addr      DCD     start_address
Undefined_Addr  DCD     OCRAM_Undefined_Handler
SWI_Addr        DCD     OCRAM_SWI_Handler
Prefetch_Addr   DCD     OCRAM_Prefetch_Handler
```

```
Abort_Addr      DCD     OCRAM_Abort_Handler
DCD  0                ; Reserved vector
IRQ_Addr        DCD     OCRAM_IRQ_Handler
FIQ_Addr        DCD     OCRAM_FIQ_Handler
SW_monitor_add  DCD   SW monitor exception

start_address   DCD start ;reset handler vector
```

6.4.8 Interrupt Handling During Boot

No special interrupt handling routines are required during the boot process. Interrupts are disabled during boot ROM execution and may be enabled in a later boot stage.

6.5 Boot Devices (Internal Boot)

The i.MX50 supports the following boot devices:

- NOR flash with EIM Interface, located on CS0, with only 16-bits bus width supported.
- OneNAND flash with EIM interface, located on CS0 with only 16-bit bus width supported.
- Raw NAND (MLC and SLC), and Toggle-mode NAND flash through GPMI-2 interface. Page sizes of 512 bytes, 2 Kbyte, 4 Kbyte and 8 Kbyte. Bus widths of 8-bit with 2 through 32-bit BCH Hardware ECC (Error Correction) supported.
- SD/MMC/eMMC and eSD through eSDHC interface, supporting high capacity cards. eMMC-4.3/4.4 boot mode (FAST BOOT) through eSDHCv3 port. The eMMC4.4 DDR mode is also supported.
- eSD FAST BOOT mode through all the eSDHC ports.
- Serial ROM boot via SPI (serial flash or EEPROM) and I^2C EEPROM.

The selection of boot device type is controlled by BT_MEM_CTL[1:0] and BT_MEM_TYPE[1:0] OCOTP bits. See Table 6-2 for the specific OCOTP bit settings.

6.5.1 NOR/OneNAND Boot from EIM Interface

The NOR flash interface works in the asynchronous mode and supports either muxed Address/Data or non-muxed schemes based on OCOTP bit settings, see Table 6-8 for details.

Table 6-8. EIM Boot OCOTP Bits Descriptions

Fuse	Config	Definition	GPIO[1]	Settings
BOOT_CFG1[7:4]	OEM	Boot Device Selection	Yes	0000 - Boot from EIM Interface
BOOT_CFG1[3]	OEM	NOR/OneNand Selection	Yes	0 - NOR 1 - OneNand
BOOT_CFG2[7:6]	OEM	Muxing Scheme	Yes	00 - Muxed, 16-bit data (low half) interface 01 - Not muxed, 16-bit data (high half) interface 10 - Reserved 11 - Reserved

1. Setting can be overridden by GPIO settings when BT_FUSE_SEL fuse is intact. See Table 6-3 for corresponding GPIO pin.

6.5.1.1 IOMUX Configuration for EIM

Because all i.MX50 pads are configured as GPIO input out of reset, IOMUX configuration is required even for EIM interface.

Table 6-9. IOMUX Configuration of EIM Interface

A0	EIM_DA0.ALT0	A26	DISP_RS.ALT3	D8	EPDC_D8.ALT2

[1] The shadowed cells are the pins which are not configured in ROM code.

[2] D[31:16] will be configured for non-mux addressing mode.

6.5.1.2 NOR Flash Boot Operation

Booting from the NOR Flash is supported via EIM interface. The ROM reads Image Vector Table and Boot Data structures to determine if the image can be executed directly from EIM address space or should be copied to other memory. The start field of Boot Data Structure specifies the final location of the image.

6.5.1.3 OneNAND Flash Boot Operation

The OneNAND flash devices are only available with a 16-bit interface. The ROM OneNAND Flash driver reads the device page size by issuing a software command to device and collecting its response.

At system power-up, OneNAND automatically copies 1 Kbyte data from start of Flash array (sector 0 and sector 1, page 0, block 0) to its Boot RAM, (oneNAND's internal RAM). For example, the Boot RAM contains the OneNAND Image Vector Table. Boot ROM copies the 1 Kbyte OneNAND Boot RAM contents to the application destination pointer (located in the boot_data structure of Image Vector Table (IVT) and decrements the length of the image to be read from OneNAND by 1k. Because the Boot RAM area is memory mapped, the copy operation is a simple memory copying operation. The length of image to be read from the OneNAND device is specified in Image Vector Table structure described in Figure 6-15. Failure loading data from OneNAND flash for any reason forces the processor Boot ROM to switch to serial download. Due to limited 1Kbyte size of OneNAND Boot RAM both IVT and DCD must fit in first 1Kbyte. This limits the max size of DCD for OneNAND device to 736 bytes as specified in Table 6-22. ROM reads rest of image and copies it to destination address during HAB authentication process.

At system power-up, the voltage detector in the device detects the rising edge of Vcc and releases internal power-up reset signal which triggers bootcode loading. Bootcode loading means that the boot loader in the OneNAND copies the designated sized data (1Kbyte) from the beginning of memory to the BootRAM. The Bootcode copy operation starts 400 µs later than POR activation and the 1Kbyte Bootcode copy takes 70 µs (estimated) from sector0 and sector1/page0/block0 of NAND Flash array to the BootRAM. The INT bit of Interrupt status register goes from 'Low' to 'High' on the condition of 'Bootcode-copy done' and RP rising edge.

Boot ROM implements OneNAND initialization in two stages:

- Use the GPT timer to introduce a delay of around 500 µS.
- Wait for INT bit on the Interrupt status register to go High. Once INT bit of interrupt status register is set to High, Boot ROM proceeds with OneNAND initialization.

NOTE

Image header, DCD and boot data must reside in the initial load region (1K) of bootable image. Image length must be specified in the boot data structure pointed to by the image header boot data element, please see Figure 6-15 for image vector table structure

6.5.2 Raw NAND Boot from GPMI-2 Interface

A number of MLC/SLC NAND flash devices, from various vendors, are supported by the i.MX50 ROM. The BCH32 ECC module is used for error detection and correction.

6.5.2.1 NAND eFUSE/GPIO Configuration

The i.MX50 ROM determines the configuration of an external NAND Flash by the following parameters, provided either by eFUSE or GPIO pins sampled at power up.

To control the external NAND device parameters, use the BOOT_CFG1, BOOT_CFG2 and BOOT_CFG3 and the CFG4 eFuses.

See Table 6-10 for the specific eFUSE settings.

Table 6-10. NAND Boot Device Fuse Settings

Fuse	Config	Definition	GPIO[1]	Settings
BOOT_CFG1[7]	OEM	Boot Device Selection	Yes	1 - Boot from Nand Interface

Table continues on the next page...

Table 6-10. NAND Boot Device Fuse Settings (continued)

Fuse	Config	Definition	GPIO[1]	Settings
BOOT_CFG1[6]	OEM	GPMI_CLK_SRC_PLL1	Yes	Only used if BT_TOGGLEMODE fuse is blown. 0 - GPMI and BCH CLK sourced from PFD4 1 - GPMI and BCH CLK sourced from PLL1 If BT_TOGGLEMODE fuse is not blown then ROM uses 24 MHz OSC as source for deriving GPMI and BCH CLKs
BOOT_CFG1[5]	OEM	BT_TOGGLEMODE	Yes	0 - Boot from legacy nand flash 1 - Boot from Samsung's togglemode DDR nand flash
BOOT_CFG1[4:3]	OEM	GPMI cle/ale/ce/ready/dqs MUX on	Yes	00 - Kpp 01 - Eim 10 - Elcdif 11 - Reserved
BOOT_CFG2[7:5]	OEM	Toggle Mode 33 MHz Preamble Delay, Read Latency	Yes	3 bits used to specify toggle mode NAND timing parameters preamble delay and read latency, default if not programmed will be a value of 2. Same value is used for both parameters. ROM will overwrite these with values read from FCBi
BOOT_CFG3[7:6]	OEM	Nand_Row_address_bytes	Yes	00 - 3 address cycles 01 - 2 address cycles 10 - 4 address cycles 11 - 5 address cycles
BOOT_CFG3[5:4]	OEM	BOOT_SEARCH_COUNT	Yes	00 - 2 01 - 2 10 - 4 11 - 8
BOOT_CFG3[3:2]	OEM	Pages In Block	Yes	00 - 128 01 - 64 10 - 32 11 - Reserved
CFG4[23:16]	OEM	NAND_READ_CMD_CODE1	No	Command for read action in the first address cycle
CFG4[15:8]	OEM	NAND_READ_CMD_CODE2	No	Command for read action in the second address cycle

1. Setting can be overridden by GPIO settings when BT_FUSE_SEL fuse is intact. See Table 6-3 for corresponding GPIO pin.

6.5.2.2 NAND Flash Boot Flow and Boot Control Blocks(BCB)

There are two BCB data structures: FCB and DBBT. As part of the NAND media initialization, the ROM driver uses safe NAND timings to search for a Firmware Configuration Block (FCB) that contains the optimum NAND timings, page address of Discovered Bad Block Table (DBBT) Search Area and start page address of primary and secondary firmware.

The hardware ECC level to use is embedded inside FCB block. The FCB data structure is itself protected

using software ECC (SEC-DED Hamming Codes). Driver reads raw 2112 bytes of first sector and runs through software ECC engine that determines whether FCB data is valid or not.

If the FCB is found, the optimum NAND timings are loaded for further reads. If the ECC fails, or the fingerprints do not match, the Block Search state machine increments page number to Search Stride number of pages to read for the next BCB until SearchCount pages have been read.

If search fails to find a valid FCB, the NAND driver responds with an error and the boot ROM enters into serial download mode.

The FCB contains the page address of DBBT Search Area, and the page address for primary and secondary boot images. DBBT is searched in DBBT Search Area just like how FCB is searched. After the FCB is read, the DBBT is loaded, and the primary or secondary boot image is loaded using starting page address from FCB.

See the flow of FCB search in Figure 6-3.

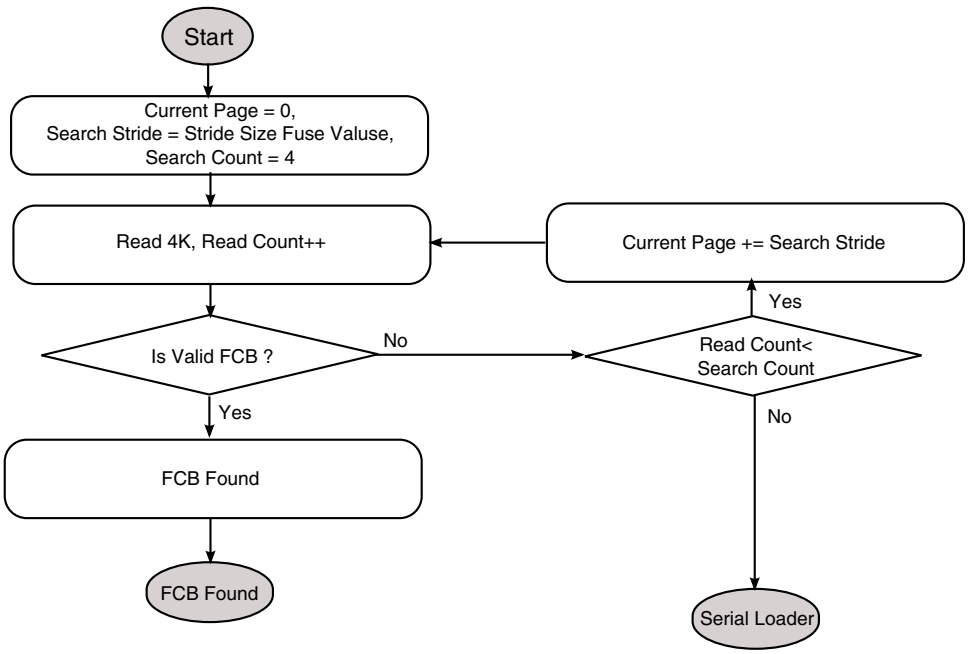

Figure 6-3. FCB Search Flow

Once FCB found the boot ROM starts searching for Discovered Bad Blocks Table (DBBT). If DBBT Search Area is 0 in FCB, then ROM assumes that there are no bad blocks on NAND device. See Figure 6-4 for DBBT search flow.

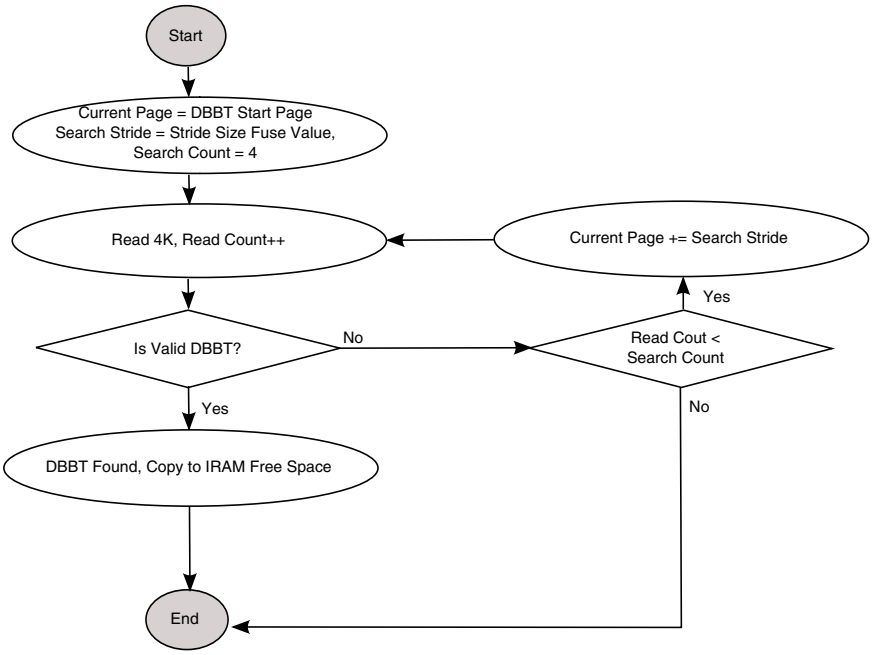

Figure 6-4. DBBT Search Flow

If during primary image read there was a page with number of errors higher than ECC can correct, the boot

ROM will turn on PERSIST_SECONDARY_BOOT bit and perform SW reset. (After SW reset secondary image will be used).

If during secondary image read there was a page with number of errors higher than ECC can correct, the boot ROM will go to serial loader.

6.5.2.3 Firmware Configuration Block

The FCB is the first sector in the first good block. The FCB should be present at each search stride of the search area. The search area contains copies of the FCB at each stride distance, so in case the first NAND block becomes corrupted, the ROM will find its copy in the next NAND block. The search area should span over at least two NAND blocks. The location information for DBBT search area, FW1, and FW2 are all specified in the FCB. Flash Control Block Structure is as shown in Table 6-11.

Table 6-11. Flash Control Block Structure

Name	Start Byte	Size in Bytes	Description
Reserved	0	4	Reserved for Fingerprint #1(Checksum)

Table continues on the next page...

Table 6-11. Flash Control Block Structure (continued)

Name	Start Byte	Size in Bytes	Description
FingerPrint	4	4	32 bit word with a value of 0x4E434220, in ascii "FCB"
Version	8	4	32-bit version number; this version of FCB is 0x00000001
m_NANDTiming	12	4	8 bytes of data for 8 NAND Timing Parameters from NAND datasheet. The 8 parameters are: data_setup, data_hold, address_setup, dsample_time, nand_timing_state, REA, RLOH, RHOH
PageDataSize	20	4	Number of bytes of data in a page. Typically, this is 2048 bytes for 2112 bytes page size or 4096 bytes for 4314 bytes page size
TotalPageSize	24	4	Total number of bytes in page. Typically, 2112 for 2 K page or 4224 or 4314 for 4 K page.
SectorsPerBlock	28	4	Number of pages per block. Typically 64 or 128 or depending on NAND device type.
NumberOfNANDs	32	4	Not used by ROM
TotalInternalDie	36	4	Not used by ROM
CellType	40	4	Not used by ROM
EccBlockNEccType	44	4	Value from 0 to 16 used to set BCH Error Corrrection level 0, 2, 4, .. or 32 for Block B0 of ECC page, used in configuring BCH32 page layout registers
EccBlock0Size	48	4	Size of block B0, used in configuring BCH32 page layout registers
EccBlockNSize	52	4	Size of block BN, used in configuring BCH32 page layout registers
EccBlock0EccType	56	4	Value from 0 to 16 used to set BCH Error Corrrection level 0, 2, 4, .. or 32 for Block BN of ECC page, used in configuring BCH32 page layout registers
MetadataBytes	60	4	Size of metadata bytes used in configuring BCH32 page layout registers
NumEccBlocksPerPage	64	4	Number of ECC blocks BN not including B0. This value is used in configuring BCH32 page layout registers
EccBlockNEccLevelSDK	68	4	Not used by ROM

Table continues on the next page...

Table 6-11. Flash Control Block Structure (continued)

Name	Start Byte	Size in Bytes	Description
EccBlock0SizeSDK	72	4	Not used by ROM
EccBlockNSizeSDK	76	4	Not used by ROM
EccBlock0EccLevelSDK	80	4	Not used by ROM
NumEccBlocksPerPageSDK	84	4	Not used by ROM
MetadataBytesSDK	88	4	Not used by ROM
EraseThreshold	92	4	Not used by ROM
Firmware1_startingPage	104	4	Page number address where first copy of bootable firmware is located
Firmware2_startingPage	108	4	Page number address where second copy of bootable firmware is located
PagesInFirmware1	112	4	Size of first copy of firmware in pages
PagesInFirmware2	116	4	Size of second copy of firmware in pages
DBBTSearchAreaStartAddress	120	4	Page address for bad block table search area
BadBlockMarkerByte	124	4	This is an input offset in BCH page for ROM to swap with first byte of metadata after reading a page using BCH32. ROM supports restoration of manufacturer marked bad block markers in the page and this offset is the bad block marker offset location
BadBlockMarkerStartBit	128	4	This is an input bit offset in BadBlockMarkerByte for ROM to use when swapping 8 bits with fiirst byte of metadata.
BBMarkerPhysicalOffset	132	4	This is the offset where manufacturer leaves bad block marker on a page
BCHType	136	4	0 for BCH20 and 1 for BCH32. MX50 is backward compatible to BCH20 and this field tell ROM to use BCH20 or BCH32 block
TMTiming2_ReadLatency	140	4	Toggle mode NAND timing parameter read latency, ROM use this vlue to configure timing2 register of GPMI
TMTiming2_PreambleDelay	144	4	Toggle mode NAND timing parameter Preamble Delay. ROM use this value to configure timing2 register of GPMI
TMTiming2_CEDelay	148	4	Toggle mode NAND timing parameter CE Delay. ROM use this value to configure timing2 register of GPMI
TMTiming2_PostambleDelay	152	4	Toggle mode NAND timing parameter Postamble Delay. ROM use this value to configure timing2 register of GPMI

Table continues on the next page...

Table 6-11. Flash Control Block Structure (continued)

Name	Start Byte	Size in Bytes	Description
TMTiming2_CmdAddPause	156	4	Toggle mode NAND timing parameter Cmd Add Pause. ROM use this value to configure timing2 register of GPMI
TMTiming2_DataPause	160	4	Toggle mode NAND timing parameter Data Pause. ROM use this value to configure timing2 register of GPMI
TMSpeed	164	4	This is the toggle mode speed for ROM to configure gpmi clock at. 0 for 33 MHz, 1 for 40 MHz and 2 for 66 MHz
TMTiming1_BusyTimeout	168	4	Toggle mode NAND timing parameter Busy Timeout. ROM use this value to configure timing1 register of GPMI
DISBBM	172	4	If 0 ROM will swap BadBlockMarkerByte with metadata[0] after reading a page using BCH32. If the value set is 1 then ROM will not do swapping
BBMark_Spare_Offset	176	4	This is the offset for the metadata area. It stores the data marked by the bad block marker.

6.5.2.4 Discovered Bad Block Table

See Table 6-12 for DBBT format.

Table 6-12. DBBT Structure

Name	Start Byte	Size in Bytes	Description
reserved	0	4	-
FingerPrint	4	4	32-bit word with a value of 0x44424254,in ascii "DBBT"
Version	8	4	32-bit version number; this version of DBBT is 0x00000001
reserved	12	4	-
DBBT_NUM_OF_PAGES	16	4	Size of DBBT in pages
reserved	20	4*PageSize-20	-
reserved	4*PageSize	4	-
Number of Entries	4*PageSize + 4	4	Number of bad blocks
Bad Block Number	4*PageSize + 8	4	First bad block number
Bad Block Number	4*PageSize + 12	4	Second bad block number
...-	-	-	...next bad block number

Table continues on the next page...

Table 6-12. DBBT Structure (continued)

Name	Start Byte	Size in Bytes	Description
...-	-	-	...-
Last bad block number	-	-	last bad block number

6.5.2.5 Bad Block Handling in the ROM

During firmware boot, at the block boundary, the Bad Block table is searched for a match to the next block. If no match is found, the next block can be loaded. If a match is found, the block must be skipped and the next block checked.

If Bad Block table start page is null, check the manufactory made Bad Block marker. The location of Bad Block maker is at the first 3 or last 3 pages in every block of the nand flash. Nand manufacturers normally use one byte in the spare area of certain pages within a block to mark a block is bad or not. 0xFF means good block, non FF means bad block.

In order to preserve the BI (bad block information), flash updater or gang programmer applications need to swap Bad Block Information (BI) data to byte 0 of metadata area for every page before programming nand flash. ROM when loading firmware copies back the value at metadata[0] to BI offset in page data. Figure 6-5 shows how the factory bad block marker is preserved.

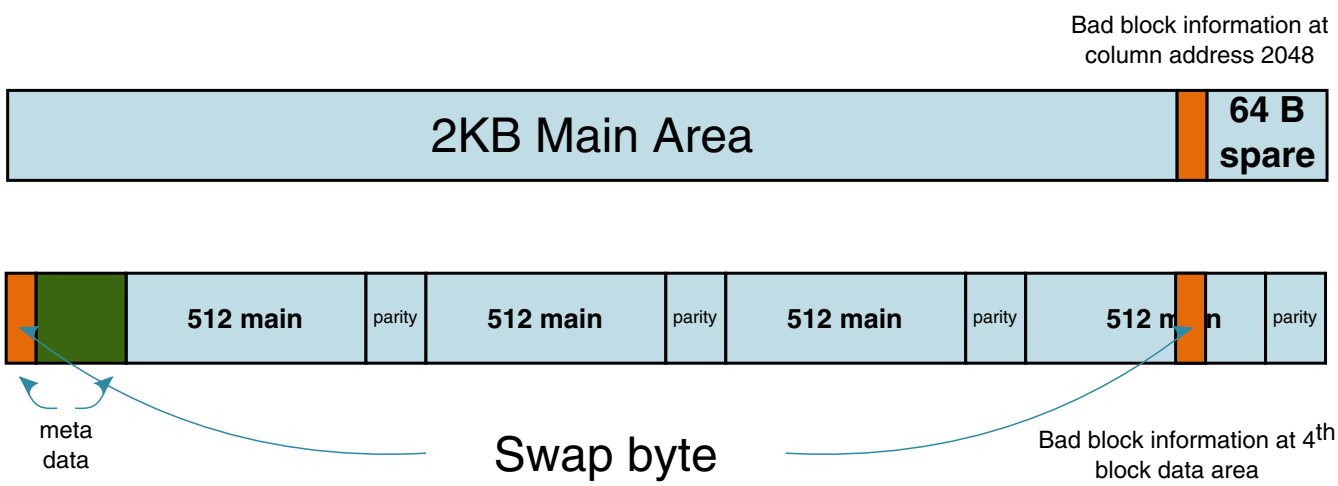

Figure 6-5. Factory Bad Block Marker Preservation

In the FCB structure, there are two elements BadBlockMarkerByte and BadBlockMarkerStartBit to indicate the byte and bit place in the page data, that manufacturer marked the bad block marker.

6.5.2.6 Toggle Mode DDR NAND Boot

If BT_TOGGLEMODE efuse is blown then ROM does the following to boot from Samsung's toggle mode DDR NAND.

6.5.2.6.1 Configures GPMI and BCH Clocks to Run at 33 MHz

if GPMI_CLK_SRC_PLL1 efuse is set then ROM will derive gpmi and bch clocks from PLL1 source otherwise will derive from 480 MHz PFD4 PLL. ROM sets the dividers in CCM registers to run GPMI CLK and BCH CLK at default 33 MHz. ROM sets default values to timing0, timing1 and timing2 gpmi registers for 33 MHz clock speed. It uses fuse BOOT_CFG2[7:5] to configure GPMI timing2 register paramters preamble delay and read latency, the default value for these parameters is 2 when fuses are not blown.

Default timing parameter values used by ROM for toggle-mode device:

- Timing0.ADDRESS_SETUP = 5
- Timing0.DATA_SETUP = 10
- Timing0.DATA_HOLD = 10
- Timing1.DEVICE_BUSY_TIMEOUT = 0 x 500
- Timing2.READ_LATENCY = BOOT_CFG2[7:5] if blown, otherwise 2
- Timing2.CE_DELAY = 2
- Timing2.PREAMBLE_DELAY = BOOT_CFG2[7:5] if blown, otherwise 2
- Timing2.POSTAMBLE_DELAY = 3
- Timing2.CMDADD_PAUSE = 4
- Timing2.DATA_PAUSE = 6

6.5.2.6.2 Setup DMA for DDR Transfers

In DMA descriptors GPMI is configured to read page data at double data rate, the word length is set to 16 and transfer count to half of page size.

6.5.2.6.3 Reconfigure Timing and Speed Using Values in FCB

After reading FCB page with GPMI set to default timings and speed 33 MHz, ROM reconfigures CCM dividers to run gpmi/bch clks to desired speed specified in FCB for rest of boot process. The GPMI timing registers are also reconfigured to values specified in FCB.

The GPMI can be configured to run at 33 MHz/40 MHz/66 MHz using FCB parameter TMSpeed, 0 for 33, 1 for 40 and 2 for 66 MHz speed.

The GPMI timing0 register fields data_setup, data_hold and address_setup are set to values specified for data_setup, data_hold and address_setup in FCB member m_NANDTiming.

The GPMI timing1.DEVICE_BUSY_TIMEOUT is set to value specified in FCB member TMTiming1_BusyTimeout.

The GPMI timing2 register values are set using FCB members TMTiming2.READ_LATENCY, CE_DELAY, PREAMBLE_DELAY, POSTAMBLE_DELAY, CMDADD_PAUSE and DATA_PAUSE

6.5.2.7 Typical NAND Page Organization

6.5.2.7.1 BCH ECC Page Organization

The first data block is called block 0 and the rest of the blocks are called block N. Separate ECC levelscan be used for block 0 and block N. The metadata bytes should be located at the beginning of a page, starting at byte 0, followed by data block 0, followed by ECC bytes for data block 0, followed by block 1 and its ECC bytes, and so on until N data blocks. The ECC level for block 0 can be different from the ECC level of rest of the blocks.

For NAND boot, with page size restrictions and data block size restricted to 512 bytes, only few combinations of ECC for block 0 and block N are possible.

Figure 6-6 shows the valid layout for 2112 byte sized page.

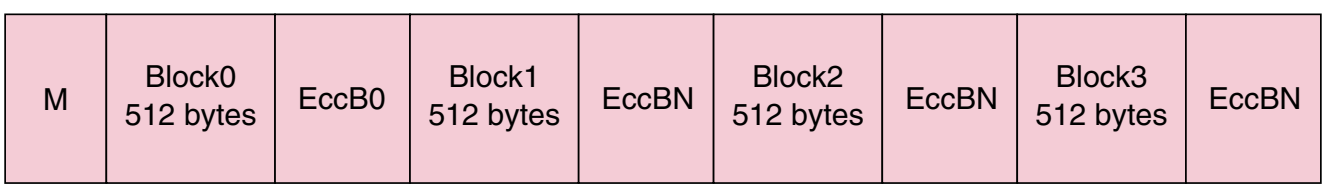

Figure 6-6. Valid Layout for 2112 bytes Sized Page

The number of ECC bits required for a data block is calculated using (ECC_Correction_Level * 13) bits.

In the above layout the ECC size for EccB0 and EccBN should be selected to not exceed a total page size of 2112 bytes. EccB0 and EccBN can be one of 2, 4, 6, 8, 10, 12, 14, 16, 18, 20 bits ECC correction level. The total bytes would then be:

[M + (data_block_size x 4) + ([EccB0 + (EccBN x 3)] x 13) / 8] <= 2112;

M = metadata bytes and data_block_size is 512.

There are 4 data blocks of 512 bytes each in a page of 2k page sized NAND. The values of EccB0 and EccBN should be such that the above calculation would not result in a value greater than 2112 bytes.

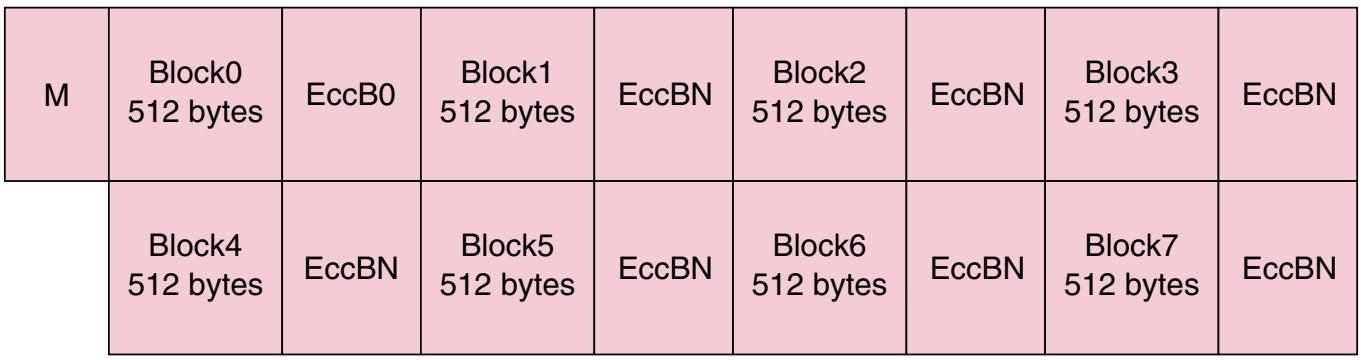

Figure 6-7. Valid Layout for 4 Kbytes Sized Page

Different NAND manufacturers have different sizes for a 4K page, 4314 bytes is typical.

[M + (data_block_size x 8) + ([EccB0 + (EccBN x 7)] x 13) / 8] <= 4314;

M=metadata bytes and data_block_size is 512.

There are 8 data blocks of 512 bytes each in a page of a 4k page sized NAND. The values of EccB0 and EccBN should be such that above calculation should not result in a value greater than the size of a page in a 4k page NAND.

6.5.2.7.2 Metadata

The number of bytes used for metadata are specified in FCB. Metadata for BCH encoded pages will be placed at the beginning of a page. ROM only cares about the first byte of metadata to swap it with bad block marker byte in page data after each page read. It is therefore important to have at least one byte for metadata bytes field in FCB data structure.

6.5.2.8 IOMUX Configuration for NAND Flash

The following table shows the RawNand IOMUX pin configuration.

Table 6-13. RawNand IOMUX Pin Configuration

	KPP	EIM	ELCDIF
CLE	KEY_COL0	EIM_DA8	DISP_D8
ALE	KEY_ROW0	EIM_DA9	DISP_D9

Table continues on the next page...

Table 6-13. RawNand IOMUX Pin Configuration (continued)

	KPP	EIM	ELCDIF
CEN0	KEY_COL1	EIM_DA10	DISP_D10
READY0	KEY_COL3	EIM_DA14	DISP_D14
DQS	KEY)ROW3	EIM_DA15	DISP_D15

RDN	SD3_CLK		
D[4]	SD3_D0		
D[5]	SD3_D1		
D[6]	SD3_D2		
D[7]	SD3_D3		
D[0]	SD3_D4		
D[1]	SD3_D5		
D[2]	SD3_D6		
D[3]	SD3_D7		
RESET N	SD3_WP		

NOTE

Image header, DCD and boot data must reside in the initial load region of bootable image (4K). Image length must be specified in the boot data structure pointed to by the image header boot data element, please see Figure 6-15 for image vector table structure

6.5.3 Expansion Device Support

The i.MX50 ROM supports to boot from MMC/eMMC and SD/eSD compliant devices. The SD/MMC/eSD/eMMC boot can be performed at either eSDHC-1, eSDHC-2, eSDHC-3, or eSDHC-4 ports, based on setting of the BOOT_CFG3[5:4] (Port Select) fuse or its associated GPIO input value at boot. For eMMC4.3 and eMMC4.4 with BOOT ACK support boot mode, only eSDHC-3 can be used. Refer to Table 6-14 for details. The boot flow for expansion devices is shown in Figure 6-8.

Table 6-14. ESDHC Boot eFUSE Descriptions

Fuse	Config	Definition	GPIO[1]	Settings
BOOT_CFG1[7:6]	OEM	Boot Device Selection	Yes	01 - Boot from ESDHC Interfaces
BOOT_CFG1[5]	OEM	SD/MMC Selection	Yes	0 - SD/eSD 1 - MMC/eMMC

Table continues on the next page...

Table 6-14. ESDHC Boot eFUSE Descriptions (continued)

Fuse	Config	Definition	GPIO[1]	Settings
BOOT_CFG1[4]	OEM	Fast Boot Support	Yes	0 - Normal Boot 1 - Fast Boot
BOOT_CFG1[3]	OEM	SD/MMC Speed Mode	Yes	0 - High Speed Mode (SCLK@40 MHz) 1 - Normal Speed Mode(SCLK@20 MHz)
BOOT_CFG2[7:5]	OEM	Bus Width	Yes	SD/eSD (BOOT_CFG1[5]=0) xx0 - 4-bit xx1 - 1-bit MMC/eMMC (BOOT_CFG1[5]=1) 000 - 4-bit 001 - 1-bit 010 - 8-bit 100 - 4-bit DDR (MMC 4.4) 110 - 8-bit DDR (MMC 4.4) Else - reserved.
BOOT_CFG3[5:4]	OEM	Port Select	Yes	00 - eSDHC1 01 - eSDHC2 10 - eSDHC3 11 - eSDHC4
CFG6[3]	OEM	DISABLE_MMC_DLL_DLY	No	0 - Boot ROM default. 1 - Apply value per fuse field MMC_DLL_DLY[3:0]
CFG6[23:18]	OEM	MMC_DLL_DLY	No	DLL Delay cycle number

1. Setting can be overridden by GPIO settings when BT_FUSE_SEL fuse is intact. See Table 6-3 for corresponding GPIO pin.

Boot code supports following standards.

- MMCv4.4 or less
- eMMCv4.4 or less
- SDv2.0 or less
- eSDv2.10 rev-0.9, with or without FAST_BOOT.

MMC/SD/eSD/eMMC can be connected to any of eSDHC1-4 module and booting can be done by copying 2 Kbyte of data from MMC/SD/eSD/eMMC device to internal RAM. After checking the Image Vector Table header value (0xD1) from boot image, the ROM code performs a DCD check. After successful DCD extraction, the Rom code extracts the destination pointer and length of image to be copied to RAM device from where code execution occurs.

Table 6-15. SD/MMC Frequencies

Frequency	AXI/DDR Freq=0	AXI/DDR Freq=1
Identification (KHz)	357.143	297.321
Normal Speed Mode (MHz)	20	16.6
High Speed Mode (MHz)	40	33.3

NOTE

Image header, DCD and boot data must reside in the initial load region of bootable image (4K). Image length must be specified in the boot data structure pointed to by the image header boot data element, please see Figure 6-15 for image vector table structure

6.5.3.1 IOMUX Configuration of eSDHC

eSDHC2 and eSDHC3 modules have a full set of dedicated signals. eSDHC1 only supports 4 bits in default; the higher 4 bits are muxed on UART signals. eSDHC4 singlas are totally muxed on UART signals or DISP signals. The lower 4 bits of eSDHC4 data signals have two different mux modes. CFG6.bit[10] is used to select the mux mode.

Table 6-16. IOMUX Configuration Table of eSDHC

	eSDHC1	eSDHC2	eSDHC3/uSDHC	eSDHC4	
				Group 0	Group 1 (enabled by fuse CFG6[10])
CLK	SD1_CLK.ALT0	SD2_CLK.ALT0	SD3_CLK.ALT0	UART2_RTS.ALT4	DISP_D9.ALT4
CMD	SD1_CMD.ALT0	SD2_CMD.ALT0	SD3_CMD.ALT0	UART2_CTS.ALT4	DISP_D8.ALT4

DATA7	UART4_RXD.ALT3	SD2_D7.ALT0	SD3_D7.ALT0	UART2_RXD.ALT4	

6.5.3.2 MMC and eMMC Boot

During initialization (normal boot mode) the MMC frequency is set to 357.143 KHz. When the MMC card enters the identification portion of the initialization, voltage validation is performed and the ROM boot code checks high voltage settings and card capacity. The ROM boot code supports both high capacity and low capacity MMC/ eMMC cards. After initialization phase is complete, the ROM boot code switches to a higher frequency (20 MHz in Normal boot mode or 40 MHz in High Speed mode). eMMC is also interfaced through eSDHC and follows same flow as does by MMC.

The boot partition can be selected for an MMC4.x card after the card initialization is complete. The ROM code reads the BOOT_PARTITION_ENABLE field in the Ext_CSD[179] to get the boot partition to be set. If there is no boot partition mentioned in BOOT_PARTITION_ENABLE field or the user partition has been mentioned, ROM boots from the user partition.

If using an eMMC4.3 or eMMC4.4 device supporting special "Boot mode", it can be initiated by pulling the CMD line low. If BOOT ACK is enabled, the eMMC4.3/ eMMC4.4 device sends the BOOT ACK via DATA lines and ROM can read the BOOT ACK [S010E] to identify the eMMC4.3/eMMC4.4 device. eMMC4.3/eMMC4.4 device with "Boot mode" feature can only be supported via eSDHC-3 and with BOOT ACK enabled. ROM waits for 50 ms to get the BOOT ACK and if BOOT ACK is received by ROM, then only eMMC4.3/eMMC4.4 is booted in "Boot mode", otherwise eMMC4.3/ eMMC4.4 boots as a normal MMC card from the selected boot partition. This boot mode can be selected by BOOT_CFG1[4] (Fast Boot) fuse.

If using eMMC4.4 device, Double Data Rate (DDR) mode can be used. This mode can be selected by BOOT_CFG2[7:5] (Bus Width) fuse.

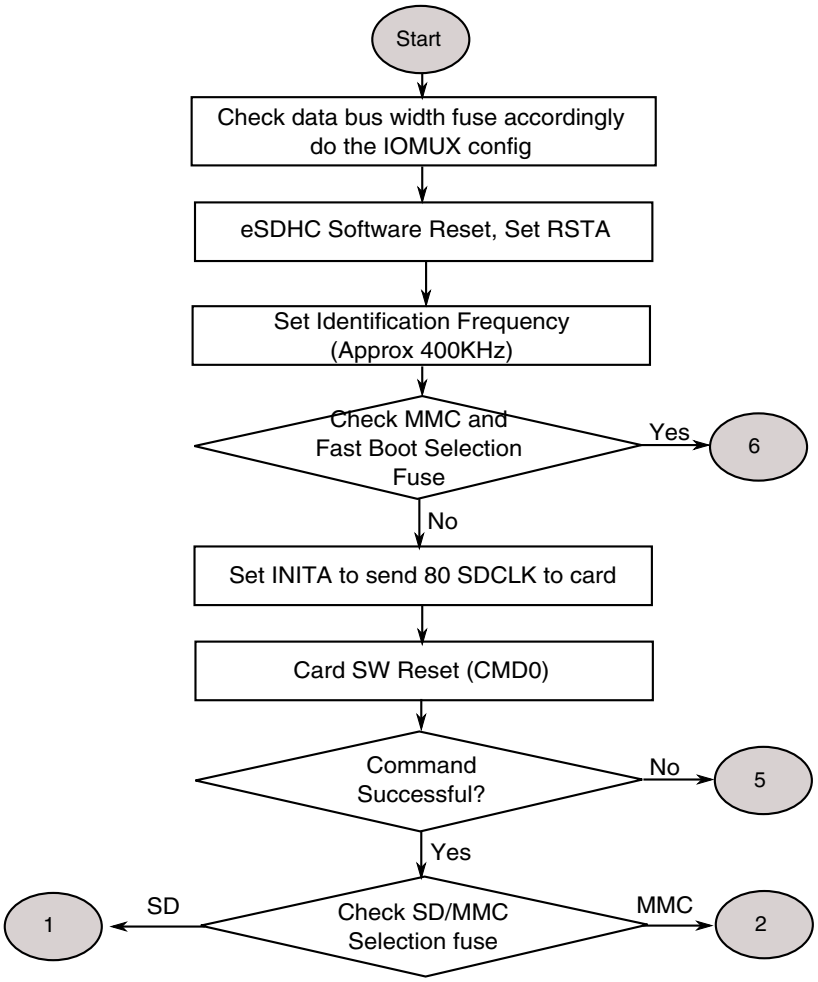

Figure 6-8. Expansion Device Boot Flow (1 of 5)

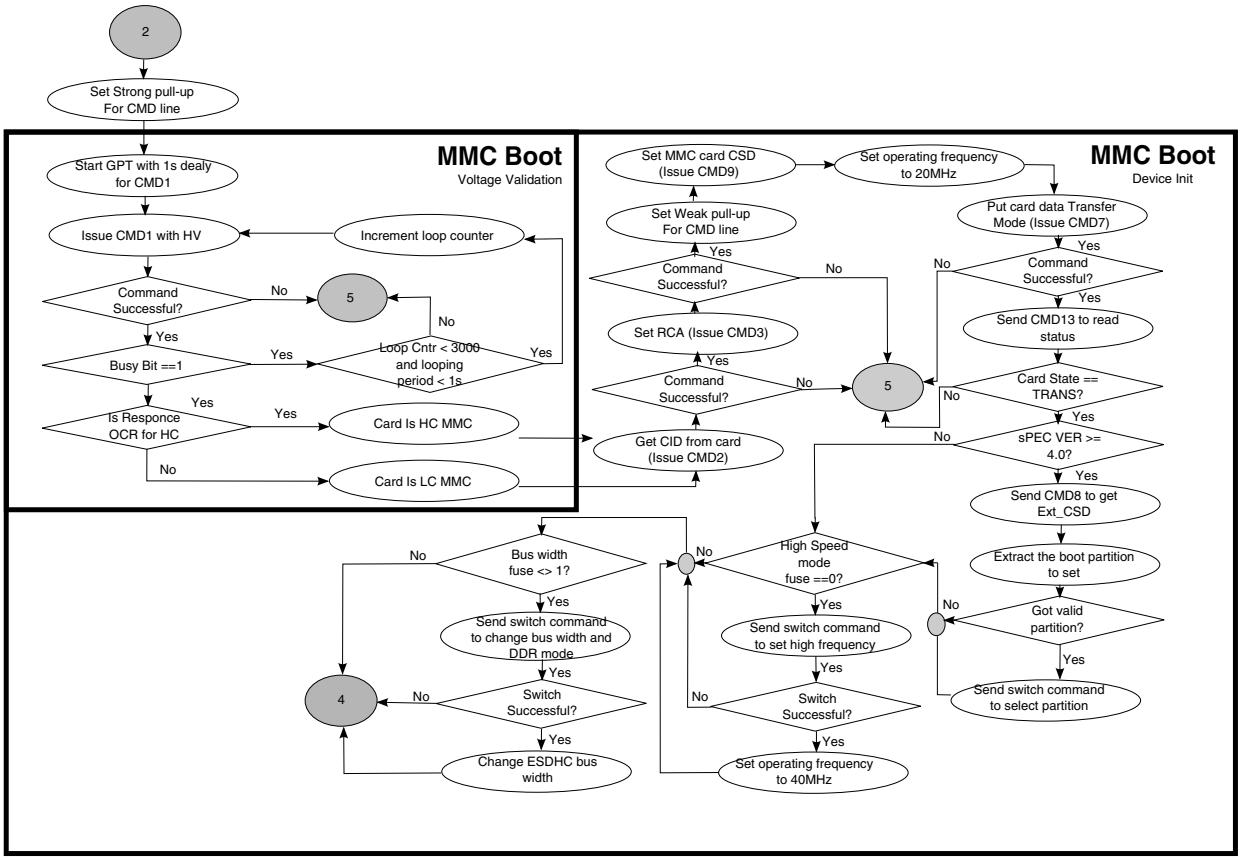

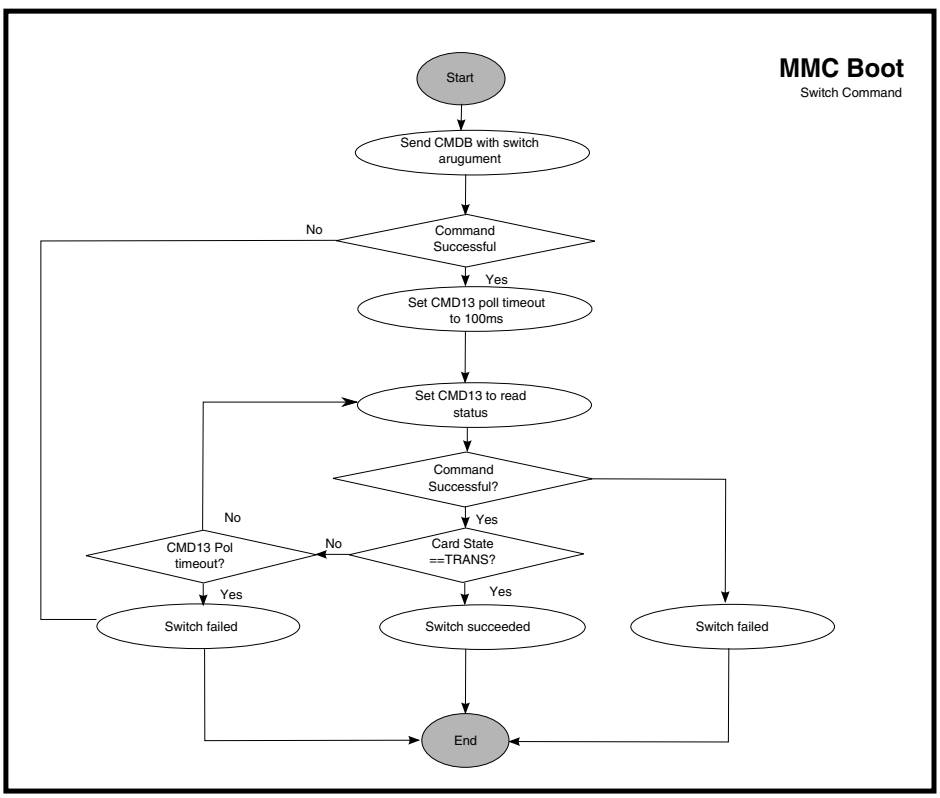

Figure 6-9. Expansion Device (MMC) Boot Flow (2 of 5)

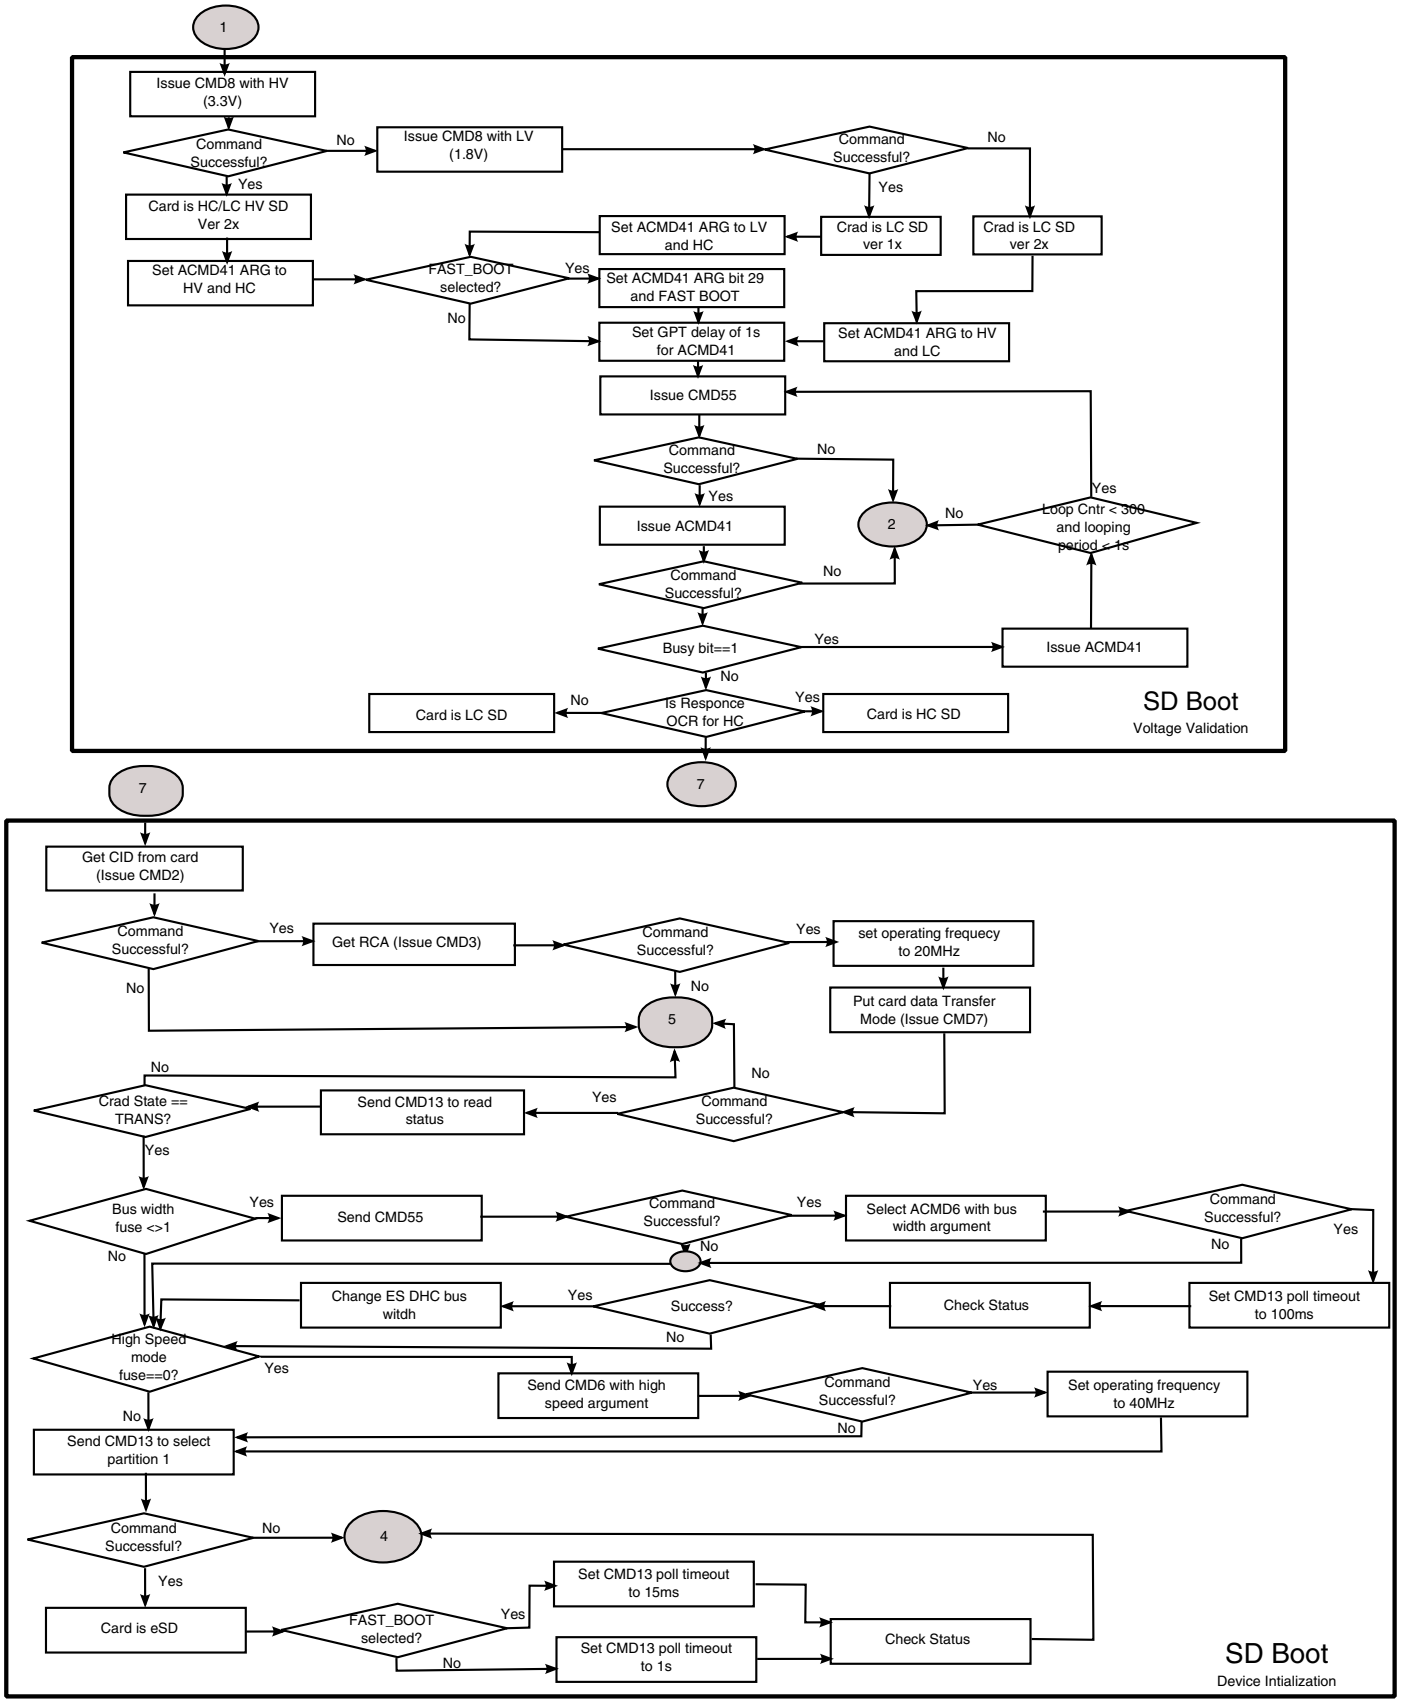

Figure 6-10. Expansion Device (SD/eSD) Boot Flow (3 of 5)

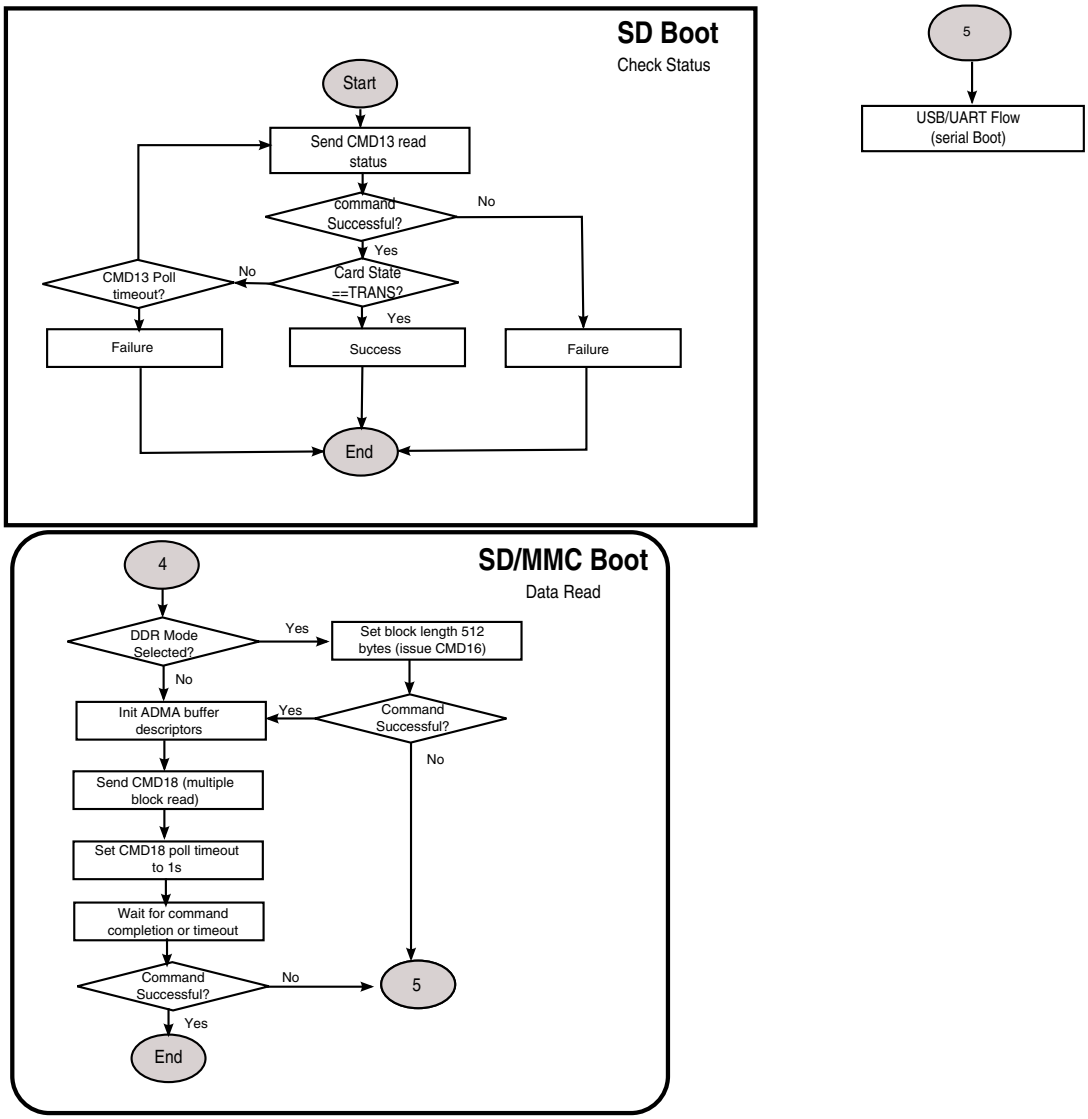

Figure 6-11. Expansion Device Boot Flow (4 of 5)

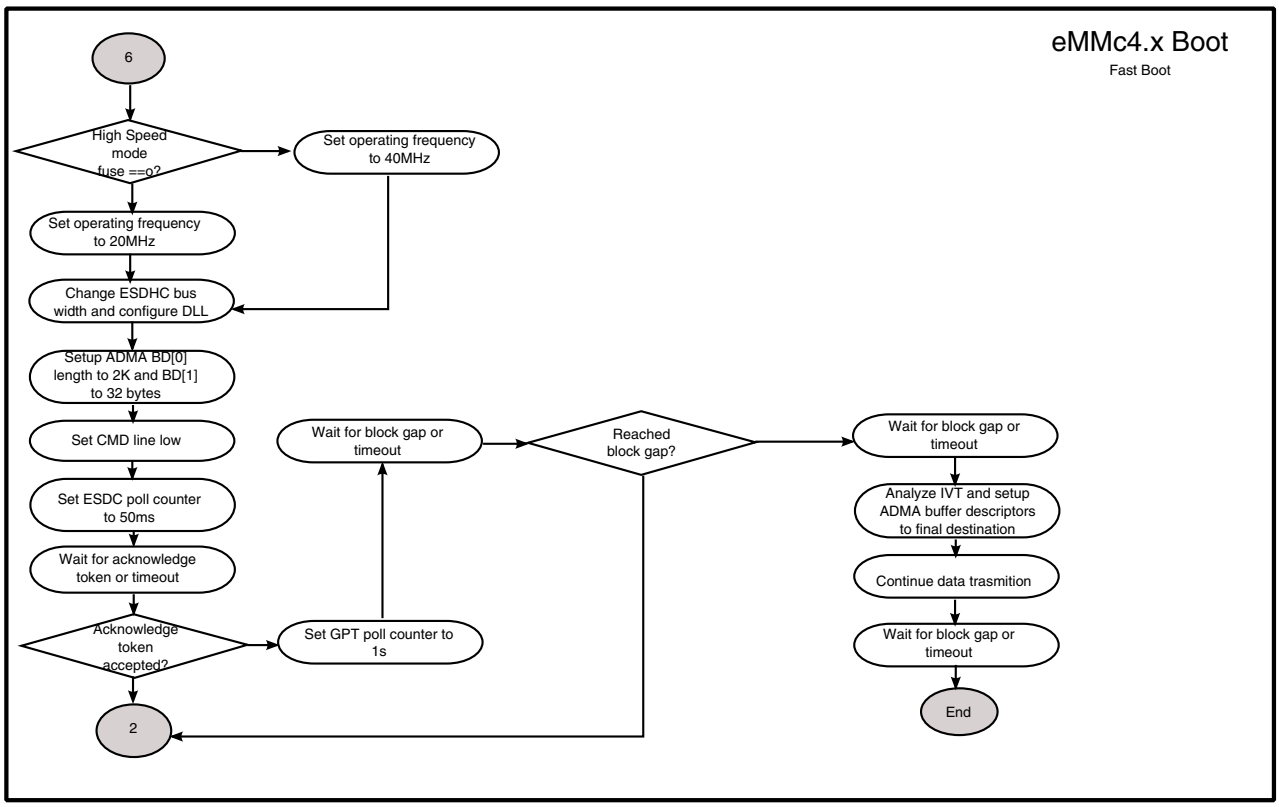

Figure 6-12. Expansion Device Boot Flow (5 of 5)

6.5.4 SD and eSD

After the normal boot mode initialization begins, the SD and eSD frequency is set to 357.143KHz. During the identification phase SD and eSD card voltage validation is performed. During voltage validation, boot code first checks with high voltage settings and if it fails it checks with low voltage settings. Capacity of card is also checked. Boot code supports high capacity and low capacity SD and eSD cards. After voltage validation card initialization is done.

During card initialization the ROM boot code attempts to set the boot partition (both SD and eSD devices). If this fails, the boot code assumes card is a normal SD card otherwise as eSD card. After initialisation phase is over, boot code switches to a higher frequency (20 MHz in Normal Speed mode or 40MHz in High Speed Mode). ROM also supports FAST_BOOT mode booting from eSD card. This mode can be selected by BOOT_CFG1[4] (Fast Boot) fuse described in Table 6-14.

NOTE

Image header, DCD and boot data must reside in the initial load region of bootable image (4K). Image length must be specified

in the boot data structure pointed to by the image header boot data element, see Figure 6-15 for image vector table structure

The table Table 6-17 list values for internal pull-ups on SD pads configured by ROM.

Table 6-17. ROM pull-up values for SD pads

SD1, SD2, SD3, SD4	SD boot modes	MMC boot modes	eMMC boot modes (SD3 only)
CMD	100K PU	22K PU11	100K PU
CLK	47K PU	47K PU	47K PU
DATA[7:0]	47K PU	47K PU	47K PU

6.5.5 Serial ROM Support via SPI and I²C

The i.MX50 supports boot from serial memory devices, such as EEPROM, and Serial Flash using the SPI (CSPI, eCSPI1, eCSPI2), and I²C (I²C1, I²C2 and I²C3) interfaces.

The boot ROM code determines the type of device using the following parameters, either provided by OCOTP bit settings or sampled on the I/O pinsat reset (See Table 6-18 for details).

Table 6-18. Serial ROM Boot eFUSE Descriptions

Fuse	Config	Definition	GPIO[1]	Settings
BOOT_CFG1[7:4]	OEM	Boot Device Selection	Yes	0011 - Boot from Serial ROM
BOOT_CFG1[3]	OEM	Serial ROM select	Yes	0 - I2C 1- SPI
BOOT_CFG2[5]	OEM	SPI Addressing	Yes	0 - 2-bytes (16-bit) 1 - 3-bytes (24-bit)
BOOT_CFG3[5:4]	OEM	Port Select	Yes	00 - I2C1 / eCSPI1 01 - I2C2 / eCSPI2 10 - I2C3 / CSPI 11 - Reserved
BOOT_CFG3[3:2]	OEM	CS select (SPI only)	Yes	00 - CS#0 01 - CS#1 10 - CS#2 11 - CS#3

1. Setting can be overridden by GPIO settings when BT_FUSE_SEL fuse is intact. See Table 6-3 for corresponding GPIO pin.

The I2C-1/I2C-2/I2C-3 module can be used as boot device when using I²C interface serial ROM boot. The I2C interface is configured to operate at 384 Kbps.

6.5.5.1 I²C EEPROM Boot

The boot flow when booting from an I²C EEPROM is shown in Figure 6-13. The boot ROM code reads the fuses BOOT_CFG1[7:4] (Boot Device Selection) and BOOT_CFG1[3] (Serial ROM select) to detect EEPROM device type. The ROM program copies 4K data from the EEPROM device to internal RAM. The boot ROM code next copies the initial 2 Kbyte of data as well as rest of image directly to application destination extracted from application image.

The i.MX50 uses the Device Select Code/Device Address in Table 6-19 to boot from an EEPROM

Table 6-19. EEPROM via I²C Device Select Code

Bits	Device Type Identifier				Chip Enable Address[1]			R/W
	7	6	5	4	3	2	1	0
Device Select Code	1	0	1	0	0	0	0	R/W

1. These address bits, should be configured at the memory device, to match this '000' value.

Table 6-20. IOMUX Configuration of I²C Modules

	I2C1	I2C2	I2C3
SCL	I2C1_SCL_ALT0	I2C2_SCL.ALT0	I2C2_SCL.ALT0
SDA	I2C1_SDA_ALT0	I2C2_SDA.ALT0	I2C3_SDA.ALT0

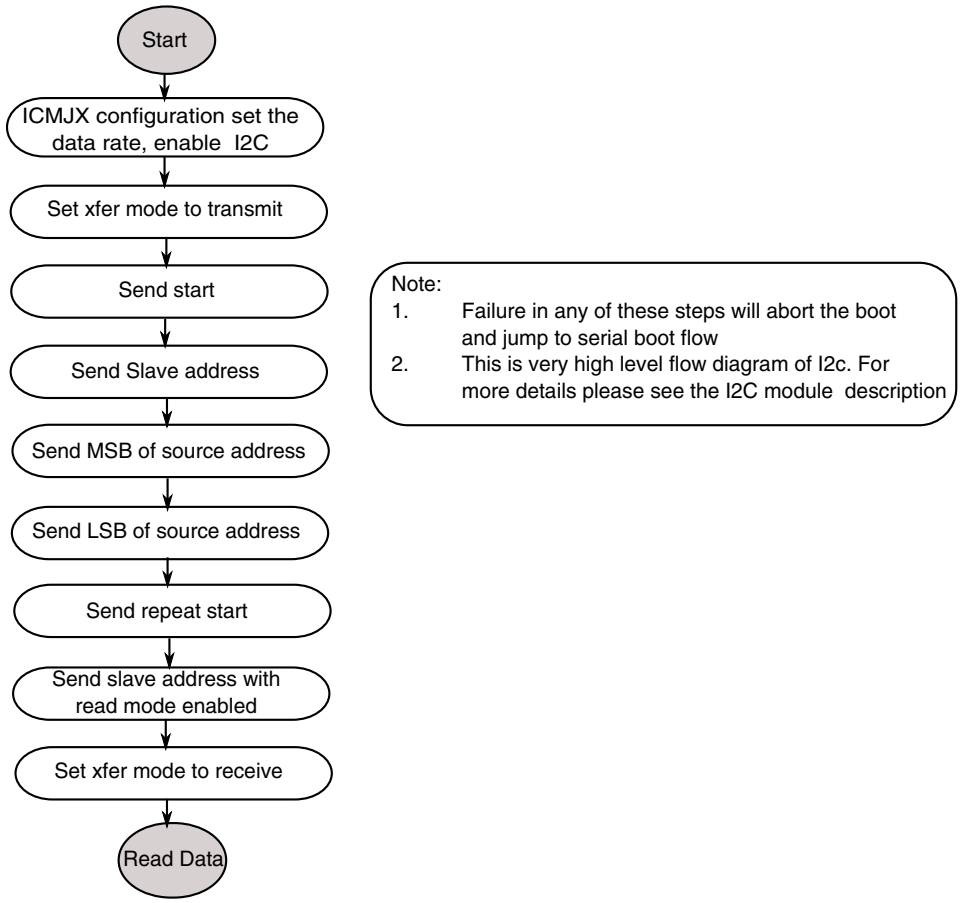

Figure 6-13. I²C Flow Chart

6.5.5.2 SPI EEPROM/Flash Boot

The CSPI/eCSPI1/eCSPI2 interface is configured in Master mode and the SPI memory device is connected to CSPI/eCSPI interfaces as slave. The boot ROM code copies 2 Kbyte data from SPImemory device to the internal RAM. If DCD verification is successful, the ROM code copies the initial 2 Kbyte data as well as the rest of image directly to application destination extracted from application image. The CSPI/ eCSPImaster can read data from theSPI memory device using 2 or 3 byte addressing and its burst length is 32 bytes.

NOTE

The Serial ROM Chip Select Number is determined by BOOT_CFG3[3:2] (Chip Select) fuse.

When using the SPI as boot device, the i.MX50 supports booting from both Serial EEPROMS and Serial Flash devices. The boot code determines which device is being used by reading the appropriate OCOTP bit or GPIO values at boot (See Table 6-18 for details).

Table 6-21. IOMUX Configuration of CSPI and eCSPI

	CSPI	eCSPI1	eCSPI2
SCLK	Cspi.SCLK.Alt0	Ecspi1.SCLK.Alt0	Ecspi2.SCLK.Alt0
MOSI	Cspi.MOSI.Alt0	Ecspi1.MOSI.Alt0	Ecspi2.MOSI.Alt0

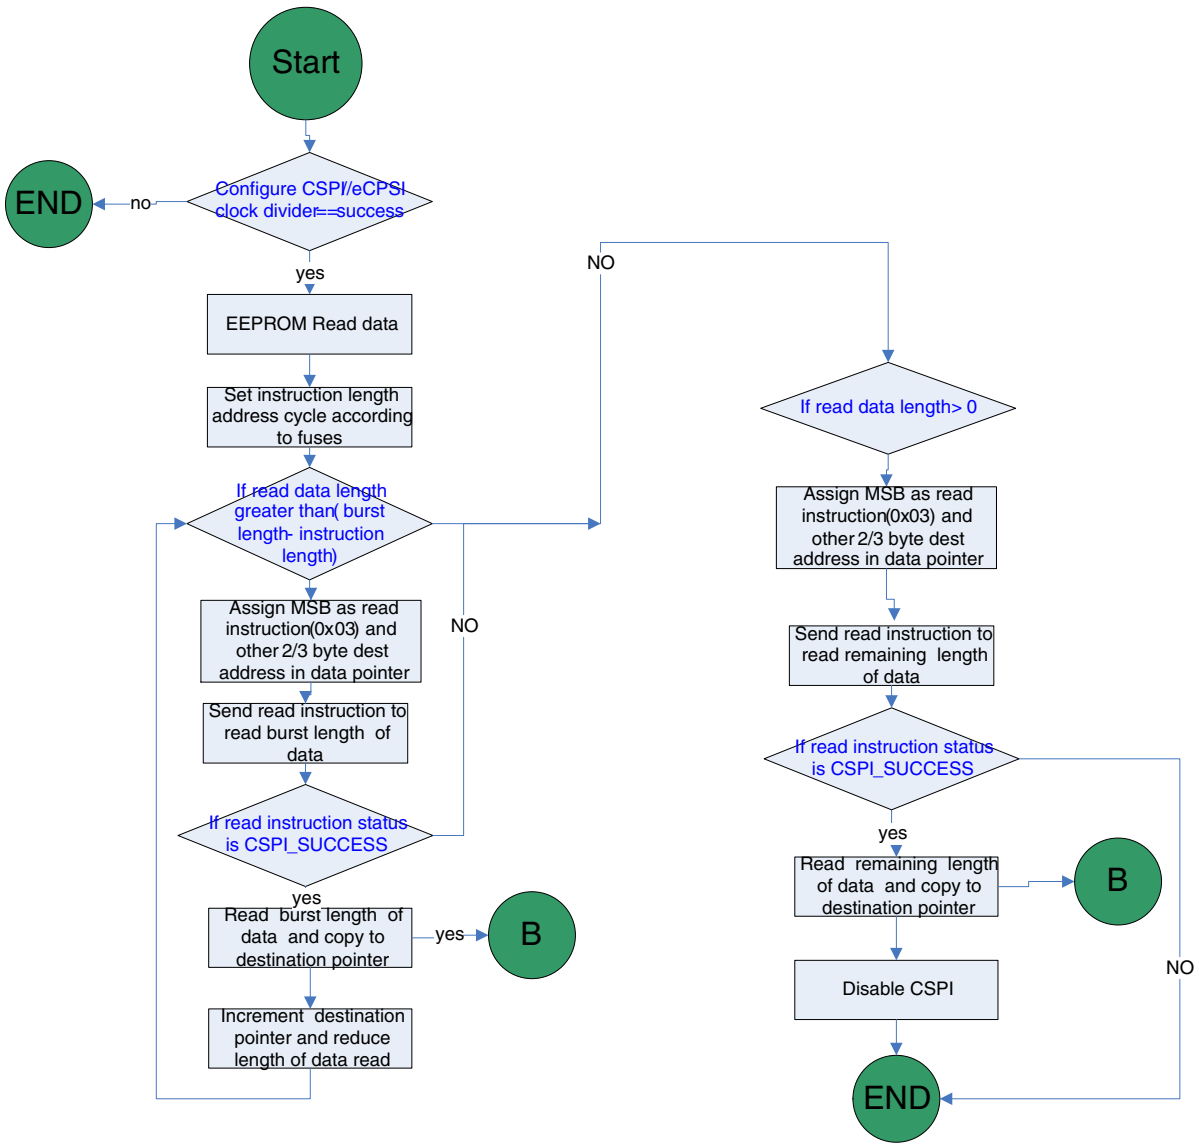

Figure 6-14. CSPI/eCSPI Boot Flow

6.6 Program Image

This section describes the data structures that are required to be included in a user's Program Image. A Program Image consists of:

- Image Vector Table-A list of pointers located at a fixed address that the ROM searches for to determine where other components of the Program Image are located.

- Boot Data-An additional header indicating the Image Location, Program Image size in bytes and plugin flag. It must be located in initial program image part (see Figure 6-1).
- Device Configuration Data-IC configuration data. It must be located in initial program image part (see Figure 6-1).
- Data used by HAB-CSF command data, signatures and certificates
- User code and data

6.6.1 Image Vector Table and Boot Data

The Image Vector Table (IVT) is the data structure that the ROM reads from the boot device supplying the external image containing the required data components to perform a successful boot. The IVT includes the image entry point, a pointer to Device Configuration Data (DCD) and other pointers used by the ROM during the boot process. The ROM locates the IVT at a fixed address that is determined by the boot device connected to i.MX50. The IVT offset from the base address and initial program image size for each boot device type is defined in Table 6-22. The location of the IVT is the only fixed requirement by the ROM. The remainder or the image memory map is flexible and is determined by the contents of the IVT.

Table 6-22. Image Vector Table Offset and Initial Image Size

Flash Type	Base Address Offset	Initial Image Size	DCD Max Size Limitation
NOR	4 Kbyte = 0x1000 bytes	Entire Image Size	1768 bytes
NAND 2KB Page Size	1 Kbyte = 0x400 bytes	2 Kbyte	1024 bytes
NAND 4KB Page Size	1 Kbyte = 0x400 bytes	4 Kbytes	1768 bytes
OneNAND	256 bytes = 0x100 bytes	1 Kbyte	736 bytes
SD/MMC/eSD/eMMC	1 Kbyte = 0x400 bytes	2 Kbyte	1024 bytes
I2C/HS-I2C/SPI EEPROM	1 Kbyte = 0x400 bytes	2 Kbyte	1024 bytes

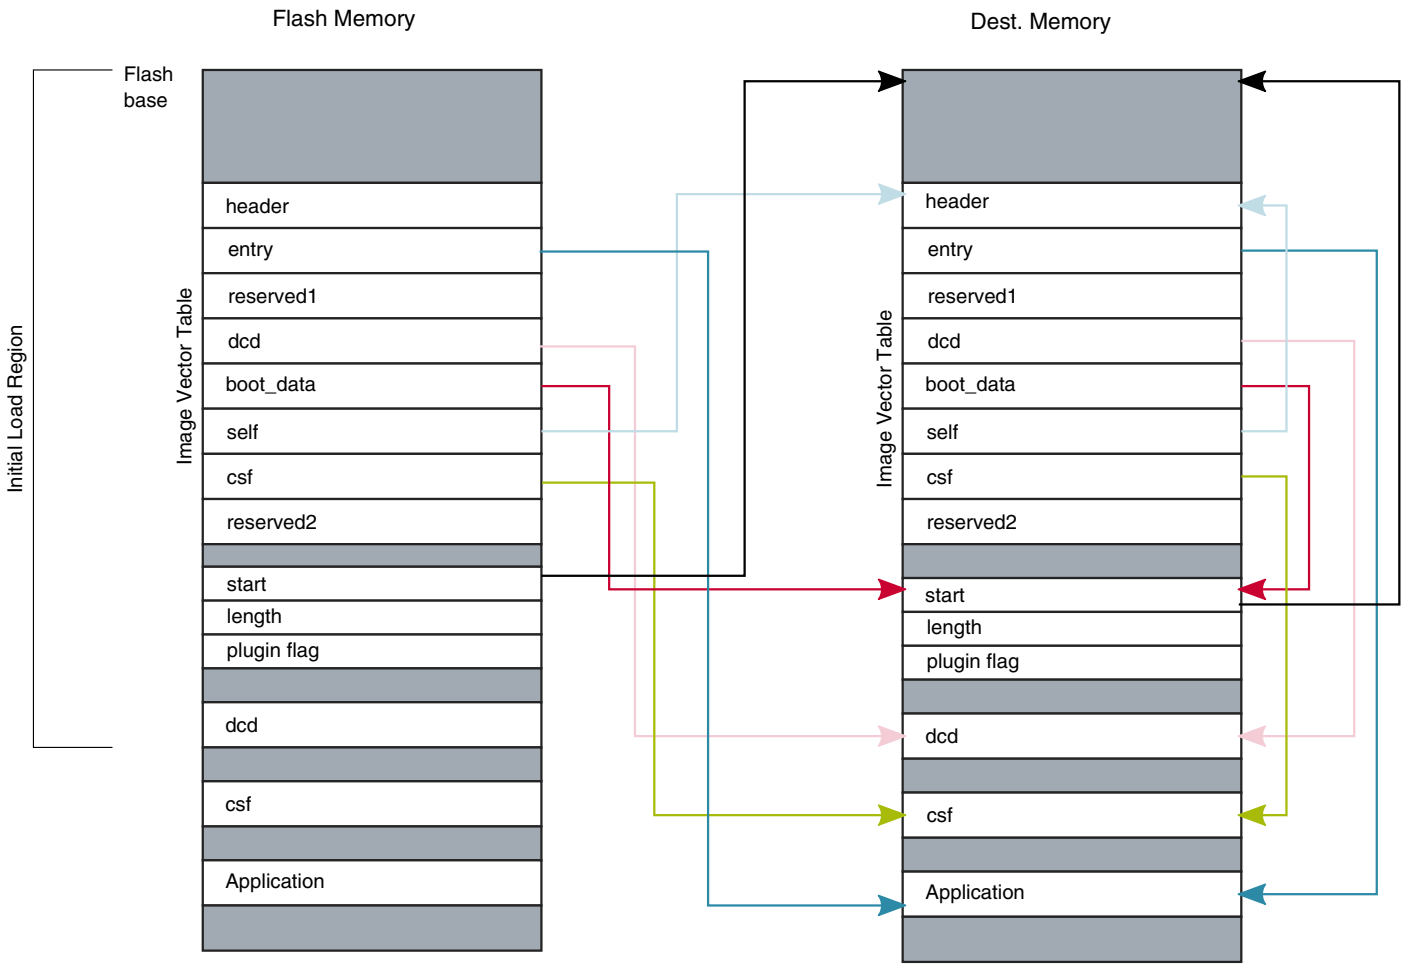

Figure 6-15. Image Vector Table Data Structure

6.6.1.1 Image Vector Table Structure

The IVT has the following format where each entry is a 32-bit word:

Table 6-23. i.MX50 IVT Format

header
entry
reserved1
dcd
boot data
self
csf
reserved2

- header: The IVT header has the following format:

Table 6-24. IVT Header Format

Tag	Length	version

where:

```
Tag: A single byte field set to 0xD1
Length: a two byte field in big endian format containing the overall length of the IVT,
in bytes, including the header. (the length is fixed and must have a value of
32 bytes)
Version: A single byte field set to 0x40
```

- entry: Absolute address of the first instruction to execute from the image.
- reserved1: Reserved and should be NULL.
- dcd: Absolute address of the image DCD. The DCD is optional so this field may be set to NULL if no DCD is required. See Device Configuration Data (DCD) for further details on DCD.
- boot data: Absolute address of the Boot Data, see Boot Data Structure.
- self: Absolute address of the IVT. Used internally by the ROM.
- csf: Absolute address of Command Sequence File (CSF) used by the HAB library. See High Assurance Boot (HAB) for details on secure boot using HAB. This field must be set to NULL when not performing a secure boot.
- reserved2: Reserved and should be NULL.

6.6.1.2 Boot Data Structure

The Boot Data must follow the format defined in Table 6-25. This data structure is pointed to by boot data element in IVT structure.

Table 6-25. i i.MX50 Boot Data Format

start
size
plugin

Where:

- start: Absolute address of the image
- size: Size of the image
- plugin: Plugin flag

6.6.2 Device Configuration Data (DCD)

Upon reset the i.MX50 uses the default register values for all peripherals in the system. The i.MX50 ROM changes some of these defaults such as clock frequencies for boot purposes. However, these settings typically are not ideal for achieving optimal system performance and there are even some peripherals that must configured before they can be used. The DCD is configuration information contained in a Program Image, external to the ROM, that the ROM interprets to configure various peripherals on i.MX50. Some components such as SDRAM require some sequence of register programming as part of configuration before it is ready to be used. The DCD feature can be used to program the EIM registers and DRAM MC registers to the optimal settings.

The ROM determines the location of the DCD table based on information located in the Image Vector Table (IVT). See Image Vector Table and Boot Data for more details. The DCD table shown in Table 6-26 is a big endian byte array of the allowable DCD commands. The maximum size of the DCD limited to 1768 bytes by the HAB. However, for some boot devices this is further restricted as indicated by Table 6-22.

Table 6-26. DCD Data format

Header
[CMD]
[CMD]
...

The DCD header is 4 bytes with the following format:

Table 6-27. DCD Header

Tag	Length	Version

where:

```
Tag: A single byte field set to 0xD2
Length: a two byte field in big endian format containing the overall length of the DCD,
in bytes, including the header
Version: A single byte field set to 0x40
```

```

6.6.2.1 Write Data Command

The Write Data Command is used to write a list of given 1, 2 or 4-byte values or bitmasks to a corresponding list of target addresses. The format of Write Data Command, again a big endian byte array, is shown in Table 6-28.

Table 6-28. Write Data Command Format

Tag	Length	Parameter
Address		
Value/Mask		
[Address]		
[Value/Mask]		
...		
[Address]		
[Value/Mask]		

where:

```
Tag: A single byte field se to 0xCC
Length: A two byte field in big endian format containing the length of the Write Data
Command, in bytes, including the header
Address: target address to which data should be written
Value/Mask: data value or bitmask to be written to preceding address
```

The Parameter field is a single byte divided into bitfields as follows:

Table 6-29. Write Data Command Parameter field

7	6	5	4	3	2	1	0
flags					bytes		

where

```
bytes: width of target locations in bytes. Either 1, 2 or 4
flags: control flags for command behavior.
Data Mask = bit 3: if set, only specific bits may be overwritten at target address
(otherwise all bits may be overwritten)
Data Set = bit 4: if set, bits at the target address overwritten with this flag
(otherwise it is ignored)
```

One or more target address and value/bitmask pairs can be specified. The same bytes and flags parameters apply to all locations in the command.

When successful, this command writes to each target address in accordance with the flags as follows:

Table 6-30. Interpretation of Write Data Command Flags

"Mask"	"Set"	Action	Interpretation
0	0	*address = val_msk	Write value
0	1	*address = val_msk	Write value
1	0	*address &= ~val_msk	Clear bitmask
1	1	*address |= val_msk	Set bitmask

Notes:

If any of the target addresses does not have the same alignment as the data width indicated in the parameter field, none of the values are written.

If any of the values is larger or any of the bitmasks is wider than permitted by the data width indicated in the parameter field, none of the values are written.

If any of the target addresses do not lie within an allowed region, none of the values are written. The list of allowable modules and target addresses fori.MX50 are given below.

Table 6-31. Valid DCD Address Ranges

Address range	Start address	Length (in bytes)
CCM register set	0x53FD4000	0x53FD7FFF
EIM register set	0x63FDA000	0x63FDAFFF
IOMUXC registers	0x53FA8000	0x53FABFFF
PLL1 registers	0x63F80000	0x63F83FFF
PLL2 registers	0x63F84000	0x63F87FFF
PLL3 registers	0x63F88000	0x63F8BFFF
DRAM MC registers	0x14000000	0x1400043b
DIGCTL registers	0x41004000	0x41005FFF

6.6.2.2 Check Data Command

The Check Data Command is used to test for a given 1, 2 or 4-byte bitmasks from a source address. The Check Data Command is a big endian byte array with format shown in Table 6-32.

Table 6-32. Check Data Command Format

Tag	Length	Parameter

Table continues on the next page...

Table 6-32. Check Data Command Format (continued)

Address
Mask
[Count]

where:

```
Tag: A single byte field se to 0xCF
Length: A two byte field in big endian format containing the length of the Check Data
Command, in bytes, including the header
Address: source address to test
Mask: bit mask to test
Count: optional poll count. If count is not specified this command will poll indefinitely
until the exit condition is met. If count = 0, this command behaves as for NOP.
```

The Parameter field is a single byte divided into bitfields as follows:

Table 6-33. Check Data Command Parameter field

7	6	5	4	3	2	1	0
flags					bytes		

where

```
bytes: width of target locations in bytes. Either 1, 2 or 4
flags: control flags for command behavior.
Data Mask = bit 3: if set, only specific bits may be overwritten at target address
(otherwise all bits may be overwritten)
Data Set = bit 4: if set, bits at the target address overwritten with this flag
(otherwise it is ignored)
```

This command polls the source address until either the exit condition is satisfied, or the poll count is reached. The exit condition is determined by the flags as follows:

Table 6-34. Interpretation of Check Data Command Flags

"Mask"	"Set"	Action	Interpretation
0	0	(*address & mask) == 0	All bits clear
0	1	(*address & mask) == mask	All bits set
1	0	(*address & mask) != mask	Any bit clear
1	1	(*address & mask) != 0	Any bit set

Notes:

If the source address does not have the same alignment as the data width indicated in the parameter field, the value is not read.

If the bitmask is wider than permitted by the data width indicated in the parameter field, the value is not read.

6.6.2.3 NOP Command

This command has no effect. The format of Check Data Command is a little endian four byte array as shown in Table 6-35.

Table 6-35. NOP Command Format

Tag	Length	Undefined

where:

```
Tag: A single byte field se to 0xC0
Length: A two byte field containing the length of the NOP Command in bytes. Fixed to a
value of 4.
Undefined: HAB ignores this byte and can be set to any value.
```

6.7 Plugin Image

i.MX50 ROM supports limited number of boot modes. For using other devices as boot source (e.g. ethernet, CDROM, USB Stick and etc...) supported boot device must be used (typically serial ROM) for firmware with the missing boot drivers.

Boot ROM will detect the image type by plugin flag of boot data structure (see Boot Data Structure). If the plugin flag is 1, then ROM will use the image as plugin function. The function must initialize boot device and copy the image to final location. At the end, the plugin function must return with the parameters of application image.

The boot ROM will authenticate the plugin image prior running plugin function and then will authenticate the application image.

The plugin function must follow the API described below:

typedef BOOLEAN(*) plugin_download_f(void **start, size_t *bytes, UINT32 *ivt_offset)

ARGUMENTS PASSED:

- start - Image load address on exit.
- bytes - Image size on exit.
- ivt_offset - Offset in bytes of the IVT from the image start address on exit.

RETURN VALUE:

- TRUE - on success
- FALSE - on failure

6.8 USB Low-Power Boot

The i.MX50 supports a Low-Power Boot (LPB) mode where a production level device can attempt to boot with a depleted or disconnected battery. This mode is independent of the boot modes derived from the BOOT_MODE[1:0] pins and allows the i.MX50 to boot using USB as the only power supply. The i.MX50 ROM code involved in LPB is minimal, with most configuration operations performed by the Power Management IC (PMIC) and USB drivers included in a Program Image.

The platform current consumption during LPB ROM stage is targeted to be less than 100 mA at VUSB. For this purpose, DRAM module is disabled and the Program Image is downloaded to OCRAM.

Low power boot is supported by default, but it can be disabled by blowing the OCOTP bit BT_DISABLE_LPB, which is located in CFG4.Bit[4].

Table 6-36. OCOTP Bits for USB Low Power Boot

Fuse	Config	Definition	GPIO	Settings
BT_DISABLE_LPB	OEM	Low power boot mode disable or enable	No	0 - LPB Enabled 1 - LPB Disabled
LOW_BATT_GPIO_LEVEL	OEM	Determines whether the LOW_BATT_GPIO (GPIO6_16) is active high or active low.	No	0 - LOW_BATT_GPIO is Active High 1 - LOW_BATT_GPIO is Active Low
BT_LPB_FREQ	OEM	The ARM core frequency at Low power boot mode	Yes	00 - 192MHz at 192MHz PLL1 01 - 133MHz at 266MHz PLL1 10 - 55.3MHz at 166MHz PLL1 11 - 220MHz at 220MHz PLL1

The i.MX50 ROM code use GPIO6_16 as the LOW_BATT_GPIO to indicate the low battery state. The board designer should connect the i.MX50 GPIO6_16 to the interrupt output pad of the PMIC. After finding the low battery state, the ROM code will check the USB OTG PHY register for the existence of USB charger or Wall charger. If a charger is found, it means the system will get enough current, and the ROM code will continue to run on the normal boot flow. Otherwise, the ROM code will have to decrease the power consumption for the 100 mA limitation of USB host. For more details of USB low power boot, refer to *USB Battery Charging Specification*.

The polarity of the LOW_BATT_GPIO signal is determined by the LOW_BATT_GPIO_LEVEL, which is located in CFG6.Bit[9].

The frequency of Low power boot is selected by BT_LPB_FREQ[1:0] illustrated in Table 6-24.

6.8.1 LPB Mode Flow

The maximum LPB ARM core frequency is selected and stored in fuses BT_LPB_FREQ[2:0]. See **USB Low-Power Boot Mode (LPB)**, for details on setting frequency selection OCOTP bits for LPB. Even though the ROM boot code supports all primary boot devices in LPB mode in almost all cases USB are not be used in LPB mode for downloading a Program Image.

The LPB flowchart is shown in Figure 6-16 and has the following steps:

1. Check if the LPB feature is disabled by reading BT_DISABLE_LPB OCOTP bit.
2. If LPB feature is disabled, boot normally
3. If LPB feature is notdisabled, execute remaining steps
4. Check LOW_BATT_GPIO_LEVEL OCOTP bit. If LOW_BATT_GPIO_LEVEL is low, and GPIO6_16 is high, the AAPL-like PMIC reports low battery state; If LOW_BATT_GPIO_LEVEL is high, and GPIO6_16 is low, the non-AAPL-like PMIC reports low battery state.Otherwise,boot normally. Check if a charger is connected to the UTMI PHY of the i.MX50 USB OTG.
5. If a charger is connected, the system can get enough current, boot normally. If no charger is found, go to step 7
6. start to configure the clocks in low power boot mode. ARM core frequency will be decreased to a lower value based on BT_LPB_FREQ[1:0].
7. After configuring the clocks, the ROM code will start the similar flow with normal boot to load boot image from the boot media.

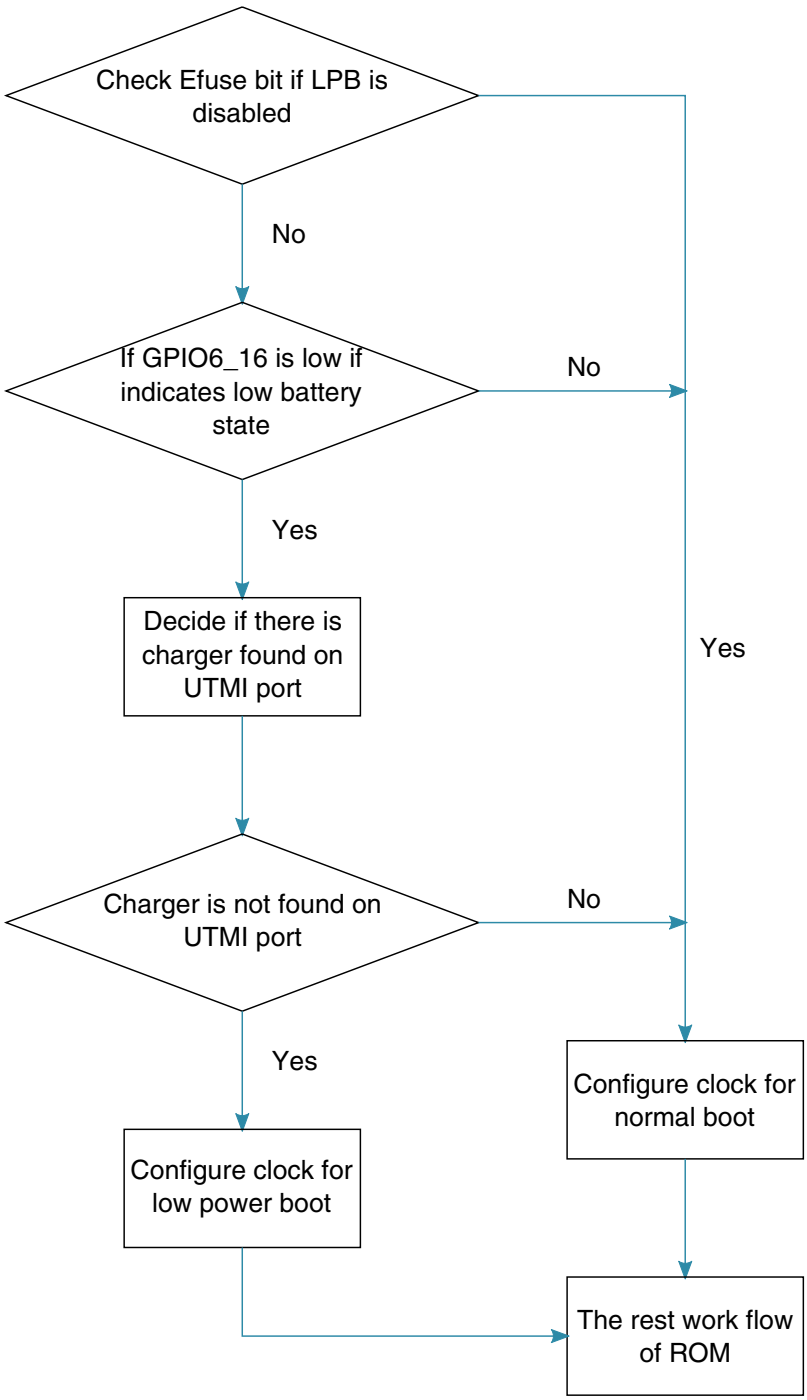

Figure 6-16. USB Low-Power Boot Flow

6.9 USB Downloader (BOOT_MODE[1:0] = 11)

The Serial Downloader provides a means to download a Program Image to the i.MX50 over a USB serial connection. In this mode if ENABLE_WDOG_TIMER_RESET fuse is blown then the ROM programs WDOG1 for a 32-second time-out and then continuously polls for USB activity. If no activity is found on USB and the watchdog timer expires the ARM core is reset. By default wdog timer reset is not enabled.

NOTE

If ENABLE_WDOG_TIMER_RESET fuse is blown then downloaded image must continue to service the watchdog timer to avoid an undesired reset from occurring.

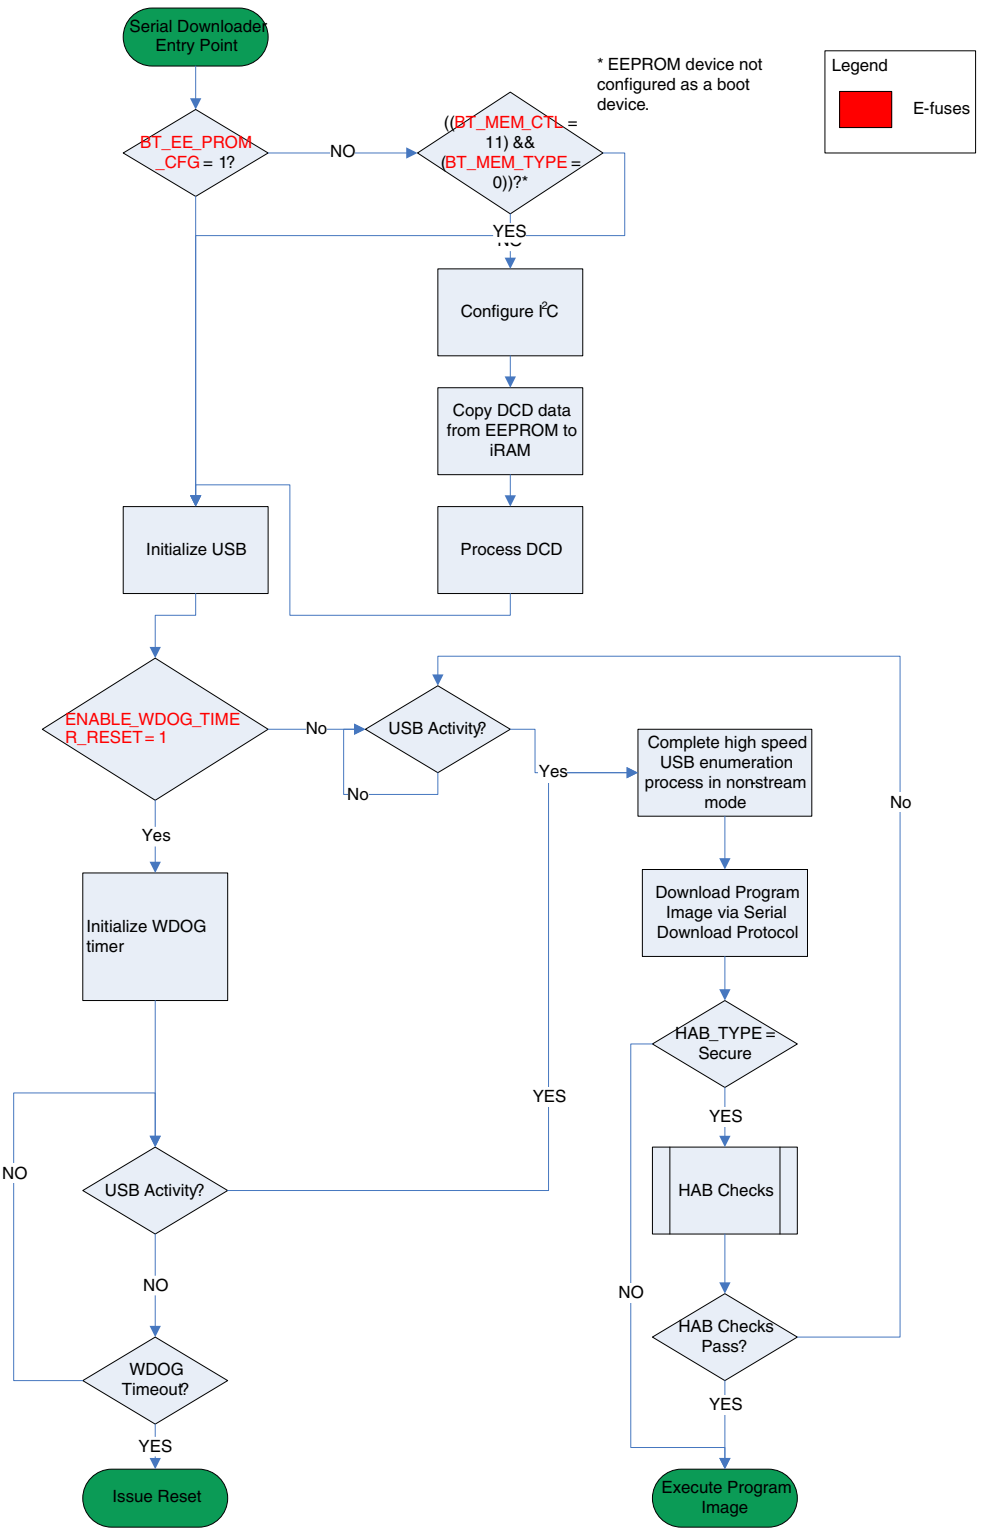

Figure 6-17. USB Boot Flow

6.9.1 USB

USB support in the i.MX50 is composed of the USB1 (USB OTG core controller, compliant with the USB 2.0 specification) and the USBPHY (HS USB transceiver). The i.MX50 ROM supports the USB OTG port for boot purposes. The other USB ports on the i.MX50 are not supported for boot purposes.

The i.MX50 USB Driver is implemented as a USB HID class. A collection of 4 HID reports are used to implement SDP protocol for data transfers.

- Report 1 transfer over control OUT endpoint, 16-byte SDP command from host to device. Total bytes are 17 with first byte reserved for report id set to 1.
- Report 2 transfer over control OUT endpoint from host to device data associated with report 1 SDP command. Max report size is 1025 bytes with first byte reserved for report id set to 2.
- Report 3 transfer over interrupt endpoint from device to host to send HAB security state. Max size of this report is 5 bytes with first byte reserved for report id set to 3. Device sends 0x12343412 in production mode and 0x56787856 in engineering mode in the remaining 4 bytes of this report.
- Report 4 transfer over interrupt endpoint from device to host to send data in response to SDP command in report 1. Max size of this report is 65 with first byte reserved for report id set to 4.

6.9.1.1 USB Configuration

The default VID/PID and strings for USB device driver are listed in Table 6-37.

The VID and PID can be customized using 16-bit efuses USB_VID and USB_PID.

Table 6-37. VID/PID and Strings for USB Device Driver

Descriptor	Value
VID	0x15A2 (Freescale vendor ID)
PID[1]	0x0052
Screen Descriptor1 (manufacturer)	Freescale Semiconductor, Inc.
Screen Descriptor2 (product)	S Blank i.MX50 SE Blank i.MX50 NS Blank i.MX50

Table continues on the next page...

Table 6-37. VID/PID and Strings for USB Device Driver (continued)

Descriptor	Value
Screen Descriptor4	Freescale Flash
Screen Descriptor5	Freescale Flash

1. Allocation based on BPN (Before Part Number)

6.9.1.2 Serial Download protocol

The 16 byte SDP command from host to device is sent using HID report 1. The following table describes 16 byte SDP command data structure:

Table 6-38. 16 Byte SDP Command Data Structure

BYTE Offset	Size	Name	Description
0	2	COMMAND TYPE	Following commands are supported for i.MX50 ROM: • 0x0101 READ_REGISTER • 0x0202 WRITE_REGISTER • 0x0404 WRITE_FILE • 0x0505 ERROR_STATUS • 0x0A0A DCD_WRITE (new to i.MX50) • 0x0B0B JUMP_ADDRESS (new to i.MX50)
2	4	ADDRESS	Only relevant for following commands: READ_REGISTER, WRITE_REGISTER, WRITE_FILE and JUMP_ADDRESS. For READ_REGISTER and WRITE_REGISTER commands, this field is address to a register. For WRITE_FILE and JUMP_ADDRESS commands, this field is an address to internal or external memory address.
6	1	FORMAT	Format of access, 0x8 for 8-bit access, 0x10 for 16-bit and 0x20 for 32-bit access. Only relevant for READ_REGISTER and WRITE_REGISTER commands.
7	4	DATA COUNT	Size of data to read or write. Only relevant for WRITE_FILE, READ_REGISTER, WRITE_REGISTER and DCD_WRITE commands. For WRITE_FILE command DATA COUNT is in bytes and for DCD_WRITE DATA COUNT means number of registers to write.
11	4	DATA	Value to write. Only relevant for WRITE_REGISTER command.
15	1	RESERVED	Not used in i.MX50 ROM

6.9.1.3 SDP Command

SDP commands are decribed in the following sections.

6.9.1.3.1 READ REGISTER

The transaction for command READ_REGISTER consists of following reports: Report1 for command, Report3 for HAB mode and Report4 for response or register value. The register to read is specified in ADDRESS field of SDP command. First device sends report-3 with hab mode followed by report 4 with bytes read at given address. If count is greater than 64 then multiple reports with report id 4 are sent until entire data requested by host is sent. The STATUS is either 0x12343412 for production parts and 0x56787856 for development parts.

Report1, Command, Host to Device:

2	Valid values for READ_REGISTER COMMAND, ADDRESS, FORMAT, DATA COUNT

ID 16 byte SDP Command

Report3, Response, Device to Host:

3	4 bytes HAB mode indicating Production/Development part

ID 4 bytes status

Report4, Response, Device to Host: first response report

4	Register Value

ID 4 bytes of data containing register value. If number of bytes requested is less than 4 then remaining bytes should be ignored by host.

... Multiple reports of report id 4 are sent until entire data requested is sent

Report4, Response, Device to Host: last respose report

4	Register Value

ID 64 bytes of data containing register value. If number of bytes requested is less than 64 then remaining bytes should be ignored by host.

6.9.1.3.2 WRITE REGISTER

The transaction for command WRITE_REGISTER consists of following reports: Report1 for command, Report3 for hab mode and Report4 for write status. Host sends Report1 with WRITE_REGISTER command. The register to write is specified in ADDRESS field of SDP command of Report1, with FORMAT field set to data type (number of bits to

write 8, 16 or 32) and value to write in DATA field of SDP command. Device writes the DATA to register address and returns WRITE_COMPLETE code using Report4 and Development/Engineering part status using Report3 to complete the transaction.

Report1, Command, Host to Device:

2	Valid values for WRITE_REGISTER COMMAND, ADDRESS, FORMAT, DATA COUNT and DATA

ID 16 byte SDP Command

Report3, Response, Device to Host:

3	4 bytes HAB mode indicating Production/Development part

ID 4 bytes status

Report4, Response, Device to Host:

4	WRITE_COMPLETE (0x128A8A12) status

ID 64 bytes of data with first 4 bytes to indicate write is completed with code 0x12828212. On failure device will report HAB error status.

6.9.1.3.3 WRITE_FILE

The transaction for command WRITE_REGISTER consists of following reports: Report1 for command, Report3 for hab mode and Report4 for write status. Host sends Report1 with WRITE_REGISTER command. The register to write is specified in ADDRESS field of SDP command of Report1, with FORMAT field set to data type (number of bits to write 8, 16, or 32) and value to write in DATA field of SDP command. Device writes the DATA to register address and returns WRITE_COMPLETE code using Report4 and Development/Engineering part status using Report3 to complete the transaction:

Report1, Command, Host to Device:

1	Valid values for WRITE_FILE COMMAND, ADDRESS, DATA COUNT

ID 16 byte SDP Command

==========Optional Begin==========

Host sends ERROR_STATUS command to query if HAB rejected the address

==========Optional End==========

Report2, Data, Host to Device:

2	File data

ID Max 1024 bytes data per report

Report2, Data, Host to Device:

2	File data

ID Max 1024 bytes data per report

…

Report3, Response, Device to Host:

3	4 bytes HAB mode indicating Production/Development part

ID 4 bytes status

Report4, Response, Device to Host:

4	COMPLETE (0x88888888) status

ID 64 bytes data with first 4 bytes to indicate file download has completed with code 0x88888888. On failure device will report HAB error status.

6.9.1.3.4 ERROR_STATUS

The transaction for SDP command ERROR_STATUS consists of three reports. Report1 is used by host to send the command; device sends global error status in 4 bytes of Report4 after returning Development/Engineering status code in Report3. When device receives ERROR_STATUS command it will return global error status that is updated for each command. This command is useful to find out if last command resulted in device error or succeeded.

Report1, Command, Host to Device:

1	ERROR_STATUS COMMAND

ID 16 byte SDP Command

Report3, Response, Device to Host:

3	4 bytes HAB mode indicating Production/Development part

ID 4 bytes status

Report4, Response, Device to Host:

4	4 bytes Error status

ID first 4 bytes status in 64 bytes report 4

6.9.1.3.5 DCD WRITE

The SDP command DCD_WRITE is used by host to send a bunch of register writes in one shot. This command is provided to speed up the process of programming register writes such as to configure external RAM device. The command goes with Report1 from host with COMMAND TYPE set to DCD_WRITE and DATA_COUNT to number of registers sent in data out phase. In data phase host sends data for number of registers using Report2. The number of registers per DCD_WRITE command is limited to 85; this is mainly to fit the data in one data out packet from host. If there are more than 85 registers to write, host will have to send additional DCD_WRITE commands to device. Each register data needs 12 bytes: 4 bytes for FORMAT (data type, 8 for byte, 16 for 2 bytes and 32 for 4 bytes), 4 bytes for address of the register and 4 bytes for value to write to the register. If there are n registers to write then host will send n times 12 bytes of data in data phase. Device completes the transaction with Report3 indicating Development/ Production STATUS and report 4 with WRITE_COMPLETE code 0x12828212.

Report1, Command, Host to Device:

1	DCD_WRITE COMMAND, DATA_COUNT

ID 16 byte SDP Command

Report2, Data, Host to Device:

2	DCD binary data

ID Max 1024 bytes (85 register writes) per report

Report3, Response, Device to Host:

3	4 bytes HAB mode indicating Production/Development part

ID 4 bytes status

Report4, Response, Device to Host:

4	WRITE_COMPLETE (0x128A8A12) status

ID 64 bytes report with first 4 bytes to indicate write is completed with code 0x128A8A12. On failure device will report HAB error status.

Table 6-39 displays the format of DCD binary data:

Table 6-39. DCD Data for n Registers

4 bytes for data format	4 bytes for register1 address	4 bytes for register1 value to set
4 bytes for data format	4 bytes for register2 address	4 bytes for register2 value to set
4 bytes for data format	4 bytes for register3 address	4 bytes for register3 value to set
...	...	...
4 bytes for format	4 bytes for last (nth) register address	4 bytes for last register (nth) value

6.9.1.3.6 JUMP ADDRESS

The SDP command JUMP_ADDRESS will be the last command host can send to the device, after this command device will jump to the address specified in the ADDRESS field of SDP command and start executing. This command should typically follow after WRITE_FILE command. The command is sent by host in command-phase of transaction using Report1, there is no data phase for this command but device send status report3 to complete the transaction. And if HAB authentication fails then it will also send report 4 with HAB error status.

Report1, Command, Host to Device:

1	JUMP_ADDRESS COMMAND

ID 16 byte SDP Command

Report3, Response, Device to Host:

3	4 bytes HAB mode indicating Production/Development part

ID 4 bytes status

This report is sent by device only in case of an error jumping to the given address, device reports error in Report4, Response, Device to Host:

4	4 bytes Error status

ID 4 bytes status, 64 bytes report length

6.9.2 External Entry

In some use cases it may be desirable to call into the ROM USB downloader from program image code. The ROM provides an entry point for the USB downloader through ROM Vector Table (hab_rvt) structure. The interface to call into usb downloader is hab_rvt.failsafe. ROM Vector Table structure is located at address 0x00000094 in ROM memory region as discussed in ROM Vector Table Addresses. The failsafe member of RVT structure is at offset 0x28. To call into ROM the program image should jump to the address at hab_rvt.failsafe.

Note that pu_irom_boot_decision is compiled for Thumb state on the ARM processor core.

6.9.2.1 pu_irom_boot_decision

Syntax:

```
void pu_irom_boot_decision(void)
```

Description:

Entry point for the USB Downloader. Performs EEPROM DCD processing if BT_EEPROM_CFG OCOTP bit is not blown.

Inputs:

None.

Returned Value:

None.

PreConditions/Assumptions:

- BT_EEPROM_CFG is set appropriately

Post Conditions:

None.

6.10 High Assurance Boot (HAB)

The High Assurance Boot (HAB) component of the ROM protects against the potential threat of attackers modifying areas of code or data in programmable memory to make it behave in an incorrect manner. The HAB also prevents attempts to gain access to features which should not be available. The integration of the HAB feature with the ROM code ensures that i.MX50 does not enter an operational state if the existing hardware security modules have detected a condition that may be a security compromise or areas of memory deemed to be important have been modified. The HAB uses RSA digital signatures to enforce these policies.

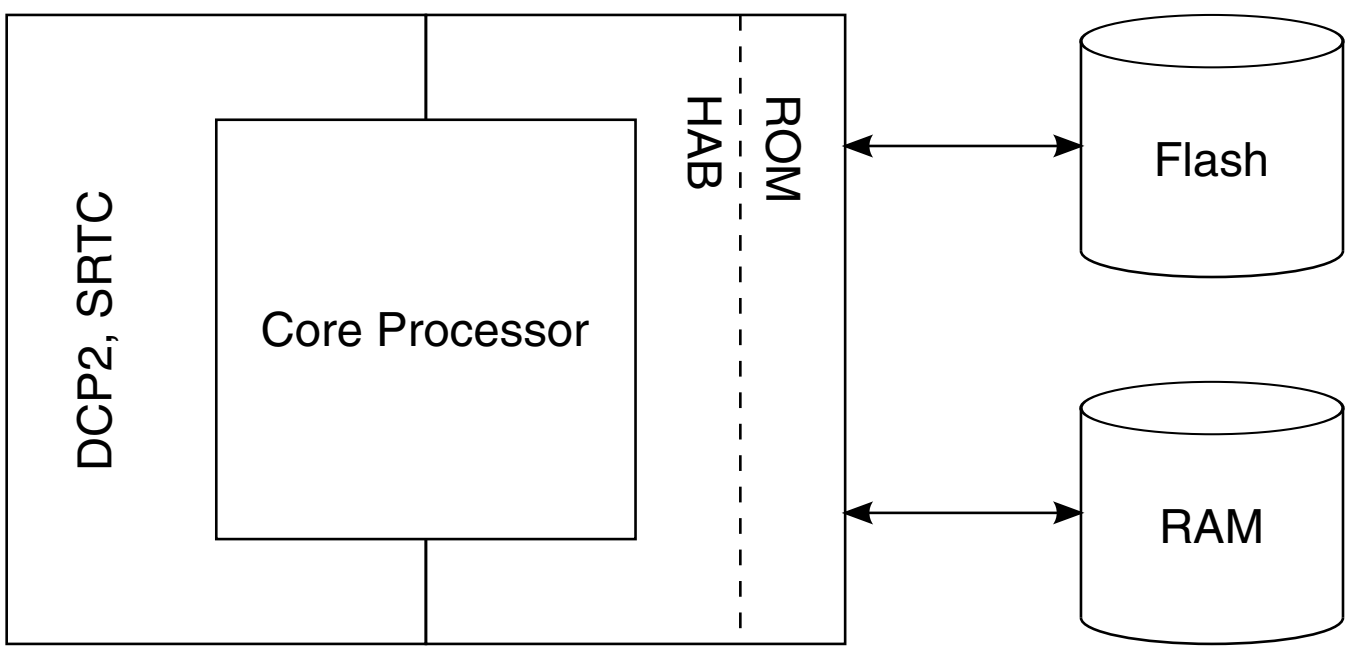

Figure 6-18. Secure Boot Components

Figure 6-18 illustrates the components used during a secure boot using HAB. The HAB makes use of the DCP2 hardware module to accelerate SHA-256 message digest operations performed during signature verifications. The HAB also includes a software implementation of SHA-256 for cases where a hardware accelerator cannot be used. The core RSA signature verification operations are performed by a software implementation contained in the HAB library. The main features supported by HAB are:

- X.509 Public key certificate support
- CMS signature format support

For further details on making use of the i.MX50 secure boot feature using HAB please contact your local Freescale representative.

6.10.1 ROM Vector Table Addresses

For devices that perform a secure boot, the HAB library may be called by boot stages that execute after ROM code. The RVT table contains the pointers to the HAB API functions and is located at 0x00000094 For additional information on secure boot on i.MX50 including the HAB API please contact your local Freescale representative

6.10.2 SRTC Initialization

For details on SRTC initialization when performing a secure boot with HAB please contact your local Freescale representative.

Chapter 7
System Debug

7.1 Overview

This chapter describes the hardware and software debug and application development features and resources of the i.MX50. There are core/platform-specific resources, resources associated with some of the more complex IP blocks, and chip-wide resources. Also discussed is the interface to external debug and development tools.

The debug architecture of the i.MX50 is based on that of previous members of the i.MX application processor family. A small number of changes and extensions were necessary to accommodate new IP.

An overview the i.MX50's primary debug capabilities and features include:

- JTAG-based access (control and monitoring), built around the System JTAG Controller (SJC)
- Trace Port
- Real-time and Halt-mode debug and profiling capabilities of the ARM Cortex™-A8 core platform
- Real-time and Halt-mode debug capabilities of the SDMA core
- An SOC-wide cross-trigger system built around ARM's Embedded Cross Trigger (ECT)
- Visibility of pre-selected critical internal signals via pin muxing
- External memory interface/controller arbitration profiling

Each of these features will be described in detail in the following sections of this chapter. The i.MX50 also support ARM CoreSight architecture for system debug and trace capabilities.

7.1.1 Debug Strategy

- Software debug-(MSFT kernel)

- Trace the ARM platform activity through ETM trace port or ETB (ARM only)
- Control and monitor through JTAG
- Monitor pre-selected critical internal signals through pin muxing-scope

7.2 System JTAG Controller-SJC

The SJC module is the bridge between external development and test instrumentation and the internal JTAG-accessible debug and test resources. It implements and manages the daisy-chained topology consisting of it's own TAP and those of the SDMA, a DSP core (not implemented on the i.MX50), the ARM core, and the ARM Debug Access Port (DAP). ARM core isn't part of a daisy-chain. Also, DSP TAP is excluded by SJC configuration tie-off, so there is no need to use BYPASS IR for it at all.

7.2.1 JTAG Topology

Figure 7-1 shows the JTAG topology.

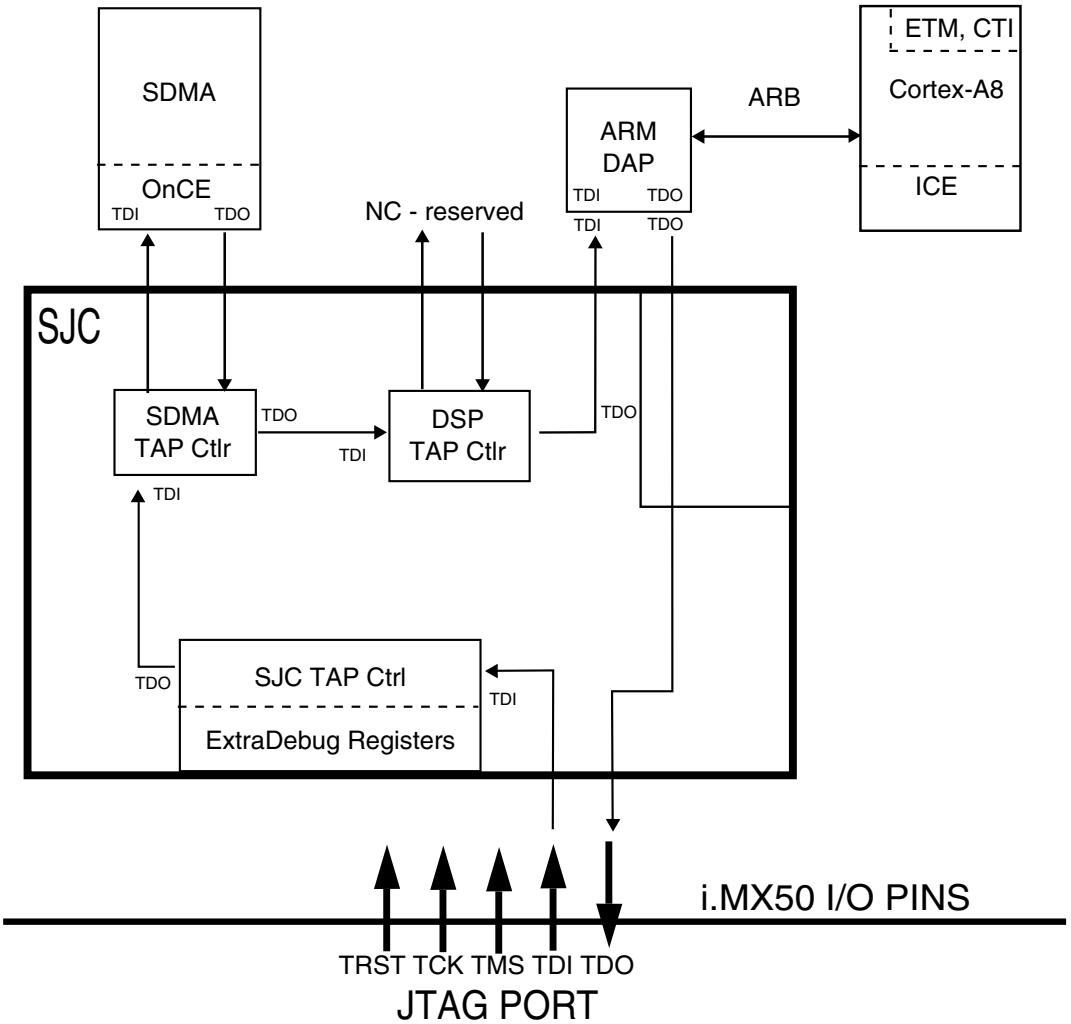

Figure 7-1. JTAG Connectivity

7.2.2 System JTAG Controller Main Features

The following list describes the System JTAG Controller's main features:

- IEEE P1149.1 (standard JTAG) interface to off-chip test and development equipment
  - includes an SJC-only mode for true IEEE 1149.1 compliance, used primarily for board-level implementation of boundary scan.
- Debug-related control and status, such as putting selected cores into reset and/or debug mode and the ability to monitor individual core status signals via JTAG.
- System status, such as the state of the PLLs (locked or not locked)
- Generic status and control, defined on a per-SOC basis by the architecture team

- Factory test related control/status such as PLL bypass and memory BIST
- 3 levels of security, ranging from no security to no JTAG accessibility to the chip.

7.2.3 SJC TAP Port

The SJC in i.MX50 supports the following standard JTAG pins: TRSTB, TDI, TDO, TCK, and TMS.

7.2.4 SJC Main Blocks

The following list describes the SJC main blocks:

- Interface to the outside world via the standard JTAG pins
- Interface to the external Debug_Event pin
- A master TAP controller, which implements the standard JTAG state machine.
- Implementation of the mandatory and optional IEEE P1149.1 (JTAG) instructions
  - Mandatory: "EXTEST", "SAMPLE/PRELOAD", and "BYPASS"
  - Optional: "ID_CODE" (SOC JTAG ID register), "HIGHZ"
- Supports the SDMA's DR-path-only JTAG architecture by implementing the controller portion of it's TAP (including "BYPASS" as the default state) within the SJC
- Provides the serial interfaces to various DSP-domain JTAG resources (not implemented on i.MX50)
- The ExtraDebug registers, which implement a variety of control and status features
  - Three 32-bit insecure general purpose status registers
  - Two 32-bit secure status registers-one predefined, one general purpose.
  - Control and status registers for debug, core, charge pump, PLL, and BIST related functions
  - Control bits for memory timing control (not used on the i.MX50)
- Three levels of fuse-defined security, ranging from no security to no access.

Both predefined and user-defined (SOC integration) Control and Status functions are supported by the SJC. The user-defined functions will be defined and documented by the SOC integration.

7.2.5 i.MX50 Specific SJC Features

7.2.5.1 JTAG Disable Mode

In addition to three different JTAG security modes that are implemented internally in the System JTAG Controller (SJC), there is an option to disable the SJC functionality by e-fuse configuration. This creates additional JTAG mode "JTAG Disabled" with highest level of JTAG protection. In this mode all JTAG features are disabled. Specifically, the following debug features are disabled in addition to the features that were already disabled in "No Debug" JTAG mode:

- Memory BIST
- Boundary scan register (BSR)
- Non-Secured JTAG control registers (PLL configuration, Deterministic Reset, PLL bypass)
- Non-Secured JTAG status registers (Core status)
- Chip Identification Code (IDCODE)

7.2.5.2 SJC i.MX50 Specific Registers Summary

There are many specific SJC registers for the i.MX50, for detailed description of System Jtag Controller(SJC) chapter.

7.2.5.3 JTAG ID

JTAG_ID:0x02D0_101D.

For detail description of the JTAG_ID, refer to the "System Jtag Controller (SJC)" chapter.

7.3 CoreSight Design Kit

The i.MX50 include ARM CoreSight component for multi core debug and trace solution. CoreSight component can be found in a few hierarchy levels: ARM core, ARM platform and top level.

- ARM core: include the following CoreSight components: ETM, CTI0
- ARM platform: include the following CoreSight components: ETB, ATB Replicator, CTI1, CTM
- Top level: include the following CoreSight components: DAP, CTI2, CTI3, TPIU

7.3.1 Memory Map and Register Definition

Each CSDK component has a 4 Kbyte location block in the CoreSight memory map. The base address of the CoreSight location block is not fixed but the address offsets are fixed. Each CSDK component has a 4KB memory map, that is, 1 K words.

Components connected to the DAP internal bus appear as part of a memory mapped structure with parallel address and two data busses, read data and write data. The bus master, JTAG-DP, controls the various APs, in this structure the slaves, using normal bus transactions. The JTAG-DP reads and writes registers within this bus.

7.3.2 CoreSight Clock Enable

By default the CoreSight component clocks are enabled, the system get out from reset with all clocks enabled. The CoreSight clocks gating are controlled by programmable CCM registers and DBGEN. CCM allow control of each CoreSight component separately (by default allowed) and DBGEN that allow and disable all debug clocks. DBGEN will be raised when detecting activity on JTAG ports (TMS) and descend on reset (by dap_sys) or controlled by ARM. Only if both CCM registers bits and DBGEN are high the clock will be propagate to CoreSight component.

7.3.3 CoreSight Debug Access Port (DAP) and DAP_SYS

ARM's Debug Access Port (DAP) has several functions. DAP_SYS is a wrapper around DAP and is the FSL block that is actually instantiated in a design (DAP is contained within DAP_SYS). The following list is a summary of the features provided by DAP_SYS:

- Enables debug-related communication between various parts of the system
  - It is a modular block
  - Slave-side support for JTAG and APB (ARM Peripheral Bus) protocols.
  - Debug master can access many debug resources in real time without having to halt the core
  - Enabling of system access to anything connected to the Debug-APB via the APB multiplexor.
- ROM Table-provides a list of memory locations of CoreSight components connected to the Debug APB. Visible from both tools and system access.
- AHB to APB gasket to translate System AHB accesses to APB (input as system APB to the DAP).
- APB Decode to issue select signals to CoreSight components on APB, and handle the PSLVERR and PREADY signals from the components to the DAP.

- AHB-Lite to AHB converter, to translate DAP's AHB-lite accesses to system's AHB protocol.
- Debug and Reset logic to generate DBGEN signal and reset signals.

The CoreSight components that reside on the Debug-APB include all Embedded Cross Trigger blocks, the ETM, and the ETB.

7.3.4 Embedded Cross Trigger (ECT)

System events, such as a debug request, a core entering or exiting debug mode, the occurrence of a breakpoint or watchpoint, the occurrence of a particular error, the state of a buffer, etc., can be useful or even essential for debugging or profiling system performance. Whatever the source of the event, the embedded cross trigger implements a flexible, programmable mechanism to transport these events from a source to one or multiple destinations. This includes handling handshake requirements with both the source and the destination as needed and synchronization of signals from different clock domains. The end result is that events of interest that occur in one domain, such as in the Cortex-A8 domain, can be recognized and responded to be a destination domain, such as the SDMA.

i.MX50 uses the CoreSight ECT (provided by ARM as part of their full CoreSight Debug Support package) and a custom wrapper to accommodate the various necessary interface scenarios. The ECT (as delivered by ARM) consists of two major blocks - a central Cross Trigger Matrix (CTM) and a Cross Trigger Interface (CTI) block. A Freescale-customized wrapper is added to the CTI to accommodate a variety of different input and output interface scenarios. The wrapped CTI is called the Extended CTI and is configured on a signal by signal basis with port tie-off's.

i.MX50's ECT architecture consists of a single CTM and three wrapped CTI's covering 3 basic groups of functionality as follows:

- CTI0-is in the Cortex-A8 core
- CTI1-is in the Tiger cortex-A8 core platform, 2 trigger in and 2 trigger out is used by the platform and the others by the device peripherals
- CTI2-is in the SOC level, is by SDMA
- CTI3-is in the SOC level, is used by MCU peripherals

Detail CTI pin assignment can be found in CoreSight CTI.

Figure 7-2 is a simple illustration of the relationship between the two processor domains, the SJC and peripherals, and the ARM CoreSight DAP. APB is an AMBA bus used for debugging. It defines what debug and trace components are required and how they are connected. The DAP is the Debug-APB master of the following debug units: 4 CTI

blocks, ETM, ETB, TPIU and Cortex-A8 debug unit. The Debug-APB bus differs from system-level APB's in that it can be directly accessed via JTAG as well as from the ARM core. Module selects for each slave module on the Debug-APB are generated by the DAP_SYS.

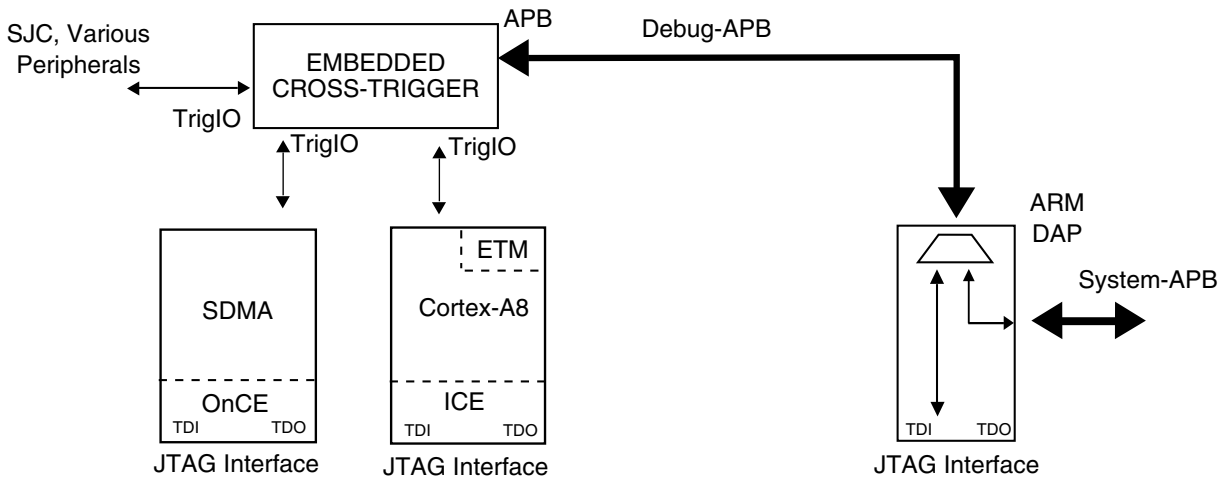

Figure 7-2. Embedded Cross Trigger Topology

Figure 7-3 illustrates the connectivity between the CTM and CTIO components of the CoreSight ECT.

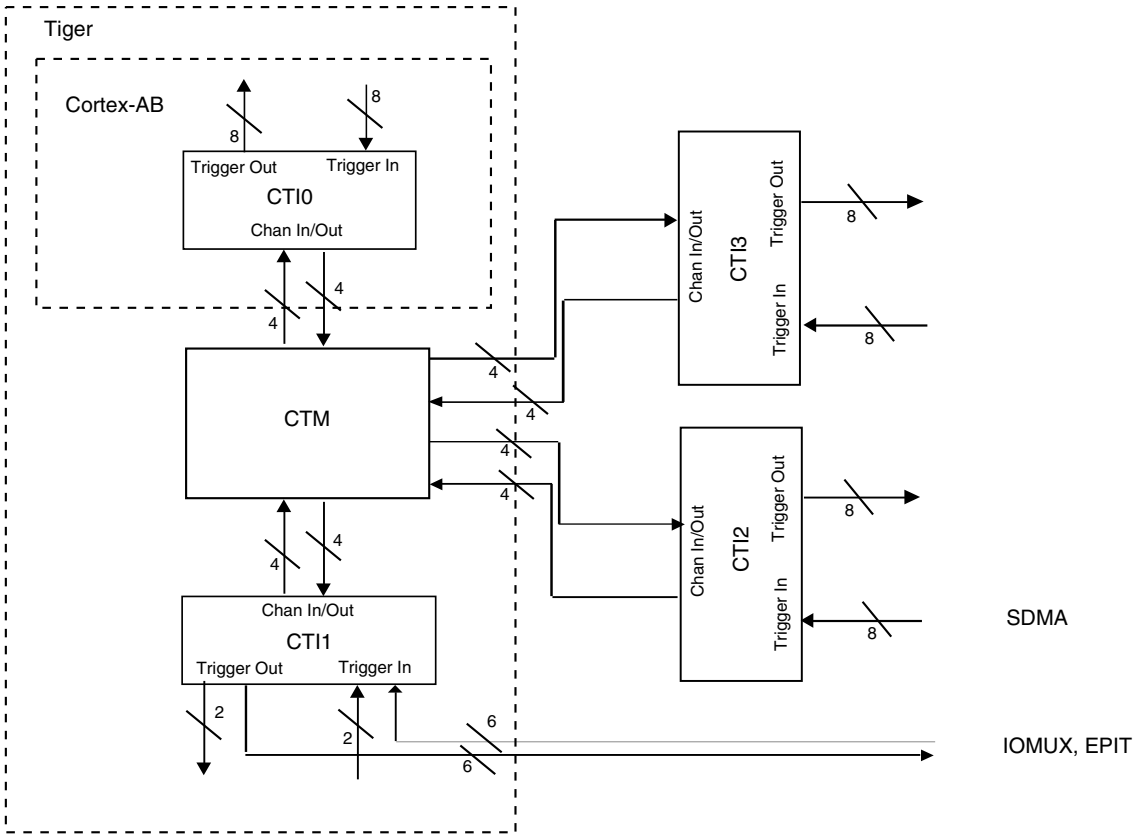

Figure 7-3. Embedded Cross Trigger-Basic Architecture

7.3.4.1 CoreSight CTM

The CTM (Cross Trigger Matrix) is provided by ARM. . The CTM is a relatively simple block with no programmability. On i.MX50, it's configured to have 4 input and 4 output channels. Whatever comes in on an input channel is simply routed to all corresponding output channels. For instance, if a trigger input comes in on input channel 0 from CTI0, it is routed to output channel 0 to CTI1, CTI2 & CTI3. All selection of drivers and receivers for an event is done in the individual CTI blocks.

The final feature provided by the CTM is handshake with each CTI. This insures that as trigger signals cross different clock domain boundaries, they won't be lost due to slower downstream sampling frequencies. It is a simple mechanism in which a CTI holds an output until it receives the acknowledgement from the CTM. Handshake is also implemented in the reverse direction, insuring that a trigger signal propagating from the CTM to a CTI won't be missed by the CTI.

7.3.4.2 CoreSight CTI

The CTI (Cross Trigger Interface) is also provided by ARM. A summary description of the CTI is provided here, but please refer to ARM documentation for detailed information. As mentioned earlier, there are 3 CTI's in i.MX50. Each of these has 8 trigger inputs and 8 trigger outputs that connect to logic in the domain to be debugged or profiled. Each CTI also includes a 4 channel interface to the CTM (4 inputs and 4 outputs as shown in Table 7-1 through Table 7-6). The CTIs are wrapped with additional logic to from the Extended CTI, which is described in the next section.

Table 7-1. CTI 1 Input Assignments

Trigger Input	Debug Resource Name	Channel Function	SYNC (dbg_atclk)	Active	ack	Comment
0	N/A	Configured interrupt	No	High	No	-
1	N/A	Configured interrupt	No	High	No	-

7.3.4.3 Extended CTI (CTI Wrapper)

This wrapper consists of additional logic for each input and each output trigger to implement several features that can be selected or enabled with hard tie-off's on the module's boundary. It is combined with ARM's CTI block to form the CTI_Extended block. A summary of the extended input features implemented by logic in the wrapper is as follows:

- Invert the incoming signal
  - The ARM CTI assumes all inputs are active-high. An active-low input must first be inverted before going into the ARM CTI
- Sample the incoming trigger signal with a clock synchronous to the incoming signal
  - Samples the incoming trigger with it's own clock
- Convert the incoming signal to a pulse
  - Used when an input trigger has a long assertion time. Destinations may be sensitive to a long assertion time and may see it as multiple input triggers.

- Implement holding logic to insure that the ARM CTI captures and acknowledges the incoming signal. The holding logic clock must be synchronous to the clock that generated the input trigger.
- Provides a synchronized or asynchronous acknowledge signal back to the origin of the trigger.

If the asynchronous trigger source requires an ACK signal back from the CTI, but a clock from that source is not available to the CTI, the source must first synchronize the received ACK before using it in the trigger source logic.

7.3.5 CoreSight Trace Port Interface (TPIU)

The TPIU is one of the CoreSight trace sink components it acts as a bridge between the on-chip trace data to a data stream that is then driven out the trace port. ATB interface is used by the TPIU accepts trace data from a trace source, either direct from a trace source or using a Trace Funnel. The TPIU has 32-bit connected to the Chip pad. The APB interface is the programming interface for the TPIU configuration.

7.4 Cortex-A8 Core and Platform

Cortex-A8 Debug architecture includes support for CoreSight. The memory-mapped external debug interface replaces the coprocessor interface defined in the previous version of the Debug architecture. A full access to the processor debug capability available by Cortex-A8 debug register map through the Advanced Peripheral Bus (APB) slave port. The core include Processor Debug Unit allow: stop program execution, examine and alter processor and coprocessor state, examine and alter memory and input/output peripheral state and restart the processor core.

7.4.1 Cortex-A8 Core Debug Support Features

- CoreSight Embedded Trace Macro (ETM11)-race generator for the Cortex-A8 core
- Support for eFuse-related 3-level debug scheme:
  - Debug everywhere
  - Debug in Non-Secure privileged and user, and Secure user
  - Debug in Non-Secure only
- Embedded ICE-RT logic
  - Support for both monitor-mode and halt-mode debugging.

    - Core run/halt control, debug status/control
    - Breakpoint/watchpoint control
    - Core- and memory-mapped resource examination/modification
- Data communication channel between ARM core and host debugger via JTAG
- PMU-Performance Metrics Unit used for system profiling and debug.
- CP15 register for debugging the MMU, I & D L1 cache, and TLB
- EVTMON - L2 Event Monitor-Supports debug and profiling of the ARM's L2 cache activity

7.4.2 Embedded Cross Trigger Interface

Please refer to the Embedded Cross Trigger section of this chapter for detailed information about the Core and platfrom interface to that subsystem.

7.4.3 Additional Platform Debug Functionality

- CoreSight Embedded Trace Buffer (ETB11)-4 Kbyte RAM array to be used for on-chip capture of trace data output from the ETM11.
- ATB Replicator to connect the trace data to TPIU (Trace Port Interface) and ETB (Embedded Trace Buffer).
- Debug Visibility-select critical signals routed to the I/O pads as alternate outputs for external visibility

7.5 Smart DMA (SDMA) Core

The SDMA is a dedicated, programmable DMA engine. It is an integration of a 32-bit RISC core and DMA-specific hardware, and includes ports for the AP domain and a peripheral domain, along with a burst-capable port for direct external memory access. The SDMA and it's integration in i.MX50 is unchanged from previous SOCs.

The main SDMA debug features:

- OnCE-On Chip Emulator, provides the following capabilities:
    - SDMA core control - run/halt/single-step
    - SDMA core register/memory-map access
    - Event detection, watchpoints, and hardware breakpoints
    - Real time buffer and PC trace buffer capability
- Trace buffer

    - Contains information to identify the 32 last changes of flow detected during a program execution
- Context dump
    - Include information about all the channel dump activity
    - Current contents of SDMA RAM
- SDMA ROMPATCH

7.5.1 SDMA On Chip Emulation Module (OnCE) Feature Summary

The SDMA debug features are primarily defined by the OnCE portion of it's design, which are summarized as follows:

- Memory And Register Access-Dedicated logic enables user-access to SDMA memory and register locations. These accesses are supported only when the processor is in debug mode.
- Event Detection Unit-Watches signals from the data memory bus (DMBus) which is used by the RISC core to access its RAM, ROM, and memory-mapped registers
- Watchpoints-One output signal is available to watch event matching conditions at the chip level. Match conditions are defined by programming memory-mapped registers.
- Hardware Breakpoint-A counter is decremented after an event detection. A debug request is sent to the SDMA core only when the counter reaches the value of zero. It is possible to program the initial value of the counter or to disable the use of the counter if a debug request must be generated after each event detection.
- Real Time Buffer-The Real Time Buffer Register (RTB) is a single 32-bit memory-mapped register which can be accessed as a regular memory location during program execution. It is used to store and retrieve run time information without putting the SDMA in debug mode. Each write to this register causes an event. This register is, in fact, located in the OnCE. Executing through JTAG, a buffer command exports the content of this register through the JTAG port.
- Core Control (Core Status/Single Stepping)-Commands are provided to monitor and control processor activity. The commands can halt the core, rerun the core from another address location, and get processor status.
- Trace Buffer-A 32x32 buffer which records the last 32 changes of flow during program execution. The buffer stores data in a modulo fashion (that is, the 33rd instruction change replaces the 1st). Captured trace information is retrieved via reads to the Trace Buffer Register.

7.5.2 Other SDMA Debug Functionality

The following list is a description of other SDMA debug functionality:

- Core Trace-basic core trace capability is available through debug visibility functionality only. ETM/Nexus trace capability does not exist.
- ROM Patch-can be accomplished by manipulating the CHN0ADDR register through JTAG or via the MCU's ability to write to SDMA OnCE registers. This must be done right after reset and before the SDMA core is enabled to begin processing events.
- Additional debug control/status interaction with the SJC module
  - SJC-controlled Debug Request
  - SJC-readable Debug Acknowledge (in debug mode)
  - Debug clock control - allows SJC to force clocks on for debug purposes
  - Debug core state (SDMA RISC Core State) - 4 bits accessible from the SJC via JTAG
- Debug Visibility-observable outputs as alternate (programmable) output functions of I/O pins
  - Debug Request, Debug Mode
  - Debug Yield
  - Debug Event Channel[5:0] (indicates requesting event or channel being processed)
  - Debug PC [13:0] (for SDMA core trace)
  - Debug core state [3:0]
  - Debug Real-time Buffer write
  - Debug Addr/Data match
  - Debug bus error
  - Debug bus device
  - Debug bus r/w
  - Debug Event Channels[7:0]
  - Debug Core Run (active when core is running)

7.6 Debug Visibility-IOMUX

Certain predefined, internal signals can be viewed at the package pins. The pad logic for most pins includes an IOMUX, allowing that pad to be shared across multiple functions. Each pad has a primary function that is selected at reset. The alternate functions, such as displaying the state of an internal signal for debug purposes, is selected by reprogramming the IOMUX.

Table 7-7. Debug Visibility

Module	Signals	Pad Frequency
SDMA	debug_mode, debug_bus_error, debug_bus_device[4:0], debug_bus_rwb, debug_matched_dmbus, debug_rtbuffer_write, debug_evt_chn_lines[7:0]	50 MHz
TPIU	TRACEDATA[15:0]	80 MHz

The i.MX50 Block Guide will contain a complete listing of debug visibility signals and their assigned pins.

7.7 Supported Tools

i.MX50 support RealView™ ARM Debugger, the debugger should be connect to i.MX50 from host by RealView ICE protocol converter.

7.8 Interrupt Visibility

Similar to debug visibility, i.MX50 includes multiplexors that allow users to view selected internal interrupts. Up to five pads support this as alternate pad output functions, allowing the user to view up to five different interrupt sources simultaneously. These five signals also route to ECT inputs, allowing them to generate ECT trigger events as desired. Table 7-8 lists the 5 pads that could be used to observe internal interrupt signals.

Table 7-8. Interrupts Observe Pads

Signal	PAD
observe_mux_out_0	I2C3_SCL
observe_mux_out_1	I2C3_SDA
observe_mux_out_2	PWM1
observe_mux_out_3	PWM2
observe_mux_out_4	OWIRE

7.9 Miscellaneous

7.9.1 SOC-Level Bus Trace

There is no SOC-level bus trace capability on i.MX50.

7.9.2 Clock/Reset/Power

The interactions between the debug system and the system clock, reset, and power control blocks will include enhancements to insure that status of critical system components can be monitored at all times, and that a debugger can insure that all critical clocks and power are enabled when needed. Specifically, a master signal coming from an SJC control bit and going to the Clock/PLL logic will be implemented for each major clock domain. The same will be done for each power domain. Historically, JTAG based operations have not been possible under certain system conditions. For i.MX50, the debugger must have the ability to determine the status of all critical system elements and to override any condition that would prevent the desired debug resources from operating properly.

Chapter 8
ARM Cortex A8 Platform (ARM Platform)

8.1 Introduction

This chapter discusses the architecture and design of the ARM™Cortex® A8 platform. Detailed design information of each block within the platform is not covered in this document.

8.2 Overview

A block diagram of the ARM platform is shown in Figure 8-1. The ARM Platform consists of the ARM Ltd. ARM processor which includes a NEON™ co-processor, L1 cache, L2 cache, Embedded Trace Macrocell (ETM) and a Cross Trigger Interface (CTI). The platform includes the essential sub-blocks: platform control, test logic and debug (Cross trigger Matrix (CTM), Embedded Trace Buffer (ETB), and a second CTI).

The ARM processor instruction and data read/write AXI master port is connected from the non-ARM Platform side of the Level 2 Cache. The L2 can access external L3 memory through this port.

The core platform supports static debug through the debug logic to SoC. This includes the capability of real time trace through ARM's Coresight ETM, ETB and CTM sub-blocks. The second CTI sub-block allows cross triggering of internal and external trigger sources.

The ARM platform has two power domains (LP & GP) which are separated by level shifters. The LP power domain serves as a interface to the rest of the SoC. The GP power domain is completely contained within the platform and allows the ARM core and subsystem to run at much higher frequencies than the rest of the SoC.

The boundary of the two power domains is also an asynchronous boundary between the ARM platform and the rest of the SoC. Synchronizers in both the GP and LP power domains of the platform allow the ARM core and subsystem to run asynchronously from the rest of the SoC.

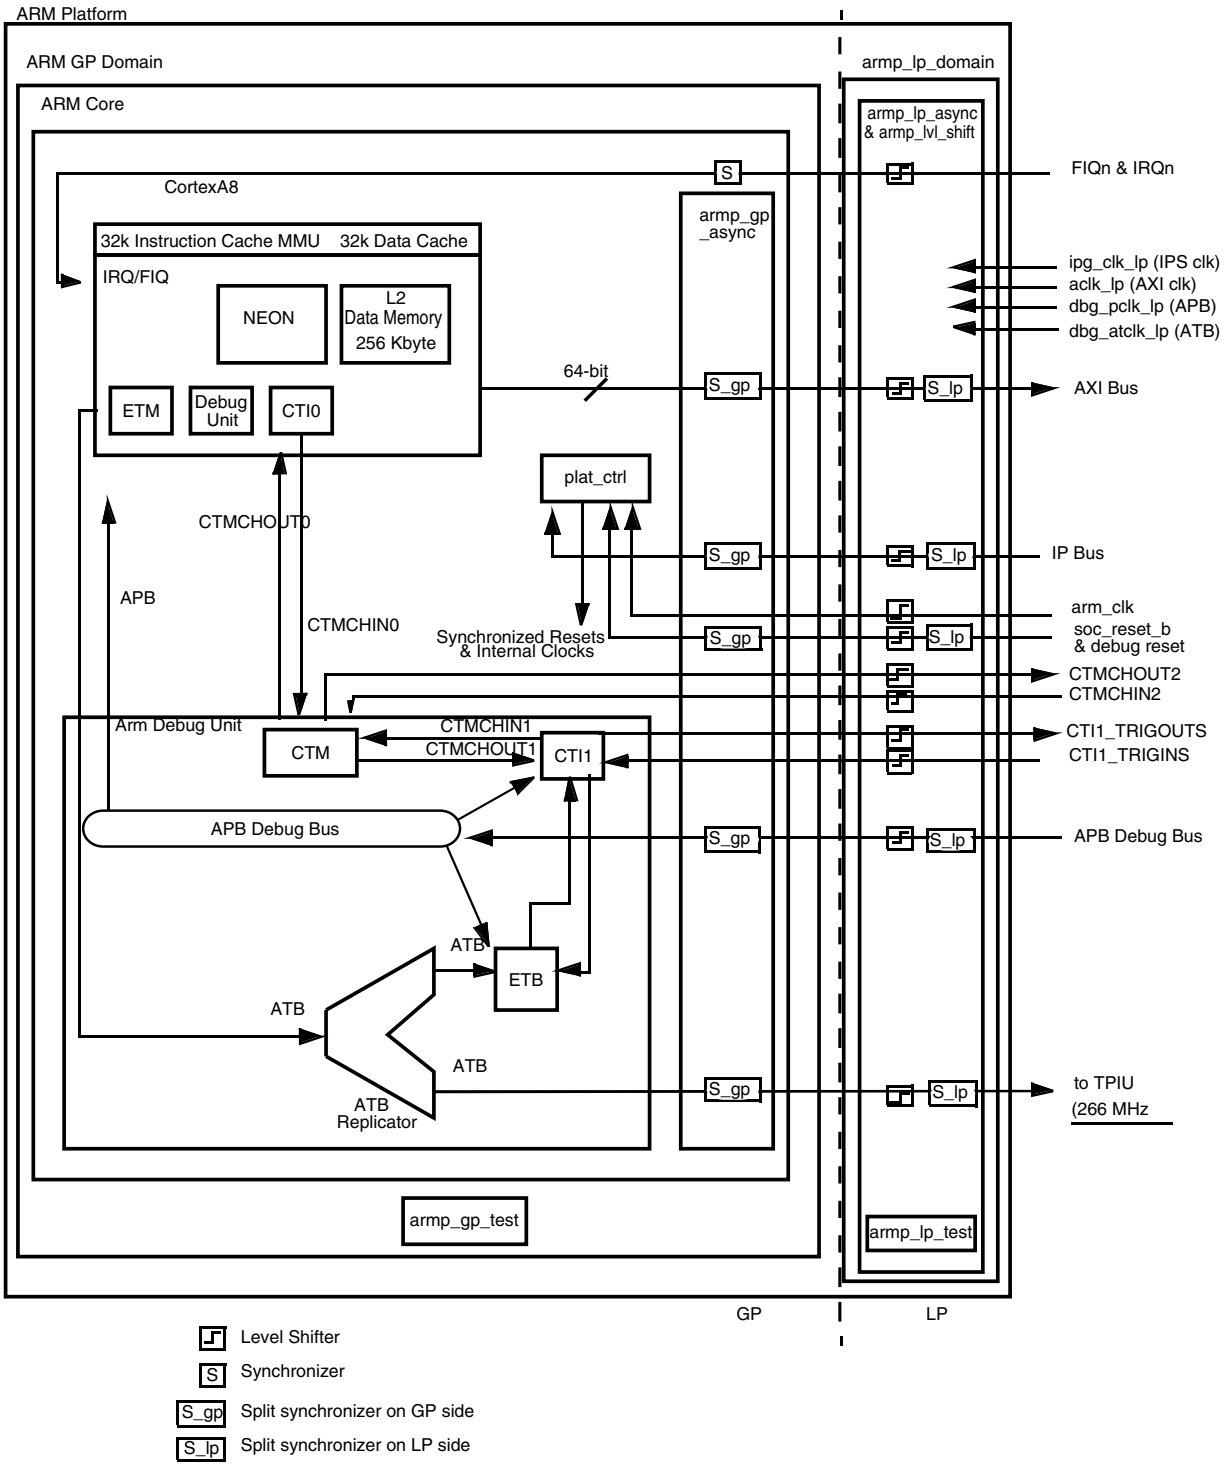

Figure 8-1. ARM platform Block Diagram

8.2.1 Core Platform Sub-Blocks

8.2.1.1 ARM platform

The information presented in this section focuses on design aspects of the ARM platform in the ARM platform subsystem. The ARM platform is ARM's first superscalar processor featuring technology for enhanced code density and performance, NEON™technology for multimedia and signal processing, and Jazelle®RCT (Runtime Compilation Target) technology for efficient support of ahead-of-time and just-in-time compilation of Java and other bytecode languages.

The ARM platform incorporates an integer core that implements the ARMv7-A architecture instruction set. It supports the ARMv7 and Thumb® -2 instruction sets. A NEON sub-block is included to accelerate the performance of multimedia applications. Included Vector Floating Point v3 architecture is IEEE 754 compliant. The processor includes an AMBA® 3 AXI high-performance 64-bit SoC interconnect.

The following are the features of ARM platform:

- The ARM platform's sophisticated pipeline architecture is based on dual, symmetric, in-order issue, 13-stage pipelines with advanced dynamic branch prediction achieving 2.0 DMIPS/MHz. The instruction execute unit consists of two symmetric Arithmetic Logical Unit (ALU) pipelines and the multiply pipeline.
  - In-order, dual-issue, superscalar microprocessor core
  - 13-stage main integer pipeline
  - 10-stage NEON media pipeline for executing NEON and VFP instruction sets
  - Dedicated L2 cache with programmable wait states
  - Global history based branch prediction
- Works in conjunction with a power optimized load store pipeline to deliver 2.0 DMIPS/MHz for power sensitive applications
- ARMv7 architecture compliant including:
  - Thumb-2 technology for greater performance, energy efficiency, and code density
  - NEON signal processing extensions to accelerate media codecs such as H.264 and MP3
  - Jazelle RCT Java-acceleration technology to optimize Just In Time (JIT) and Dynamic Adaptive Compilation (DAC), and reduce memory footprint by up to three times
- Integrated Level 2 Cache
  - Built using standard compiled LP RAMs

    - Sized at 256 Kb
    - Programmable delay
- Optimized Level 1 Caches
    - Customized design for performance and power optimization
    - Sized at 32 Kb Instruction and 32 Kb Data
    - Combine minimal access latency with hash way determination to maximize performance and minimize power consumption.
- Dynamic Branch Prediction
    - Enabled by branch target and global history buffers
    - Achieves 95% accuracy across industry benchmarks.
    - Replay mechanism minimizes miss-predict penalty
- Memory System
    - Single-cycle load-use penalty for access to the L1 cache
    - Hash array in the L1 cache limits activation of the memories to when they are likely to be needed.
    - Direct interface between the integrated, configurable L2 cache and the NEON media unit for data streaming
    - Banked L2 cache design that enables only one bank at a time
- Memory Management Unit (MMU) and separate instruction and data Translation Look-aside Buffers (TLBs) of 32 entries each
- Embedded Trace Macrocell (ETM) support for nonintrusive debug
- ARMv7 debug with watchpoint and breakpoint registers and a 32-bit Advanced Peripheral Bus (APB) interface to the CoreSight debug system.

8.2.1.2 Instruction Fetch

The instruction fetch unit predicts the instruction stream, fetches instructions from the L1 instruction cache, and places the fetched instructions into a buffer for consumption by the decode pipeline. The instruction fetch unit also includes the L1 instruction cache.

8.2.1.3 Instruction Decode

The instruction decode unit decodes and sequences all ARM and Thumb-2 instructions including the debug control coprocessor, CP14, and the system control coprocessor, CP15 instructions.

The instruction decode unit handles the sequencing of:

- Exceptions
- Debug Events
- Reset Initialization

- Memory Built-In Self Test (MBIST) for L1 cache
- Wait-for-interrupt
- Other Unusual Events
- Instruction Cycle Timing

8.2.1.4 Instruction Execute

The instruction execute unit consists of two symmetric Arithmetic Logical Unit (ALU) pipelines and the multiply pipeline. The execute pipelines also perform register write back.

The instruction execute unit:

- executes all integer ALU and multiply operations including flag generation
- generates the virtual addresses for loads and stores and the base write-back value, when required
- supplies formatted data for stores and also forwards data and flags
- processes branches and other changes of instruction stream and evaluates instruction condition codes.

8.2.1.5 Load/Store

The load/store unit encompasses the entire L1 data side memory system and the integer load/store pipeline. This includes the:

- L1 data cache.
- data side TLB.
- integer store buffer.
- NEON store buffer.
- integer load data alignment and formatting.
- integer store data alignment and formatting.

The pipeline accepts one load or store per cycle that can be present in either pipeline 0 or pipeline 1. This gives the processor flexibility when scheduling load and store instructions.

8.2.1.6 L2 Cache

The L2 cache unit includes the L2 cache and the Buffer Interface Unit (BIU). It services L1 cache misses from both the instruction fetch unit and the load/store unit.

8.2.1.7 NEON

The NEON unit includes the full 10-stage NEON pipeline that decodes and executes the NEON media instruction set. The NEON unit includes:

- the NEON instruction queue
- the NEON load data queue
- two pipelines of NEON decode logic
- three execution pipelines for NEON integer instructions
- two execution pipelines for NEON floating-point instructions
- one execution pipeline for NEON and VFP load/store instructions
- the VFP engine for full execution of the VFPv3 data-processing instruction set.

8.2.1.8 Processor Debug Unit

The processor debug unit assists in debugging software running on the processor. In combination with a software debugger program, the debug unit enables debugging the following:

- application software
- operating systems
- hardware systems based on an ARM processor

The debug unit enables:

- stopping program execution
- examining and altering processor and coprocessor states
- examining and altering memory and input/output peripheral states
- restarting the processor core

8.2.1.9 Embedded Trace Marcocell (ETM)

The ETMv3.3 unit is a nonintrusive trace macrocell that filters and compresses an instruction and data trace for use in system debugging and system profiling. The ETM unit has an external interface outside of the processor called the Advanced Trace Bus (ATB) interface.

The ARM platform ETM provides real time instruction trace for the ARM platform. It is designed to be used with the CoreSight Design Kit. Unlike previous versions of the ARM platforms, this ETM is embedded inside the Processor Core.

Real time tracing is controlled by specifying a set of filtering and triggering resources which include address and data comparators, counters and sequencers. Though data trace can not be enabled, the ETM can still trigger based on data values. Also, the ETM can trace data address values.

The ARM platform ETM contains the following main components:

- Core interface
- Trace generation
- Filtering and triggering resources
- Main FIFO
- AMBA 3 ATB interface
- AMBA 3 APB interface

8.2.1.10 Cross Trigger Interface 0 (CTI0)

This block controls the Trigger Interface (TI). The CTI combines and maps the trigger requests, and broadcasts them to all other interfaces on the embedded cross trigger (ECT) as channel events. When the CTI receives a channel event it maps this onto a trigger output. This enables subsystems to cross trigger with each other. The receiving and transmitting of triggers is performed through the TI.

Each CTI has 8 trigger inputs, 8 trigger outputs and 4 sets of 4 channel I/O(s).

8.2.2 Summary of Remaining Platform Components

8.2.2.1 Platform Controller

The Platform Control contains all the miscellaneous logic required for the platform. The main purpose of the Platform Control Module within the ARM platform is to implement a set of control and/or status registers and associated logic for the management of certain platform functions such as internally generated clocks, debug enable/status, low power control, platform version ID, etc.

The Platform Control Module provides these main features:

- Internal clock generation with the ability to programatically set the frequency (divide-by) for each clock independently.
- Ability to force (down-counter) preload for any one or more clocks at anytime independent of preload set.
- Provides a gated clock for the IP Bus asynchronous bridge for power savings.

- Provides 16 bits of General Purpose register bits for routing out to Platform boundary.
- Provides 8 bits of Platform Internal Control register bits for external Platform (SoC) use.
- Provides a set of Low Power control and status bits.
- Control bit to enable Debug along with Debug active status bit.
- NEON activity monitor which can be used in determining when to disable NEON thus saving power.

8.2.2.2 Debug Sub-Blocks

The ARM platform debug blocks are part of the overall Coresight debug system which include the ETB, CTM, CTI1, ATB replicator and APB address decode. It is expected that a DAP block and one or more additional CTI will be included at the SoC level. This section gives a brief overview of the sub-blocks that are implemented within the ARM platform. For details of the full Coresight debug subsystem, please refer to the SoC debug section.

8.2.2.2.1 Embedded Trace Buffer (ETB)

The ETB provides on-chip storage of trace data using 32-bit RAM. The ETB accepts trace data from the ARM ETM through an ATB port (passing through a replicator in between). Providing an on-chip buffer alleviates the pin count, bandwidth, and pad design requirements associated with sending trace data to a debugger directly through package pins in a real-time fashion.

Features:

- 4Kbyte compiled memory for the trace buffer and optionally can be used as a general purpose memory
- Only 32-bit accesses to the 4Kbyte buffer is supported
- AMBA Peripheral Bus programming interface for configuration and memory access

8.2.2.2.2 AMBA Trace Bus (ATB) Replicator

The ATB Replicator enables two trace sinks (ETB and an off platform port generally connected to a Trace Port Interface Unit - TPIU) to be wired together and receive ATB trace data from the same trace source (ETM). There are no programable registers. It takes incoming trace data from a single source (ETM) and replicates it as multiple masters.

The CSREPLICATOR is part of the armp_gp_platform block. Two output master ports are required for this design - one for the on-platform ETB and one for the off-platform TPIU. Placing the TPIU off platform allows future debug trace sources to connect to the TPIU via a FUNNEL, without the need to modify the ARM platform.

8.2.2.2.3 Cross Trigger Interface 1 (CTI1)

This block controls the Trigger Interface (TI). The CTI combines and maps the trigger requests, and broadcasts them to all other interfaces on the ECT as channel events. When the CTI receives a channel event it maps this onto a trigger output. This enables subsystems to cross trigger with each other. The receiving and transmitting of triggers is performed through the TI.

Each CTI has 8 trigger inputs, 8 trigger outputs and 4 sets of 4 channel I/O(s).

8.2.2.2.4 Cross Trigger Matrix - CTM

This block controls the distribution of channel events. It provides channel interfaces to the CTIs. The CTM can also connect to another CTM via a channel interface. This allows multiple CTMs to be connected.

The ARM platform has one CTM inside the platform to handle events between the platform's CTI, the processor's CTI and the rest of the ECT system outside the platform. Placing a CoreSight cross trigger matrix (CSCTM) on platform minimizes the event cycle time between the ETB and the ETM. The handshaking between the CTIs on-platform and the on-platform CTM are not enabled. This requires the ARM's CTI, the on-platform CTI1 and the on-platform CTM to all be in the same clock domain. The on-platform CTM connects to the ECT system via an off-platform CTM and the respective channels require synchronizing and handshaking enabled.

8.2.2.2.5 Advanced Peripheral Bus - APB Debug Bus

The APB originates off platform generally from a Debug Access Port (DAP) block. This bus allows access to the registers in all of the debug blocks which have addressable registers.

8.2.2.3 Asynchronous Wrapper

The ARM platform hard macro contains synchronizers for most signals into and out of the platform where synchronization is required. This means the ARM platform can function asynchronously from the rest of the SoC.

8.2.3 Configuration

There are several configuration options associated with the ARM platform. These are determined at the platform level and selected as follows:

- The L1 cache size is 32 Kb instruction and 32 Kb data
- There is parity on the L1 cache
- There is no error correction on the L1 cache
- The L2 cache size is 256 Kb
- There is no parity on the L2 cache
- There is no error correction on the L2 cache
- There are 2 L2 tag banks and 4 data banks per tag bank
- The AXI data bus width out of the platform is 64-bit

8.2.4 Endian Modes

The ARM platform supports Little Endian mode only.

8.2.5 Bus Interfaces

This section will discuss the major bus interfaces of the ARM platform. The ARM platform has the following bus interfaces:

- AMBA AXI interface
- APB CoreSight interface
- ATB CoreSight interface
- Peripheral Interface (IP Bus)

8.2.5.1 AMBA AXI Interface

The AXI bus interface is the main interface to the system bus. It performs L2 cache fills and noncacheable accesses for both instructions and data. The AXI interface utilizes a 64-bit wide input and output data bus. It also supports multiple outstanding requests on the AXI bus. The AXI bus is allowed to be asynchronous between the platform and SoC domains. This provides maximum flexibility at the SoC level.

8.2.5.2 APB CoreSight Interface

The APB is an AMBA bus used for debugging. The CoreSight interface is the ARM architecture for multi-processor trace and debug. It defines what debug and trace components are required and how they are connected. The platform Debug APB should be connected to the SoC DAP APB mux. The APB is allowed to be asynchronous between the platform and SoC domains. This provides maximum flexibility at the SoC level.

8.2.5.3 ATB CoreSight Interface

The ATB is a trace output bus used for debugging. The CoreSight components are programmed with the DAP using the APB programming bus. Trace is output over the ATB trace bus. The ATB is allowed to be asynchronous between the platform and SoC domains. This provides maximum flexibility at the SoC level.

8.2.5.4 Peripheral Interface (IP Bus)

The IP Bus interface to the platform connects the on-chip registers to the memory map and internal buses at the SoC level. Location (addresses of the registers) is determined at the SoC level. The platform acts as a slave to an SoC based IP Bus controller.

8.3 Memory Map and Register Definition

The memory map for ARM platform specific registers is shown below. This does not include coprocessor registers contained in the ARM platform or the ARM Coresight Debug. For documentation of registers contained in those blocks, please refer to the appropriate technical reference manual.

This register block address space uses five address lines which are fully decoded. The space includes nine registers and 23 unimplemented locations. The unimplemented locations will return an error if they are accessed. Depending on how the SoC decodes the register block, the entire 32-word register block could alias in the larger memory space.

ARM memory map

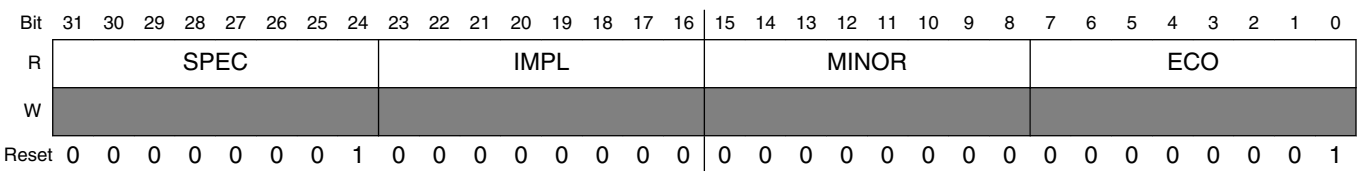
Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
63FA_0000	Platform Version ID (ARM_PVID)	32	R	0100_0001h	8.3.1/513
63FA_0004	General Purpose Control (ARM_GPC)	32	R/W	0004_FF00h	8.3.2/514
63FA_000C	Low Power Control (ARM_LPC)	32	R/W	0000_0000h	8.3.3/515
63FA_0010	NEON Low Power Control (ARM_NLPC)	32	R/W	0000_0000h	8.3.4/516
63FA_0014	Internal Clock Generation Control (ARM_ICGC)	32	R/W	0000_7777h	8.3.5/517
63FA_0018	ARM Memory Configuration (ARM_AMC)	32	R/W	0000_0003h	8.3.6/519
63FA_0020	NEON Monitor Control (ARM_NMC)	32	R/W	000F_F000h	8.3.7/520
63FA_0024	NEON Monitor Status (ARM_NMS)	32	w1c	0000_0000h	8.3.8/521

8.3.1 Platform Version ID (ARM_PVID)

The platform version ID register (ARM_PVID) contains a 32-bit version ID which can be used to link the silicon to a specific version of the platform database. The version ID should match our release label applied to the platform database.

This register can be accessed by a 32-bit secure/non-secure, user/supervisor, read transaction. Writes return an error.

Address: ARM_PVID is 63FA_0000h base + 0h offset = 63FA_0000h



ARM_PVID field descriptions

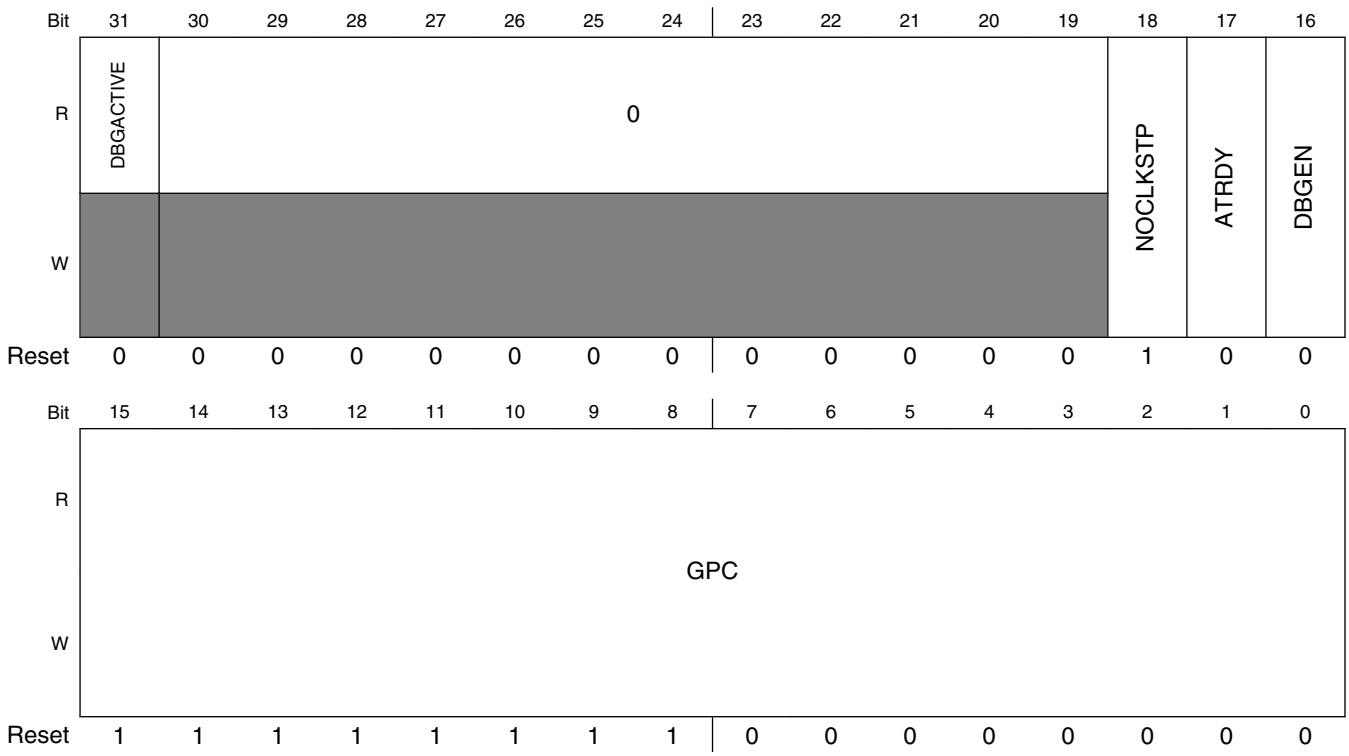
Field	Description
31–24 SPEC	Major architectural or significant spec changes
23–16 IMPL	Implementation changes
15–8 MINOR	Minor changes (bug fixes, I/O changes)
7–0 ECO	ECO changes

8.3.2 General Purpose Control (ARM_GPC)

This register contains 16-bits of general purpose control which drive core platform outputs that can be used within the SoC for general purpose control. This register also contains the DBG_ACTIVE status bit and DBG_EN control bit for entering Debug mode via a software access to this register.

This register can only be accessed by 32-bit secure supervisor transactions.

Address: ARM_GPC is 63FA_0000h base + 4h offset = 63FA_0004h



ARM_GPC field descriptions

Field	Description
31 DBGACTIVE	This bit indicates the status of debug. This allows the user to determine if debug has been enabled either from off platform, via the external DAP_SYS JTAG interface (dbgen_in platform input), or via software accesses to the DBGEN bit in this register. 0 debug is not enabled. Debug clocks are off and debug registers are inaccessible. 1 debug is enabled. Debug clocks are on and the debug system is ready to be used.
30–19 Reserved	This read-only field is reserved and always has the value zero. Reserved
18 NOCLKSTP	This bit is used to control clock-gating within the CORTEX-A8n. Note that this is distinctly different than the higher-level (platform-level) clock-gating/low-power control afforded by the other Plat_Ctrl low-power functionality (dsm_request along with the DSM and DBG_DSM control bits within the Low Power Control register).

Table continues on the next page...

ARM_GPC field descriptions (continued)

Field	Description
	1 All normal clock-gating activity (WFI, NEON, and so on) will be overridden and no clock gating will occur within the CORTEX-A8n. NOCLKSTP, however, has no affect on the higher-level platform clock-gating, and the low-power functions discussed in the LPC register will work as architected. 0 clock-gating within the CORTEX-A8n will be enabled. This is the recommended setting in order to reduce run mode power consumed by the clocking network within the Integer core as well as the Neon co-processor.
17 ATRDY	1 this bit disables the platform boundary ATB interface. In most SoCs this will be connected to a TPIU. This prevents traces to the ETB from stalling due to the ASYNCATB FIFO overflowing. 0 this bit allows the platform boundary ATB interface to be active. In this case, traces to the ETB could stall due to ASYNCATB FIFO becoming full. This may cause the ETM data loss.
16 DBGEN	Debug enable. This allows the user to manually activate clocks within the debug system. This register bit directly controls the platform's dbgen_out output signal which connects to the DAP_SYS to enable all debug clocks. Once enabled, the clocks cannot be disabled except by asserting the disable_trace input of the DAP_SYS.
15–0 GPC	General Purpose Control bits directly control the general_purpose_outs[15:0] output ports of the ARM Platform. These bits will be connected at the SoC level and therefore will control functions decided by the SoC architects, and must be documented by the SoC team.

8.3.3 Low Power Control (ARM_LPC)

This register is used to control entry to low power mode and can only be accessed by 32-bit secure supervisor transactions.

There exists a platform output, dsm_request, that when asserted, requests the SoC to turn off clocks to the platform, and optionally deactivate one or more power supplies. DSM can only be entered after the ARM Platform has executed a WFI instruction, completed all outstanding bus transactions, and all activity at the L2 level has completed. Assertion of either irq_b, fiq_b, or dbg_edbgrq platform inputs will cause the ARM platform to complete the WFI instruction and will result in the negation of dsm_request.

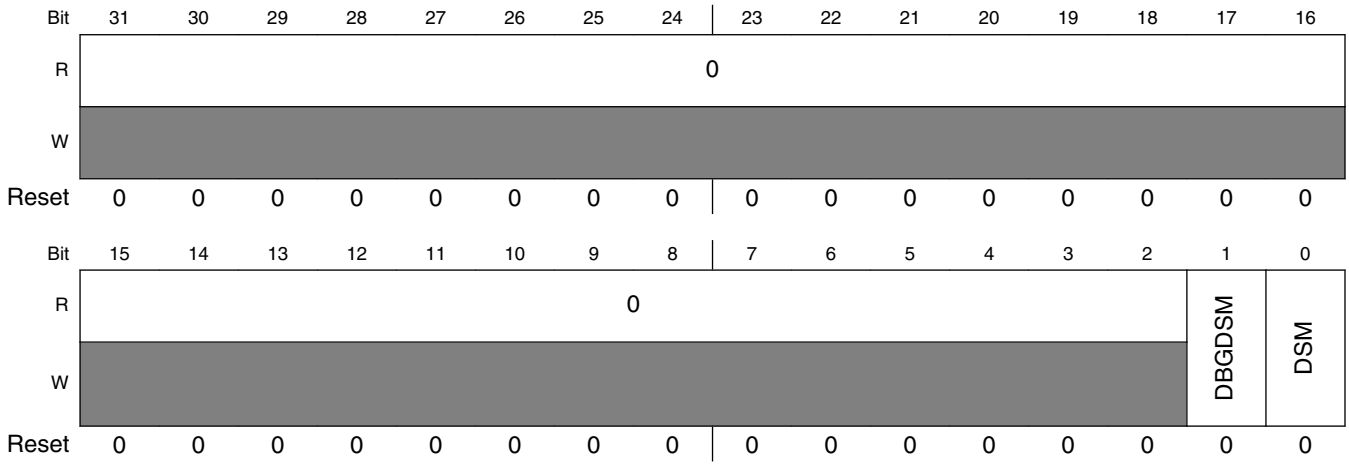
The DSM bit configures the platform to either: block deep sleep mode entry (default), or allow DSM entry when requested.

The DBG_DSM bit configures the platform to block deep sleep mode entry when debug mode is enabled (dbgen_in platform input is asserted high). This will allow the user to ensure deep sleep mode is not entered when debug is enabled.

The NEON_RST bit is used for placing the ARM NEON processor into, or releasing it from, reset.

This register can only be accessed by 32-bit secure supervisor transactions.

Address: ARM_LPC is 63FA_0000h base + Ch offset = 63FA_000Ch



ARM_LPC field descriptions

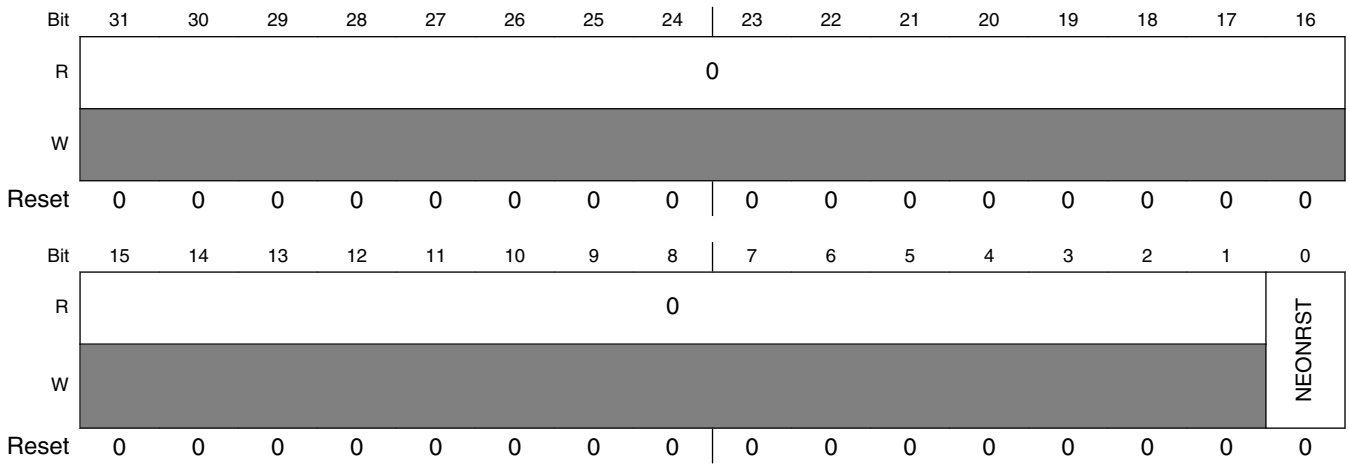
Field	Description
31–2 Reserved	This read-only field is reserved and always has the value zero. Reserved
1 DBGDSM	Debug Deep Sleep Mode Enable 1 DSM can be entered (dsm_request will not be blocked) regardless if debug is enabled or not. 0 DSM can NOT be entered (dsm_request will be blocked) if debug is enabled
0 DSM	Deep Sleep Mode Enable is used to gate the platform's dsm_request signal, preventing the platform from issuing a deep sleep mode request. 1 DSM can be entered (dsm_request will not be blocked). 0 DSM can NOT be entered (dsm_request will be blocked).

8.3.4 NEON Low Power Control (ARM_NLPC)

This register is used to place the ARM NEON processor into, or releasing it from, reset. Refer to the table below for a description of this control bit.

This register can only be accessed by 32-bit secure supervisor transactions.

Address: ARM_NLPC is 63FA_0000h base + 10h offset = 63FA_0010h



ARM_NLPC field descriptions

Field	Description
31–1 Reserved	This read-only field is reserved and always has the value zero. Reserved
0 NEONRST	Hold the ARM NEON in its reset state in preparation for a low power mode. 1 ARESETNEONn input to the ARM is driven low - placing NEON into reset. 0 ARESETNEONn input to the ARM is driven high - releasing NEON from reset.

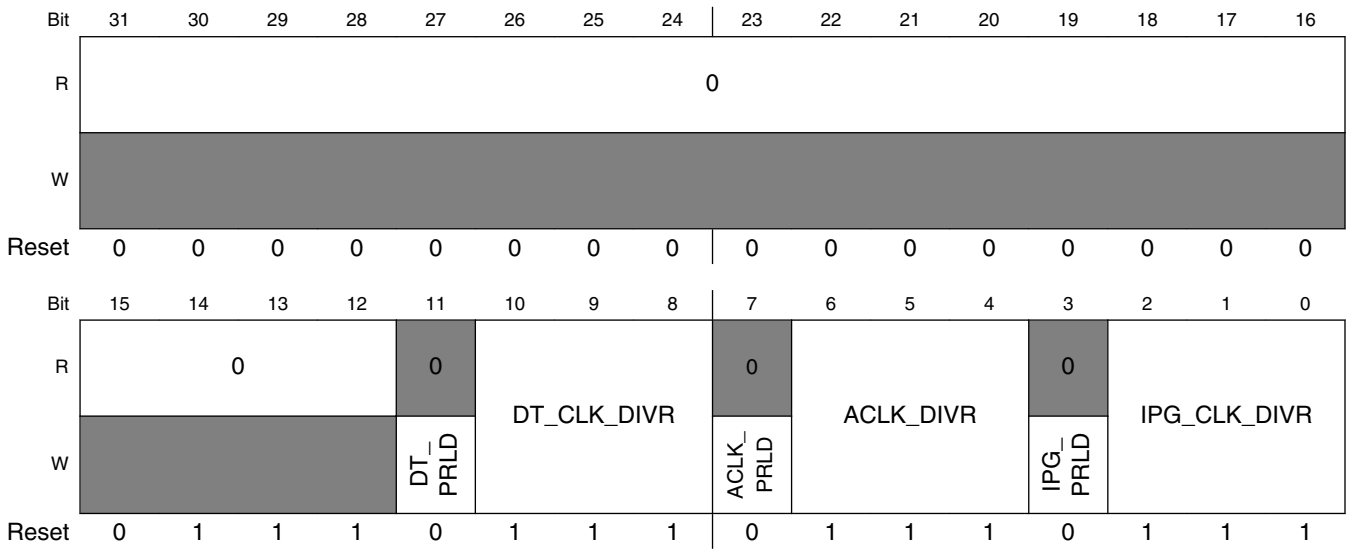
8.3.5 Internal Clock Generation Control (ARM_ICGC)

This register is used to control the clock generation circuitry for all derived clocks used within the ARM platform (ipg_clk, aclk, dbg_atclk, and dbg_pclk). The dbg_pclk clock is generated as a straight divide-by-2 of dbg_atclk.

Note: At reset, all generated clocks are edge aligned and are generated at 8:1. dbg_pclk will require 1 dbg_atclk clock cycle before it begins clocking as a divided dbg_atclk.

This register can only be accessed by 32-bit secure supervisor transactions.

Address: ARM_ICGC is 63FA_0000h base + 14h offset = 63FA_0014h



ARM_ICGC field descriptions

Field	Description
31–12 Reserved	This read-only field is reserved and always has the value zero. Reserved
11 DT_PRLD	Debug AMBA Trace Bus Clock Down Counter Preload Reads always return 0 0 has no effect. If preload is 0 during a write of a new divide ratio, the down counter will not be loaded with the new value until it reaches 0 (rolls over). 1 A write of 1 will force the DBG_ATCLK down counter to preload on the next arm_clk.
10–8 DT_CLK_DIVR	Debug AMBA Trace Bus Clock Divide Ratio These bits control the clock divide ratio for the debug AMBA trace bus (ATB) and GP async interface clocks. The ATB bus is used to transfer trace messages from the ETM to the ETB or TPIU. When ETM trace data is being transferred over the ATB to the embedded trace buffer (ETB), the ATB is capable of running up to half the ARM Platform frequency. However, when ETM trace data is being transferred to the TPIU to be sent out the trace port, the ATB should be slowed to some appropriate SoC frequency. DT_CLK_DIVR[2:0] = 0b000 results in a 1:1 clock ratio DT_CLK_DIVR[2:0] = 0b001 results in a 2:1 clock ratio DT_CLK_DIVR[2:0] = 0b010 results in a 3:1 clock ratio DT_CLK_DIVR[2:0] = 0b011 results in a 4:1 clock ratio DT_CLK_DIVR[2:0] = 0b100 results in a 5:1 clock ratio DT_CLK_DIVR[2:0] = 0b101 results in a 6:1 clock ratio DT_CLK_DIVR[2:0] = 0b110 results in a 7:1 clock ratio DT_CLK_DIVR[2:0] = 0b111 results in a 8:1 clock ratio
7 ACLK_PRLD	AXI Master Port Clock Down Counter Preload Reads always return 0

Table continues on the next page...

ARM_ICGC field descriptions (continued)

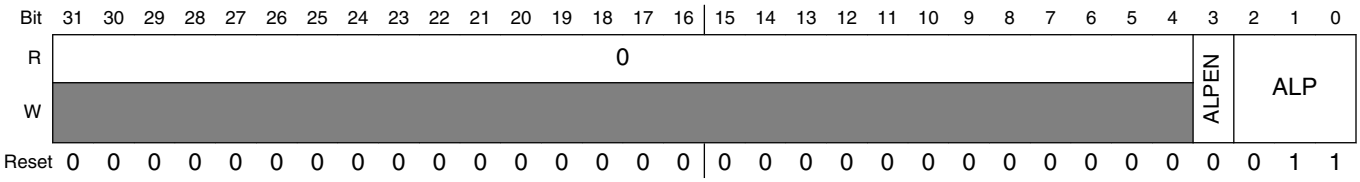
Field	Description
	0 has no effect. If preload is 0 during a write of a new divide ratio, the down counter will not be loaded with the new value until it reaches 0 (rolls over). 1 will force the ACLK down counter to preload on the next arm_clk
6–4 ACLK_DIVR	AXI Master Port Clock Divide Ratio Controls the clock divide ratio for the ARM Platform AXI bus and GP AXI async interface clocks and clock enable. The ratio of clock cycles generated for arm_clk to aclk is: ACLK[2:0] +1 : 1 ACLK_DIVR[2:0] = 0b000 results in a 1:1 clock ratio ACLK_DIVR[2:0] = 0b001 results in a 2:1 clock ratio ACLK_DIVR[2:0] = 0b010 results in a 3:1 clock ratio ACLK_DIVR[2:0] = 0b011 results in a 4:1 clock ratio ACLK_DIVR[2:0] = 0b100 results in a 5:1 clock ratio ACLK_DIVR[2:0] = 0b101 results in a 6:1 clock ratio ACLK_DIVR[2:0] = 0b110 results in a 7:1 clock ratio ACLK_DIVR[2:0] = 0b111 results in a 8:1 clock ratio
3 IPG_PRLD	Platform IP Bus Port Clock Down Counter Preload Reads always return 0 0 has no effect. If preload is 0 during a write of a new divide ratio, the down counter will not be loaded with the new value until it reaches 0 (rolls over). 1 will force the ACLK down counter to preload on the next arm_clk
2–0 IPG_CLK_DIVR	Platform IP Bus Port Clock Divide Ratio Controls the clock divide ratio for the Platform Controller and GP async IP Bus clock and clock enable. The ratio of clock cycles generated for arm_clk to ipg_clk is: IPG_CLK[2:0] +1 : 1 IPG_CLK_DIVR[2:0] = 0b000 results in a 1:1 clock ratio IPG_CLK_DIVR[2:0] = 0b001 results in a 2:1 clock ratio IPG_CLK_DIVR[2:0] = 0b010 results in a 3:1 clock ratio IPG_CLK_DIVR[2:0] = 0b011 results in a 4:1 clock ratio IPG_CLK_DIVR[2:0] = 0b100 results in a 5:1 clock ratio IPG_CLK_DIVR[2:0] = 0b101 results in a 6:1 clock ratio IPG_CLK_DIVR[2:0] = 0b110 results in a 7:1 clock ratio IPG_CLK_DIVR[2:0] = 0b111 results in a 8:1 clock ratio

8.3.6 ARM Memory Configuration (ARM_AMC)

This register is used to configure the ALP inputs to the ARM platform memories. These bits are used to set the leakage configuration bits on the memories.

This register can only be accessed by 32-bit secure supervisor transactions.

Address: ARM_AMC is 63FA_0000h base + 18h offset = 63FA_0018h



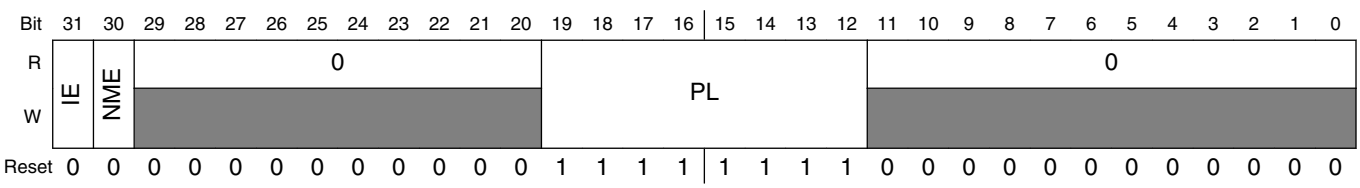
ARM_AMC field descriptions

Field	Description
31–4 Reserved	This read-only field is reserved and always has the value zero. Reserved
3 ALPEN	ALPEN - ALP Enable is used to activate the ALP bits in this register to override the default memory leakage configuration setting. 1 ALP bits of the memory are over-written with the ALP bits of this register. 0 ALP bits of the memory are driven to the default (reset) value of 3'b000.
2–0 ALP	ALP Memory leakage configuration bits

8.3.7 NEON Monitor Control (ARM_NMC)

This register is used to control the NEON monitor and can only be accessed by 32-bit secure/non-secure supervisor transactions.

Address: ARM_NMC is 63FA_0000h base + 20h offset = 63FA_0020h



ARM_NMC field descriptions

Field	Description
31 IE	Interrupt Enable 1 The monitor interrupt output is enabled and plat_ctrl_nm_irq_b is asserted when the monitor counter expires. 0 The monitor interrupt output is disabled.
30 NME	NEON Monitor Enable
29–20 Reserved	This read-only field is reserved and always has the value zero. Reserved
19–12 PL	Preload value for the upper 8 bits of the 16 bit NEON activity counter.

Table continues on the next page...

ARM_NMC field descriptions (continued)

Field	Description
11–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

8.3.8 NEON Monitor Status (ARM_NMS)

This register is used to read the status of the NEON monitor and can only be accessed by 32-bit secure/non-secure supervisor transactions.

Address: ARM_NMS is 63FA_0000h base + 24h offset = 63FA_0024h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

ARM_NMS field descriptions

Field	Description
31 NI	NEON Idle Status 1 Indicates that the NEON activity counter has expired. plat_ctrl_nm_irq_b will assert if the IE bit is set. 0 Indicates that the NEON activity counter has not expired.
30–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

8.4 Platform Clocks

The clocking strategy of the ARM platform can be summarized by the following bullets:

- The ARM platform will receive one functional clock from the clock control module (CCM), **arm_clk**, and several SoC clocks for boundary synchronization purposes (**arm_clk** can be completely asynchronous from any other SoC clocks).
- The ARM platform, in conjunction with an external CCM, will support dynamic clock frequency scaling.

- Divided clocks based on **arm_clk** will be generated within the platform for clocking buses which cannot operate at the high **arm_clk** frequencies. These divided clock ratios can be configured by on-platform registers.
  - Derived Clocks:
    - ipg_clk: This clock is used for IP Bus logic.
    - aclk: This clock is used for AXI bus logic.
    - dbg_atclk: This clock is used for the Debug AMBA Trace logic.
    - dbg_pclk: This clock is used for the Debug synchronizer logic.
- Two-level clock gating will be employed.
  - Block level clock gating will be used when possible. A specific block's clock will be gated off when it is not in use.
  - Register level clock gating will be used throughout the platform via power design tools.
- **arm_clk** may be turned off for various low-power use cases by an external CCM which will monitor the **DSM_request** output.

8.5 Platform Power Management

The ARM platform contains low voltage logic elements, an asynchronous and level shifted interface, state retention latches, low leakage power switches, and floating node isolation circuits. These elements each serves a specific purpose in the power management scheme implemented in the ARM platform. The power management capabilities of the ARM platform are summarized in this section.

8.5.1 Voltage and Frequency Scaling

The ARM platform contains structures necessary for the independent voltage scaling of the GP supply. Voltage and frequency scaling control systems are implemented at the chip level with the ARM platform acting as an object of the control. Asynchronous Interface Logic and Level-shifting between SoC-logic and ARM-logic have been implemented in the ARM platform to support the voltage and frequency scaling capabilities of the integrated system.

8.5.1.1 Asynchronous Interface Logic

Voltage and frequency scaling is most effective when there is a continuum of available frequencies at which the ARM platform may be clocked. Asynchronous Interface Logic removes the clock ratio dependencies between the ARM platform and the system in which it operates.

8.5.1.2 Level Shifting between SoC-logic and ARM-logic

Independent voltage scaling of the ARM platform requires a distinct power supply for the GP logic. Level shifters exist at the interface of the SoC logic and the ARM logic to allow independent voltage control of the SoC power supply and the ARM power supply.

8.5.2 Power Gating in the ARM platform

To reduce standby leakage power consumption, the ARM platform contains internal power supplies that may be completely power gated during wait for interrupt modes. Entry and exit sequences of power gating modes are completely controlled by programmed operation of the General Power Controller, so this section will only serve to describe what is possible in terms of how the ARM platform may be powered down during wait for interrupt modes.

8.5.2.1 Isolation Circuitry at the ARM platform Interface

In order to power down digital logic correctly, a special interface must exist which will protect the system from floating signals. Such isolation circuitry has been carefully designed in order to allow glitch-free power down modes of the ARM platform.

8.5.2.2 Power Gating the Memory Peripheries

Once the STANDBYWFI mode has been invoked, all of the ARM platform memory peripheries may be power gated by the assertion of both the l1_pwrdwn and the l2_pwrdwn signals. This will significantly reduce the amount of leakage from the GP supply.

8.5.2.3 Retaining the State of the ARM platform Registers

The ARM platform has been implemented using State Retention Power Gating (SRPG) register elements. In order to safely enter a power gated mode that includes power gating of the ARM platform high performance logic gates, a sequenced assertion of signals must occur. Similarly, a sequenced deassertion is necessary when emerging from power gated states. The required sequences are automatically provided to the ARM platform by the General Power Controller.

8.5.2.4 Power Gating the ARM platform High Performance Logic Gates

Once the STANDBYWFI mode has been invoked, the ARM platform high performance logic gates are power gated by assertion and negation of signals by internal Power management sub-blocks. This will turn off a portion of the leakage from the GP supply.

8.5.2.5 Power Gating the L2 Bit Arrays

If the L2 cache has been flushed, the L2 bit array may be power gated during the subsequent STANDBYWFI mode. Once the STANDBYWFI mode has been invoked, the L2 memory bit arrays may be power gated. This will turn off a portion of the leakage from the LP supply.

8.5.2.6 Controlling Power Gating using the General Power Controller (GPC)

Specific details concerning the power gating entry and exit sequence may be obtained from the block guide of the General Power Controller (GPC). This high level summary is intended to provide some overview.

Code must be formed that will take advantage of low workloads by putting the ARM platform into a STANDBYWFI state whenever possible. Prior to entering the STANDBYWFI state, the code should assess several things about the workload and the battery conservation requirements:

- What is the maximum acceptable interrupt service latency?
- What is the expected time to be spent in STANDBYWFI?

Once these time requirements are understood, then Table 8-10 can be used to determine the appropriate STANDBYWFI mode to invoke. The GPC registers can be programmed with the appropriate values to invoke the appropriate STANDBYWFI mode. After GPC programming is complete, the code should execute the STANDBYWFI instruction.

The GPC will enforce the appropriate sequence for entering and exiting the programmed power gated modes.

8.5.2.7 Power Gating the NEON Block

The NEON co-processor in the ARM platform can be put into a state retention mode and powered down to reduce current consumption when it is not needed. The sequence is shown in the flow diagram of Figure 8-10. Each box in the diagram is numbered to correspond to the following more thorough description:

1. User Selects NEON to be Powered Down

   The NEON Coprocessor is enabled out of reset and will remain powered up unless the user decides to power it down. This method will power down NEON after a user programmable time of NEON inactivity. The current state of the NEON is held in SRPG flops. To select this operation:

   The user code will program the amount of time that the NEON needs to be inactive before powerdown in the NEON Monitor Control Register. Effectively, the user programs the upper 8 bits of a 20-bit counter. This counter runs at the arm_clk rate and so the user can program a timeout from 4K to 1M arm_clk rising edges.

   In the same register, the user code enables the NEON Monitor and enables the NEON Monitor Interrupt.

2. Pre-Set Timer Count

   The timer is loaded (automatically by hardware) with the count value chosen by the user.

3. Decision: NEON Instruction Encountered?

   If a NEON instruction is encountered the sequence is aborted until the NEON is no longer in use. As long as NEON Instructions are executing, the NEON status bit will remain in the active state and the counter gets forced with the pre-set count.

4. Decrement Timer

   When no NEON instructions are encountered, the timer will count towards the timeout.

5. Decision: Timed Out?

   If the user selected time has lapsed without any NEON activity, then the hardware will generate an interrupt.

6. Exception Sequence: Power Down NEON

   The interrupt service routine disables the NEON sub-block with the following sequence:

   A. Software must disable access to the NEON unit using the Coprocessor Access Control Register, see c1, Coprocessor Access Control Register on page 3-64 of the ARM TRM. All outstanding NEON instructions retire and all subsequent NEON instruction cause an Undefined instruction exception.

```
MRC p15, 0, <Rd>, c1, c0, 2; Read Coprocessor Access Control Register
BIC <Rd>, <Rd>, #0xF00000; Disable access to CP10 and CP11
MCR p15, 0, <Rd>, c1, c0, 2; Write Coprocessor Access Control Register
```

   B. Activate the NEON output clamps.

   C. Place NEON into state retention.

   D. Prepare the NEON memory for power down keeping the state of its bits.

   E. Separate the NEON power supplies so that the ones that retain state can continue to have power.

   F. Remove power from the NEON power domain.

7. Decision: NEON Instruction Attempted

   The part will continue running regular ARM Platform instructions with the NEON in low power state as long as no NEON instructions are attempted. When a NEON instruction is attempted, an unimplemented instruction exception occurs.

8. Exception Sequence: Power Up NEON

   An exception is taken when a NEON instruction is attempted with the NEON is disabled. The exception routine will determine that this is indeed what occurred, enable the NEON block and wait for the NEON to power up. Returning from the exception will cause the NEON instruction to be restarted and run successfully. This is a more detailed description of the sequence:

   A. Power is turned on to the NEON power domain.

   B. Reconnect the NEON power supplies together.

   C. Restore the NEON memory power maintaining the state of it's saved bits.

   D. Reload the flops with the SRPG saved contents.

E. Release the NEON output clamps.

F. Software must enable access to the NEON unit using the Coprocessor Access Control Register, see c1, Coprocessor Access Control Register on page 3-64 of the ARM TRM.

```
MRC p15, 0, <Rd>, c1, c0, 2; Read Coprocessor Access Control Register
ORR <Rd>, <Rd>, #0xF00000; Enable access to CP10 and CP11
MCR p15, 0, <Rd>, c1, c0, 2; Write Coprocessor Access Control Register
```

G. Return from the exception causing the NEON instruction to be reloaded and executed.

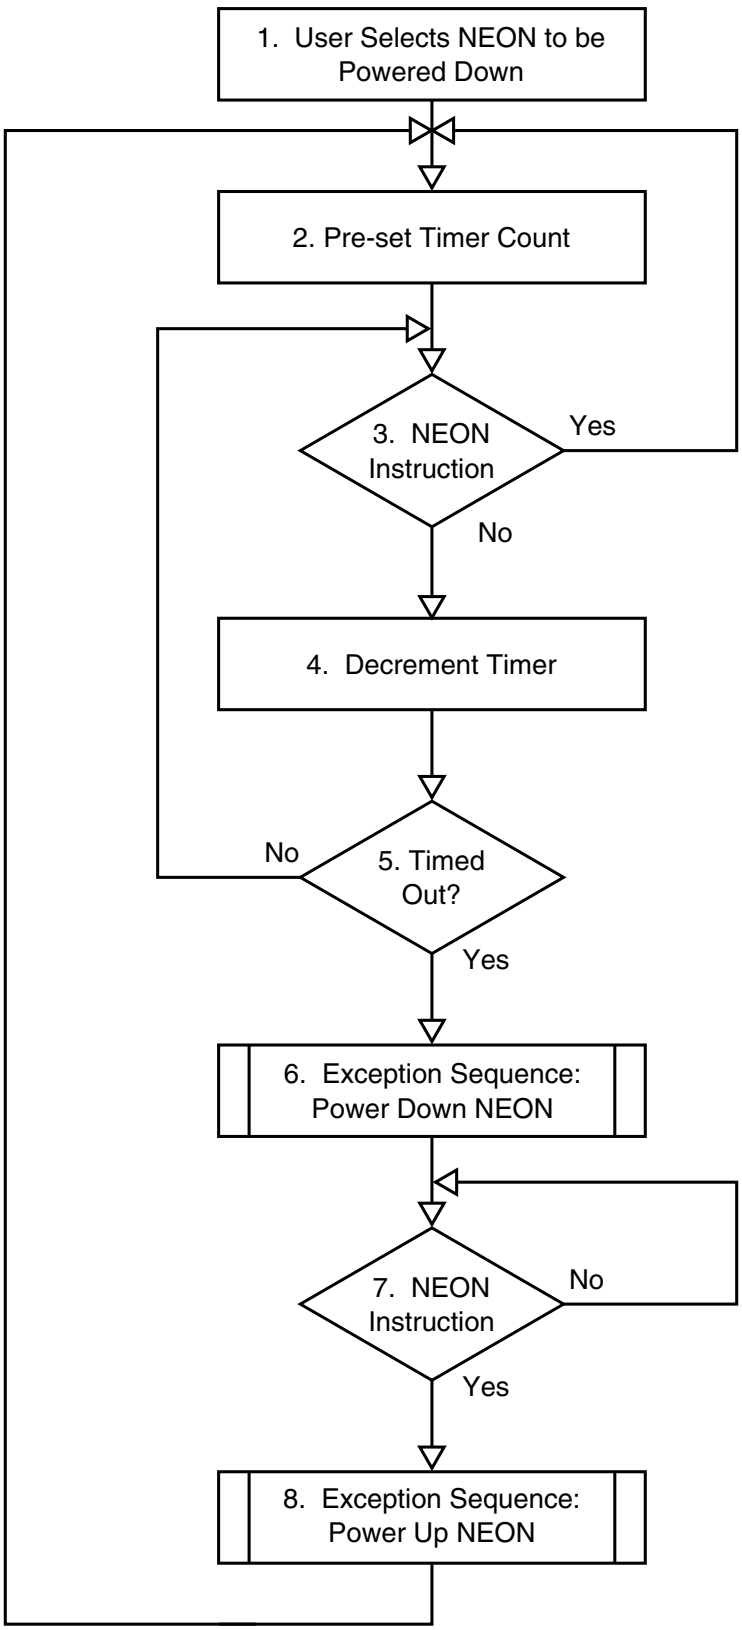

Figure 8-10. Flow Diagram of NEON Power Down Sequence

8.5.3 Modes of Operation

There are several basic low power modes of the ARM platform.

Table 8-10. Modes of Operation of the ARM platform

MODE	Description
RUN	ARM_CLK running, code executing
CLOCKED_WAIT	ARM_CLK running, STANDBYWFI=TRUE
UNCLOCKED_WAIT	ARM_CLK off, STANDBYWFI=TRUE
STOP1	UNCLOCKED_WAIT plus L1 and L2 peripheries power gated
STOP2	UNCLOCKED_WAIT plus L1 and L2 peripheries power gated, ARM_HiP_logic power gated
STOP3	UNCLOCKED_WAIT plus L1 and L2 peripheries power gated, ARM_HiP_logic power gated, L2 cache flushed, and L2 bit arrays power gated

There are several combinations of reduced power in which one of more portions of the platform are in a power saving mode.

Table 8-11. Platform Power Modes

Core and Platform	NEON	L1	L2
Powered Up	Powered Up	Powered Up	Powered Up
Powered Up	Reset (ARM Mode)	Powered Up	Powered Up
State Retention	State Retention	State Retention	State Retention
State Retention	State Retention	Powered Down	State Retention
State Retention	State Retention	State Retention	Powered Down
State Retention	State Retention	Powered Down	Powered Down

Chapter 9
ARM Platform Debug

9.1 Introduction

The purpose of this document is to provide an overview of the ARM platform debug. It will cover the sub-blocks inside the armp_gp_debug block and also the blocks that support the platform debug within the SOC, but external to the ARM platform.

Debug for the ARM platform uses ARM's DK11 CoreSight Debug Kit. The following CoreSight blocks are used: Debug Access Port (DAP) , Embedded Trace Macrocell v 3.3 (ETM), CoreSight replicator (CSREPLICATOR), CoreSight trace port interface unit (CSTPIU), CoreSight embedded trace buffer (CSETB), CoreSight cross trigger interface (CSCTI) and the CoreSight cross trigger matrix (CSCTM). In this introduction, a brief description of each block will be given. For more in depth information, please refer to the CoreSight_DK_TRM and other relative documentation from ARM.

9.1.1 Overview

ARM's CoreSight Design Kit (CSDK) provides a single solution for multi core and bus trace. The CSDK provides the following capabilities for system-wide trace:

- debug and trace visibility of the entire system
- cross triggering support between SOC subsystems
- multi-source trace in a single stream
- higher data compression than previous solutions
- standard programmer's models for standard tools solutions

The CoreSight Design Kit comprises the following main components: Control and access, sources, links and sinks.

- Control and access components configure, access and control the generation of trace. They do not generate, nor process trace data. Examples include the debug access port (DAP) and the embedded cross trigger (ECT) interface.

- Source components generate trace data. Example source components are the ETM and the future AXI trace macrocell (XTM).
- Link components provide connection, triggering and flow of trace data. Link examples include the ATB replicator and the CoreSight Trace funnel.
- Sink components are the end point for trace data on an SOC. Example sinks are the trace port interface unit (TPIU) and the embedded trace buffer (ETB).

The figure below shows the ARM Platform debug block diagram. Further detail of the sub-blocks will be provided in the sections that follow.

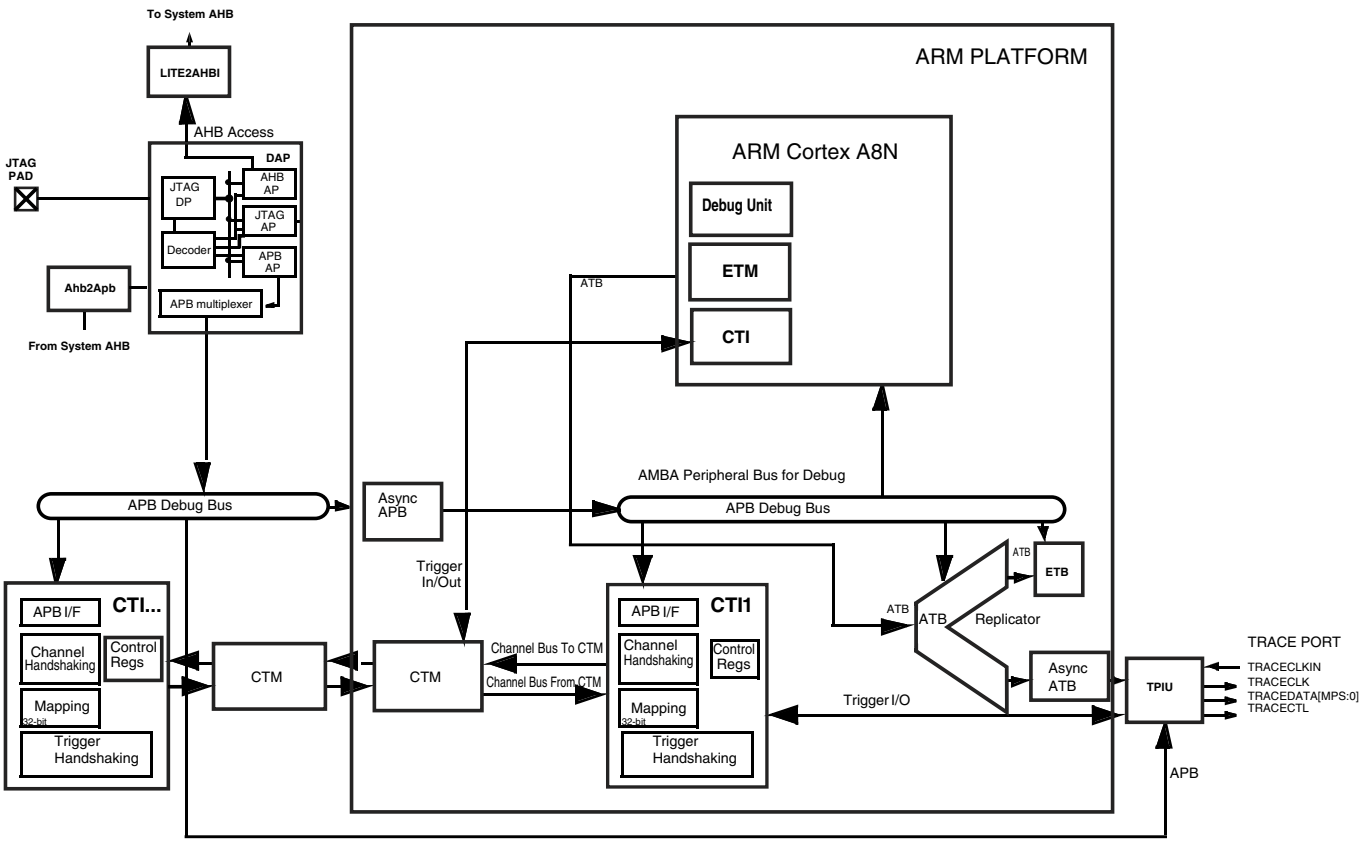

Figure 9-1. Block Diagram

9.1.2 ARM Debug Blocks

This section gives an overview of the Debug blocks used in the ARM platform and also the blocks outside the platform that are included in the CoreSight debug system.

The following blocks are included in the ARM platform debug block: CSETB, CSCTI, CSCTM, CSREPLICATOR and APB address decode logic.

The following blocks are part of the ARM platform, outside the debug block: ETM (embedded in the Cortex), CTI (also embedded in the Cortex), the Processor Debug Unit and two asynchronous bridges - the asyncapb and the asyncatb.

Also included in this block guide is an overview of the DAP and TPIU which reside outside the ARM platform, yet are key components to the debug system.

9.1.2.1 Processor Debug Unit

The processor debug unit assists in debugging software running on the processor. In combination with a software debugger program, the debug unit enables debugging the following:

- application software
- operating systems
- hardware systems based on an ARM processor

The debug unit enables:

- stopping program execution
- examining and altering processor and coprocessor states
- examining and altering memory and input/output peripheral states
- restarting the processor core

There are three ways to debug software running on the processor:

- Halt debug-mode debugging
- Monitor debug-mode debugging
- Trace debugging (ETM) - covered in a different section

9.1.2.1.1 Halting Debug-Mode Debugging

Halting debug-mode debugging is invasive. The processor halts when a debug event, such as a break point, occurs. An external debugger can examine and modify the processor state via the APB while the processor is halted.

9.1.2.1.2 Monitor Debug-Mode Debugging

When a debug event occurs during monitor debug-mode debugging, instead of halting the processor, the processor takes an exception. Special software can then take control to examine or alter the processor state. When execution of a monitor target starts, the state of the processor is preserved in the same manner as all ARM exceptions.

9.1.2.1.3 Programming the Debug Unit

The processor unit is programmed using the APB slave port. Features that can be accessed using the memory-mapped APB registers are:

- instruction address comparators for triggering break points
- data address comparators for triggering watchpoints
- a bidirectional Debug Communication Channel (DCC)
- all other state information associated with the debug unit

9.1.2.2 ARM embedded trace macrocell (ARM ETM)

The ARM ETM provides real time instruction trace for the Cortex A8N processor. It is designed to be used with the CoreSight Design Kit. Unlike previous versions of the ARM platforms, this ETM is embedded inside the ARM Core.

Real time tracing is controlled by specifying a set of filtering and triggering resources which include address and data comparators, counters and sequencers.

NOTE

Though data trace can not be enabled, the ETM can still trigger based on data values. The ETM can also trace data address values.

The ARM ETM contains the following main components:

- Core interface
- Trace generation
- Filtering and triggering resources
- Main FIFO
- AMBA 3 ATB interface
- AMBA 3 APB interface

The ETMv3.3 provides a number of configurations. The table below shows the options implemented in the ETM.

Table 9-1. ETMv3.3 Configurations

Resource Description	Configuration
Instruction trace	Yes
Data address trace	Yes
Data value trace	No
Jazelle trace	-

Table continues on the next page...

Table 9-1. ETMv3.3 Configurations (continued)

Resource Description	Configuration
Address comparator pairs	2
Data comparator	4
Context ID comparators	1
Sequencer	Yes
Start/stop sub-block	Yes
Embedded ICE comparators	0
External inputs	4
External outputs	2
Extended external inputs	49
Extended external input selectors	2
Instrumentation resources	4
FIFO full	No
FIFO full level setting	N/A
Branch broadcasting	Yes
ASIC control register (bits)	8
Data suppression	Yes
Software access to registers	Memory
Readable registers	Yes
FIFO size	128 bytes
Minimum port size	32
Maximum port size	32
Port modes	Dynamic
Asynchronous ATB	Yes
Load pc first	No
Fetch comparisons	No

9.1.2.3 CoreSight Embedded Trace Buffer (CSETB)

The ETB provides on chip storage of trace data. The ARM platform implements a 32-bit 4K RAM.

The ETB accepts trace data from a CoreSight replicator via an ATB write port. The ETB is configurable through an APB port.

Features:

- 4kB compiled memory for the trace buffer. Note: It can no longer be used as a general purpose memory.
- Only 32-bit accesses to the 4kB buffer is supported (Note: RAM size is 4K "bytes" - i.e. 1Kx32)
- Amba Peripheral Bus interface for configuration and memory access

9.1.2.4 CoreSight Replicator (CSREPLICATOR)

The ATB Replicator enables two trace sinks (TPIU and ETB) to be wired together and receive ATB trace data from the same trace source (ETM). There are no programable registers. It takes incoming trace data from a single source (ETM) and replicates it to two master ports.

The CSREPLICATOR is part of the armp_gp_debug block. Two output master ports are required for this design - one for the on-platform ETB and one for the off-platform TPIU. Placing the TPIU off platform allows future debug trace sources to connect to the TPIU through a FUNNEL, without the need to modify the ARM platform. The figure below shows a block diagram for the CSREPLICATOR.

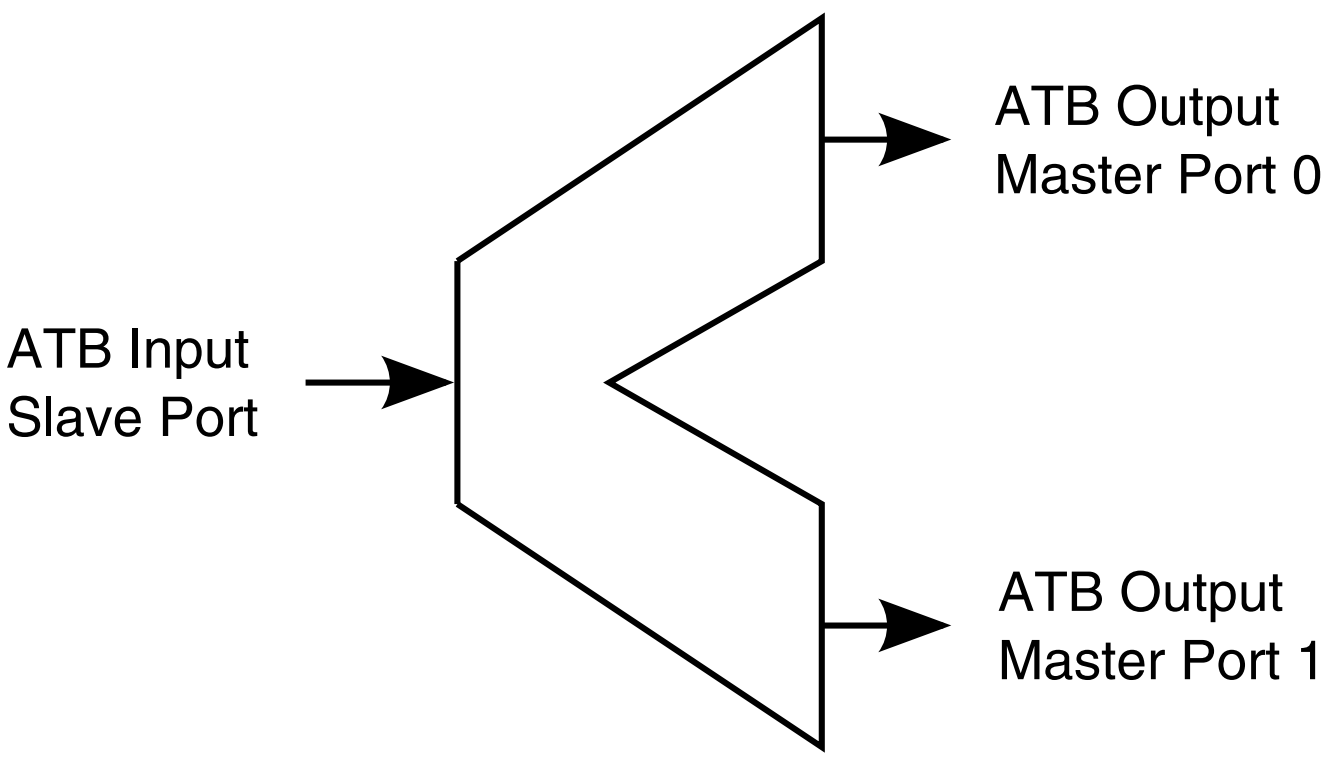

Figure 9-2. CSREPLICATOR Block Diagram

9.1.2.5 CoreSight trace port interface unit (CSTPIU)

The TPIU acts as a bridge between on-chip trace data, ID distinguishable, and a TPA. It receives ATB trace data and sends it off chip via ARM's standard trace signals TRACECLK, TRACEDATA and TRACECTL. The following sub-blocks are included in the TPIU (see the figure below): ATB interface, APB interface, Formatter, Asynchronous FIFO, Register bank, Trace out serializer and a Pattern generator. Further information on the TPIU can be found in ARM's technical reference manuals.

The TPIU is not on the ARM platform and is configurable via the APB.

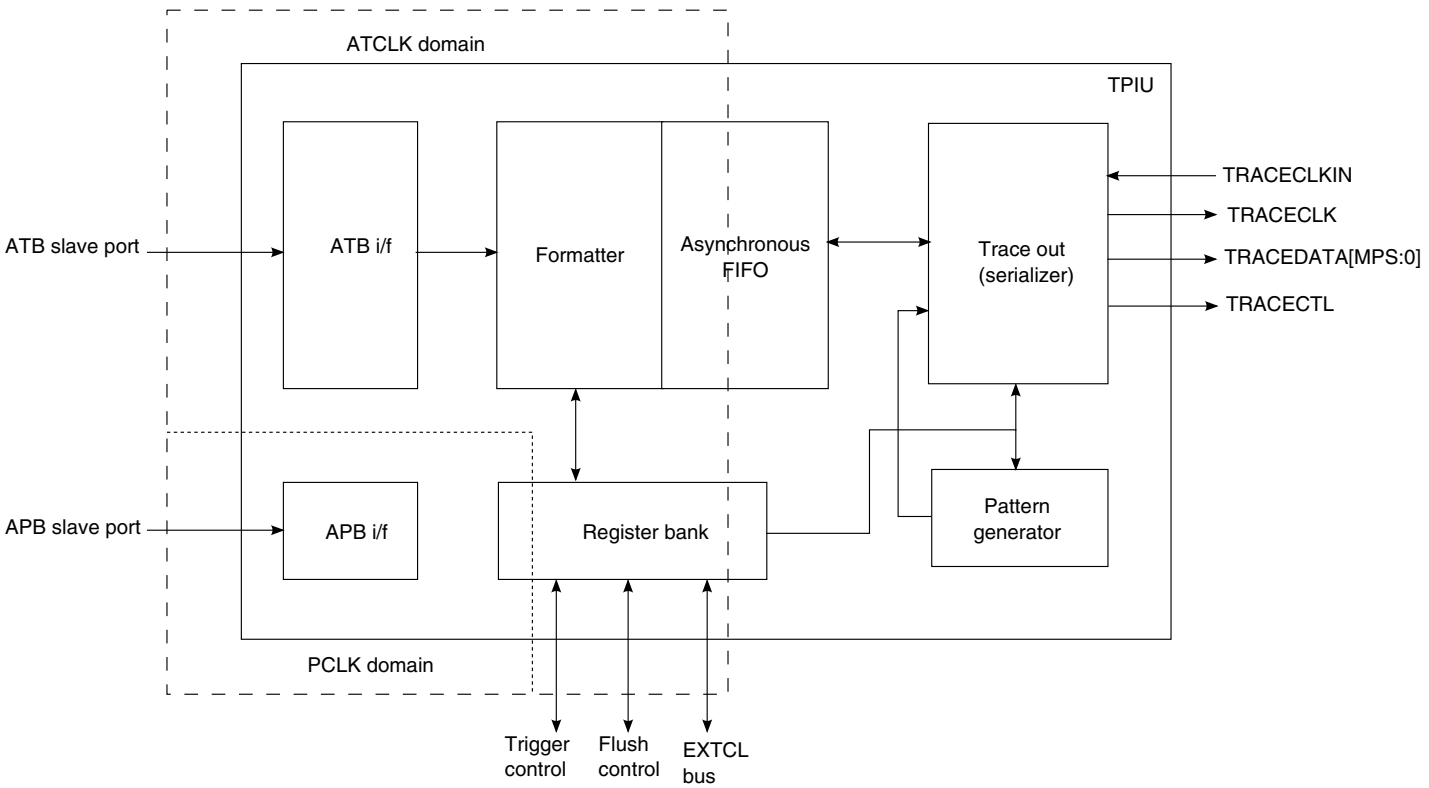

Figure 9-3. TPIU Block Diagram

All signal paths to the pads are subject to wire delays. Special consideration should be taken to re-balance the paths, removing the relative skews between the signals. An extra delay must be added on the TRACECLK path to ensure its rising and falling edge are during the stable part of TRACEDATA and TRACECTL.

9.1.2.6 CoreSight cross trigger interface (CSCTI)

The CSCTI is the CoreSight cross trigger interface component of an Embedded Cross Trigger (ECT) system. The CSCTI combines and maps trigger requests, broadcasting them to all other interfaces on the ECT as channel events. This enables subsystems to cross trigger with each other.

Each CTI has 8 trigger inputs, 8 trigger outputs and 4 sets of 4 channel I/Os. There are also acknowledge signals, configurable on/off, for the trigger and channel outputs. The channels connect to a CoreSight Cross Trigger Matrix (CSCTM). The CSCTM is off-platform, so special consideration should be taken when enabling the synchronizers and handshaking features on both the CSCTI and the CSCTM.

The platform requires one CTI block in addition to the embedded CTI in the ARM core. CTI0 resides in the Core and handles triggers/events from the CSETM and the CORE; CTI1 handles the triggers/events for the TPIU (off platform) and the CSETB. Since the TPIU is outside the platform (asynchronous), the TRIGIN synchronizers are enabled and handshaking is turned on.

The on-platform CTI1 is synchronous and at the same clock speed as the on-platform CTM. This allows the channel handshaking and channel synchronizers to be bypassed.

The figure below shows the recommended connections for CSCTI1.

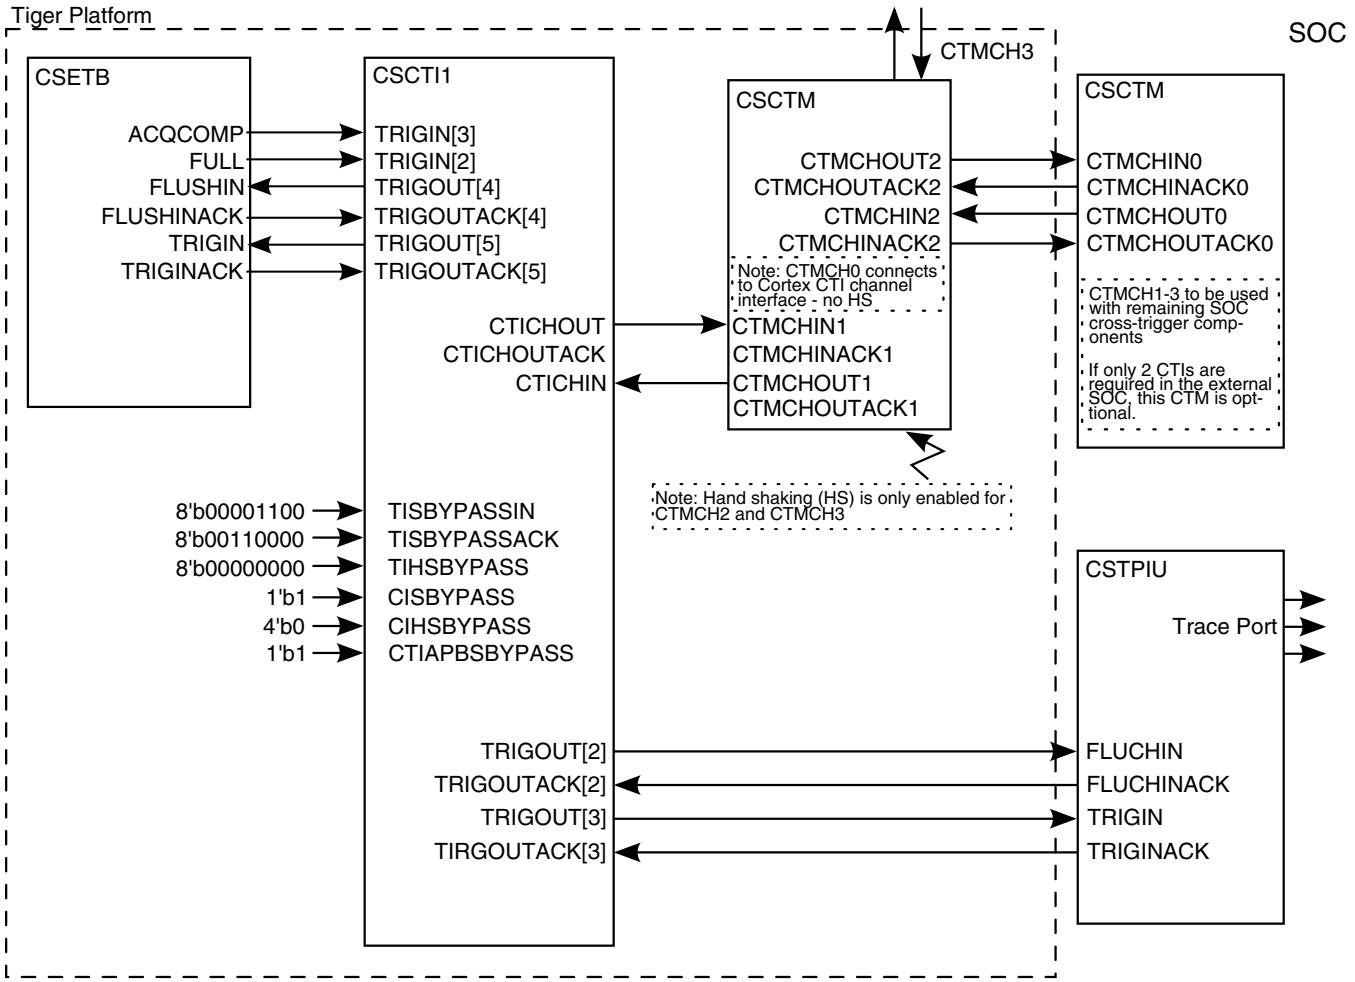

Figure 9-4. CSCTI1 Connections

The SOC CTIs require additional logic to support asynchronous trigger sources/ destinations. The cscti_extended sub-block includes logic, in addition to the CSCTI block, to support triggering across asynchronous boundaries where the source/destination might not have the necessary logic to support asynchronous boundaries.

9.1.2.7 CoreSight Cross Trigger Matrix (CSCTM)

This block controls the distribution of channel events. It provides channel interfaces to the CSCTIs. The CSCTM can also connect to another CSCTM via a channel interface. This allows multiple CSCTMs to be connected.

The ARM has one CSCTM inside the platform to handle events between the platform's CSCTIs and the rest of the ECT system outside the platform. Placing a CSCTM on platform minimizes the event cycle time between the ETB and the ETM. The handshaking between the CTIs on-platform and the on-platform CTM are not enabled.

This requires the Cortex's CTI, the on-platform CTI1 and the on-platform CTM to all be in the same clock domain. The on-platform CTM connects to the ECT system via an off-platform CTM and the respective channels require synchronizing and handshaking enabled.

If only two CTIs are required in the SOC, they can be connected directly to the on-platform CTM eliminating the need for a CTM outside the platform.

More information on the CoreSight ECT system can be found in ARM's Technical Reference manuals.

9.1.2.8 Debug Access Port (DAP)

The DAP provides multiple master driving ports, all accessible via a single external interface port. Components that access the DAP are called Debug Ports (DP) and components that access internal interfaces are called Access Ports.

The DAP provides real time access for the debugger without halting the core to:

- All debug configuration registers
- AMBA system memory and peripheral registers.

The DAP enables debug access to the complete SOC through a number of access ports. Access to the CoreSight Debug APB is enabled through the APB access port (APB-AP). System access can be accomplished via an AHB access port (AHB-AP). An APB multiplexer allows system accesses to debug CoreSight components connected to the APB.

There is also a JTAG access port (JTAG-AP) providing accesses to on-chip JTAG components. The DAP acts as a JTAG master. This feature will not be used for the ARM platform since the core's debug logic is now accessible through the APB.

The figure below shows a block diagram of the DAP.

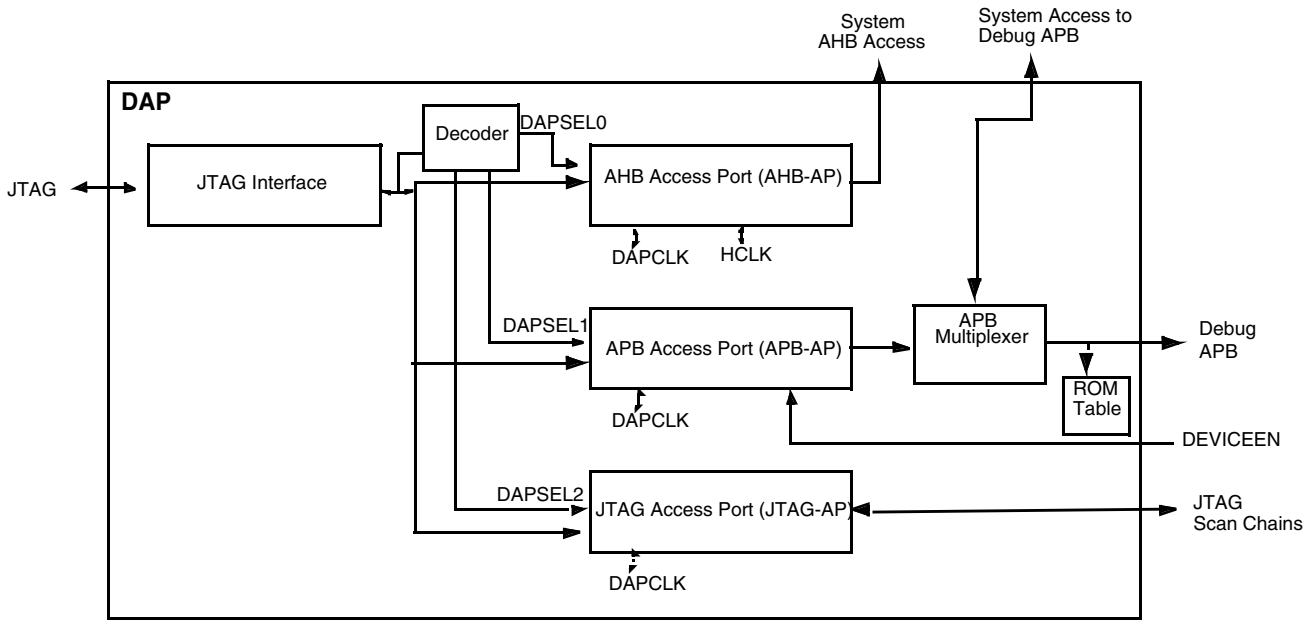

Figure 9-5. DAP Block Diagram

9.1.2.8.1 DAP_SYS

The DAP also requires decode logic for the CoreSight component PSEL signals, an AHB to APB bridge, an AHB lite to AHB bridge, detect logic to enable debug and reset synchronization logic. The dap_sys sub-block wraps these components with the DAP. The figure below shows a block diagram of the DAP_SYS.

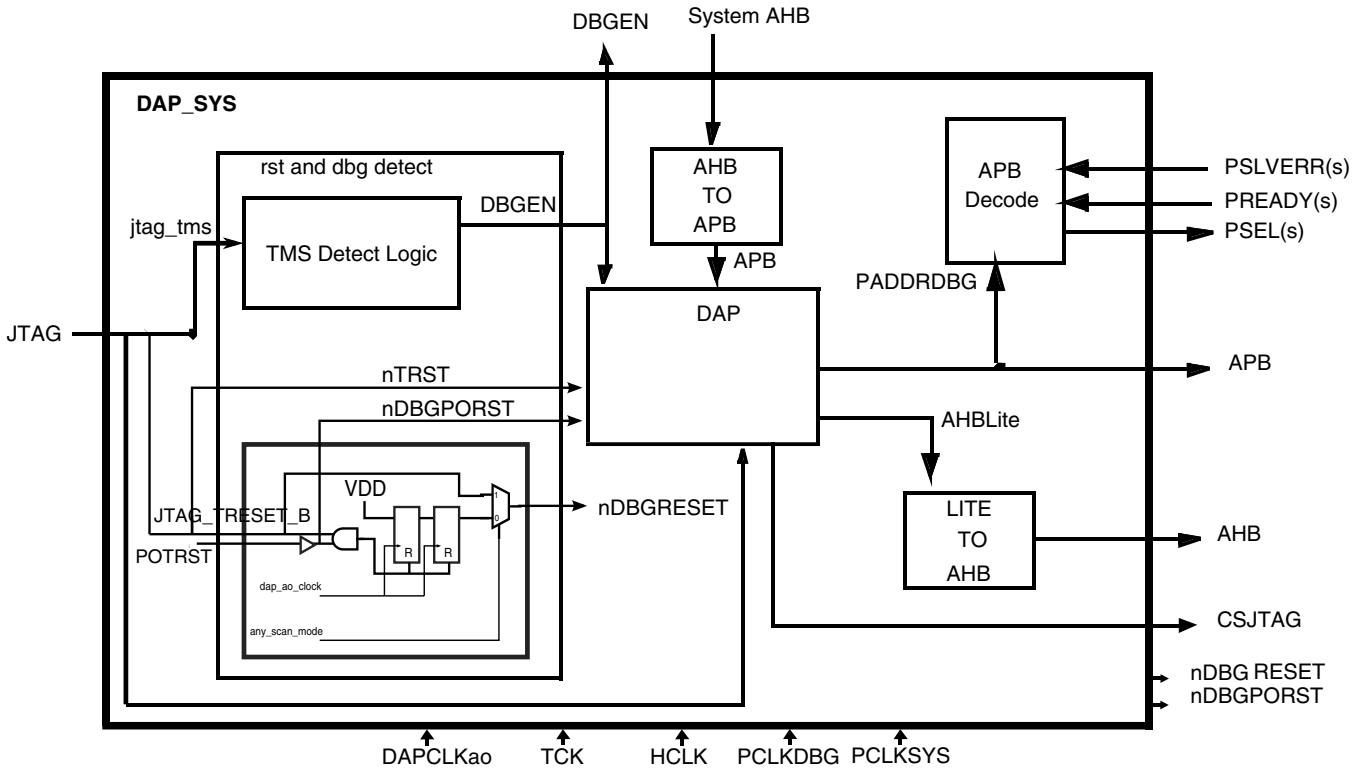

Figure 9-6. DAP_SYS Block Diagram

9.1.3 Modes of Operation

9.1.3.1 ARM Invasive Debug Mode

ARM Invasive Debug mode is usually entered through the JTAG port. Inside the dap_sys there is logic to assert DBGEN high when jtag_tms is active. The user can also invoke DBGEN by writing to a register inside the ARM plat_ctrl sub-block.

It is required that NIDEN is asserted while DBGEN is asserted. Otherwise, CTI functionality is limited when TINIDENSEL is tied to 0. Due to this requirement, NIDEN into the Core and the Debug block is a combination of dbg_niden ored with dbgen_in.

9.1.3.2 ARM Non-Invasive Debug Mode (Real-time Trace)

There are two methods to enter non-invasive debug mode - through JTAG or via memory mapped accesses. For memory mapped accesses, non-invasive debug can be enabled by writing to two secure supervisor registers, one within the Central Security Unit (CSU) and one within the ARM platform.

9.1.3.3 Normal Operating Modes

During normal operating mode, debug is not enabled.

9.1.3.4 Low Power Modes

During deep sleep mode (DSM) all debug is disabled. The platform_ctl sub-block has a bit allocated to overriding DSM when debug is enabled. This bit currently resets to a state disabling DSM while debug is enabled. For more information, refer to the platform control block guide.

The core has an input, DBGNOCLKSTOP (from ARM_GPC[NOCLKSTOP]), allowing the core's debug clocks to stay on while in WFI. The same bit used to override DSM should be connected to DBGNOCLKSTOP (inverted). Another solution is to allocated separate bit for this function in the platform_ctl sub-block. Make note that if the dsm override bit is not set and the platform goes into DSM, it doesn't matter what DBGNOCLKSTOP is set to.

9.2 Memory Map and Register Definition

Each CoreSight component has an allocated 4K. CoreSight components are part of either CoreSight Class or ROM Class. The figure below shows the CoreSight class layout for a 4KB block.

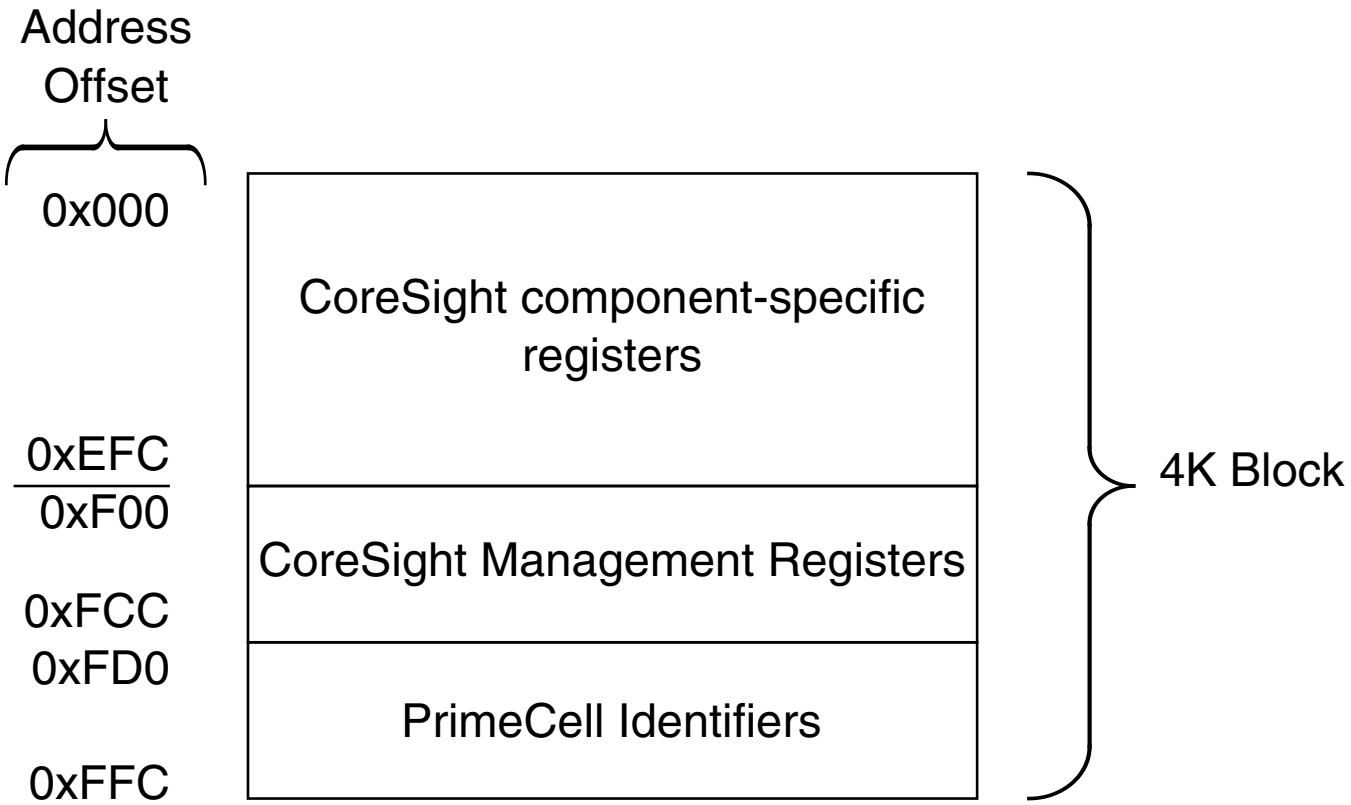

Figure 9-7. CoreSight Component Memory Map

The following table shows an example Debug memory map. The most significant half-word of the address will change based on the chip level memory map.

Table 9-2. Block Memory Map

Start Address	End Address	Size	Target IP	Comments
B0C00000	B0C00FFF	4K	Debug ROM	Located inside DAP
B0C01000	B0C01FFF	4K	ETB	
B0C02000	B0C02FFF	4K	ETM	
B0C03000	B0C03FFF	4K	TPIU	
B0C04000	B0C04FFF	4K	CTI0	On platform
B0C05000	B0C05FFF	4K	CTI1	On platform
B0C06000	B0C06FFF	4K	CTI2	Off platform
B0C07000	B0C07FFF	4K	CTI3	Off platform

9.2.1 Register Summary

This section summarizes the CoreSight Component registers in a table format. The tables are divided by Components. For a more detailed description of each register, refer to the CoreSight_DK_TRM.

The conventions in the table below serve as a key for the register summary.

Table 9-3. Register Conventions

Register Field Types	
RO	Read only. Writing this bit has no effect.
WO	Write only.
R/W	Standard read/write bit. Only software can change the bit's value (other than a hardware reset).
rwm	A read/write bit that may be modified by a hardware in some fashion other than by a reset.
w1c	Write one to clear. A status bit that can be read, and is cleared by writing a one.
RAZ	Read-as-zero
WI	Writes ignored
Self-clearing bit	Writing a one has some effect on the Block, but it always reads as zero. (Previously designated slfclr)

9.2.1.1 DAP JTAG DP Registers

Accessing a JTAG DP register depends on both the instruction register (IR) value of the DAP access and the address field of the DAP access.

The following table shows a register summary table for the DAP DP. Detailed register descriptions can be found inside the CoreSight_DK_TRM provided by ARM.

Table 9-4. DAP JTAG DP Registers

Address Field	IR Contents	Type	Register Name
1	IDCODE	RO	Identification Control Register
0x0	DAPACC	RAZ/WI	Reserved
0x4	DAPACC	R/W	DP Control/Status Register
0x8	DAPACC	R/W	Select Register
0x0	ABORT	WO	DAP Abort Register
0x4-0xC	ABORT	2	Reserved

1. There is no address associated with the ID code register. For more information, see the CoreSight_DK_TRM.
2. The value read on the abort scan chain is unpredictable. The result of accessing the abort scan chain without the address set to 0x0 is unpredictable.

9.2.1.2 DAP ROM Register Summary

The ROM table stores the locations of components on the debug APB. The DAP ROM is read only and configurable through the DAPROM.v and DapRomDefs.v RTL files. Writes are ignored.

The following table shows a register summary table for the DAP Rom. Detailed descriptions can be found inside the CoreSight_DK_TRM provided by ARM.

Table 9-5. DAP ROM Registers

Offset	Name	Type	Description
0xFD0	Peripheral ID4	RO	See CoreSight_DK_TRM
0xFD4	Peripheral ID5	RAZ	Reserved
0xFD8	Peripheral ID6	RAZ	Reserved
0xFDC	Peripheral ID7	RAZ	Reserved
0xFE0	Peripheral ID0	RO	See CoreSight_DK_TRM
0xFE4	Peripheral ID1	RO	See CoreSight_DK_TRM
0xFE8	Peripheral ID2	RO	See CoreSight_DK_TRM
0xFEC	Peripheral ID3	RO	See CoreSight_DK_TRM
0xFF0	Component ID0	RO	Set to 0x0D
0xFF4	Component ID1	RO	Set to 0x10
0xFF8	Component ID2	RO	Set to 0x05
0xFFC	Component ID3	RO	Set to 0xB1

9.2.1.3 Processor Debug Unit Register Summary

Most of the debug unit registers are accessible through the APB. There are some registers that can also be accessed through a coprocessor interface - CP14.

By default, CP14 registers can be accessed from a non-privileged mode. However, the processor can be programmed to disable user access modes using bit [12] of the Debug Status and Control Register (DSCR). For more information on the DSCR and access to CP14 registers, refer to the CortexA8 TRM document.

9.2.1.3.1 Coprocessor Registers Summary

The table below shows the valid debug instructions for accessing the debug registers.

Table 9-6. CP14 Debug Registers Summary

Instruction	Mnemonic	Description
MRC p14, 0, <Rd>, c0, c0, 0	DIDR	Debug Identification Register
MRC p14, 0, <Rd>, c1, c0, 0	DRAR	Debug ROM Address Register
MRC p14, 0, <Rd>, c2, c0, 0	DSAR	Debug Self Address Register
MRC p14, 0, <Rd>, c0, c5, 0 STC p14, c5, <addressing mode>	DTRRX	Data Transfer Register - Receive
MCR p14, 0, <Rd>, c0, c5, 0 LDC p14, c5, <addressing mode>	DTRTX	Data Transfer Register - Transmit
MRC p14, 0, <Rd>, c0, c1, 0 MRC p14, 0, PC, c0, c1, 0	DSCR	Debug Status and Control Register

9.2.1.3.2 Memory Mapped Registers Summary

The table below shows a complete list of memory mapped registers accessible using the APB slave port.

Table 9-7. Debug Unit APB Accessible Registers Summary

Offset	Register Number	Mnemonic	Type	Description
0x000	c0	DIDR	R	CP14 c0, Debug ID Register
0x004-0x014	c1-c5	-	R	RAZ
0x018	c6	WFAR	R/W	Watchpoint Fault Address Register
0x01C	c7	VCR	R/W	Vector Catch Register
0x020	c8	-	R	RAZ
0x024	c9	ECR	R/W	Event Catch Register
0x028	c10	DSCCR	R/W	Debug State Cache Control Register
0x02C	c11	-	R	RAZ
0x030-0x07C	c12-c31	-	R	RAZ
0x080	c32	DTRRX	R/W	Data Transfer Register - Receive
0x084	c33	ITR	W	Instruction Transfer Register
0x088	c34	DSCR	R/W	CP14 c1, Debug Status and Control Register
0x08C	c35	DTRTX	R/W	Data Transfer Register - Transmit
0x090	c36	DRCR	W	Debug Run Control Register
0x094-0x09C	c37-c63	-	R	RAZ
0x100-0x114	c64-c69	BVR	R/W	Breakpoint Value Registers
0x118-0x13c	c70-c79	-	R	RAZ
0x140-0x154	c80-c85	BCR	R/W	Breakpoint Control Register

Table continues on the next page...

Table 9-7. Debug Unit APB Accessible Registers Summary (continued)

Offset	Register Number	Mnemonic	Type	Description
0x158-0x17C	c86-c95	-	R	RAZ

9.2.2 Clocks

The list below describes the Debug clocks within the ARM platform.

- ATCLK - This is the AMBA Trace Bus (ATB) clock. This clock is also used to clock the on-platform CTICLK and on-platform CTMCLK. ATCLK needs to be synchronous (equivalent or faster) to PCLKDBG.
- CTICLK - This is the main clock for the CTI block. The current ARM configuration requires this clock to be synchronous to the on-platform CTM clock.
- PCLKDBG - This is the Debug APB clock. It must be synchronous (equivalent or slower) to the ATCLK.
- TRACECLKIN - This is the Trace Port Interface Unit trace clock input. Since the trace port pads are limited to 133 mhz, TRACECLKIN is pad limited to less than or equal to 266 mhz.
- TRACECLK - This is the clock for the external trace port. It's a DDR clock and runs at 1/2 the speed of TRACECLKIN.

The platform control block generates the debug clocks from the arm clock. The requirement above states that the PCLKDBG needs to be synchronous to the ATCLK. When configuring the divide by settings, make sure this requirement is followed. PCLKDBG is a divide by 2 of ATCLK.

9.2.3 Reset

All debug resets are derived from JTAG_TRST_B and POR. These two resets go into the DAP_SYS to be combined and de-asserted synchronously to the DAPCLKao (always on clock). They also go into the ARM platform, being synchronously de-asserted inside the plat_cntrl block, generating resets for the debug logic inside the platform. Debug resets

that do not require synchronous de-assertion are routed directly to their destination, such as por for the Core and ETM. The figure below shows a diagram of the ARM platform debug reset strategy.

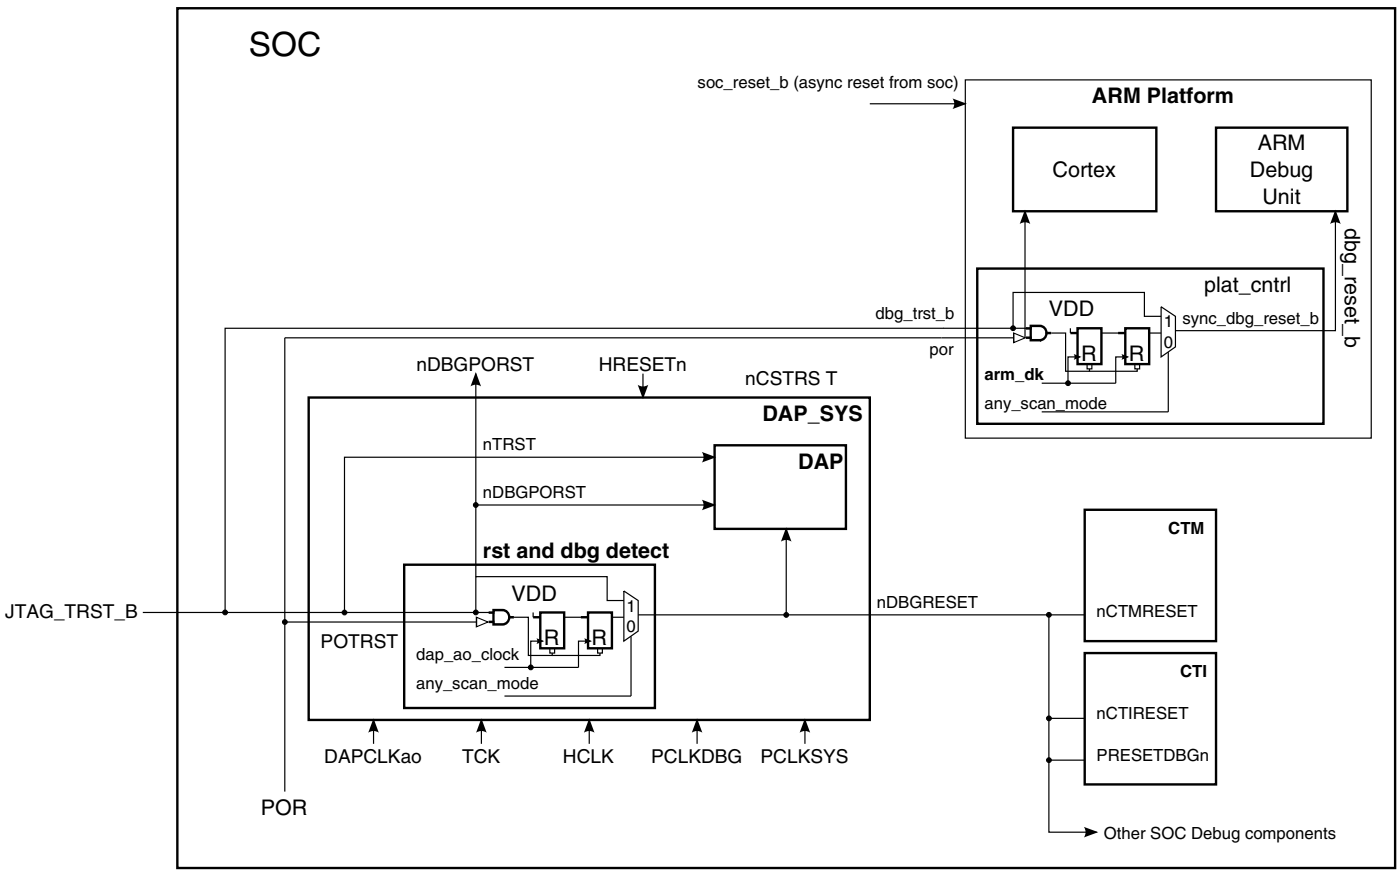

Figure 9-8. ARM Debug Reset Strategy

Chapter 10
Multi-Layer AHB Crossbar Switch (AHBMAX)

10.1 Overview

This section provides an overview of the Multi-Layer AHB Crossbar Switch (AHBMAX). The purpose of the AHBMAX is to concurrently support up to four simultaneous connections between master ports and slave ports. The AHBMAX supports a 32-bit address bus width and a 32-bit data bus width at all master and slave ports. A simplified block diagram is shown in Figure 10-1.

NOTE

The AHBMAX implements a 7 master by 4 slave configuration.

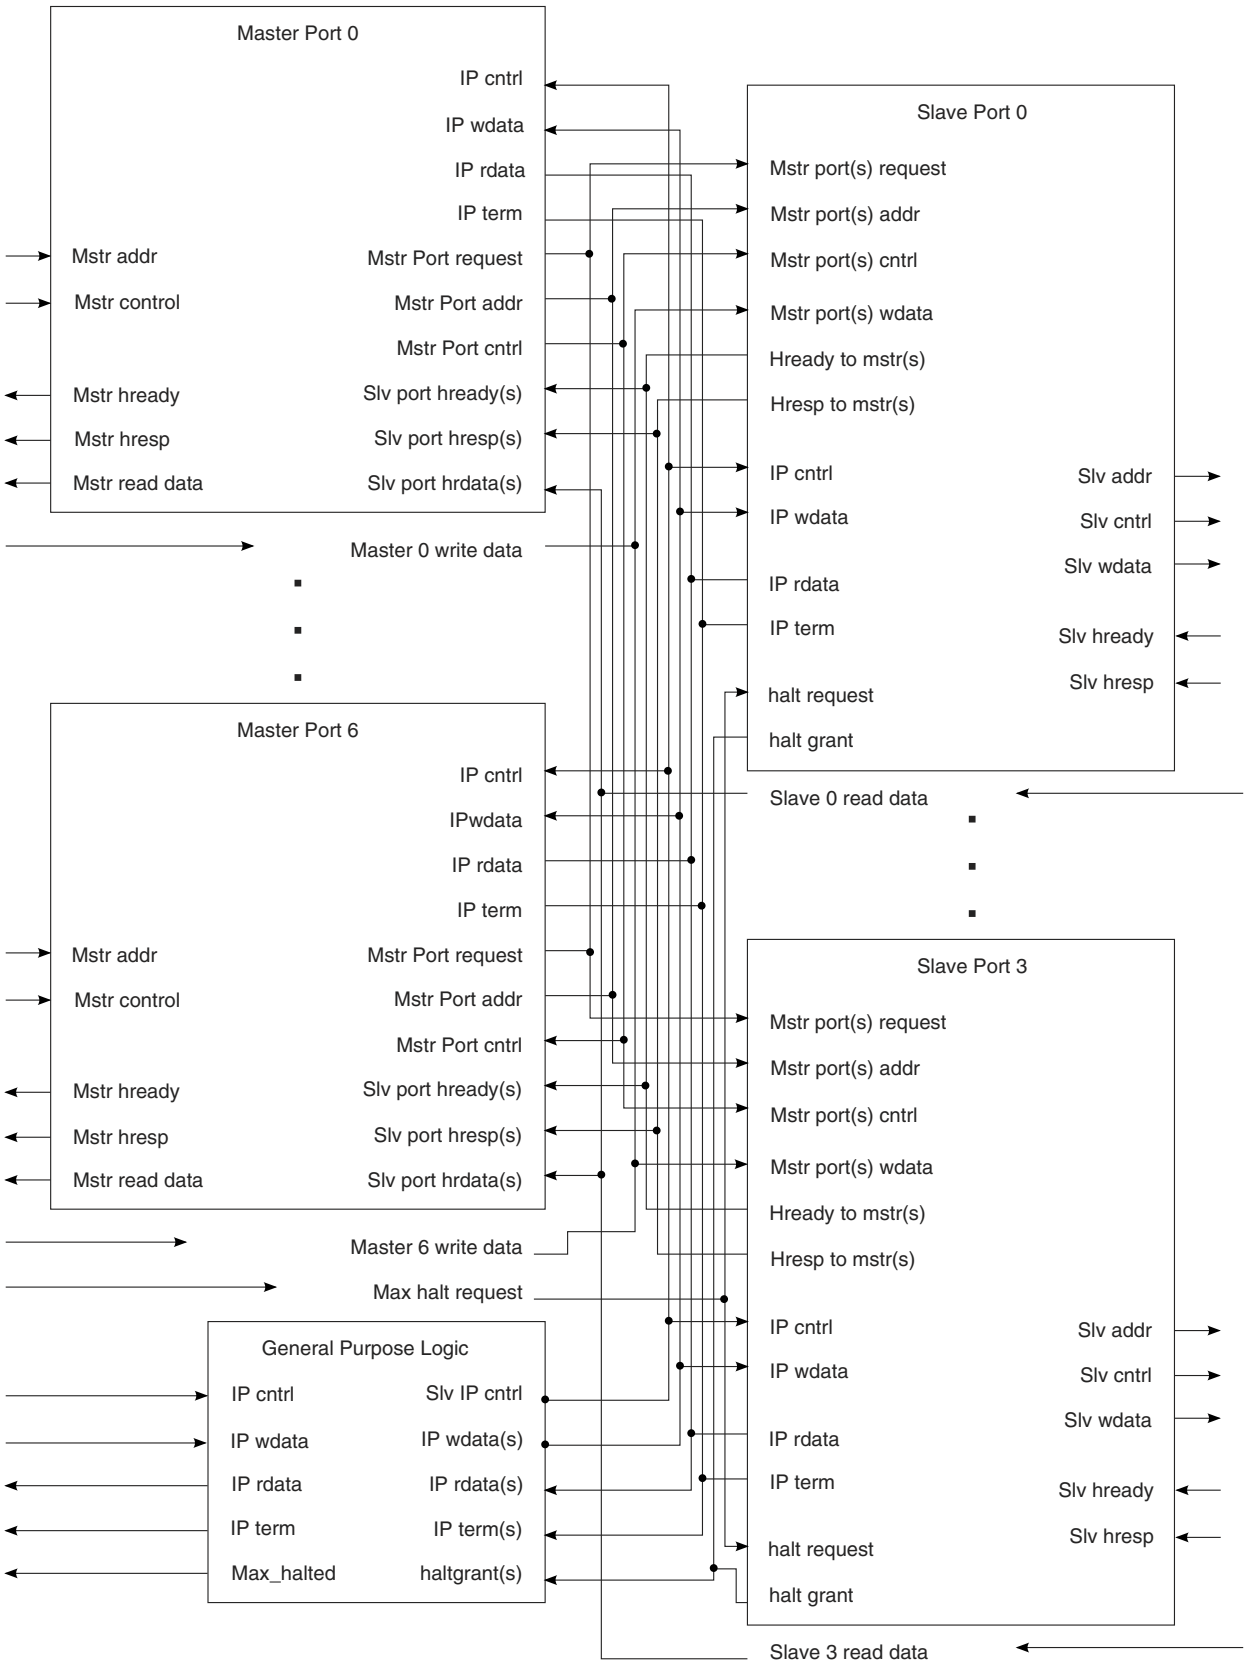

Figure 10-1. AHBMAX Block Diagram

10.2 Features

The AHBMAX has the ability to gain control of all the slave ports and prevent any masters from making accesses to the slave ports. This feature is useful when the user wishes to turn off the clocks to the system and needs to ensure that no bus activity will be interrupted.

The AHBMAX can put each slave port into a low power park mode so that slave port will not dissipate any power transitioning address, control or data signals when not being actively accessed by a master port.

Each slave port can also support multiple master priority schemes. Each slave port has a hardware input which selects the master priority scheme so the user can dynamically change master priority levels on a slave port by slave port basis.

The AHBMAX will allow for concurrent transactions to occur from any master port to any slave port. It is possible for four master ports and all slave ports to be in use at the same time as a result of independent master requests. If a slave port is simultaneously requested by more than one master port, arbitration logic will select the higher priority master and grant it ownership of the slave port. All other masters requesting that slave port will stalled until the higher priority master completes its transactions.

10.2.1 Limitations

The AHBMAX routes bus transactions initiated on the master ports to the appropriate slave ports. There is no provision included to route transactions initiated on the slave ports to other slave ports or to master ports. Simply put, the slave ports do not support the bus request/bus grant protocol, the AHBMAX assumes it is the sole master of each slave port.

Because the AHBMAX does not support the bus request/bus grant protocol, if multiple masters are to be connected to a single master port an external arbiter will need to be used. In the case of a single master connecting to a master port the single master's bus grant signal must be tied off in the asserted state.

Each master and slave port is fully AHB-Lite + AMBA V6 extensions compliant. The ports are not fully AHB compliant because the AHBMAX does not support SPLITs or RETRYs.

10.2.2 General Operation

When a master makes an access to the AHBMAX the access will be immediately taken by the AHBMAX. If the targeted slave port of the access is available then the access will be immediately presented on the slave port. It is possible to make single clock (zero wait state) accesses through the AHBMAX. If the targeted slave port of the access is busy or parked on a different master port the requesting master will simply see wait states inserted (hready held negated) until the targeted slave port can service the master's request. The latency in servicing the request will depend on each master's priority level and the responding peripheral's access time.

Because the AHBMAX appears to be just another slave to the master device, the master device will have no knowledge of whether or not it actually owns the slave port it is targeting. While the master does not have control of the slave port it is targeting it will simply be wait stated.

A master will be given control of the targeted slave port only after a previous access to a different slave port has completed, regardless of its priority on the newly targeted slave port. This prevents deadlock from occurring when a master has an outstanding request to one slave port that has a long response time, has a pending access to a different slave port, and a lower priority master is also making a request to the same slave port as the pending access of the higher priority master.

Once the master has control of the slave port it is targeting the master will remain in control of that slave port until it gives up the slave port by running an IDLE cycle or by leaving that slave port for its next access. The master could also lose control of the slave port if another higher priority master makes a request to the slave port; however, if the master is running a locked or fixed length burst transfer it will retain control of the slave port until that transfer is completed. Based on the AULB bit in the MGPCR (Master General Purpose Control Register) the master will either retain control of the slave port when doing undefined length incrementing burst transfers or will lose the bus to a higher priority master.

The AHBMAX will terminate all master IDLE transfers (as opposed to allowing the termination to come from one of the slave busses). Additionally, when no master is requesting access to a slave port the AHBMAX will drive IDLE transfers onto the slave bus, even though a default master may be granted access to the slave port. When the AHBMAX is controlling the slave bus (i.e. during low power park or halt mode) the hmaster field will indicate 4'b0000.

When a slave bus is being IDLEd by the AHBMAX it can park the slave port on the master port indicated by the PARK bits in the AHBMAX_SGPCR (Slave General Purpose Control Register). This can be done in an attempt to save the initial clock of

arbitration delay that would otherwise be seen if the master had to arbitrate to gain control of the slave port. The slave port can also be put into low power park mode in attempt to save power.

10.3 AHBMAX Interface Signals

This section provides information on AHBMAX interface signals, including AHB master and slave interface signals as well as IP bus interface signals.

10.3.1 AHBMAX Signal Descriptions

Please reference the AMBA Specification Rev 2.0 for a description of the AHB signals in the AHBMAX and the IP Bus Specification Rev 2.0 for a description of the IP Bus signals in the AHBMAX.

10.3.1.1 max_halt_request

This input signal is a request to halt all slave port bus activity (run AHBMAX originated IDLE cycles on each slave port bus, blocking all master port accesses). This signal can be used to gracefully shut down the AHBMAX so the system clock can be stopped for low power mode. This signal is captured by a flop inside the AHBMAX before use.

Once the AHBMAX is halted it will remain halted until max_halt_request is negated.

10.3.1.2 max_halted

This output is asserted once the AHBMAX is in control and running IDLE cycles on each slave port.

10.4 Coherency

Since the content of the registers has a real time effect on the operation of the AHBMAX it is important for the user to understand that any register modifications take effect as soon as the register is written. The values of the registers do not track with slave port related AHB accesses but instead track only with IP bus accesses.

The exception to this rule are the AULB bits in the AHBMAX_MGPCR*n*. The update of these bits is only recognized when the master on that master port runs an IDLE cycle, even though the IP bus cycle to write them will have long since terminated successfully. If the AULB bits in the AHBMAX_MGPCR*n* are written in between two burst accesses the new AULB encodings will not take effect until an IDLE cycle has been initiated by the master on that master port.

10.5 Detailed Functional Description

This section describes the functionality of the AHBMAX in greater detail.

10.5.1 Arbitration

The AHBMAX supports two arbitration schemes; a simple fixed-priority comparison algorithm, and a simple round-robin fairness algorithm. The arbitration scheme is independently programmable for each slave port.

10.5.1.1 Arbitration During Undefined Length Bursts

Arbitration points during an undefined length burst are defined by the current master's AHBMAX_MGPCR*n*[AULB] field setting. When a defined length is imposed on the burst via the AULB bits the undefined length burst will be treated as a single or series of single back to back fixed length burst accesses.

Example: A master runs an undefined length burst and the AULB bits in the AHBMAX_MGPCR*n* indicate arbitration will occur after the fourth beat of the burst. The master runs two sequential beats and then starts what will be an 12 beat undefined length burst access to a new address within the same slave port region as the previous access. The AHBMAX will not allow an arbitration point until the fourth overall access (second beat of the second burst). At that point all remaining accesses will be open for arbitration until the master loses control of the slave port.

Assume the master loses control of the slave port after the fifth beat of the second burst. Once the master regains control of the slave port no arbitration point will be available until after the master has run four more beats of its burst. After the fourth beat of the (now continued) burst (ninth beat of the second burst from the master's perspective) is taken all beats of the burst will once again be open for arbitration until the master loses control of the slave port.

Assume the master again loses control of the slave port on the fifth beat of the third (now continued) burst (10th beat of the second burst from the master's perspective). Once the master regains control of the slave port it will be allowed to complete its final two beats of its burst without facing arbitration.

Note that fixed length burst accesses will not be affected by the AULB bits. All fixed length burst accesses will lock out arbitration until the last beat of the fixed length burst.

10.5.1.2 Fixed Priority Operation

When operating in fixed-priority mode, each master is assigned a unique priority level in the AHBMAX_MPR*n* (Master Priority Register). If two masters both request access to a slave port the master with the highest priority in the selected priority register will gain control over the slave port.

Any time a master makes a request to a slave port the slave port checks to see if the new requesting master's priority level is higher than that of the master that currently has control over the slave port (unless the slave port is in a parked state). The slave port does an arbitration check at every clock edge to ensure that the proper master (if any) has control of the slave port.

If the new requesting master's priority level is higher than that of the master that currently has control of the slave port the new requesting master will be granted control over the slave port at the next clock edge. The exception to this rule is if the master that currently has control over the slave port is running a fixed length burst transfer or a locked transfer. In this case the new requesting master will have to wait until the end of the burst transfer or locked transfer before it will be granted control of the slave port. If the master is running an undefined length burst transfer the new requesting master must wait until an arbitration point for the undefined length burst transfer before it will be granted control of the slave port. Arbitration points for an undefined length burst are defined in the MGPCR for each master.

If the new requesting master's priority level is lower than that of the master that currently has control of the slave port the new requesting master will be forced to wait until the master that currently has control of the slave port either runs an IDLE cycle or runs a non IDLE cycle to a location other than the current slave port.

10.5.1.3 Round-Robin Priority Operation

When operating in round-robin mode, each master is assigned a relative priority based on the master number. This relative priority is compared to the ID of the last master to perform a transfer on the slave bus. The highest priority requesting master will become

owner of the slave bus as the next transfer boundary (accounting for locked and fixed-length burst transfers). Priority is based on how far ahead the ID of the requesting master is to the ID of the last master (ID is defined by master port number, not the hmaster field).

Once granted access to a slave port, a master may perform as many transfers as desired to that port until another master makes a request to the same slave port. The next master in line will be granted access to the slave port at the next assertion of slave "n" hready, or possibly on the next clock cycle if the current master has no pending access request.

As an example of arbitration in round-robin mode, assume the AHBMAX is implemented with master ports 0, 1, 2, 3, 4 and 5. If the last master of the slave port was master 1, and master 0, 4 and 5 make simultaneous requests, (master ports 2 and 3 make no requests), they will be serviced in the order 4, 5 and then 0.

Parking may still be used in a round-robin mode, but will not affect the round-robin pointer unless the parked master actually performs a transfer. Handoff will occur to the next master in line after one cycle of arbitration. If the slave port is put into low power park mode the round-robin pointer will be reset to point at master port 0, giving it the highest priority.

10.5.2 Priority Assignment

Each master port needs to be assigned a unique 3 bit priority level. If an attempt is made to program multiple master ports with the same priority level within a register (MPR) the AHBMAX will respond with an error and the registers will not be updated.

10.5.3 Master Port Functionality

10.5.3.1 Master Port General Information

Each master port consists of two decoders, a capture unit, a register slice, a mux and a small state machine.

The first decoder is used to decode the haddr and control signals coming directly from the master, telling the state machine where the master's next access will be and if it is in fact a legal access. The second decoder gets its input from the capture unit, so it may be looking directly at the signals coming from the master or it may be looking at captured signals coming from the master, depending entirely on the state of the targeted slave port. The second decoder is then used to generate the access requests that go to the slave ports.

The capture unit is used to capture the address and control information coming from the master in the event that the targeted slave port cannot immediately service the master. The capture unit is controlled by outputs from the state machine which tell it to either pass through the original master signals or the captured signals.

The register slice contains the registers associated with the specific master port. The registers have a quasi-IP bus interface at this level for reads and writes and the outputs feed directly into the state machine.

The mux is used simply to select which slave's read data is sent back to the master. The mux is controlled by the state machine.

The state machine controls all aspects of the master port. It knows which slave port the master wants to make a request to and controls when that request is made. It also has knowledge of each slave port, knowing whether or not the slave port is ready to accept an access from the master port. This will determine whether or not the master may immediately have its request taken by the slave port or whether the master port will have to capture the master's request and queue it at the slave port boundary.

For a block diagram of a master port see Figure 10-2.

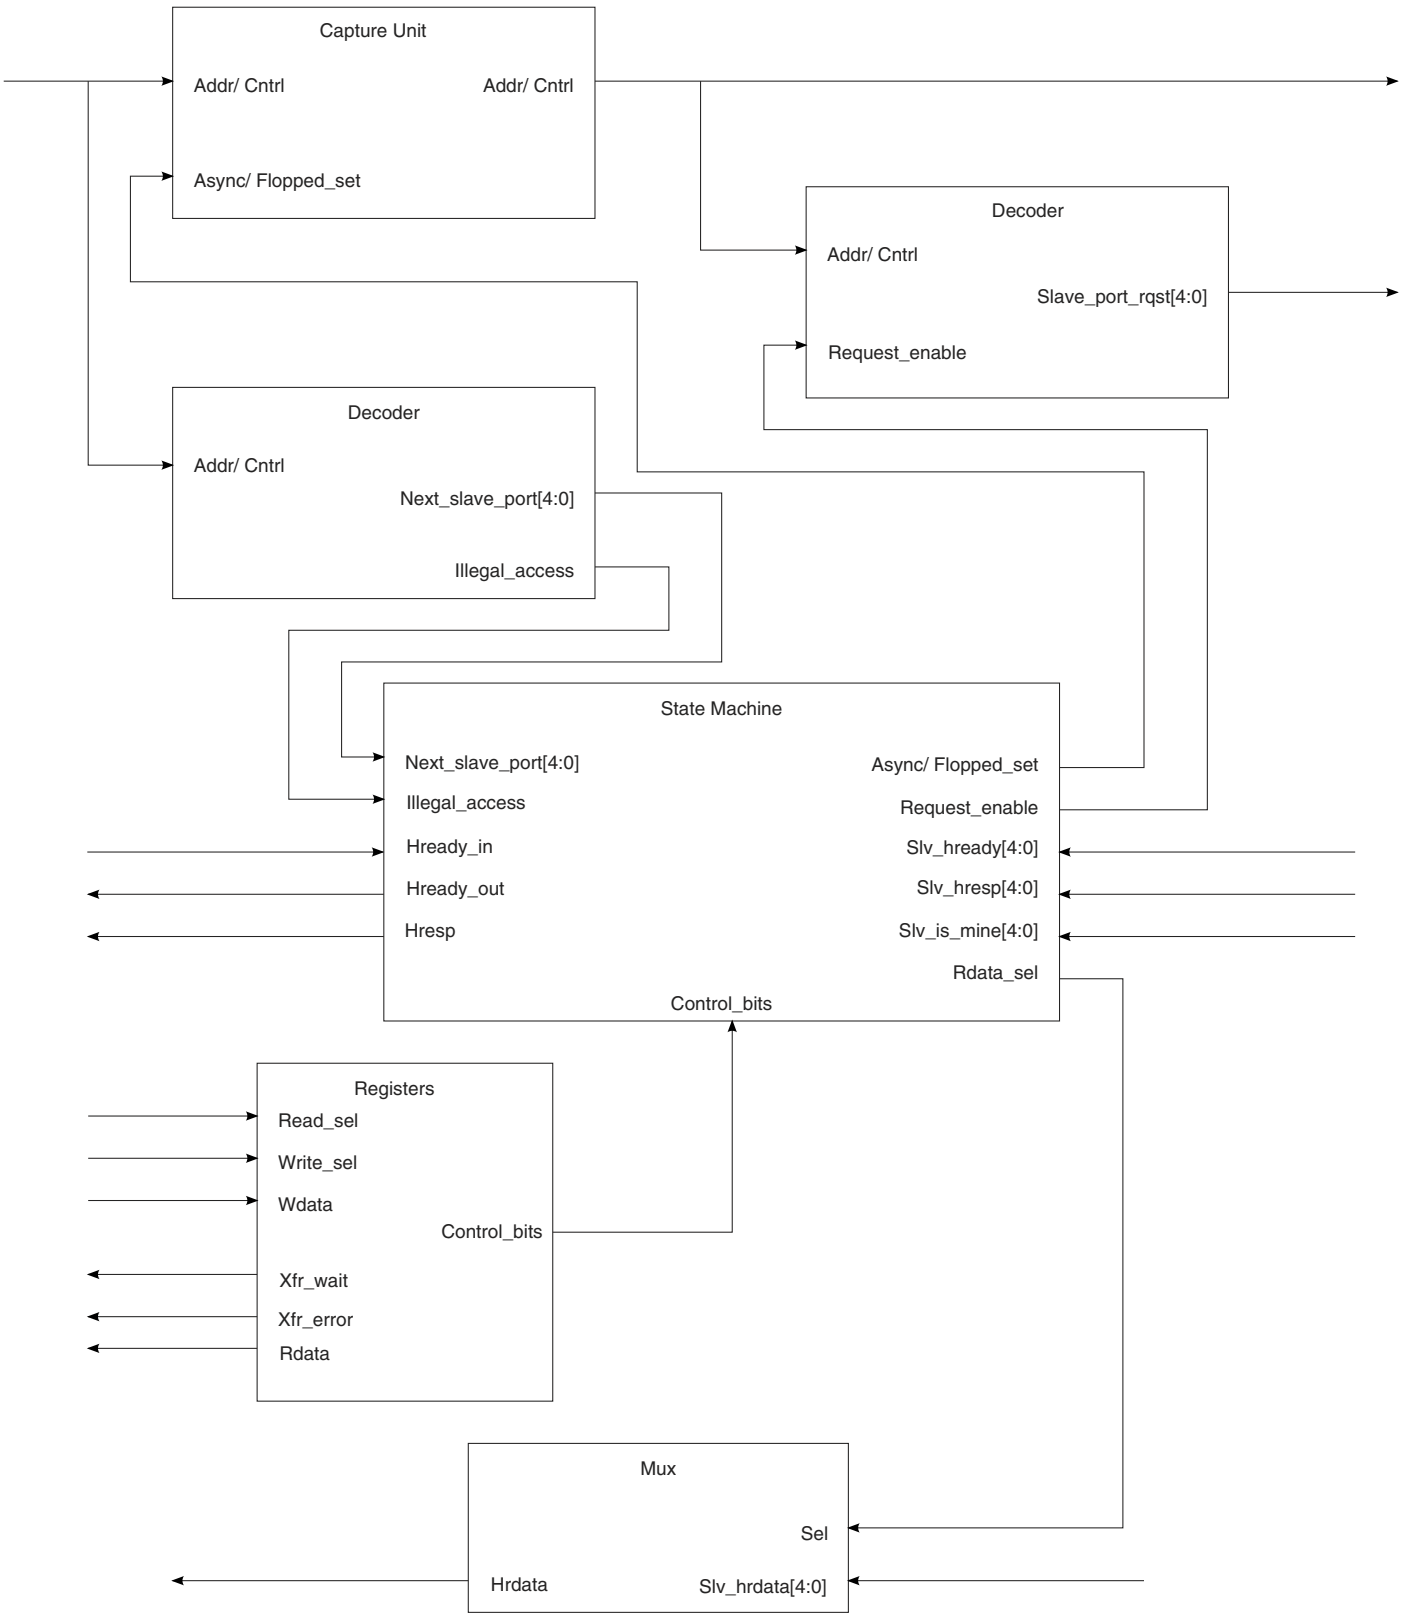

Figure 10-2. AHBMAX Master Port Block Diagram

10.5.3.2 Master Port Decoders

The decoders are very simple as they ensure an access request is allowed to be made and that the slave port targeted is actually present in the design. The decoders feeding the state machine are always enabled. The decoders that select the slave are enabled only when the master port controlling state machine wants to make a request to a slave port. This is necessary so that if a master port is making an access to a slave port and is being wait stated, and its next access is to a different slave port, the request to the second slave port can be held off until the access to the first slave port is terminated.

The decoders also output a "hole decode" or illegal access signal which tells the state machine that the master is trying to access a slave port that does not exist.

10.5.3.3 Master Port Capture Unit

The capture unit simply captures the state of the master's address and control signals if the AHBMAX cannot immediately pass the master's request through to the proper slave port. The capture unit consists of a set of flops and a mux which selects either the asynchronous path from address and control or the flopped (captured) address and control information.

10.5.3.4 Master Port Registers

The registers in the master port are only those registers associated with this particular master port. The read and write interface for the registers is a quasi-IP bus interface. It is not a full IP bus interface at this level because not all the IP bus signals are routed this deep in the design.

There is a register control block at the same level of the master port and slave port instantiations in the AHBMAX. This control block ensures that all accesses are 32-bit supervisor accesses before passing them on to the master ports.

The register outputs are connected directly to the state machine.

10.5.3.5 Master Port State Machine

10.5.3.5.1 Master Port State Machine States

The master side state machine's main function is to monitor the activities of the master port. The state machine has six states: busy, idle, stalled, steady state, first cycle error response and second cycle error response.

The busy state is used when the master runs a BUSY cycle to the master port. The master port maintains its request to the slave port if it currently owns the slave port; however, if it loses control of the slave port it will no longer maintain its request. If the master port loses control of the slave port it will not be allowed to make another request to the slave port until it runs a NSEQ or SEQ cycle.

The idle state is used when the master runs a valid IDLE cycle to the master port. The master port makes no requests to the slave ports (disables the slave port decoder) and terminates the IDLE cycle.

The stalled state is used when the master makes a request to a slave port that is not immediately ready to receive the request. In this case the state machine will direct the capture unit to send out the captured address and control signals and will enable the slave port decoder to indicate a pending request to the appropriate slave port.

The steady state is used when the master port and slave port are in fully asynchronous mode, making the AHBMAX completely transparent in the access. The state machine selects the appropriate slave's hresp0, hready and hrdata to pass back to the master.

The first cycle error response and second cycle error response states are self explanatory. The AHBMAX will respond with an error response to the master if the master tries to access an unimplemented memory location through the AHBMAX (i.e. a slave port that does not exist).

10.5.3.5.2 Master Port State Machine Slave Swapping

The design of the master side state machine is fairly straight forward. The one real decision to be made is how to handle the master moving from one slave port access to another slave port access. The approach that was taken was to minimize or eliminate, when possible, any "bubbles" that would get inserted into the access due to switching slave ports.

The state machine will not allow the master to request access to another slave port until the current access being made is terminated. This prevents a single master from owning two slave ports at the same time (the slave port it is currently accessing and the slave port it wishes to access next).

The state machine also maintains watch on the slave port the master is accessing as well as the slave port the master wishes to switch to. If the new slave port is parked on the master then the master will be able to make the switch without incurring any delays. The termination of the current access will also act as the launch of the new access on the new slave port. If the new slave port is not parked on the master then the master will incur a minimum one clock delay before it can launch its access on the new slave port.

This is the same for switching from the busy or idle state to actively accessing a slave port. If the slave port is parked on the master the state machine will go to the steady state and the access will begin immediately. If the slave port is not parked on the master (serving another master, parked on another master or in low power park mode) then the state machine will transition to the stalled state and at least a one clock penalty will be paid.

10.5.4 Slave Port Functionality

10.5.4.1 Slave Port General Information

Each slave port consists of a register slice, a bank of muxes and a state machine.

The register slice contains the registers associated with the specific slave port. The registers have a quasi-IP bus interface at this level for reads and writes and the outputs feed directly into the state machine.

The muxes are a series of 6 to 1 multiplexers that take in all the address, control and write data information from each of the master ports and then pass the correct master's signals to the slave port. The state machine controls all the muxes.

The state machine is where the main slave port arbitration occurs, it decides which master is in control of the slave port and which master will be in control of the slave port in the next bus cycle.

For a block diagram of a slave port see Figure 10-3.

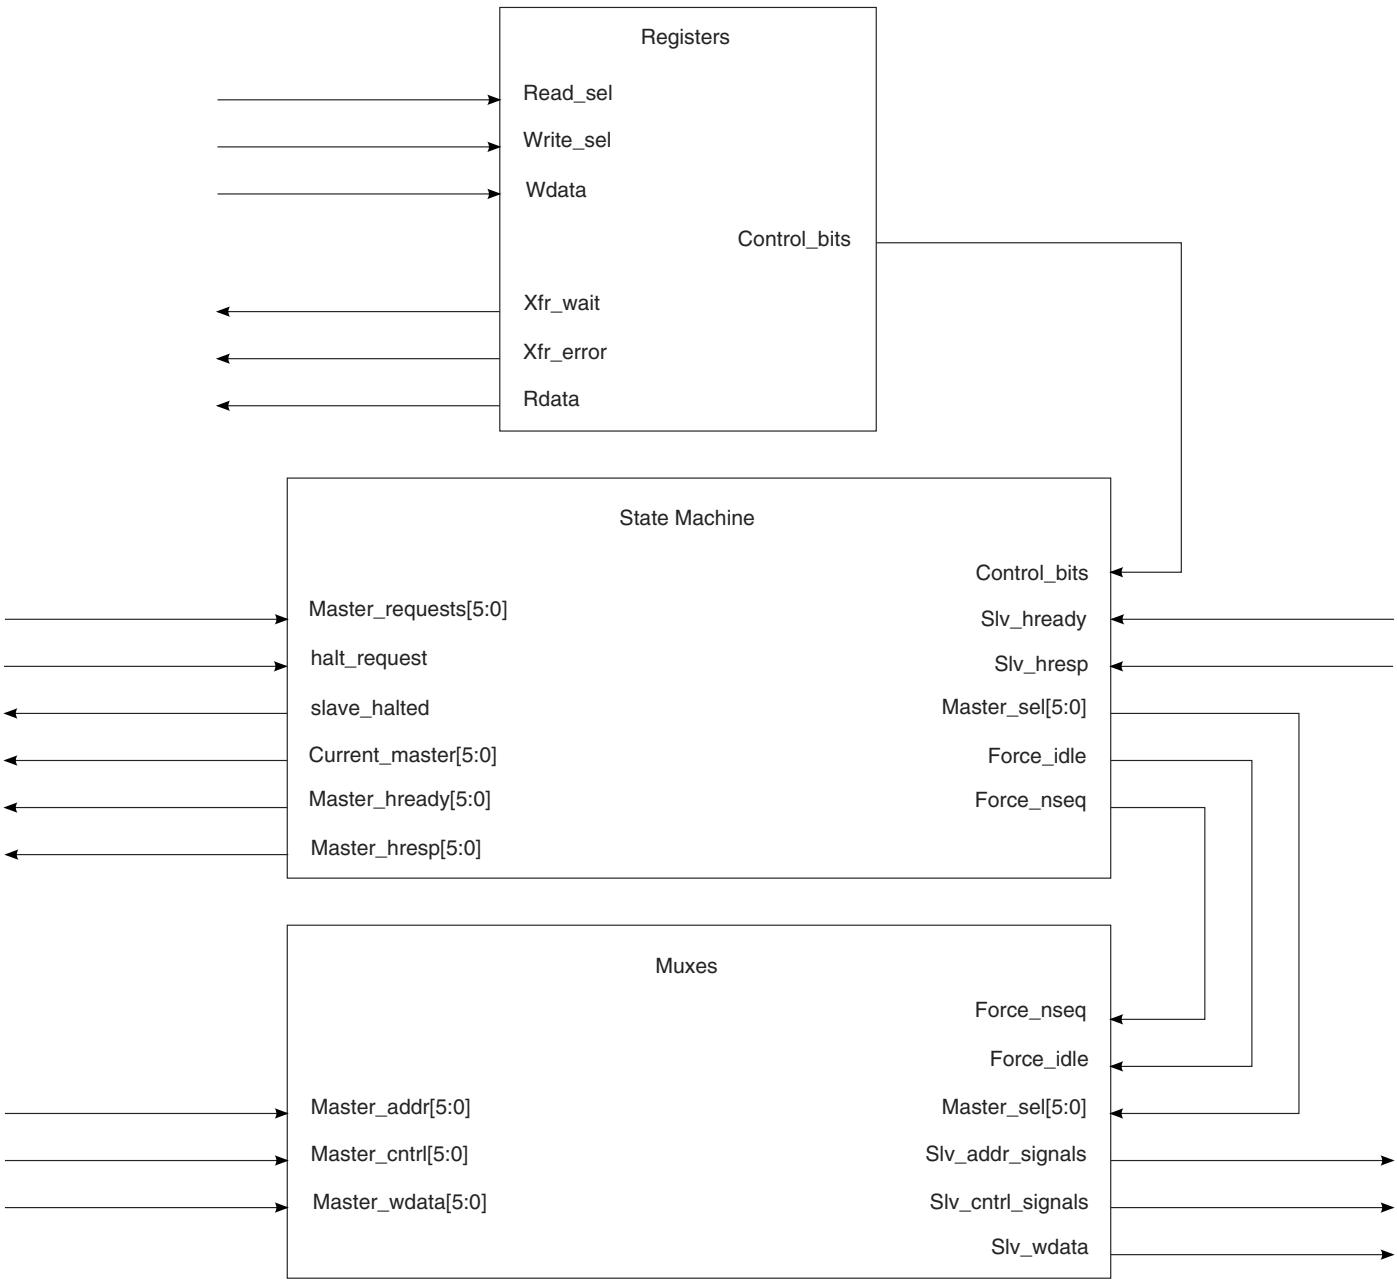

Figure 10-3. AHBMAX Slave Port Block Diagram

10.5.4.2 Slave Port Muxes

The block diagram (Figure 10-3) shows only one block for all the muxes. In reality that block instantiates many 6 to 1 muxes, one for each master-to-slave signal in fact. All the muxes are designed in an AND - OR fashion, so that if no master is selected the output of the muxes will be zero. (This is an important feature for low power park mode.)

The muxes also have an override signal which is used by the slave port to asynchronously force IDLE cycles onto the slave bus. When the state machine forces an IDLE cycle it zeros out htrans and hmastlock, making sure the slave bus sees a valid IDLE cycle being run by the AHBMAX.

The enable to the mux controlling htrans also contains an additional control signal from the state machine so that a NSEQ transaction can be forced. This is done any time the slave port switches masters to ensure that no IDLE-SEQ, BUSY-SEQ or NSEQ-SEQ transactions are seen on the slave port when they shouldn't be. If the state machine indicates to run both an IDLE and an NSEQ cycle, the IDLE directive will have priority.

NOTE

IDLE-SEQ is in fact an illegal access, but a possible scenario given the multi-master environment in the AHBMAX unless corrected by the AHBMAX.

10.5.4.3 Slave Port Registers

There is a register control block at the same level of the master port and slave port instantiations in the AHBMAX. This control block ensures that all accesses are 32-bit supervisor accesses before passing them on to the master and slave ports.

The registers in the slave port are only those registers associated with this particular slave port. The read and write interface for the registers is a quasi-IP bus interface. It is not a full IP bus interface at this level because not all the IP bus signals are routed this deep in the design.

The register outputs are connected directly to the slave state machine. The registers can be read from an unlimited number of times. The registers can only be written to as long as the RO bit is written to 0 in the AHBMAX_SGPCRn, once it is written to a 1 only a hardware reset will allow the registers to be written again.

10.5.4.4 Slave Port State Machine

10.5.4.4.1 Slave Port State Machine States

At the heart of the slave port is the state machine. The state machine is simplicity itself, requiring only four states - steady state, transition state, transition hold state and hold state. Either the slave port is owned by the same master it was in the last clock cycle (either by active use or by parking), it is transitioning to a new master (either for active use or parking), it is transitioning to a new master during wait states or it is being held on the same master pending a transition to a new master.

10.5.4.4.2 Slave Port State Machine Arbitration

The real work in the state machine is determining which master port will be in control of the slave port in the next clock cycle, the arbitration. Each master is programmed with a fixed 3 bit priority level. The AHBMAX uses these bits in determining priority levels when programmed for fixed priority mode of operation.

Arbitration always occurs on a clock edge, but only occurs on edges when a change in mastership will not violate AHB-Lite protocols. Valid arbitrations points include any clock cycle in which slave n hready is asserted (provide the master is not performing a burst or locked cycle) and any wait state in which the master owning the bus indicates a transfer type of IDLE (provided the master is not performing a locked cycle).

Since arbitration can occur on every clock cycle the slave port masks off all master requests if the current master is performing a locked transfer or a protected burst transfer, guaranteeing that no matter how low its priority level it will be allowed to finish its locked or protected portion of a burst sequence.

10.5.4.4.3 Slave Port State Machine Master Handoff

The only times the slave port will switch masters when programmed for fixed priority mode of operation is when a higher priority master makes a request or when the current master is the highest priority and it gives up the slave port by either running and IDLE cycle to the slave port or running a valid access to a location other than the slave port.

If the current master loses control of the slave port because a higher priority master takes it away the slave port will not incur any wasted cycles. The current master will get its current cycle terminated by the slave port at the same time the new master's address and control information will be recognized by the slave port. This will look like a seamless transition on the slave port.

If the current master is being wait stated when the higher priority master makes its request, then the current master will be allowed to make one more transaction on the slave bus before giving it up to the new master. Figure 10-4 illustrates the effect of a higher priority master taking control of the bus when the slave port is programmed for a fixed priority mode of operation.

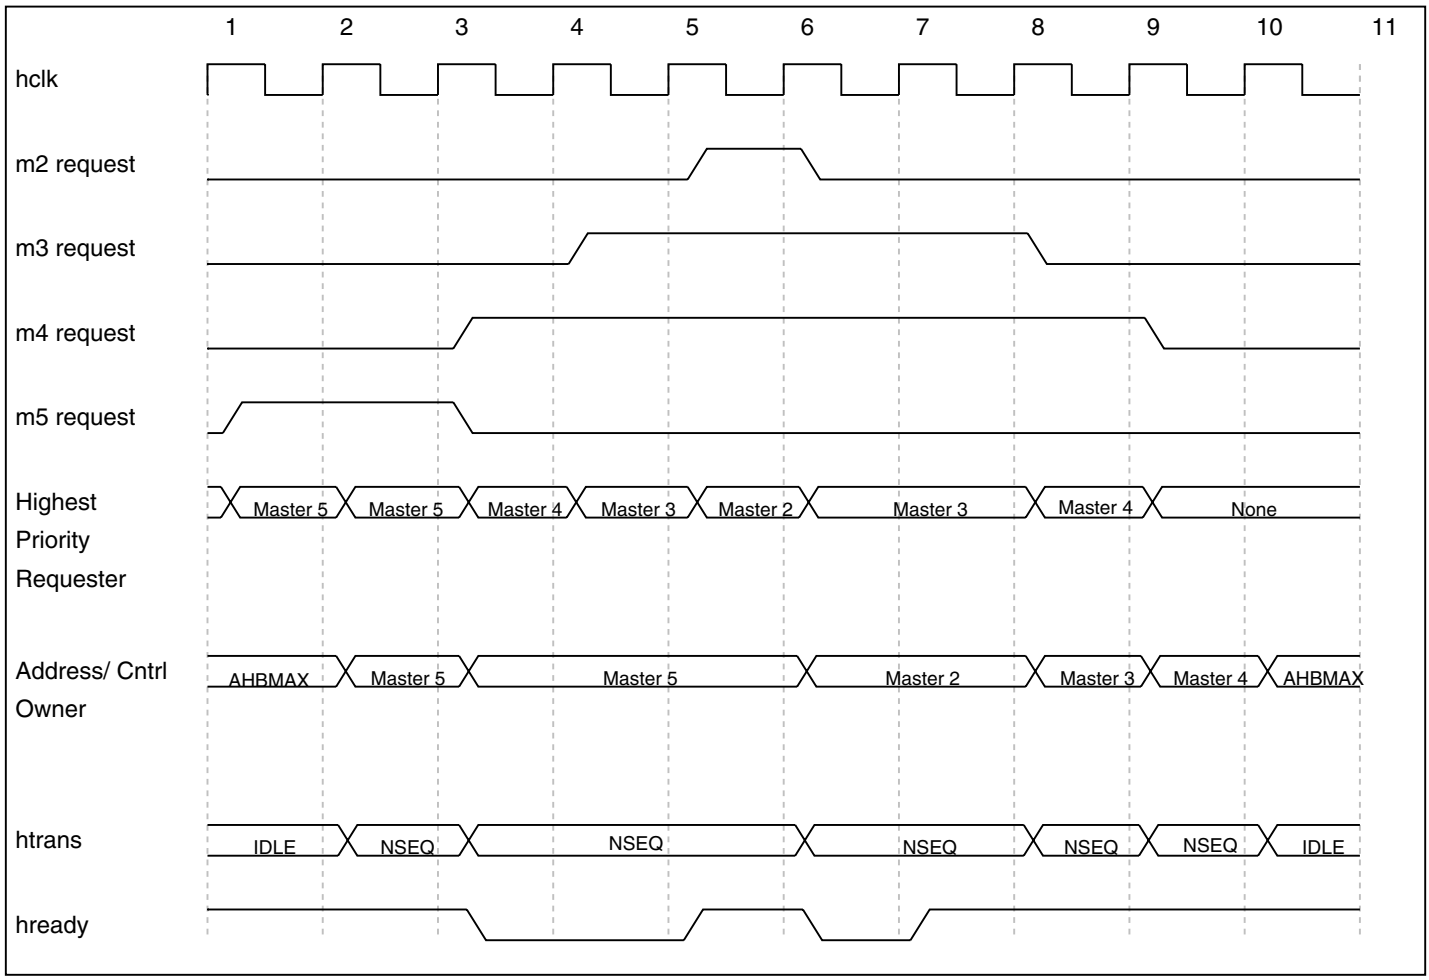

Figure 10-4. Low to High Priority Mastership Change

If the current master is the highest priority master and it gives up the slave port by running an IDLE cycle or by running a valid cycle to another location other than the slave port the next highest priority master will gain control of the slave port. If the current access incurs any wait states then the transition will be seamless and no bandwidth will be lost; however, if the current transaction is terminated without wait states then one IDLE cycle will be forced onto the slave bus by the AHBMAX before the new master will be able to take control of the slave port. If no other master is requesting the bus then IDLE cycles will be run by the AHBMAX but no bandwidth will truly be lost since no master is making a request.

Figure 10-5 illustrates the effect of a higher priority master giving up control of the bus.

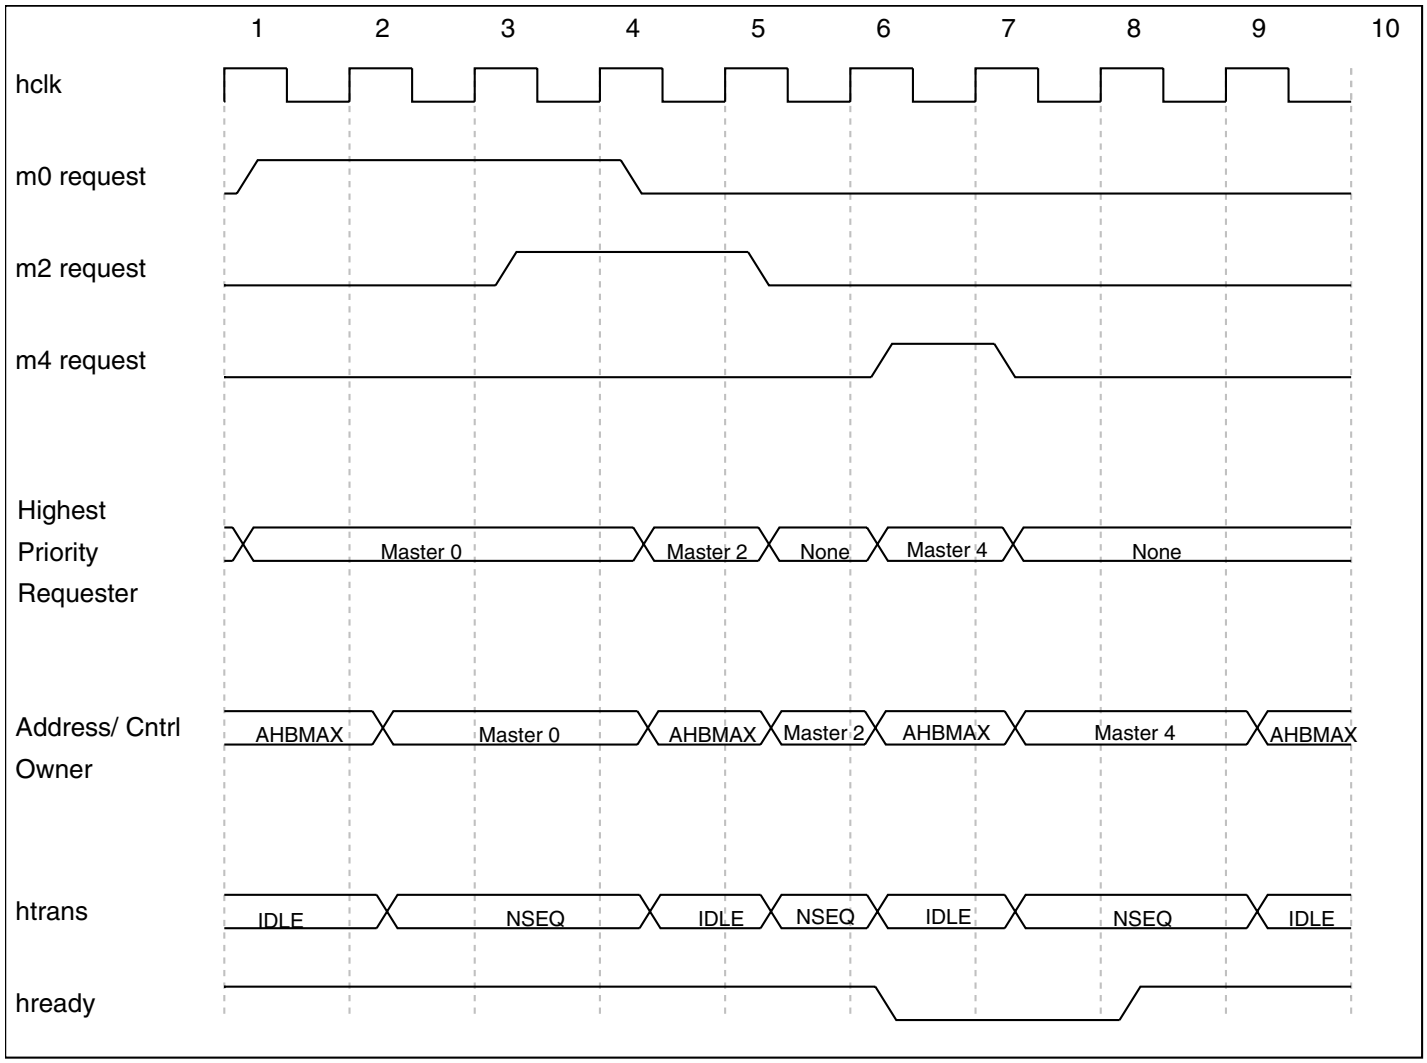

Figure 10-5. High to Low Priority Mastership Change

When the slave port is programmed for round-robin mode of arbitration then the slave port will switch masters any time there is more than one master actively making a request to the slave port. This will happen because any master other than the one which presently owns the bus will be considered to have higher priority.

Figure 10-6 shows an example of round-robin mode of operation.

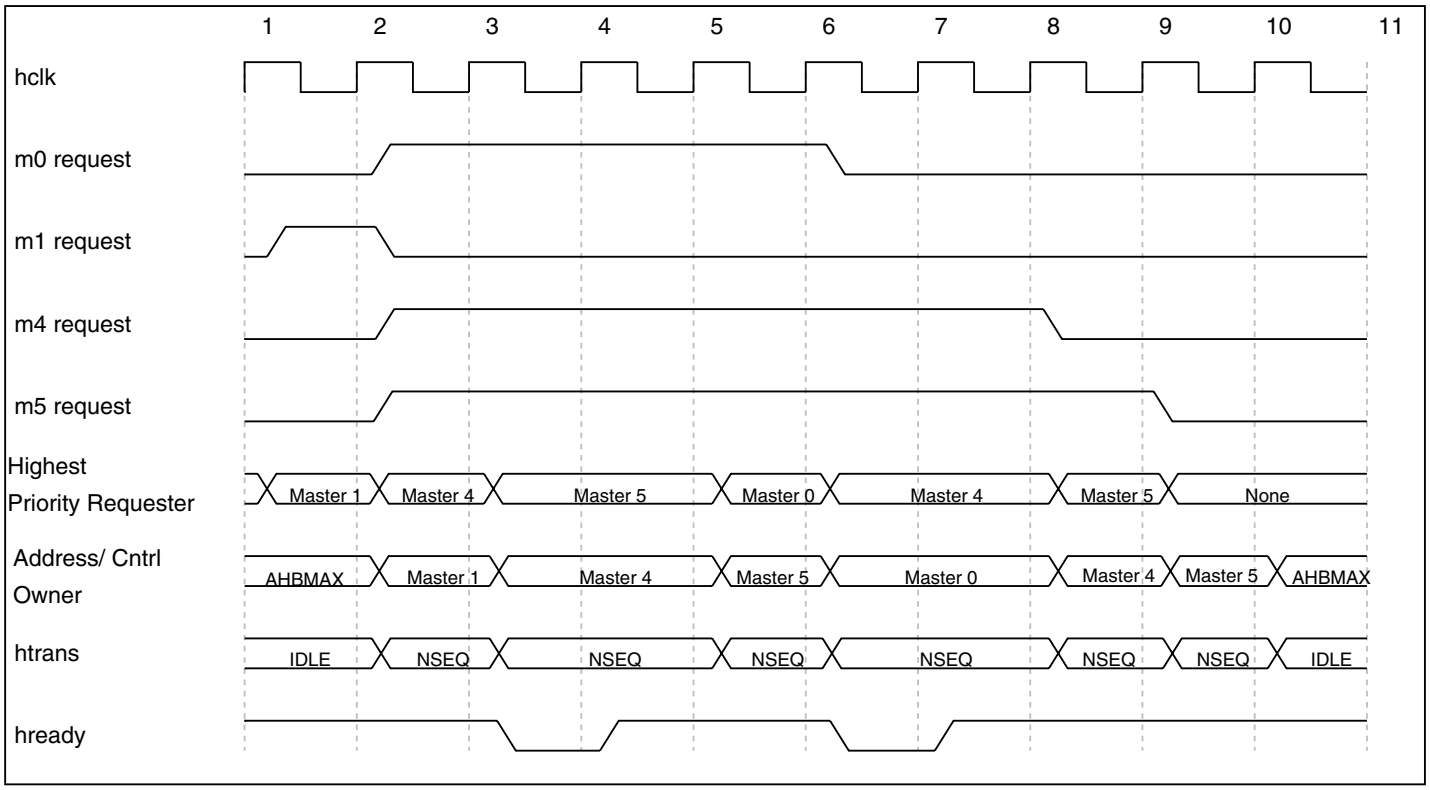

Figure 10-6. Round-robin Mastership Change

10.5.4.4.4 Slave Port State Machine Parking

If no master is currently making a request to the slave port then the slave port will be parked. It will park in one of four places, dictated by the PCTL and PARK bits in the AHBMAX_SGPCR and the locked state of the last master to access it.

If the last master to access the slave port ran a locked cycle and continues to run locked cycles even after leaving the slave port the slave port will park on that master without regard to the bit settings in the AHBMAX_SGPCR and without regard to pending requests from other masters. This is done so a master can run a locked transfer to the slave port, leave it, and return to it and be guaranteed that no other master has had access to it (provided the master maintains all transfers are locked transfers). If locking is not an issue for parking the AHBMAX_SGPCR bits will dictate the parking method.

If the PCTL bits are set for "low power park" mode then the slave port will enter low power park mode. It will not recognize any master as being in control of it and it will not select any master's signals to pass through to the slave bus. In this case all slave bus activity will effectively halt because all slave bus signals being driven from the AHBMAX will be 0. This of course can save quite a bit of power if the slave port will not

be in use for some time. The down side is that when a master does make a request to the slave port it will be delayed by one clock since it will have to arbitrate to acquire ownership of the slave port.

If the PCTL bits are set to "park on last" mode then the slave port will park on the last master to access it, passing all that masters signals through to the slave bus. The AHBMAX will asynchronously force htrans[1:0], hmaster[3:0], hburst[2:0] and hmastlock to 0 for all access that the master does not run to the slave port. When that master access the slave port again it will not pay any arbitration penalty; however, if any other master wishes to access the slave port a one clock arbitration penalty will be imposed.

If the PCTL bits are set to "use PARK" mode then the slave port will park on the master designated by the PARK bits. The behavior here is the same as for the "park on last" mode with the exception that a specific master will be parked on instead of the last master to access the slave port. If the master designated by the PARK bits tries to access the slave port it will not pay an arbitration penalty while any other master will pay a one clock penalty. Figure 10-7 illustrates parking on a specific master.

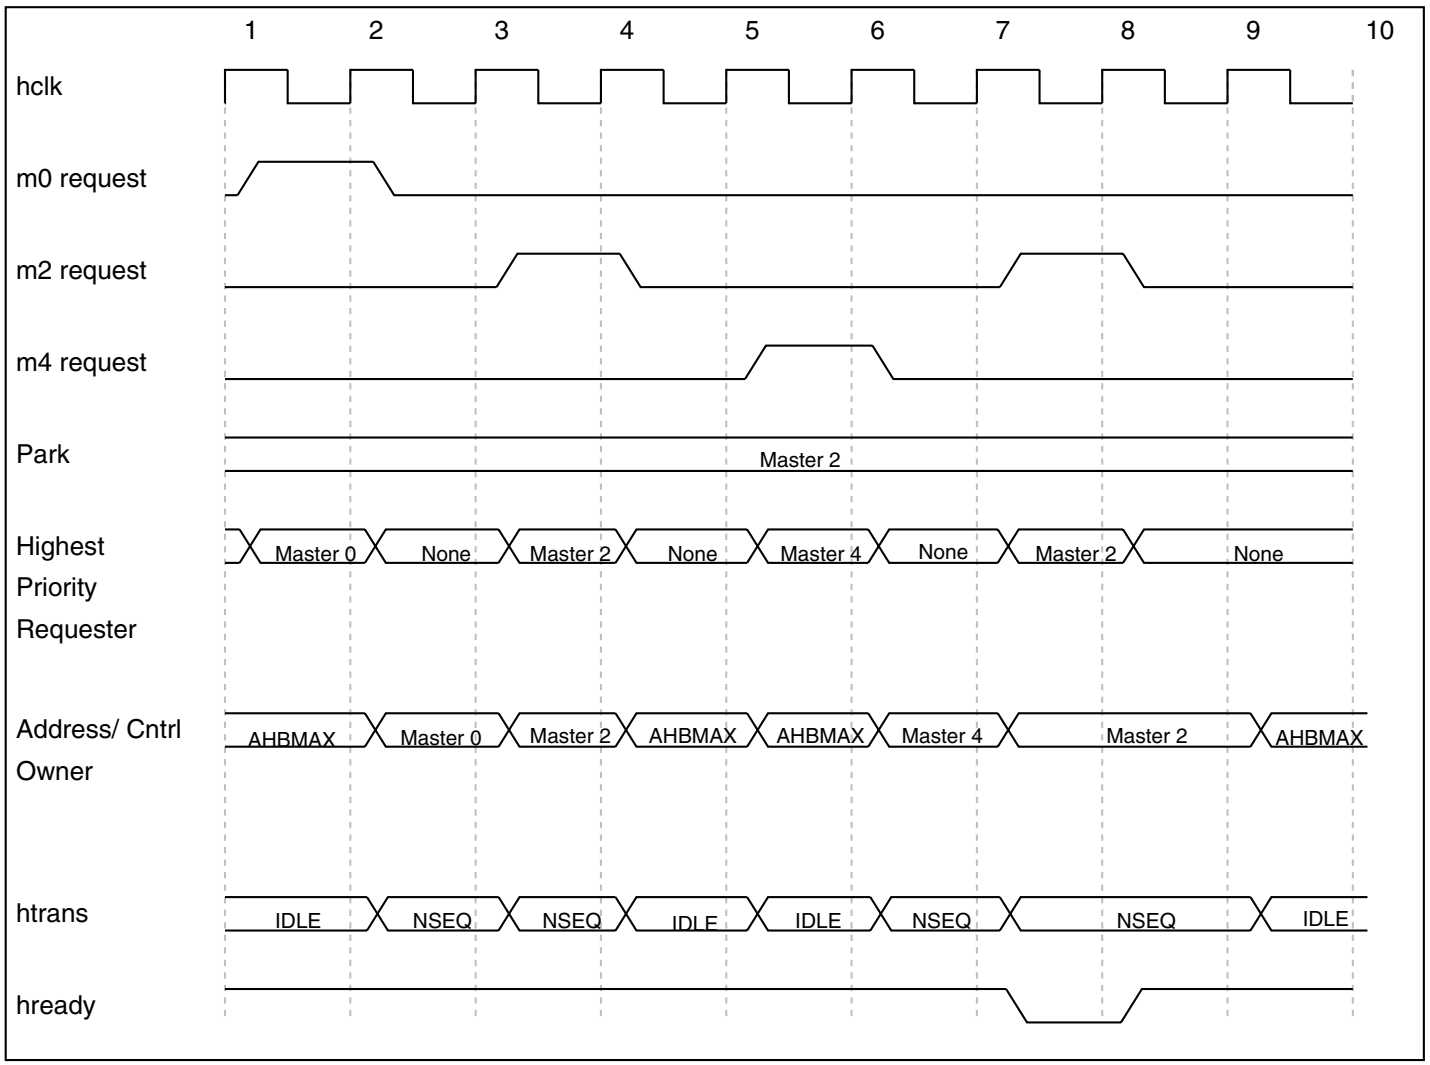

Figure 10-7. Parking on a Specific Master

Figure 10-8 illustrates parking on the last master. Note that in cycle 6 simultaneous requests are made by master 2 and master 4. Although master 2 has higher priority, the slave bus is parked on master 4 so master 4's access will be taken first. The slave port parks on master 2 once it has given control to master 2. This same situation can occur when parking on a specific master as well.

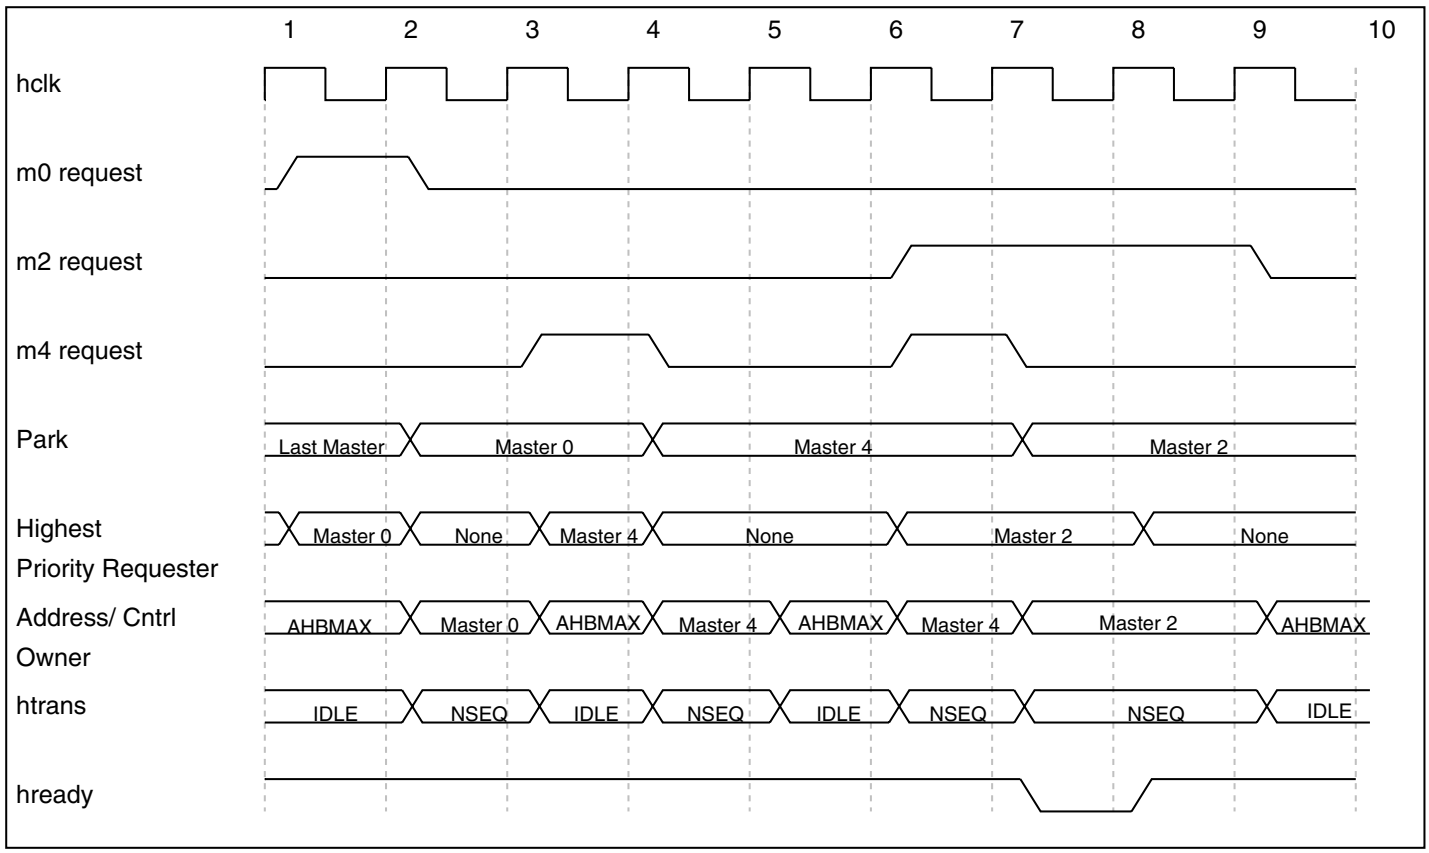

Figure 10-8. Parking on Last Master

10.5.4.4.5 Slave Port State Machine Halt Mode

If the max_halt_request input is asserted the slave port will eventually halt all slave bus activity and go into halt mode, which is almost identical to low power park mode. The HLP bit in the AHBMAX_SGPCR controls the priority level of the max_halt_request in the arbitration algorithm. If the HLP bit is cleared then the max_halt_request will have the highest priority of any master and will gain control of the slave port at the next arbitration point (most likely the next bus cycle, unless the current master is running a locked or fixed length burst transfer). If the HLP bit is set then the slave port will wait until no masters are actively making requests before moving to halt mode.

Regardless of the state of the HLP bit, once the slave port has gone into halt mode as a result of max_halt_request being asserted, it will remain in halt mode until max_halt_request is negated, regardless of the priority level of any masters that may make requests.

In halt mode no master is selected to own the slave port so all the outputs of the slave port are set to 0.

10.6 Initialization/Application Information

No initialization is required by or for the AHBMAX. Hardware reset ensures all the register bits used by the AHBMAX are properly initialized.

10.7 AHBMAX Interface

This section provides information on the AHBMAX interface.

10.7.1 AHBMAX Interface Overview

The main goal of the AHBMAX is to increase overall system performance by allowing multiple masters to communicate in parallel with multiple slaves. In order to maximize data throughput it is essential to keep arbitration delays to a minimum.

This section examines data throughput from the point of view of masters and slaves, detailing when the AHBMAX will stall the masters or insert bubbles on the slave side.

10.7.2 Master Ports-AHBMAX Interface

Master accesses will receive one of four responses from the AHBMAX. They will either be terminated, taken, stalled or responded to with an error.

10.7.2.1 Terminated Accesses

A master access will be terminated if the transfer type is IDLE. The AHBMAX will terminated the access and it will not be allowed to pass through the AHBMAX.

10.7.2.2 Taken Accesses

A master access will be taken if the transfer type is non IDLE and the slave port to which the access decodes is either currently servicing the master or is parked on the master. In this case the AHBMAX will be completely transparent and the master's access will be immediately seen on the slave bus and no arbitration delays will be incurred.

10.7.2.3 Stalled Accesses

A master access will be stalled if the transfer type is non IDLE and the access decodes to a slave port that is busy serving another master, parked on another master or is in low power park mode. The AHBMAX will indicate to the master that the address phase of the access has been taken but will then queue the access to the appropriate slave port to enter into arbitration for access to that slave port.

If the slave port is currently parked on another master or is in low power park mode and no other master is requesting access to the slave port then only one clock of arbitration will be incurred. If the slave port is currently serving another master of a lower priority and the master has a higher priority than all other requesting masters then the master will gain control over the slave port as soon as the data phase of the current access is completed (burst and locked transfers excluded). If the slave port is currently servicing another master of a higher priority then the master will gain control of the slave port once the other master releases control of the slave port if no other higher priority master is also waiting for the slave port.

10.7.2.4 Error Response Terminated Accesses

A master access will be responded to with an error if the transfer type is non IDLE and the access decodes to a location not occupied by a slave port.

10.7.3 Slave Ports-AHBMAX Interface

The goal of the AHBMAX with respect to the slave ports is to keep them 100% saturated when masters are actively making requests. In order to do this the AHBMAX must not insert any bubbles onto the slave bus unless absolutely necessary.

There is only one instance when the AHBMAX will force a bubble onto the slave bus when a master is actively making a request. This occurs when a higher priority master has control of the slave port and is running single clock (zero wait state) accesses while a lower priority master is stalled waiting for control of the slave port. When the higher priority master either leaves the slave port or runs an IDLE cycle to the slave port the AHBMAX will take control of the slave bus and run a single IDLE cycle before giving the slave port to the lower priority master that was waiting for control of the slave port.

The only other times the AHBMAX will have control of the slave port is when the AHBMAX is halting or when no masters are making access requests to the slave port and the AHBMAX is forced to either park the slave port on a specific master or put the slave port into low power park mode.

In most instances when the AHBMAX has control of the slave port it will indicate IDLE for the transfer type, negate all control signals and indicate ownership of the slave bus via the hmaster encoding of b0000. One exception to this rule is when a master running locked cycles has left the slave port but continues to run locked cycles. In this case the AHBMAX will control the slave port and will indicate IDLE for the transfer type but it will not affect any other signals.

NOTE

When a master runs a locked cycle through the AHBMAX, the master will be guaranteed ownership of all slave ports it accesses while running locked cycles for one cycle beyond when the master finishes running locked cycles.

10.8 Programmable Registers

There are four registers that reside in each slave port of the AHBMAX and one register that resides in each master port of the AHBMAX. These registers are IP bus compliant registers. Read and write transfers both require two IP bus clock cycles. The registers can only be read from and written to in supervisor mode. Additionally, these registers can only be read from or written to by 32-bit accesses.

The registers are fully decoded and an error response is returned if an unimplemented location is accessed within the AHBMAX.

The slave registers also feature a bit, which when written with a 1, will prevent the registers from being written to again. The registers will still be readable, but future write attempts will have no effect on the registers and will be terminated with an error response.

10.8.1 Master Priority Register for Slave port n (AHBMAX_MPR*n*)

The Master Priority Register (MPR) sets the priority of each master port on a per slave port basis and resides in each slave port.

The Master Priority Register can only be accessed in supervisor mode with 32-bit accesses. Once the RO (Read Only) bit has been set in the Slave General Purpose Control Register the Master Priority Register (MPR) can only be read from, attempts to write to it will have no effect on the MPR and result in an error response.

Additionally, no two available master ports may be programmed with the same priority level. Attempts to program two or more available masters with the same priority level will result in an error response and the MPR will not be updated.

Addresses: AHBMAX_MPR0 is 63F9_4000h base + 0h offset = 63F9_4000h
AHBMAX_MPR1 is 63F9_4000h base + 100h offset = 63F9_4100h

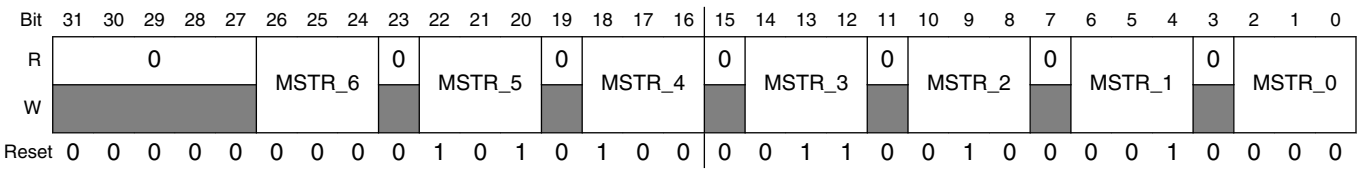
AHBMAX_MPR3 is 63F9_4000h base + 300h offset = 63F9_4300h



AHBMAX_MPR*n* field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved. They are read as zero and should be written with zero for upward compatibility.
26–24 MSTR_6	Master 6Priority. These bits set the arbitration priority for master port 6 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111 This master has the lowest priority when accessing the slave port.
23 Reserved	This read-only field is reserved and always has the value zero. Reserved. They are read as zero and should be written with zero for upward compatibility.
22–20 MSTR_5	Master 5 Priority. These bits set the arbitration priority for master port 5 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111 This master has the lowest priority when accessing the slave port.
19 Reserved	This read-only field is reserved and always has the value zero. Reserved. They are read as zero and should be written with zero for upward compatibility.
18–16 MSTR_4	Master 4 Priority. These bits set the arbitration priority for master port 4 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111 This master has the lowest priority when accessing the slave port.
15 Reserved	This read-only field is reserved and always has the value zero. Reserved. They are read as zero and should be written with zero for upward compatibility.
14–12 MSTR_3	Master 3 Priority. These bits set the arbitration priority for master port 3 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111 This master has the lowest priority when accessing the slave port.
11 Reserved	This read-only field is reserved and always has the value zero. Reserved. They are read as zero and should be written with zero for upward compatibility.

Field	Description
10–8 MSTR_2	Master 2 Priority. These bits set the arbitration priority for master port 2 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111 This master has the lowest priority when accessing the slave port.
7 Reserved	This read-only field is reserved and always has the value zero. Reserved. They are read as zero and should be written with zero for upward compatibility.
6–4 MSTR_1	Master 1 Priority. These bits set the arbitration priority for master port 1 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111 This master has the lowest priority when accessing the slave port.
3 Reserved	This read-only field is reserved and always has the value zero. Reserved. They are read as zero and should be written with zero for upward compatibility.
2–0 MSTR_0	Master 0 Priority. These bits set the arbitration priority for master port 0 on the associated slave port. These bits are initialized by hardware reset. 000 This master has the highest priority when accessing the slave port. 111 This master has the lowest priority when accessing the slave port.

10.8.2 General Purpose Control Register for Slave port n (AHBMAX_SGPCR*n*)

The Slave General Purpose Control Register (AHBMAX_SGPCR*n*) controls several features of each slave port.

The Read Only (RO) bit will prevent any registers associated with this slave port from being written to once set. This bit may be written with 0 as many times as the user desires, but once it is written to a 1 only a reset condition will allow it to be written again.

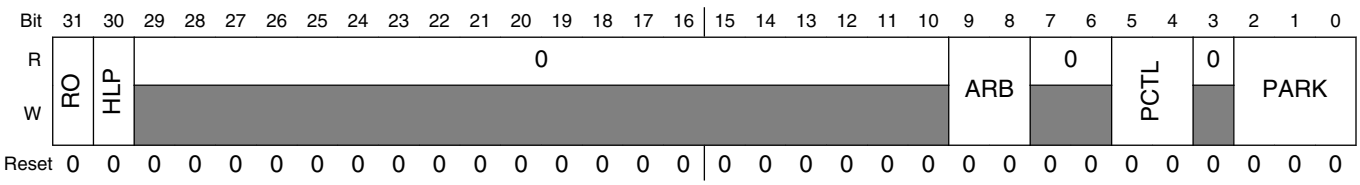
The Halt Low Priority (HLP) bit will set the priority of the max_halt_request input to the lowest possible priority for initial arbitration of the slave ports. By default it is the highest priority. Please note, setting this bit will not effect the max_halt_request from attaining highest priority once it has control of the slave ports.

The PCTL bits determine how the slave port will park when no master is actively making a request. The available options are to park on the master defined by the PARK bits, park on the last master to use the slave port, or go into a low power park mode which will force all the outputs of the slave port to inactive states when no master is requesting an access. The low power park feature can result in an overall power savings if a the slave port is not saturated; however, it will force an extra clock of latency whenever any master tries to access it when it is not in use because it will not be parked on any master.

The PARK bits determine which master the slave will park on when no master is making an active request and the max_halt_request input is negated. Please use caution to only select master ports that are actually present in the design. If the user programs the PARK bits to a master not present in the current design implementation undefined behavior will result.

The AHBMAX_SGPCR*n* can only be accessed in supervisor mode with 32-bit accesses. Once the RO (Read Only) bit has been set in the AHBMAX_SGPCR*n* the AHBMAX_SGPCR*n* can only be read, attempts to write to it will have no effect on the AHBMAX_SGPCR*n* and result in an error response.

Addresses: AHBMAX_SGPCR0 is 63F9_4000h base + 10h offset = 63F9_4010h
AHBMAX_SGPCR1 is 63F9_4000h base + 110h offset = 63F9_4110h
AHBMAX_SGPCR2 is 63F9_4000h base + 210h offset = 63F9_4210h
AHBMAX_SGPCR3 is 63F9_4000h base + 310h offset = 63F9_4310h



AHBMAX_SGPCR*n* field descriptions

Field	Description
31 RO	Read Only. This bit is used to force all of a slave port's registers to be read only. Once written to 1 it can only be cleared by hardware reset. This bit is initialized by hardware reset. 0 All this slave port's registers can be written. 1 All this slave port's registers are read only and cannot be written (attempted writes have no effect and result in an error response).
30 HLP	Halt Low Priority. This bit is used to set the initial arbitration priority of the max_halt_request input. This bit is initialized by hardware reset. 0 The max_halt_request input has the highest priority for arbitration on this slave port 1 The max_halt_request input has the lowest initial priority for arbitration on this slave port.
29–10 Reserved	This read-only field is reserved and always has the value zero. Reserved. They read as zero and should be written with zero for upward compatibility.
9–8 ARB	Arbitration Mode. These bits are used to select the arbitration policy for the slave port. These bits are initialized by hardware reset. 00 Fixed Priority. 01 Round Robin (rotating) Priority. 10 Reserved 11 Reserved
7–6 Reserved	This read-only field is reserved and always has the value zero. Reserved. They read as zero and should be written with zero for upward compatibility.

10.8.3 General Purpose Control Register for Master port n (AHBMAX_MGPCR*n*)

The Master General Purpose Control Register (AHBMAX_MGPCR*n*) presently controls only whether or not the master's undefined length burst accesses will be allowed to complete uninterrupted or whether they can be broken by requests from higher priority masters.

The AULB (Arbitrate on Undefined Length Bursts) bit field determines whether (and when) or not the AHBMAX will arbitrate away the slave port the master owns when the master is performing undefined length burst accesses.

The AHBMAX_MGPCR*n* can only be accessed in supervisor mode with 32-bit accesses.

Addresses: AHBMAX_MGPCR0 is 63F9_4000h base + 800h offset = 63F9_4800h

Chapter 11
AHB-to-APBH Bridge with DMA (APBH-Bridge-DMA)

11.1 Overview

The AHB-to-APBH bridge provides the i.MX50 with an inexpensive peripheral attachment bus running on the AHB's HCLK.

(The H in APBH denotes that the APB*H* is synchronous to HCLK, as compared to APB*X*, which runs on the crystal-derived XCLK.)

As shown in the figure below, the AHB-to-APBH bridge includes the AHB-to-APB PIO bridge for a memory-mapped I/O to the APB devices, as well as a central DMA facility for devices on this bus and a vectored interrupt controller for the ARM Cortex-A8 core. Each one of the APB peripherals, including the vectored interrupt controller, is documented in their respective chapters.

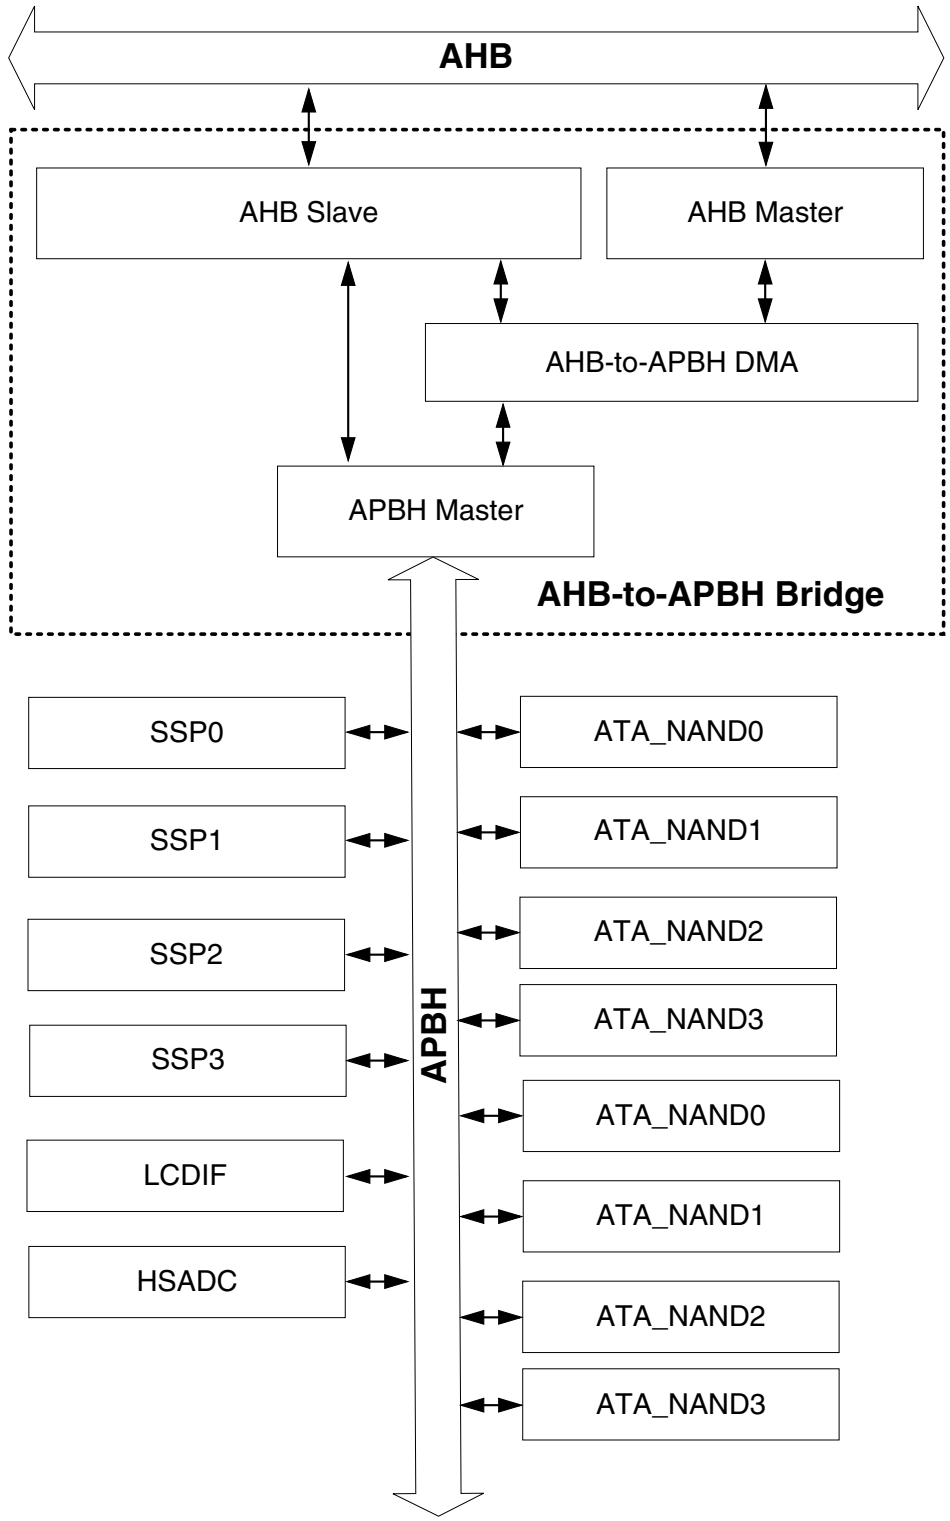

Figure 11-1. AHB-to-APBH Bridge DMA Block Diagram

The DMA controller uses the APBH bus to transfer read and write data to and from each peripheral. There is no separate DMA bus for these devices. Contention between the DMA's use of the APBH bus and the AHB-to-APB bridge functions' use of the APBH is mediated by an internal arbitration logic. For contention between these two units, the

DMA is favored and the AHB slave will report "not ready" through its HREADY output until the bridge transfer can complete. The arbiter tracks repeated lockouts and inverts the priority, guaranteeing the ARM platform every fourth transfer on the APB.

11.2 APBH DMA

The DMA supports sixteen channels of DMA services, as shown in the following table. The shared DMA resource allows each independent channel to follow a simple chained command list.

Command chains are built up using the general structure, as shown in Figure 11-2.

Table 11-1. APBH DMA Channel Assignments

A single command structure or channel command word specifies a number of operations to be performed by the DMA in support of a given device. Thus, the ARM platform can set up large units of work, chaining together many DMA channel command words, pass them off to the DMA, and have no further concern for the device until the DMA completion interrupt occurs. The goal is to have enough intelligence in the DMA and the devices to keep the interrupt frequency from any device below 1 KHz (arrival intervals longer than 1 ms).

A single command structure can issue 32-bit PIO write operations to key registers in the associated device using the same APB bus and the controls, it uses to write DMA data bytes to the device. For example, this allows a chain of operations to be issued to the GPMI controller to send NAND command bytes, address bytes, and data transfers where the command and the address structure is completely under software control, but the administration of that transfer is handled autonomously by the DMA. Each DMA structure can have 0–15 PIO words appended to it. The #PIOWORDs field, if non-zero, instructs the DMA engine to copy these words to the APB, beginning at PADDR = 0x0000 and incrementing its PADDR for each cycle.

The DMA master generates only normal read/write transfers to the APBH. It does *not* generate set, clear, or toggle (SCT) transfers.

After any requested PIO words have been transferred to the peripheral, the DMA examines the two-bit command field in the channel command structure. Table 11-2 shows the four commands implemented by the DMA.

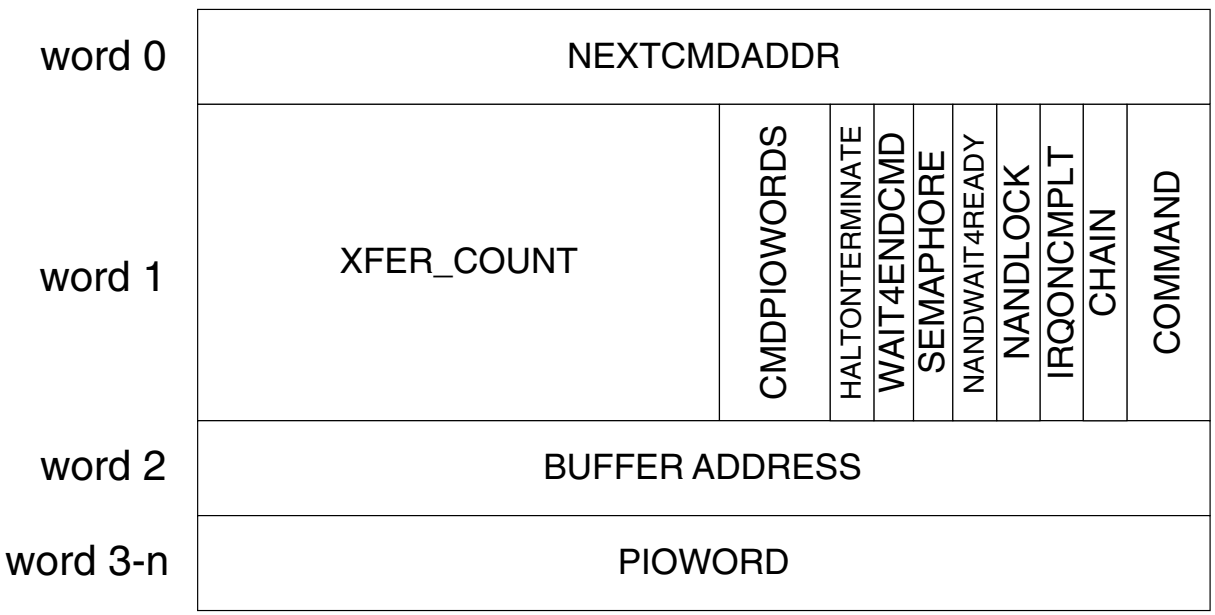

Figure 11-2. AHB-to-APBH Bridge DMA Channel Command Structure

Table 11-2. APBH DMA Commands

DMA COMMAND	USAGE
00	NO_DMA_XFER. Perform any requested PIO word transfers, but terminate the command before any DMA transfer.
01	DMA_WRITE. Perform any requested PIO word transfers, then perform a DMA transfer from the peripheral for the specified number of bytes.
10	DMA_READ. Perform any requested PIO word transfers and then perform a DMA transfer to the peripheral for the specified number of bytes.

Table continues on the next page...

Table 11-2. APBH DMA Commands (continued)

DMA COMMAND	USAGE
11	DMA_SENSE. Perform any requested PIO word transfers, then perform a conditional branch to the next chained device. Follow the NEXTCMD_ADDR pointer if the peripheral sense is false. Follow the BUFFER_ADDRESS as a chain pointer if the peripheral sense line is true. This command becomes a no-operation for any channel other than a GPMI channel.

DMA_WRITE operations copy data bytes to the system memory (on-chip RAM or SDRAM) from the associated peripheral. Each peripheral has a target PADDR value that it expects to receive DMA bytes. This association is synthesized in the DMA. The DMA_WRITE transfer uses the BUFFER_ADDRESS word in the command structure to point to the beginning byte to write data from the peripheral.

DMA_READ operations copy data bytes to the APB peripheral from the system memory. The DMA engine contains a shared byte aligner that aligns bytes from system memory to or from the peripherals. Peripherals always assume little-endian-aligned data arrives or departs on their 32-bit APB. The DMA_READ transfer uses the BUFFER_ADDRESS word in the command structure to point to the DMA data buffer to be read by the DMA_READ command.

The NO_DMA_XFER command is used to write PIO words to a device without performing any DMA data byte transfers. This command is useful in such applications as activating the NAND devices CHECKSTATUS operation. The check status command in the NAND peripheral reads a status byte from the NAND device, performs an XOR and MASK against an expected value supplied as part of the PIO transfer. Once the read check completes (see NAND Read Status Polling Example),the NO_DMA_XFER command completes. The result in the peripheral is that its PSENSE line is driven by the results of the comparison. The sense flip-flop is only updated by CHECKSTATUS for the device that is executed. At some future point, the chain contains a DMA command structure with the fourth and final command value, that is, the DMA_SENSE command.

As each DMA command completes, it triggers the DMA to load the next DMA command structure in the chain. The normal flow list of DMA commands is found by following the NEXTCMD_ADDR pointer in the DMA command structure. The DMA_SENSE command uses the DMA buffer pointer word of the command structure to point to an alternate DMA command structure chain or list. The DMA_SENSE command examines the sense line of the associated peripheral. If the sense line is false, then the DMA follows the standard list found whose next command is found from the pointer in the NEXTCMD_ADDR word of the command structure. If the sense line is true, then the DMA follows the alternate list whose next command is found from the pointer in the DMA Buffer Pointer word of the DMA_SENSE command structure (see Figure 11-2). The sense command ignores the CHAIN bit, so that both pointers must be valid when the DMA comes to a sense command.

If the wait-for-end-command bit (WAIT4ENDCMD) is set in a command structure, then the DMA channel waits for the device to signal completion of a command by toggling the endcmcd signal before proceeding to load and execute the next command structure. Then, if DECREMENT_SEMAPHORE is set, the semaphore will be decremented after the end command is seen.

A detailed bit-field view of the DMA command structure is shown in the following table, which shows a field that specifies the number of bytes to be transferred by this DMA command. The transfer-count mechanism is duplicated in the associated peripheral, either as an implied or as a specified count in the peripheral.

Table 11-3. DMA Channel Command Word in System Memory

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	09	08	07	06	05	04	03	02	01	00
NEXT_COMMAND_ADDRESS																															
Number DMA Bytes to Transfer																Number PIO Words to Write						HALTONTERMINATE	WAIT4ENDCMD	DECREMENT SEMAPHORE	NANDwAIT4READY	NANDLOCK	IRQ_COMPLETE	CHAIN	COMMAND		
DMA Buffer or Alternate CCW																															
Zero or More PIO Words to Write to the Associated Peripheral Starting at its Base Address on the APBH Bus																															

Figure 11-2 also shows the CHAIN bit in bit 2 of the second word of the command structure. This bit is set to 1, if the NEXT_COMMAND_ADDRESS contains a pointer to another DMA command structure. If a null pointer (0) is loaded into the NEXT_COMMAND_ADDRESS, it is not detected by the DMA hardware. Only the CHAIN bit indicates whether a valid list exists beyond the current structure.

If the IRQ_COMPLETE bit is set in the command structure, then the last act of the DMA before loading the next command is to set the interrupt-status bit corresponding to the current channel. The sticky interrupt request bit in the DMA CSR remains set until cleared by the software. It can be used to interrupt the ARM platform.

The NAND_LOCK bit is monitored by the DMA channel arbiter. After a NAND channel (from channel 4 to channel 11) succeeds in the arbiter with its NAND_LOCK bit set, then the arbiter ignores the other seven NAND channels until a command is completed in which the NAND_LOCK is not set. Notice that the semantic here is that the NAND_LOCK state is to limit scheduling of a non-locked DMA. A DMA channel can go from unlocked to locked in the arbiter at the beginning of a command when the

NAND_LOCK bit is set. When the last DMA command of an atomic sequence is completed, the lock should be removed. To accomplish this, the last command does not have the NAND_LOCK bit. It is still locked in the atomic state within the arbiter when the command starts, so that it is the only NAND command that can be executed. At the end, it drops from the atomic state within the arbiter.

The NAND_WAIT4READY bit also has a special use for DMA channels (from channel 4 to channel 11), i.e., the NAND device channels. The NAND device supplies a sample of the ready line for the NAND device. This ready value is used to hold off of a command with this bit set until the ready line is asserted to 1. Once the arbiter sees a command with a wait-for-ready set, it holds off that channel until ready is asserted.

Receiving an IRQ for HALTONTERMINATE (HOT) is a new feature in the APBH DMA descriptor that allows GPMI (as well as SSP and I2C) to signal to the DMA engine that an error has occurred. In prior chips, if a block is stalled due to an error, the only practical way to discover this in software was through a timer of some sort, or to poll the block. Now, an HOT signal is sent from the peripheral to the DMA engine and causes an IRQ after terminating the DMA descriptor being executed. Note not all peripheral block support this termination feature.

Therefore, it is recommended that software use this signal as follows:

- Always set HALTONTERMINATE to 1 in a DMA descriptor. That way, if a peripheral signals HOT, the transfer will end, leaving the peripheral block and the DMA engine synchronized (but at the end of a command).
- When an IRQ from an APBH channel is received, and the IRQ is determined to be due to an error (as opposed to an IRQONCOMPLETE interrupt) the software should:
    - Reset the channel.
    - Determine the error from error reporting in the peripheral block, then manage the error in the peripheral that is attached to that channel in whatever appropriate way exists for that device (software recovery, device reset, block reset, etc).

Each channel has an eight-bit counting semaphore that controls whether it is in the run or idle state. When the semaphore is non-zero, the channel is ready to run, process commands and perform DMA transfers. Whenever a command finishes its DMA transfer, it checks the DECREMENT_SEMAPHORE bit. If set, it decrements the counting semaphore. If the semaphore goes to 0 as a result, then the channel enters the IDLE state and remains there until the semaphore is incremented by the software. When the semaphore goes to non-zero and the channel is in its IDLE state, then it uses the value in the APBH_CHn_NXTCMDAR register (next command address register) to fetch a

pointer to the next command to process. NOTE: This is a double indirect case. This method allows the software to append to a running command list under the protection of the counting semaphore.

To start processing the first time, software creates the command list to be processed. It writes the address of the first command into the APBH_CHn_NXTCMDAR register, and then writes 1 to the counting semaphore in APBH_CHn_SEMA. The DMA channel loads APBH_CHn_CURCMDAR register and then enters the normal state machine processing for the next command. When the software writes a value to the counting semaphore, it is added to the semaphore count by hardware, protecting the case where both hardware and software are trying to change the semaphore on the same clock edge.

Software can examine the value of APBH_CHn_CURCMDAR at any time to determine the location of the command structure currently being processed.

11.3 NAND Read Status Polling Example

The following figure shows a more complicated scenario. This subset of a NAND device workload shows that the first two command structures are used during the data-write phase of an NAND device write operation (CLE and ALE transfers omitted for clarity).

- After writing the data, one must wait until the NAND device status register indicates that the write charge has been transferred. This is built into the workload using a check status command in the NAND in a loop created from the next two DMA command structures.
- The NO_DMA_TRANSFER command is shown here performing the read check, followed by a DMA_SENSE command to branch the DMA command structure list, based on the status of a bit in the external NAND device.

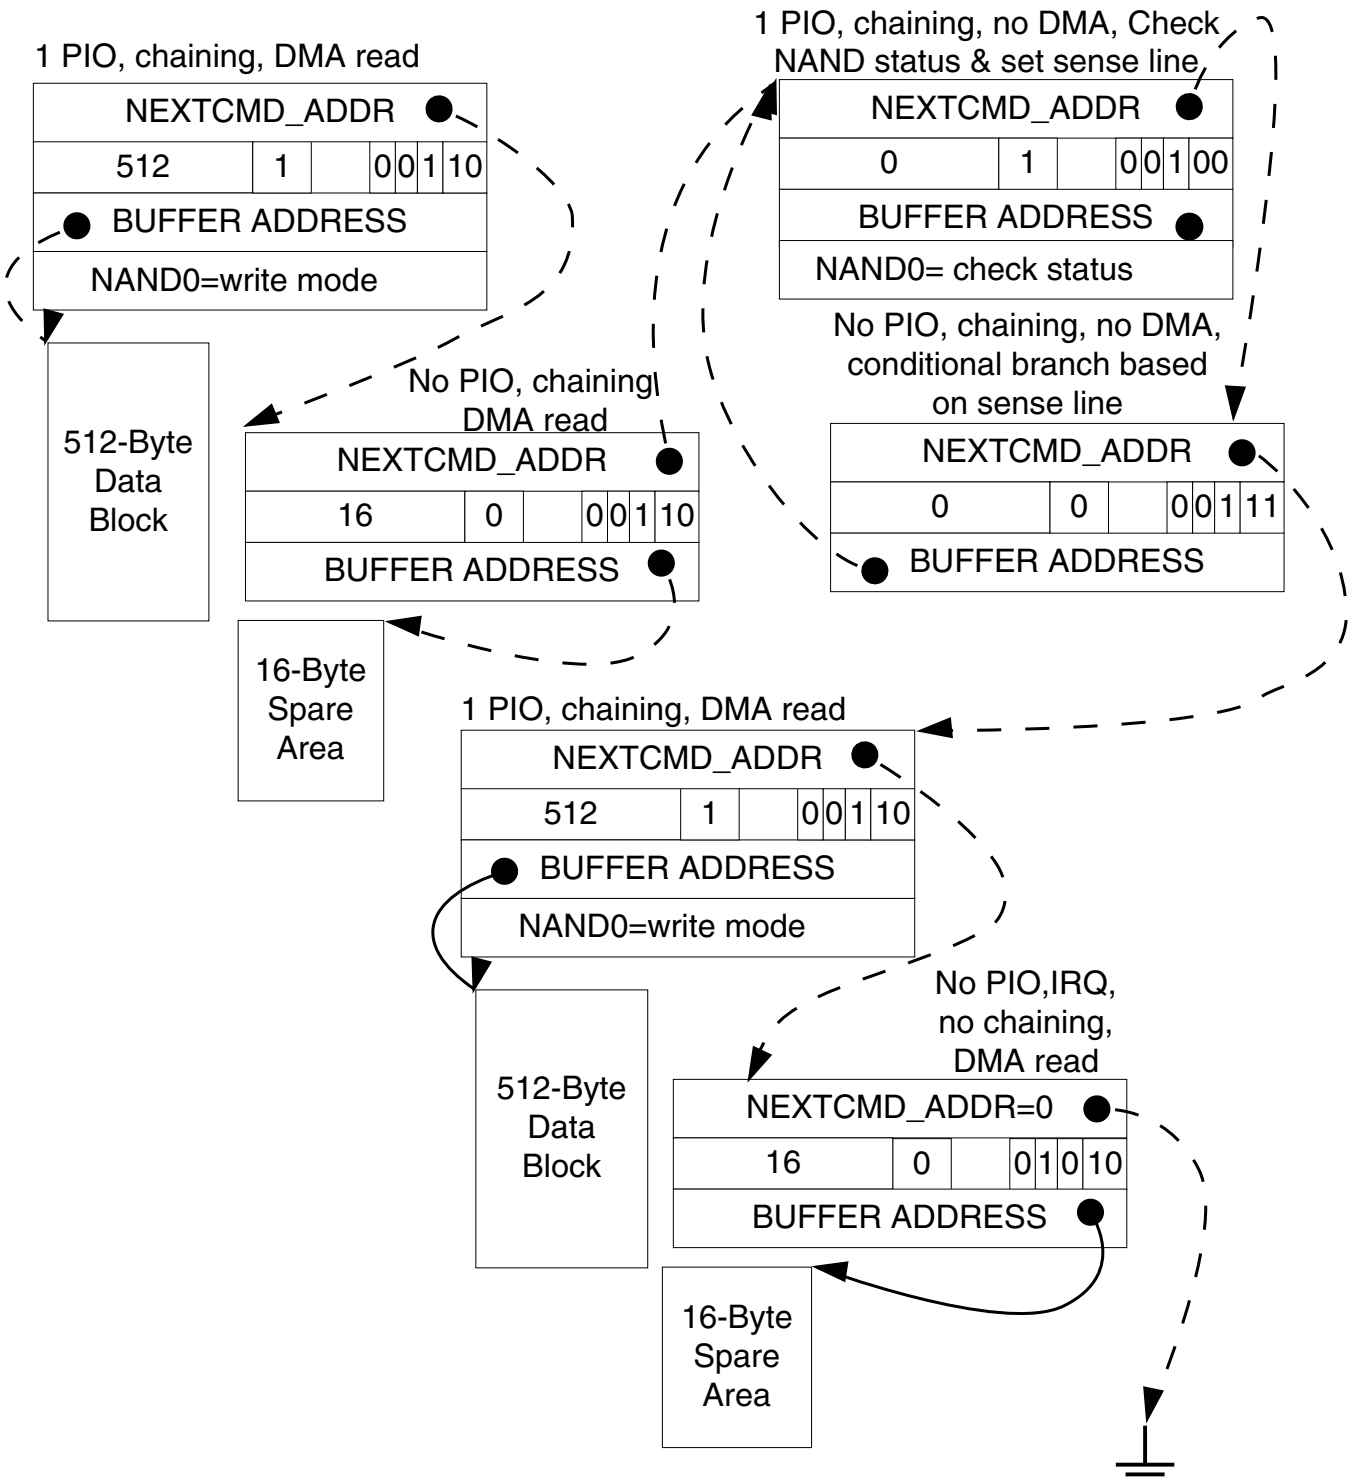

Figure 11-3. AHB-to-APBH Bridge DMA NAND Read Status Polling with DMA Sense Command

The example in the above figure shows the workload continuing immediately to the next NAND page transfer. However, one could perform a second sense operation to see if an error has occurred after the write. One could then point the sense command alternate branch at a NO_DMA_XFER command with the interrupt bit set. If the CHAIN bit is not

set on this failure branch, then the ARM platform is interrupted immediately, and the channel process is also immediately terminated in the presence of a workload-detected NAND error bit.

Note that each word of the three-word DMA command structure corresponds to a PIO register of the DMA that is accessible on the APBH bus. Normally, the DMA copies the next command structure onto these registers for processing at the start of each command by following the value of the pointer previously loaded into the NEXTCMD_ADDR register.

To start DMA processing for the first command, initialize the PIO registers of the desired channel, as follows:

- First, load the next command address register with a pointer to the first command to be loaded.
- Then, write 1 to the counting semaphore register. This causes the DMA to schedule the targeted channel for the DMA command structure load, as if it just finished its previous command.

11.4 Programmable Registers

APBH Hardware Register Format Summary

11.4.1 AHB to APBH Bridge Control and Status Register 0 (APBH_CTRL0*n*)

The APBH CTRL 0 provides overall control of the AHB to APBH bridge and DMA.

This register contains module softreset, clock gating, channel clock gating/freeze bits.

Addresses: APBH_CTRL0 is 4100_0000h base + 0h offset = 4100_0000h

APBH_CTRL0_SET is 4100_0000h base + 4h offset = 4100_0004h

APBH_CTRL0_CLR is 4100_0000h base + 8h offset = 4100_0008h

APBH_CTRL0_TOG is 4100_0000h base + Ch offset = 4100_000Ch

APBH_CTRL0*n* field descriptions

Field	Description
31 SFTRST	Set this bit to zero to enable normal APBH DMA operation. Set this bit to one (default) to disable clocking with the APBH DMA and hold it in its reset (lowest power) state. This bit can be turned on and then off to reset the APBH DMA block to its default state.
30 CLKGATE	This bit must be set to zero for normal operation. When set to one it gates off the clocks to the block.
29 AHB_BURST8_EN	Set this bit to one (default) to enable AHB 8-beat burst. Set to zero to disable 8-beat burst on AHB interface.
28 APB_BURST_EN	Set this bit to one to enable apb master do a continous transfers when a device request a burst dma. Set to zero will treat a burst dma request as 4/8 individual requests.
27–16 RSVD0	Reserved, always set to zero.
15–0 CLKGATE_CHANNEL	These bits must be set to zero for normal operation of each channel. When set to one they gate off the individual clocks to the channels. 0x0001 **NAND0** — 0x0002 **NAND1** — 0x0004 **NAND2** — 0x0008 **NAND3** — 0x0010 **NAND4** — 0x0020 **NAND5** — 0x0040 **NAND6** — 0x0080 **NAND7** — 0x0100 **SSP** —

11.4.2 AHB to APBH Bridge Control and Status Register 1 (APBH_CTRL1*n*)

The APBH CTRL one provides overall control of the interrupts generated by the AHB to APBH DMA. This register contains the per channel interrupt status bits and the per channel interrupt enable bits. Each channel has a dedicated interrupt vector in the vectored interrupt controller.

EXAMPLE

```
                    BF_WR(APBH_CTRL1, CH5_CMDCMPLT_IRQ, 0);  // use bitfield write macro
                    BF_APBH_CTRL1.CH5_CMDCMPLT_IRQ = 0;      // or, assign to register
struct's bitfield
```

Addresses: APBH_CTRL1 is 4100_0000h base + 10h offset = 4100_0010h

APBH_CTRL1_SET is 4100_0000h base + 14h offset = 4100_0014h

APBH_CTRL1_CLR is 4100_0000h base + 18h offset = 4100_0018h

APBH_CTRL1_TOG is 4100_0000h base + 1Ch offset = 4100_001Ch

Field	Description
1 CH1_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA channel 1. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.
0 CH0_ CMDCMPLT_ IRQ	Interrupt request status bit for APBH DMA channel 0. This sticky bit is set by DMA hardware and reset by software. It is ANDed with its corresponding enable bit to generate an interrupt.

11.4.3 AHB to APBH Bridge Control and Status Register 2 (APBH_CTRL2*n*)

The APBH CTRL 2 provides channel error interrupts generated by the AHB to APBH DMA. This register contains the per channel interrupt status bits and the per channel interrupt enable bits. Each channel has a dedicated interrupt vector in the vectored interrupt controller.

EXAMPLE

```
                    BF_WR(APBH_CTRL1, CH5_CMDCMPLT_IRQ, 0);  // use bitfield write macro
                    BF_APBH_CTRL1.CH5_CMDCMPLT_IRQ = 0;      // or, assign to register
struct's bitfield
```

9 CH9_ERROR_ IRQ	Error interrupt status bit for APBH DMA Channel 9. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
8 CH8_ERROR_ IRQ	Error interrupt status bit for APBH DMA Channel 8. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
7 CH7_ERROR_ IRQ	Error interrupt status bit for APBX DMA Channel 7. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
6 CH6_ERROR_ IRQ	Error interrupt status bit for APBX DMA Channel 6. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
5 CH5_ERROR_ IRQ	Error interrupt status bit for APBX DMA Channel 5. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
4 CH4_ERROR_ IRQ	Error interrupt status bit for APBX DMA Channel 4. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
3 CH3_ERROR_ IRQ	Error interrupt status bit for APBX DMA Channel 3. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
2 CH2_ERROR_ IRQ	Error interrupt status bit for APBX DMA Channel 2. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
1 CH1_ERROR_ IRQ	Error interrupt status bit for APBX DMA Channel 1. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.
0 CH0_ERROR_ IRQ	Error interrupt status bit for APBX DMA Channel 0. This sticky bit is set by DMA hardware and reset by software. It is ORed with the corresponding cmdcmplt irq to generate an irq to ARM.

11.4.4 AHB to APBH Bridge Channel Register (APBH_CHANNEL_CTRL*n*)

The APBH CHANNEL CTRL provides reset/freeze control of each DMA channel. This register contains individual channel reset/freeze bits.

Addresses: APBH_CHANNEL_CTRL is 4100_0000h base + 30h offset = 4100_0030h
APBH_CHANNEL_CTRL_SET is 4100_0000h base + 34h offset = 4100_0034h
APBH_CHANNEL_CTRL_CLR is 4100_0000h base + 38h offset = 4100_0038h
APBH_CHANNEL_CTRL_TOG is 4100_0000h base + 3Ch offset = 4100_003Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

APBH_CHANNEL_CTRL*n* field descriptions

Field	Description
31–16 RESET_ CHANNEL	Setting a bit in this field causes the DMA controller to take the corresponding channel through its reset state. The bit is reset after the channel resources are cleared. 0x0001 **NAND0** — 0x0002 **NAND1** — 0x0004 **NAND2** — 0x0008 **NAND3** — 0x0010 **NAND4** — 0x0020 **NAND5** — 0x0040 **NAND6** — 0x0080 **NAND7** — 0x0100 **SSP** —
15–0 FREEZE_ CHANNEL	Setting a bit in this field will freeze the DMA channel associated with it. This field is a direct input to the DMA channel arbiter. When frozen, the channel is deined access to the central DMA resources. 0x0001 **NAND0** — 0x0002 **NAND1** — 0x0004 **NAND2** — 0x0008 **NAND3** — 0x0010 **NAND4** — 0x0020 **NAND5** — 0x0040 **NAND6** — 0x0080 **NAND7** — 0x0100 **SSP** —

11.4.5 AHB to APBH DMA Device Assignment Register (APBH_DEVSEL)

This register allows reassignment of the APBH device connected to the DMA Channels.

In this chip, apbhdma channel resource is enough for high speed peripherals, so this register is of no use and reserved.

Address: APBH_DEVSEL is 4100_0000h base + 40h offset = 4100_0040h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

11–10 CH5	DMA burst size for GPMI channel 5. Do not change. GPMI only support burst size 4.
9–8 CH4	DMA burst size for GPMI channel 4. Do not change. GPMI only support burst size 4.
7–6 CH3	DMA burst size for GPMI channel 3. Do not change. GPMI only support burst size 4.
5–4 CH2	DMA burst size for GPMI channel 2. Do not change. GPMI only support burst size 4.
3–2 CH1	DMA burst size for GPMI channel 1. Do not change. GPMI only support burst size 4.
1–0 CH0	DMA burst size for GPMI channel 0. Do not change. GPMI only support burst size 4.

11.4.7 AHB to APBH DMA Debug Register (APBH_DEBUG)

This register is for debug purpose.

The debug register is for internal use only. Not recommend for customer useage.

Address: APBH_DEBUG is 4100_0000h base + 60h offset = 4100_0060h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

APBH_DEBUG field descriptions

Field	Description
31–1 -	Reserved, always set to zero.
0 GPMI_ONE_FIFO	Set to 0ne and the 8 GPMI channels will share the DMA FIFO, and when set to zero, the 8 GPMI channels will use its own DMA FIFO.

11.4.8 APBH DMA Channel n Current Command Address Register (APBH_CH_CURCMDAR)

The APBH DMA channel n current command address register points to the multiword command that is currently being executed. Commands are threaded on the command address.

APBH DMA Channel n is controlled by a variable sized command structure. This register points to the command structure currently being executed.

EXAMPLE

```
pCurCmd = (apbh_chn_cmd_t *) APBH_CHn_CURCMDAR_RD(0);              // read the whole
register, since there is only one field
pCurCmd = (apbh_chn_cmd_t *) BF_RDn(APBH_CHn_CURCMDAR, 0, CMD_ADDR);  // or, use multi-
register bitfield read macro
pCurCmd = (apbh_chn_cmd_t *) APBH_CHn_CURCMDAR(0).CMD_ADDR;        // or, assign from
bitfield of indexed register's struct
```

Addresses: 4100_0000h base + 100h offset + (112d × *n*), where *n* = 0d to 15d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	CMD_ADDR																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

APBH_CH*n*_CURCMDAR field descriptions

Field	Description
31–0 CMD_ADDR	Pointer to command structure currently being processed for channel n.

11.4.9 APBH DMA Channel n Next Command Address Register (APBH_CH_NXTCMDAR)

The APBH DMA Channel n Next Command Address register contains the address of the next multiword command to be executed. Commands are threaded on the command address. Set CHAIN to 1 in the DMA command word to process command lists.

APBH DMA Channel n is controlled by a variable sized command structure. Software loads this register with the address of the first command structure to process and increments the Channel n semaphore to start processing. This register points to the next command structure to be executed when the current command is completed.

EXAMPLE

```
APBH_CHn_NXTCMDAR_WR(0, (reg32_t) pCommandTwoStructure);         // write the entire
register, since there is only one field
BF_WRn(APBH_CHn_NXTCMDAR, 0, (reg32_t) pCommandTwoStructure);       // or, use multi-
register bitfield write macro
APBH_CHn_NXTCMDAR(0).CMD_ADDR = (reg32_t) pCommandTwoStructure;  // or, assign to bitfield
of indexed register's struct
```

Addresses: 4100_0000h base + 110h offset + (112d × *n*), where *n* = 0d to 15d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	CMD_ADDR																															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

APBH_CH*n*_NXTCMDAR field descriptions

Field	Description
31–0 CMD_ADDR	Pointer to next command structure for channel n.

11.4.10 APBH DMA Channel n Command Register (APBH_CH_CMD)

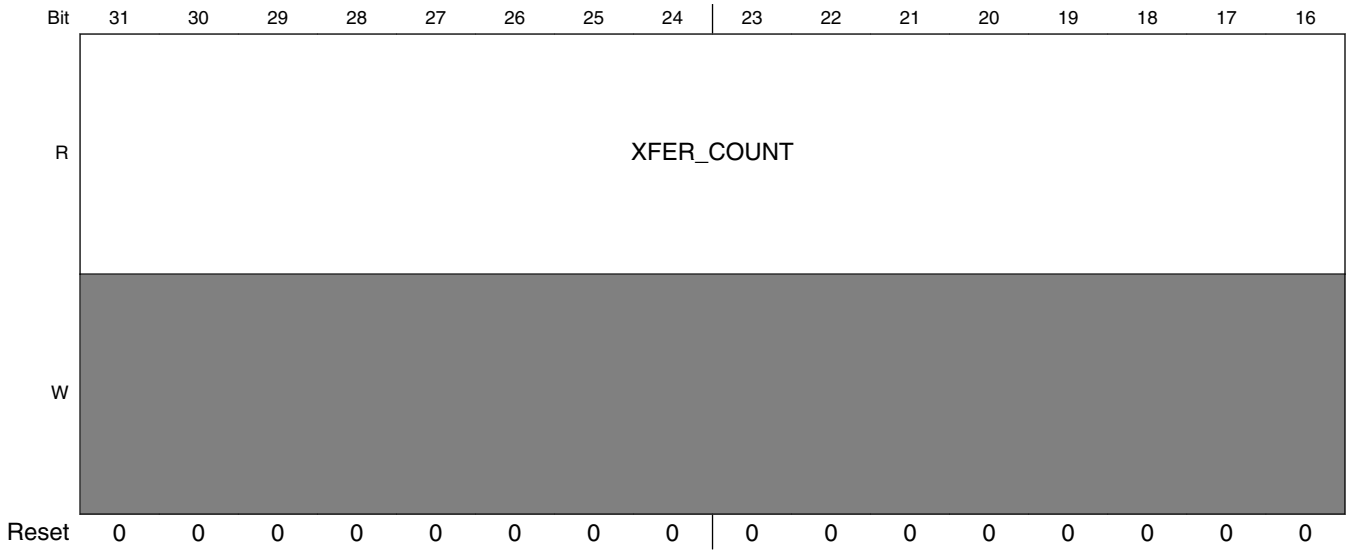
The APBH DMA Channel n command register specifies the DMA transaction to perform for the current command chain item.

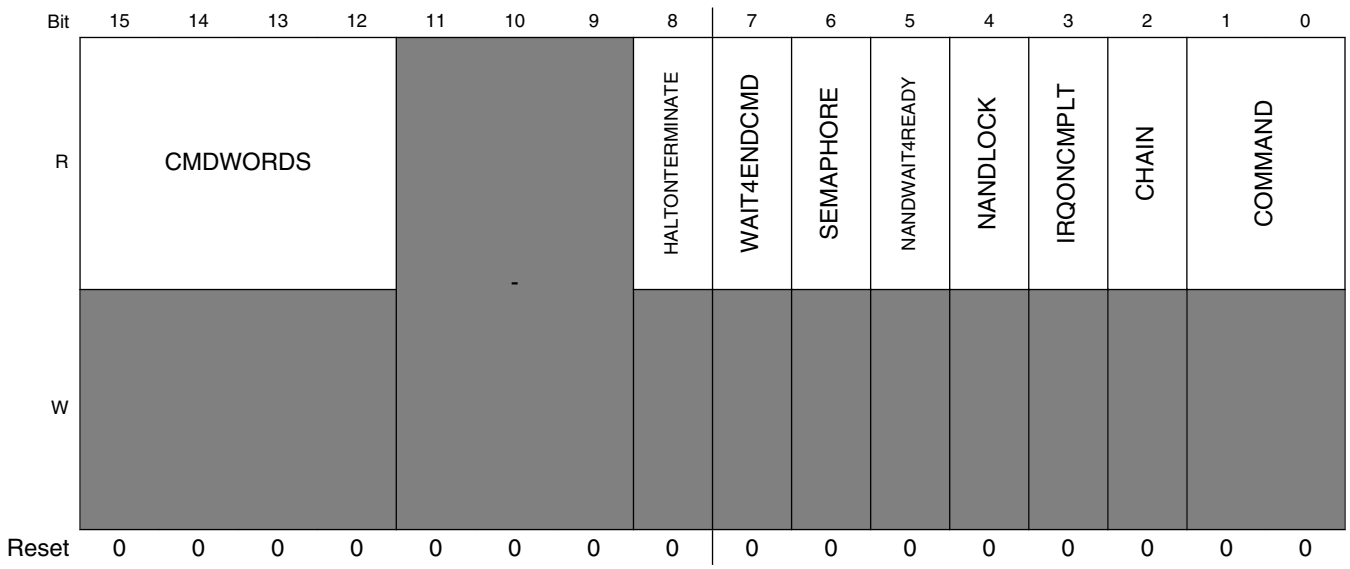
The command register controls the overall operation of each DMA command for this channel. It includes the number of bytes to transfer to or from the device, the number of APB PIO command words included with this command structure, whether to interrupt at command completion, whether to chain an additional command to the end of this one and whether this transfer is a read or write DMA transfer.

EXAMPLE

```
apbh_chn_cmd_t  dma_cmd;
dma_cmd.XFER_COUNT = 512;                                   // transfer 512 bytes
dma_cmd.COMMAND = BV_APBH_CHn_CMD_COMMAND__DMA_WRITE;  // transfer to system memory from
peripheral device
dma_cmd.CHAIN = 1;                                          // chain an additional command
structure on to the list
dma_cmd.IRQONCMPLT = 1;                                     // generate an interrupt on
completion of this command structure
```

Addresses: 4100_0000h base + 120h offset + (112d × *n*), where *n* = 0d to 15d





APBH_CH*n*_CMD field descriptions

Field	Description
31–16 XFER_COUNT	This field indicates the number of bytes to transfer to or from the appropriate PIO register in the GPMI0 device. A value of 0 indicates a 64 KBytes transfer.
15–12 CMDWORDS	This field indicates the number of command words to send to the GPMI0, starting with the base PIO address of the GPMI0 control register and incrementing from there. Zero means transfer NO command words
11–9 -	Reserved, always set to zero.
8 HALTONTERMINATE	A value of one indicates that the channel will immeditately terminate the current descriptor and halt the DMA channel if a terminate signal is set. A value of 0 will still cause an immediate terminate of the channel if the terminate signal is set, but the channel will continue as if the count had been exhausted, meaning it will honor IRQONCMPLT, CHAIN, SEMAPHORE, and WAIT4ENDCMD.

Table continues on the next page...

APBH_CH*n*_CMD field descriptions (continued)

Field	Description
7 WAIT4ENDCMD	A value of one indicates that the channel will wait for the end of command signal to be sent from the APBH device to the DMA before starting the next DMA command.
6 SEMAPHORE	A value of one indicates that the channel will decrement its semaphore at the completion of the current command structure. If the semaphore decrements to zero, then this channel stalls until software increments it again.
5 NANDWAIT4READY	A value of one indicates that the NAND DMA channel will will wait until the NAND device reports "ready" before executing the command. It is ignored for non-NAND DMA channels.
4 NANDLOCK	A value of one indicates that the NAND DMA channel will remain "locked" in the arbiter at the expense of other NAND DMA channels. It is ignored for non-NAND DMA channels.
3 IRQONCMPLT	A value of one indicates that the channel will cause the interrupt status bit to be set upon completion of the current command, i.e. after the DMA transfer is complete.
2 CHAIN	A value of one indicates that another command is chained onto the end of the current command structure. At the completion of the current command, this channel will follow the pointer in APBH_CHn_CMDAR to find the next command.
1–0 COMMAND	This bitfield indicates the type of current command: 0x0 **NO_DMA_XFER** — Perform any requested PIO word transfers but terminate command before any DMA transfer. 0x1 **DMA_WRITE** — Perform any requested PIO word transfers and then perform a DMA transfer from the peripheral for the specified number of bytes. 0x2 **DMA_READ** — Perform any requested PIO word transfers and then perform a DMA transfer to the peripheral for the specified number of bytes. 0x3 **DMA_SENSE** — Perform any requested PIO word transfers and then perform a conditional branch to the next chained device. Follow the NEXCMD_ADDR pointer if the perpheral sense is true. Follow the BUFFER_ADDRESS as a chain pointer if the peripheral sense line is false.

11.4.11 APBH DMA Channel n Buffer Address Register (APBH_CH_BAR)

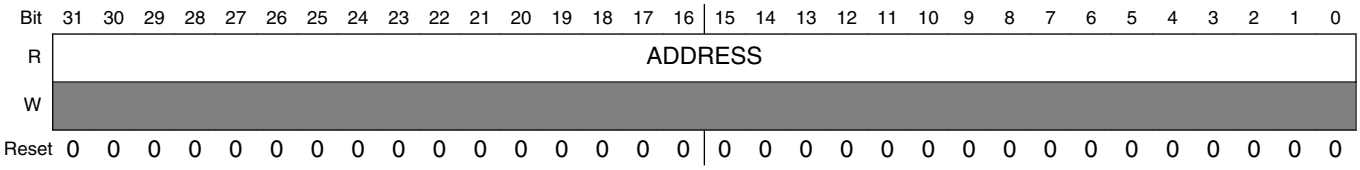
The APBH DMA Channel n buffer address register contains a pointer to the data buffer for the transfer. For immediate forms, the data is taken from this register. This is a byte address which means transfers can start on any byte boundary.

This register holds a pointer to the data buffer in system memory. After the command values have been read into the DMA controller and the device controlled by this channel, then the DMA transfer will begin, to or from the buffer pointed to by this register.

EXAMPLE

```
apbh_chn_bar_t  dma_data;
dma_data.ADDRESS = (reg32_t) pDataBuffer;
```

Addresses: 4100_0000h base + 130h offset + (112d × *n*), where *n* = 0d to 15d



APBH_CH*n*_BAR field descriptions

Field	Description
31–0 ADDRESS	Address of system memory buffer to be read or written over the AHB bus.

11.4.12 APBH DMA Channel n Semaphore Register (APBH_CH_SEMA)

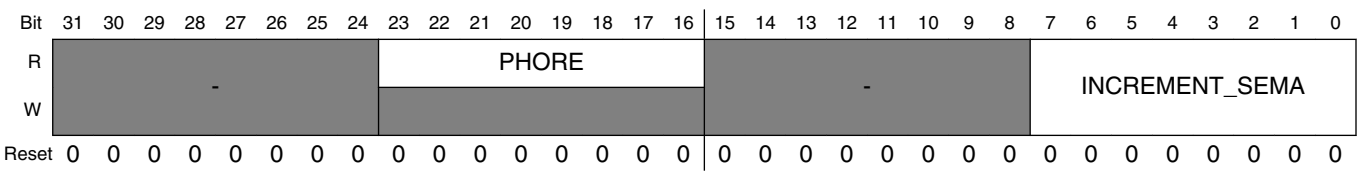
The APBH DMA Channel n semaphore register is used to synchronize the ARM platform instruction stream and the DMA chain processing state.

Each DMA channel has an 8 bit counting semaphore that is used to synchronize between the program stream and and the DMA chain processing. DMA processing continues until the DMA attempts to decrement a semaphore that has already reached a value of zero. When the attempt is made, the DMA channel is stalled until software increments the semaphore count.

EXAMPLE

```
BF_WR(APBH_CHn_SEMA, 0, INCREMENT_SEMA, 2);      // increment semaphore by two
current_sema = BF_RD(APBH_CHn_SEMA, 0, PHORE);  // get instantaneous value
```

Addresses: 4100_0000h base + 140h offset + (112d × *n*), where *n* = 0d to 15d



APBH_CH*n*_SEMA field descriptions

Field	Description
31–24 -	Reserved, always set to zero.
23–16 PHORE	This read-only field shows the current (instantaneous) value of the semaphore counter.
15–8 -	Reserved, always set to zero.

Table continues on the next page...

APBH_CH*n*_SEMA field descriptions (continued)

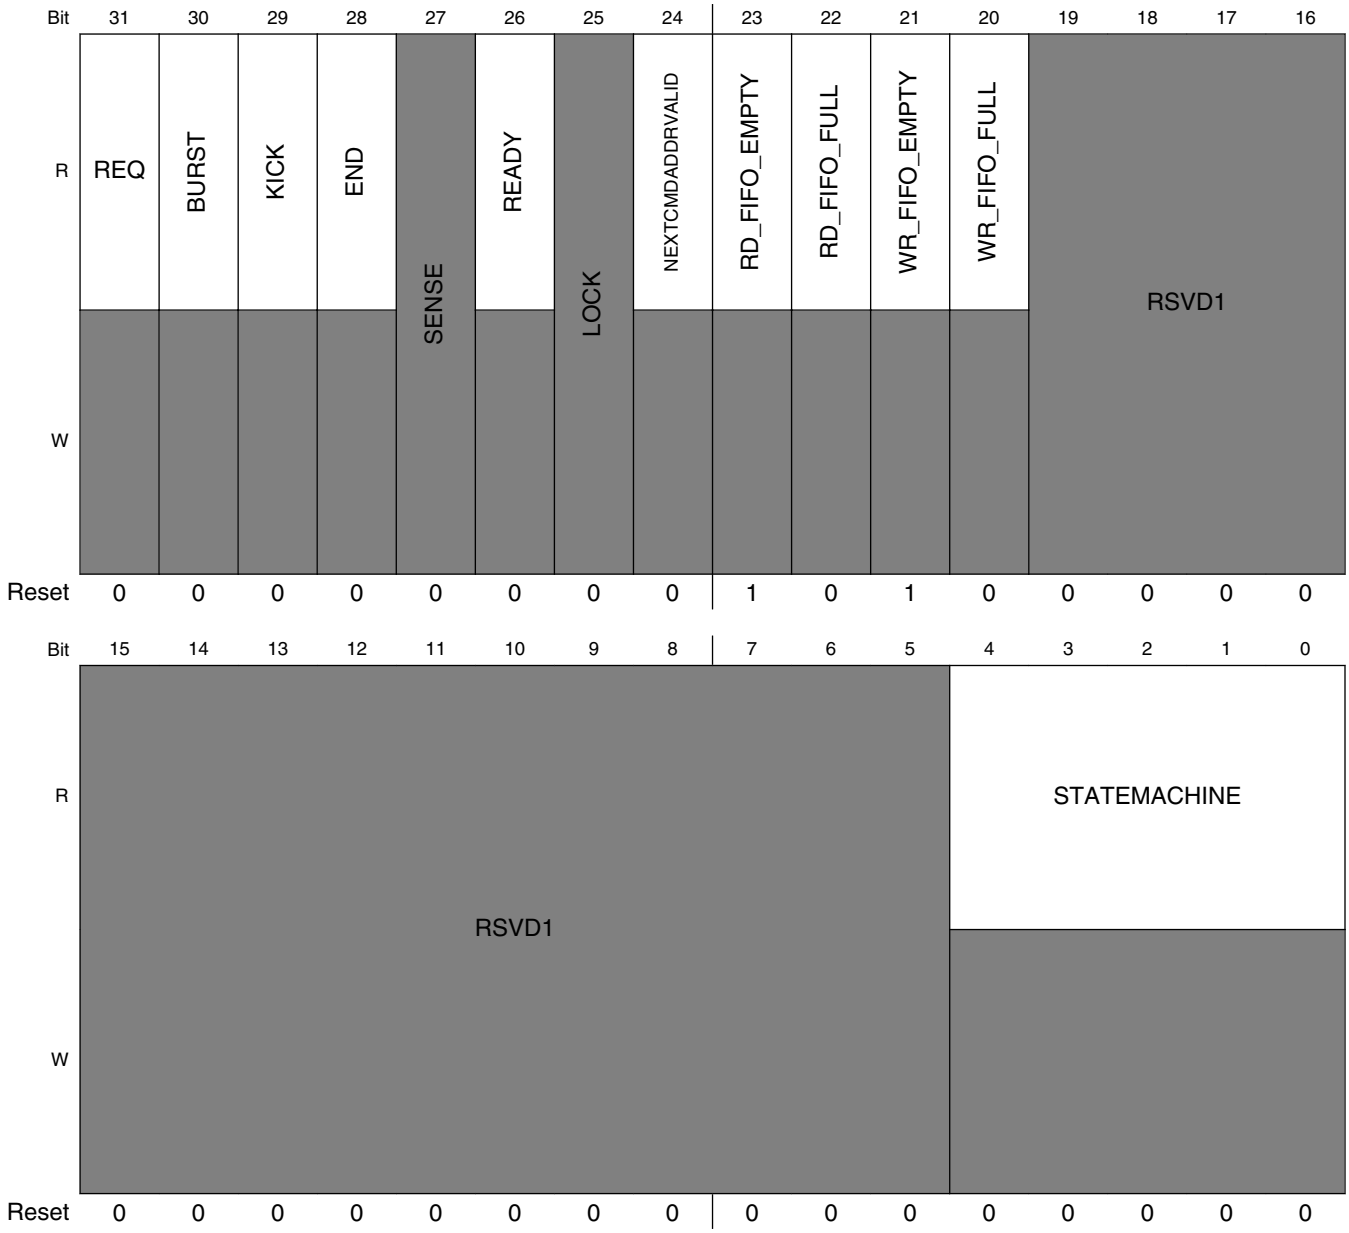
Field	Description
7–0 INCREMENT_ SEMA	The value written to this field is added to the semaphore count in an atomic way such that simultaneous software adds and DMA hardware substracts happening on the same clock are protected. This bit field reads back a value of 0x00. Writing a value of 0x02 increments the semaphore count by two, unless the DMA channel decrements the count on the same clock, then the count is incremented by a net one.

11.4.13 AHB to APBH DMA Channel n Debug Information (APBH_CH_DEBUG1)

This register gives debug visibility into the APBH DMA Channel n state machine and controls.

This register allows debug visibility of the APBH DMA Channel n.

Addresses: 4100_0000h base + 150h offset + (112d × *n*), where *n* = 0d to 15d



APBH_CH*n*_DEBUG1 field descriptions

Field	Description
31 REQ	This bit reflects the current state of the DMA Request Signal from the APB device
30 BURST	This bit reflects the current state of the DMA Burst Signal from the APB device
29 KICK	This bit reflects the current state of the DMA Kick Signal sent to the APB Device
28 END	This bit reflects the current state of the DMA End Command Signal sent from the APB Device

Table continues on the next page...

APBH_CH*n*_DEBUG1 field descriptions (continued)

Field	Description
27 SENSE	This bit is reserved for this DMA Channel and always reads 0.
26 READY	This bit is reserved for this DMA Channel and always reads 0.
25 LOCK	This bit is reserved for this Channel and always reads 0.
24 NEXTCMDADDRVALID	This bit reflects the internal bit which indicates whether the channel's next command address is valid.
23 RD_FIFO_EMPTY	This bit reflects the current state of the DMA Channel's Read FIFO Empty signal.
22 RD_FIFO_FULL	This bit reflects the current state of the DMA Channel's Read FIFO Full signal.
21 WR_FIFO_EMPTY	This bit reflects the current state of the DMA Channel's Write FIFO Empty signal.
20 WR_FIFO_FULL	This bit reflects the current state of the DMA Channel's Write FIFO Full signal.
19–5 RSVD1	Reserved
4–0 STATEMACHINE	PIO Display of the DMA Channel n state machine state. 0x00 **IDLE** — This is the idle state of the DMA state machine. 0x01 **REQ_CMD1** — State in which the DMA is waiting to receive the first word of a command. 0x02 **REQ_CMD3** — State in which the DMA is waiting to receive the third word of a command. 0x03 **REQ_CMD2** — State in which the DMA is waiting to receive the second word of a command. 0x04 **XFER_DECODE** — The state machine processes the descriptor command field in this state and branches accordingly. 0x05 **REQ_WAIT** — The state machine waits in this state for the PIO APB cycles to complete. 0x06 **REQ_CMD4** — State in which the DMA is waiting to receive the fourth word of a command, or waiting to receive the PIO words when PIO count is greater than 1. 0x07 **PIO_REQ** — This state determines whether another PIO cycle needs to occur before starting DMA transfers. 0x08 **READ_FLUSH** — During a read transfers, the state machine enters this state waiting for the last bytes to be pushed out on the APB. 0x09 **READ_WAIT** — When an AHB read request occurs, the state machine waits in this state for the AHB transfer to complete. 0x0C **WRITE** — During DMA Write transfers, the state machine waits in this state until the AHB master arbiter accepts the request from this channel. 0x0D **READ_REQ** — During DMA Read transfers, the state machine waits in this state until the AHB master arbiter accepts the request from this channel. 0x0E **CHECK_CHAIN** — Upon completion of the DMA transfers, this state checks the value of the Chain bit and branches accordingly. 0x0F **XFER_COMPLETE** — The state machine goes to this state after the DMA transfers are complete, and determines what step to take next. 0x14 **TERMINATE** — When a terminate signal is set, the state machine enters this state until the current AHB transfer is completed.

Table continues on the next page...

APBH_CH*n*_DEBUG1 field descriptions (continued)

Field	Description
	0x15 **WAIT_END** — When the Wait for Command End bit is set, the state machine enters this state until the DMA device indicates that the command is complete. 0x1C **WRITE_WAIT** — During DMA Write transfers, the state machine waits in this state until the AHB master completes the write to the AHB memory space. 0x1D **HALT_AFTER_TERM** — If HALTONTERMINATE is set and a terminate signal is set, the state machine enters this state and effectively halts. A channel reset is required to exit this state 0x1E **CHECK_WAIT** — If the Chain bit is a 0, the state machine enters this state and effectively halts. 0x1F **WAIT_READY** — When the NAND Wait for Ready bit is set, the state machine enters this state until the GPMI device indicates that the external device is ready.

11.4.14 AHB to APBH DMA Channel n Debug Information (APBH_CH_DEBUG2)

This register gives debug visibility for the APB and AHB byte counts for DMA Channel n.

This register allows debug visibility of the APBH DMA Channel n.

Addresses: 4100_0000h base + 160h offset + (112d × *n*), where *n* = 0d to 15d

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

APBH_CH*n*_DEBUG2 field descriptions

Field	Description
31–16 APB_BYTES	This value reflects the current number of APB bytes remaining to be transfered in the current transfer.
15–0 AHB_BYTES	This value reflects the current number of AHB bytes remaining to be transfered in the current transfer.

11.4.15 APBH Bridge Version Register (APBH_VERSION)

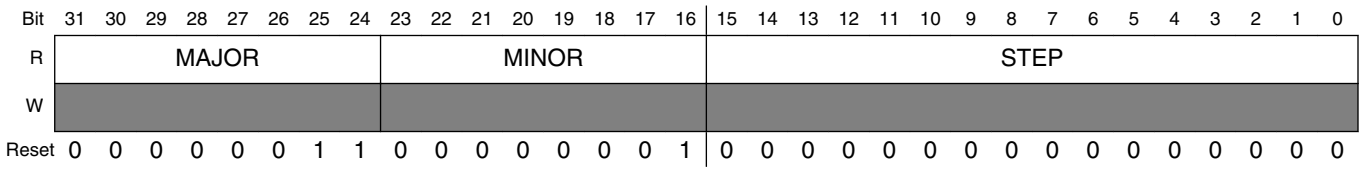
This register always returns a known read value for debug purposes it indicates the version of the block.

This register indicates the RTL version in use.

EXAMPLE

```
if (APBH_VERSION.B.MAJOR != 3)
   Error();
```

Address: APBH_VERSION is 4100_0000h base + 800h offset = 4100_0800h



APBH_VERSION field descriptions

Field	Description
31–24 MAJOR	Fixed read-only value reflecting the MAJOR field of the RTL version.
23–16 MINOR	Fixed read-only value reflecting the MINOR field of the RTL version.
15–0 STEP	Fixed read-only value reflecting the stepping of the RTL version.

Chapter 12
Digital Audio Multiplexer (AUDMUX)

12.1 Overview

The Digital Audio Multiplexer (AUDMUX) provides a programmable interconnect device for voice, audio, and synchronous data routing between host serial interfaces such as the Synchronous Serial Interface Controller (SSI) and peripheral serial interfaces (audio and voice codecs, also known as coder-decoders).

This section includes a top level diagram that shows the functional organization of the block, including all off-chip signals.

AUDMUX allows the audio system connectivity to be modified through programming, as opposed to altering the PCB schematics of the system. The full description of the block is in Functional Description.

Figure 12-1 shows the block diagram.

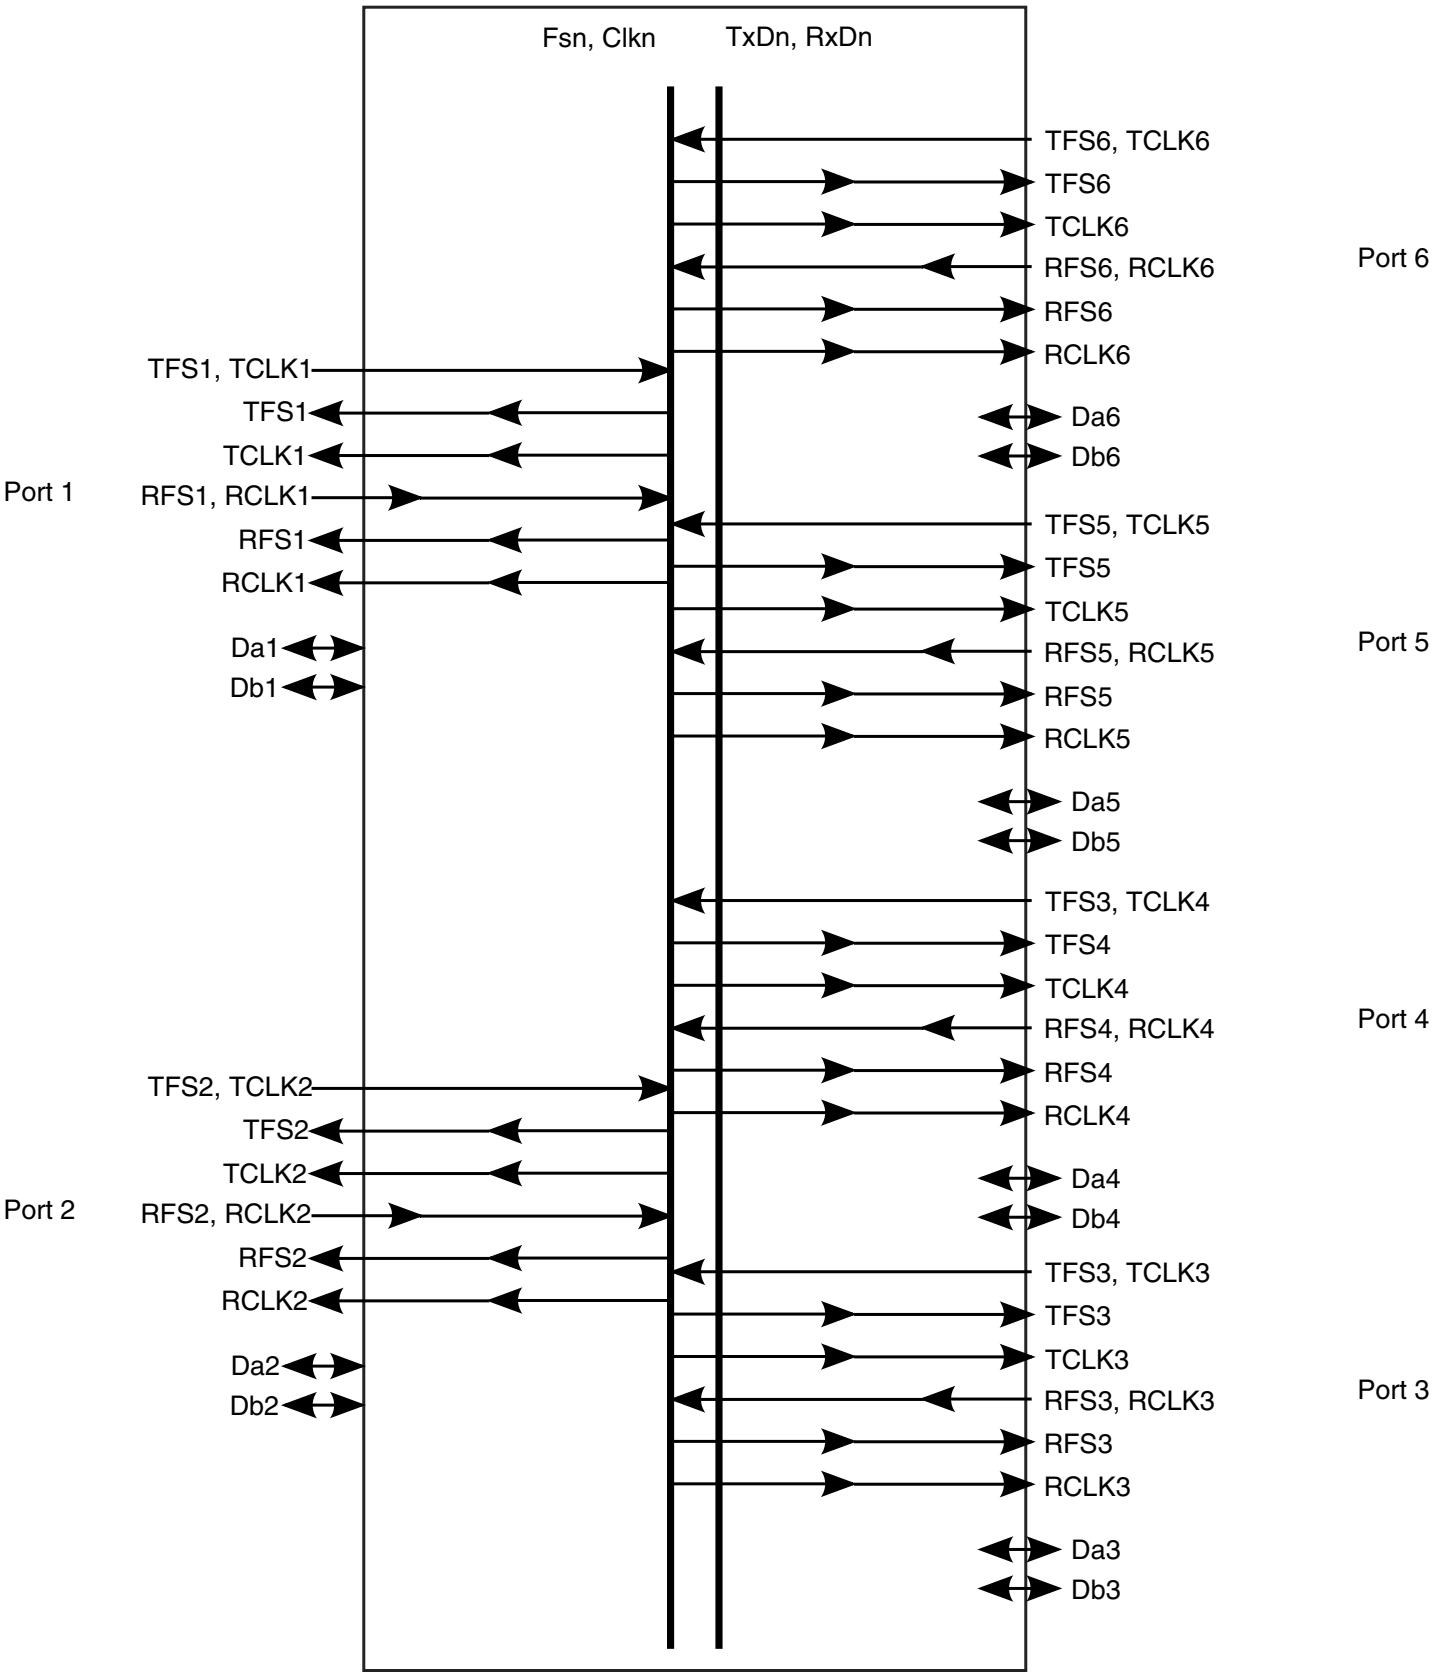


Figure 12-1. AUDMUX Block Diagram

With AUDMUX, resources do not need to be hard-wired and can be effectively shared in different configurations. AUDMUX interconnections allow multiple, simultaneous audio/voice/data flows between the ports in point-to-point or point-to-multipoint configurations.

AUDMUX includes two types of interfaces. Internal ports connect to the processor serial interfaces, and external ports connect to off-chip audio devices and serial interfaces of other processors. The desired connectivity is achieved by configuring the appropriate internal and external ports.

12.1.1 Features

Key features of the block include:

- Two internal ports
- Four external ports
- Full 6-wire SSI interfaces for asynchronous receive and transmit
- Configurable 4-wire (synchronous) or 6-wire (asynchronous) peripheral interfaces
- Independent Tx/Rx Frame sync and clock direction selection for host or peripheral
- Each host interface's capability to connect to any other host or peripheral interface in a point-to-point or point-to-multipoint (network mode)
- Transmit and Receive Data switching to support external network mode

12.1.2 Modes and Operations

The AUDMUX supports the modes described in Operating Modes.

12.2 External Signal Description

The following table lists the off-chip signals of the AUDMUX for the external ports, where P*n* is P3 to P6 and m = (n-2).

Table 12-1. Off-Chip Block Signals

Name	Block Port	I/O	Function	Reset State	Pull-up
AUDm_TXD	P*n*	I/O	Transmit Data from Pn	1	Active
AUDm_RXD	P*n*	I/O	Receive Data at Pn	1	Active
AUDm_TXC	P*n*	I/O	Transmit Clock input/output at Pn	1	-

AUDm_RXFS	P*n*	I/O	Receive Frame sync input/output at Pn	1	-

12.3 Default Register Configuration

There are two configuration registers for each port. Each pair of configuration registers is identical for each port; however, the default values following a reset differ as shown in the Memory Map.

- Default Port Configuration, describes the default configuration of the ports.

12.3.1 Default Port Configuration

After a reset, each port defaults to normal mode (PDCR*n*[MODE] = 0) with synchronous timing mode (PTCR*n*[SYN] = 1) enabled.

The default port-to-port connections are as follows:

- Port 1 to Port 6
  - Port 6 provides the clock and frame sync.
- Port 2 to Port 5
  - Port 5 provides the clock and frame sync.
- Port 3 to Port 4
  - Port 4 provides the clock and frame sync.

12.4 Functional Description

This section provides a complete functional description of the AUDMUX.

12.4.1 Operating Modes

This section describes all functional operation modes of the AUDMUX.

Figure 12-1 shows the AUDMUX block diagram.

All of the ports are essentially identical; there is no functional difference among Ports 1 through 7. The main difference is whether a port is connected to an on-chip serial interface (SSI for example) or connected to the chip's pads to connect to off-chip serial devices (that is, any 4-wire or 6-wire external SSI, voice, I2S, or AC97 codec).

All ports can be configured as four- or six-wire interfaces. When configured as a six-wire interface, the additional RFS and RCLK signals of the interface enable the serial interface to be used in asynchronous mode with separate receive and transmit clocks.

All ports have a Tx/Rx switch to provide flexibility in supporting network mode configurations. The Tx/Rx switch enables the transmit and receive data lines to be swapped so that mastership of the serial bus can be passed among multiple external devices connected to a single port.

In addition to supporting the default external network mode, all ports support an internal network mode:

- With internal network mode, a point-to-multipoint network configuration with an arbitrary number of slaves can be supported if the external slaves are put into the high-impedance state (as defined in the SSI network mode protocol) and have pull-up resistors on their TxD pins. (Alternatively, this can be viewed as requiring a pull-up resistor on the corresponding AUDMUX RxD pin.)

Bit clock direction selection enables each port to be configured as a master or slave in the flow.

Possible scenarios include:

- SSI (internal port) drives a voice codec and a BT (Blue tooth) codec (both on external Port 5) and the Bottom Connector (on external Port 6) simultaneously using network mode. SSI is the master.
- An external processor (external port - Port 4) drives a voice codec and a BT codec (both on external Port 5) and the Bottom Connector (on Port 6) simultaneously using network mode. The external processor is the master.

12.4.1.1 Port Receive Data Modes

Each port has logic to select which data lines are used to create the RxD line for the corresponding host interface.

Figure 12-2 shows the logic used to create the RxD line for Port 1. This logic has the following modes of operation (as determined by MODE):

- Normal
- Internal network mode

The subsequent sections describe the various modes of the port receive data logic. The following terms are used to define the operation of the AUDMUX:

- Network mode- Time-Division Multiplexed protocol for sending unique data to multiple devices on a serial bus.
- Internal network mode-Physical bus configuration where multiple serial buses are effectively connected within the AUDMUX via digital logic to create point-to-multipoint connectivity. An arbitrary number of devices are supported. Devices must be put into the high-impedance state as specified by the network mode protocol. TxDATA lines of devices must be pulled high.
- External network mode-Physical bus configuration where multiple serial buses are electrically connected together on a printed circuit board (that is, external to the AUDMUX). Devices must put their TxDATA lines into the high-impedance state as specified by the network mode protocol.

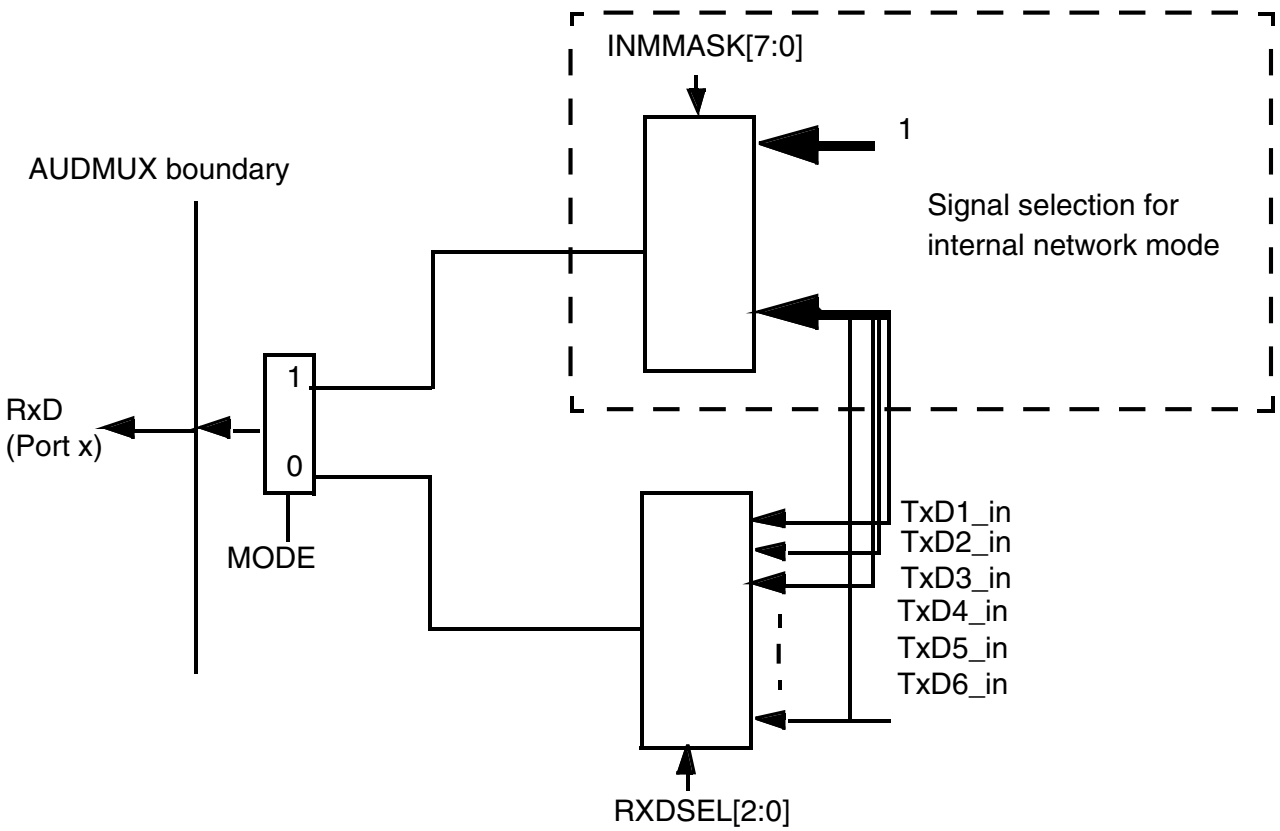

Figure 12-2. Receive Data Logic for Port x

12.4.1.1.1 Normal Mode

In normal mode (MODE = 0) , the port is connected in a point-to-point configuration (as a master or a slave) and the RXDSEL[2:0] setting selects the transmit signal from any port. In normal mode, any data format can be used (that is, SSI normal mode, SSI network mode, AC-97, and others.

12.4.1.1.2 Internal Network Mode

In internal network mode (MODE = 1) , the output of the AND gate is routed (via the output of the port) to the RxD signal of the corresponding host interface.

The INMMASK bit vector selects the transmit signals of the ports that are to be connected in network mode. The transmit signals received at the AUDMUX ports (TxDn_in) are ANDed together to form the output. In internal network mode, only one device can be transmitting in its predesignated timeslot and all other transmit signals must remain high (be in high-impedance state and pulled-up). Therefore, non-active signals in the selection will be high and do not influence the output of the AND gate.

Network mode is a protocol where a master SSI is connected to more than one slave SSI device and communication occurs on a time-slotted frame. Though network mode can allow master-slave and slave-slave communication, internal network mode supports only master-slave communication.

There are two scenarios where internal network mode can be used with external network mode:

1. Slave-only devices are attached to an external port.
2. A master device is attached to an external port and all slave devices connected to the same external port are disabled.

NOTE

When internal network mode is enabled at an external port, RXDSEL[3:0] for RxDn_obe selection is ignored and RxD_obe is always driven high (that is, asserted for all timeslots). All slave devices connected to the same port must be disabled.

Internal Network Mode Example 1

SSI_m and SSI_n are used with Port 4 in internal network mode as shown in Figure 12-3. No pull-up resistors are required because the interfaces combined in internal network mode are on-chip interfaces.

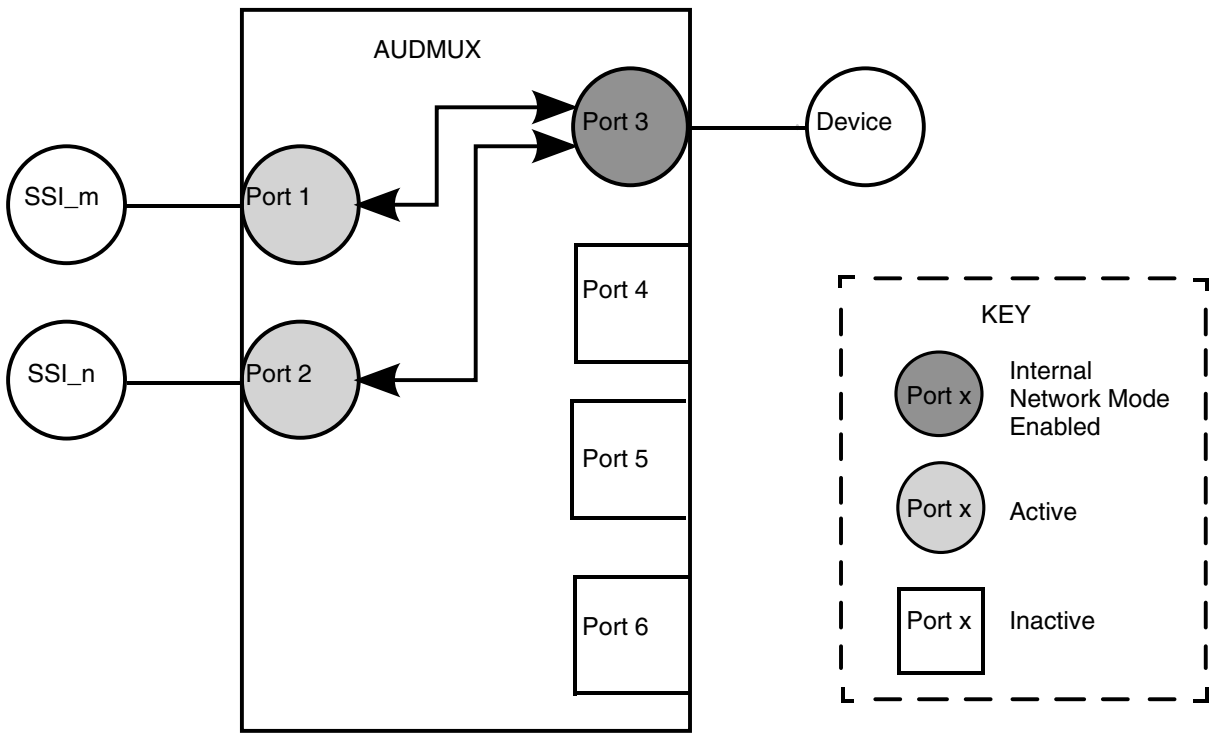

Figure 12-3. Block Diagram For Example 1

See Figure 12-4 for the timing diagram of Example 1. The clock and frame sync signals show the bit and frame timing for the serial bus. The vertical dashed lines divide the frame into four timeslots.

The data lines for SSI_m and SSI_n (as well as their output enables) are shown. Note that the on-chip interfaces drive a logic '1' when their output enables are logic '0'. The combined TxDATA line, which is the logical AND of the individual TxDATA lines, is used for Port3's TxDATA line.

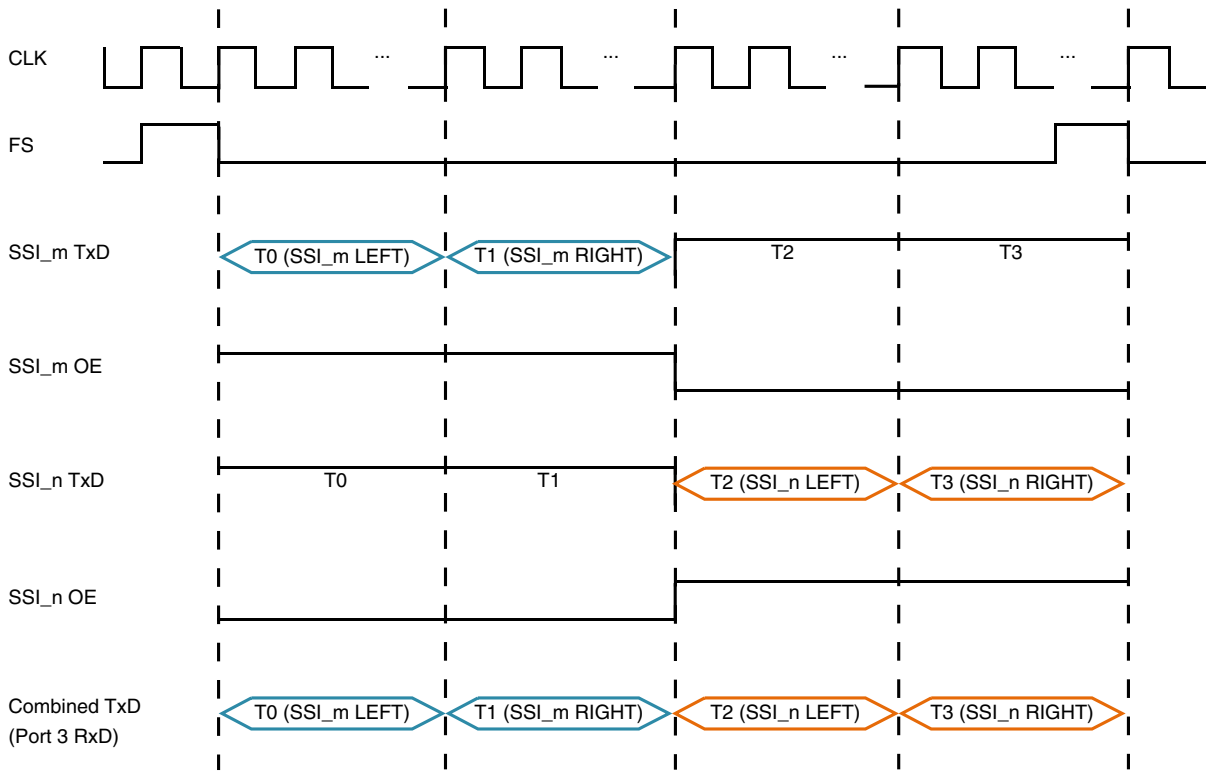

Figure 12-4. Example Using Internal Ports For Transmit Data

Internal Network Mode Example 2

The SSI, Port 3, and Port 4 are used with Port 5 in internal network mode, as shown in the following figure. Note that Port 3 and Port 4 are external ports. Therefore, pull-up resistors are required on the Port 4 RxDATA and Port 5 RxDATA pins. This example shows the timing associated with using adjacent timeslots for the SSI, Port 3 and Port 4.

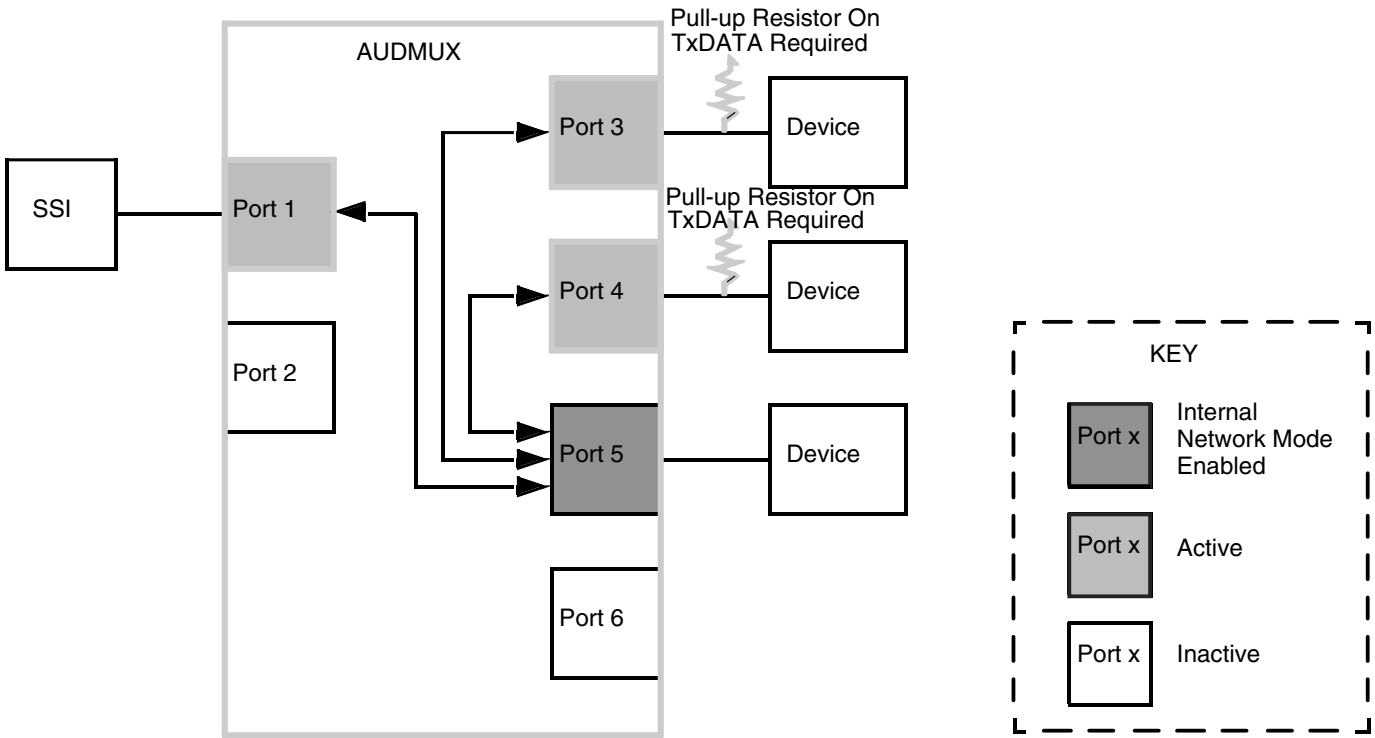

Figure 12-5. Block Diagram For Example 2

The resistance value of the pull-up resistors must be sufficiently high such that a value of '0' can be pulled up to logic '1' within half of a period of the bitclock. The required resistance must be no larger than:

Rmax = 1 / (2 * f_{bc} * C) where:

- f_{bc} is the frequency of the bitclock
- C is the total system capacitance (ICs, board traces, and so on)

The following figure shows the timing diagram for this example. The clock and frame sync signals show the bit and frame timing for the serial bus. The vertical dashed lines divide the frame into four timeslots.

The data lines for the SSI, Port 3 and Port 4 are shown. Note that the SSI transmits a logic '1' when its corresponding output enable is a logic '0'. The data lines from Port 3 and Port 4 at the pad are pulled high by pull-up resistors when they are in the high-impedance state. The data lines from Port 3 and Port 4 at the AUDMUX are pure digital signals and are constantly driven. The combined TxDATA line, which is the logical AND of the SSI, Port 3 and Port 4's TxDATA lines, is used for Port 5's TxDATA line.

Note the highlighted areas in the following figure. This shows the transition time that occurs while a TxDATA line is being pulled high. In this example, this transition time is a maximum of 1/2 the period of the serial bitclock. This prevents corruption of the first data bit of the next timeslot. It is critical that the pull-up resistance is sufficient for the given bitclock frequency and system capacitance.

Note that hysteresis should be enabled at Port 3's RxDATA pad and Port 4's RxDATA pad to prevent the digital signals created by the pad from toggling rapidly during the pull-up period. The pads typically require a transition within 25ns unless hysteresis is enabled. Instead of using hysteresis, one could select a pull-up resistor sufficiently high to pull-up the signal at the pad within 25 ns; however, that would result in a higher resistance value and higher current drain.

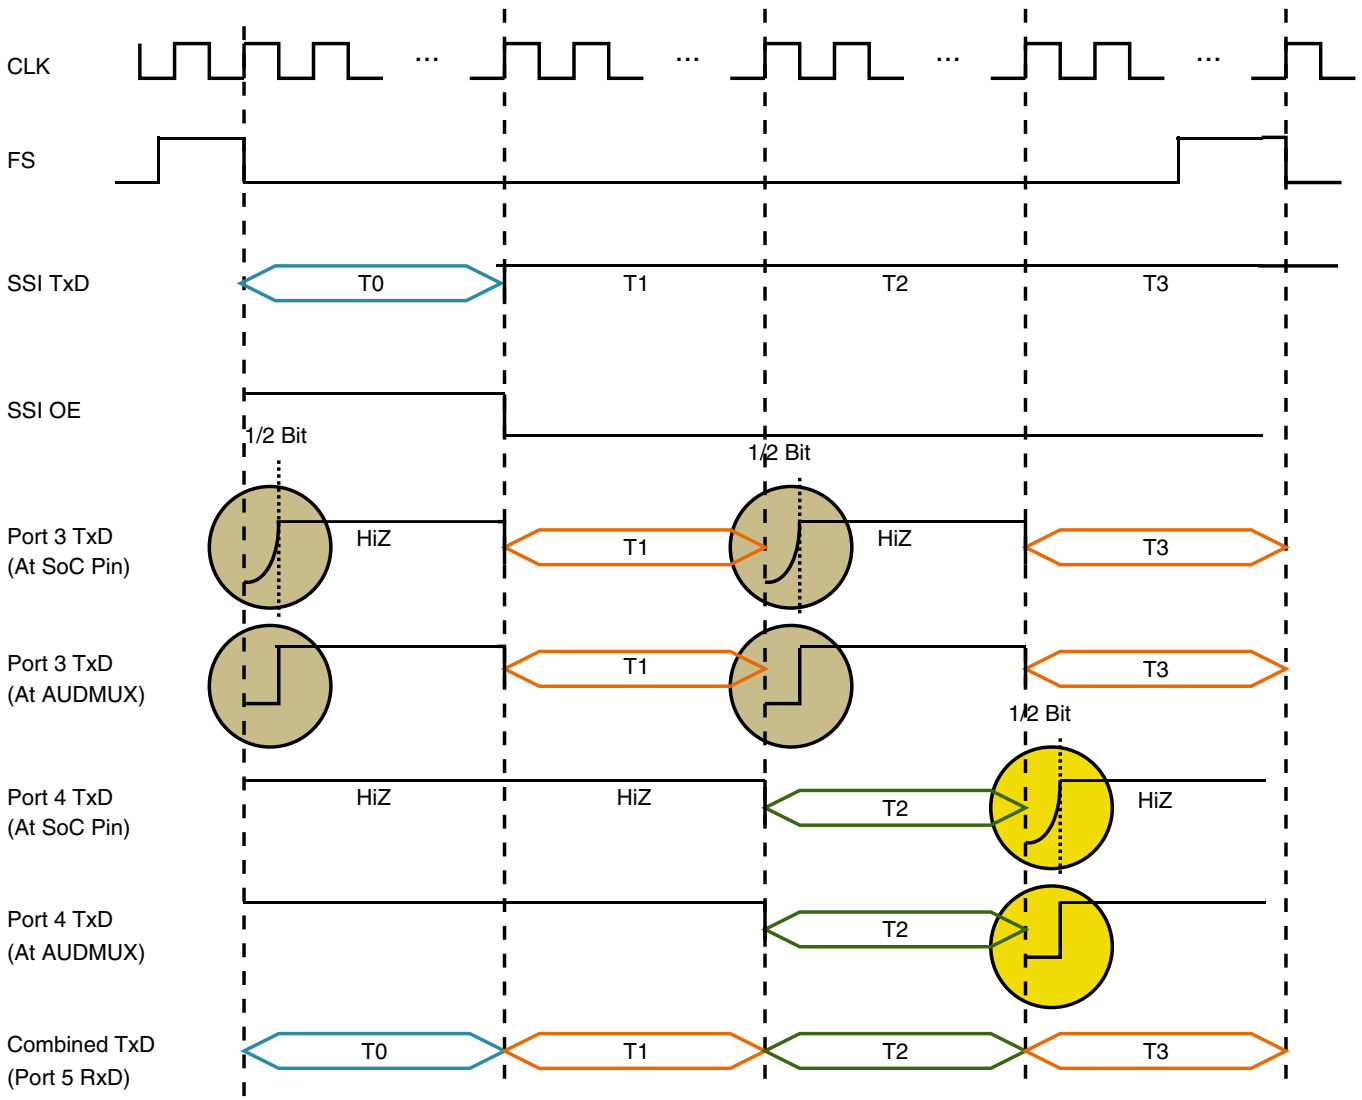

Figure 12-6. Example Using External Ports for Transmit Data in Consecutive Timeslots

Internal Network Mode Example 3

The SSI and Port 3 are used with Port 5 in internal network mode as shown in the following figure. Note that Port 3 is an external port. Therefore, a pull-up resistor is required on the Port 3 TxDATA pin. This example shows the timing associated with inserting empty timeslots after the timeslots have been used by external ports.

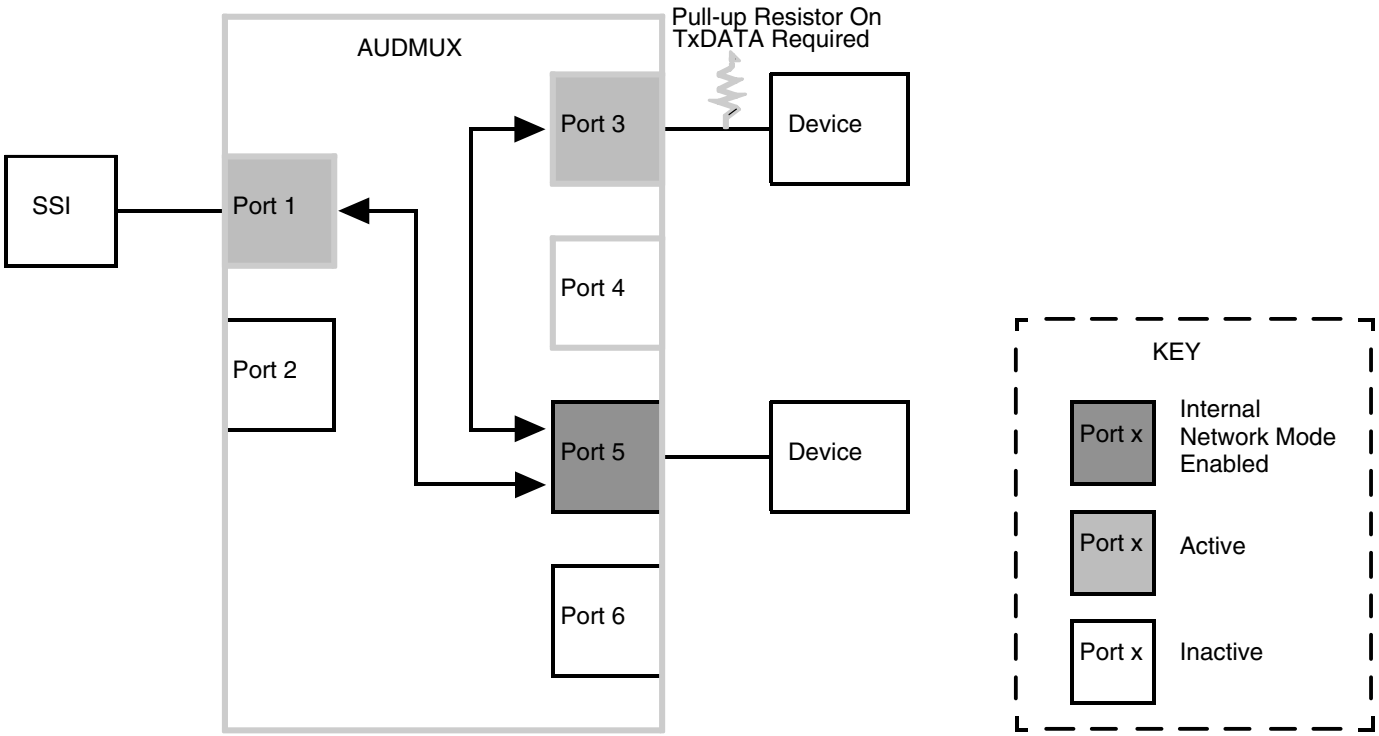

Figure 12-7. Block Diagram For Example 3

The resistance value of the pull-up resistors must be sufficiently high such that a value of '0' can be pulled up to logic '1' by the time that the next occupied timeslot occurs. This allows a much weaker pull-up to be used as compared to Example 2. The required resistance must be no larger than:

Rmax = (4 * n + 1) / (2* f_{bc} * C) where:

- n is the number of bits per timeslot
- f_{bc} is the frequency of the bitclock
- C is the total system capacitance (ICs, board traces, and so on)

The figure below shows the timing diagram for this example. The clock and frame sync signals show the bit and frame timing for the serial bus. The vertical dashed lines divide the frame into four timeslots.

The data lines for the SSI and Port 3 are shown. Note that the SSI transmits a logic '1' when its corresponding output enable is a logic '0'. The data line from Port 3 at the pad is pulled high by a pull-up resistor when they are in the high-impedance state. The data line from Port 3 at the AUDMUX is a pure digital signal and is constantly driven. The combined TxDATA line, which is the logical AND of the SSI and Port 3's TxDATA lines, is used for Port 5's RxDATA line.

Note the highlighted area in the following figure. This shows the transition time that occurs while Port 3's TxDATA line is being pulled high. In this example, this transition time is a maximum of two timeslots plus 1/2 the period of the serial bitclock. This prevents corruption of the first data bit of the next timeslot. It is critical that the pull-up resistance is sufficient for the given bitclock frequency and system capacitance.

Note that hysteresis must be enabled at Port 3's RxDATA pad to prevent the digital signal created by the pad from toggling rapidly during the extended pull-up period. The pads typically require a transition within 25 ns unless hysteresis is enabled.

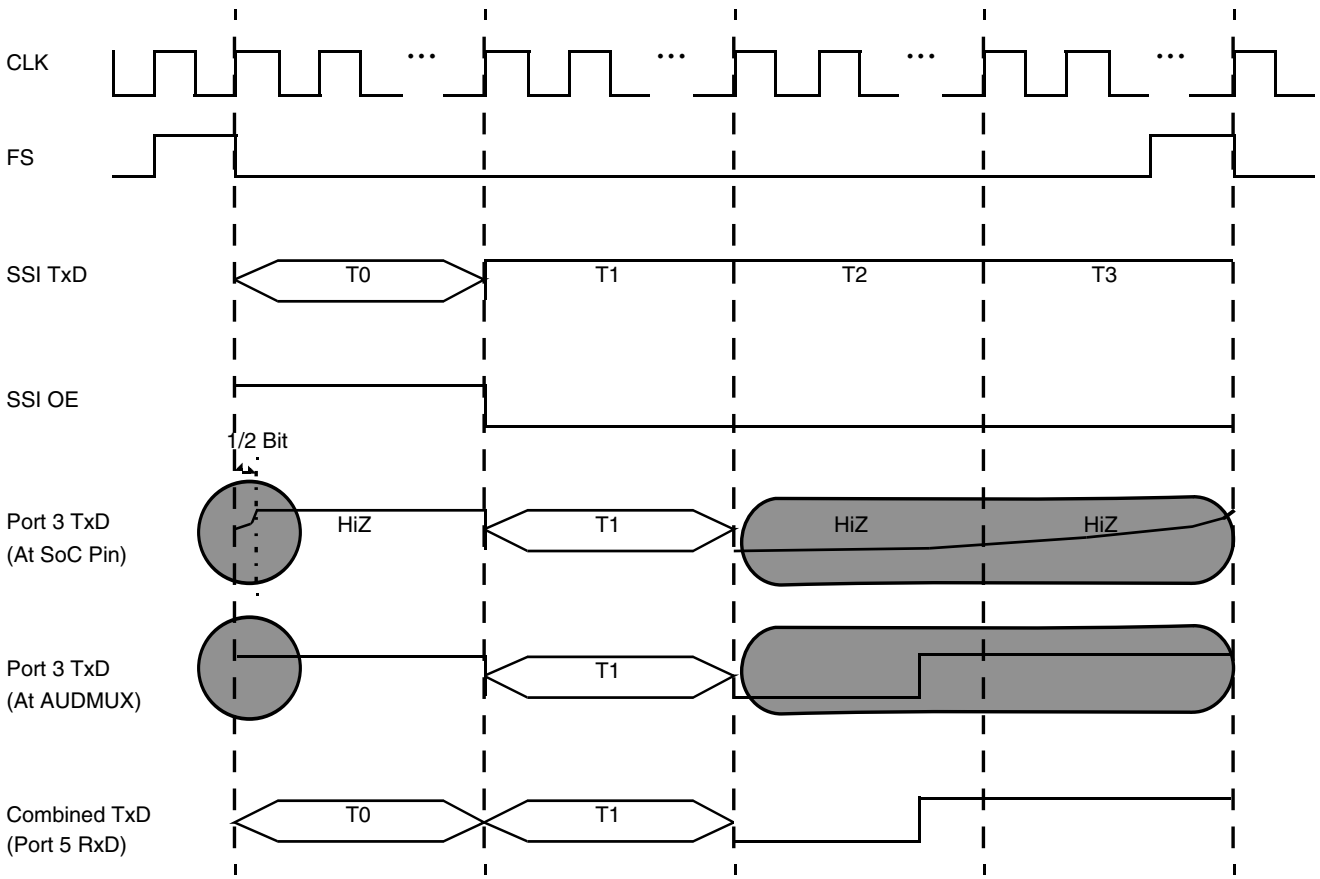

Figure 12-8. Example Using External Ports For Transmit Data In Nonconsecutive Timeslots

12.4.1.1.3 Transmit Data Output Enable Assertion

The TxDATA line from the internal network mode master (connected at any internal port) is put into the high-impedance state at the pad depending upon the assertion or deassertion of TxD_obe, its corresponding output enable generated by the network mode master.

In the case of an external network mode master (connected at an external port), the corresponding TxD_obe is always asserted after the port data register configuration.

12.4.1.2 Tx/Rx Switch and External Network Mode

External network mode is the traditional network mode connection. It is called external network mode to differentiate from the internal network mode. In external network mode, devices are connected to a single external port in a star or multi-drop configuration.

In network mode, there can be only one master (driving the frame sync and clock source) with the other devices configured in normal slave mode or network slave mode. Unlike internal network mode, both master-slave and slave-slave communication can take place in external network mode. Codec devices transmit on a single timeslot while processor serial interfaces (that is, SSI) can process more than one timeslot of data while in network master or slave mode.

The following figure shows the Tx/Rx data switch. RxD_obe is the output buffer enable signal and RxD_out is the data transmit signal from the serial interface. The TxD_in signal is the receive data signal going towards the RXDSEL muxes of all ports.

D_TxRx is the data pin which serves as the chip-level transmit data pin when the TxRx switch is not enabled. D_RxTx is the data pin which serves as the chip-level receive data pin when the TxRx switch is not enabled. The roles of these pins are reversed when the TxRx switch is enabled.

When TXRXEN is disabled (TXRXEN=0), RxD_out is routed to D_TxRx and D_RxTx is routed to TxD_in. The output buffer enable, selected by RXDSEL[2:0], is routed to Db_obe.

When the Tx/Rx switch is enabled (TXRXEN=1), RxD_out is routed to D_RxTx and D_TxRx is routed to TxD_in. The output buffer enable, selected by RXDSEL[2:0], is routed to Da_obe.

If the RXDSELn[2:0] field for any Port *n* is configured to select data from an internal port, the output buffer enable is selected by RXDSELn[2:0] and is routed to Da*n*_obe/ Db*n*_obe. In the case when the RXDSELn[2:0] field for Port *n* is configured to select data from an external port, the output buffer enable is always high and routed to Dan_obe/Dbn_obe, depending on the TXRXENn switch configuration.

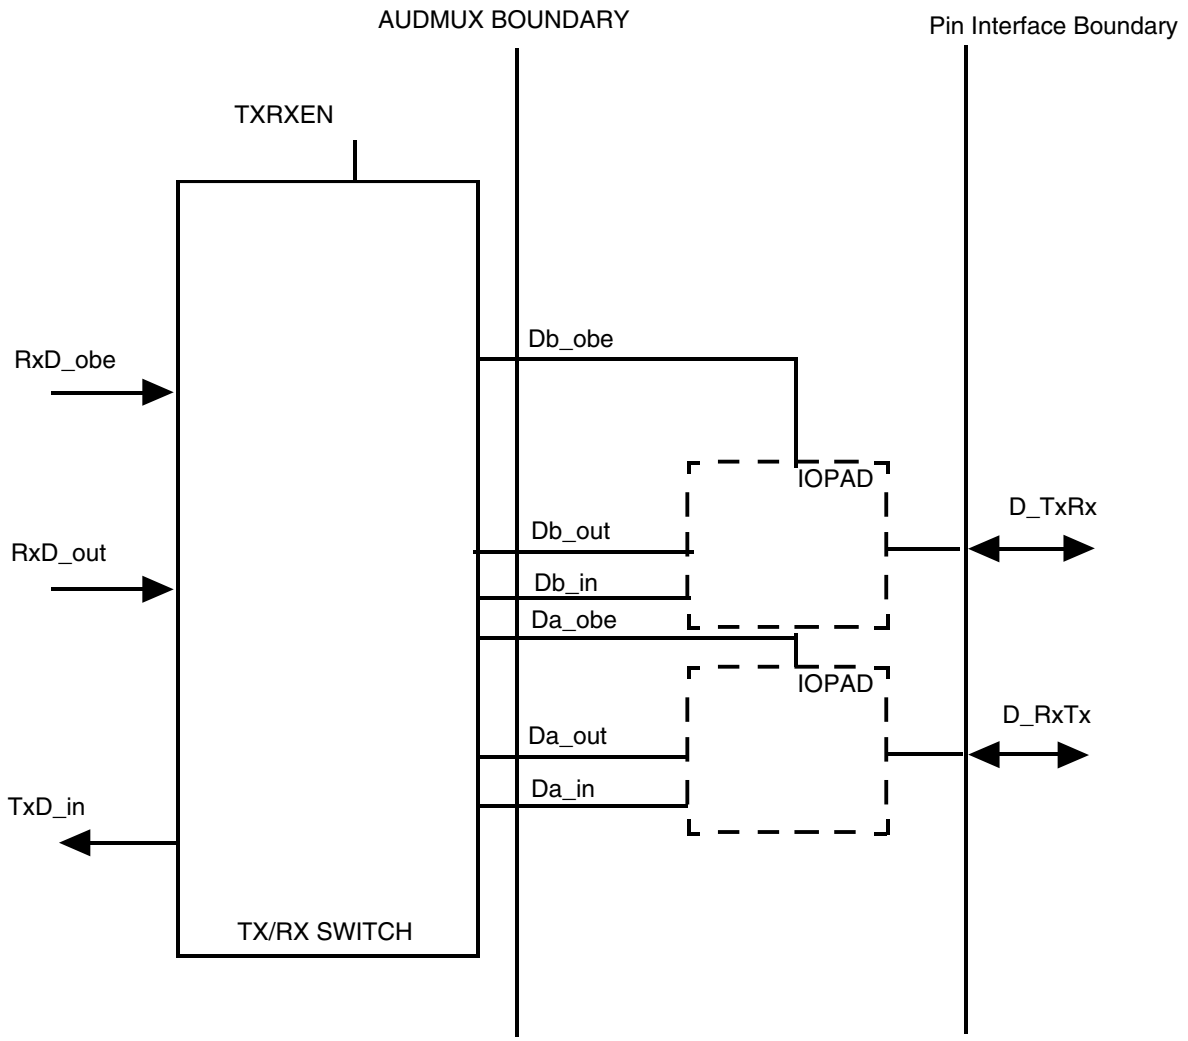

Figure 12-9. Tx/Rx Switch

12.4.1.3 Timing Modes

The AUDMUX ports are constructed as 6-wire interfaces. However, they can be used either in synchronous or asynchronous modes as determined by the SYN bit.

12.4.1.3.1 Synchronous Mode (4-Wire Interface)

In Synchronous mode, the port has a 4-wire interface (that is, RxD, TxD, TxCLK, TxFS). The receive data timing is determined by TxCLK and TxFS.

As shown in the following figure, Port x signals can be routed to Port y, producing 6-wire to 4-wire port connectivity.

TFS_in, RFS_in, TCLK_in, and RCLK_in are the input frame sync and bit clocks from the serial interface (Port x) with their corresponding output buffer enable signals (_obe). TFS_out, RFS_out, TCLK_out, and RCLK_out are the frame sync and bit clocks that are transmitted to the serial interface from the other ports.

The TFS_out and TCLK_out are selected at Port x by the TFSEL and TCSEL mux settings, respectively. RFS_out and RCLK_out are selected at Port x by the RFSEL and RCSEL mux settings, respectively. Similarly, in the external direction, Port y is configured as a 4-wire port; TFSEL selects the FS_obe and FS_out signals. In this mode, the configuration of RFSEL and RCSEL is not used, since the RFS_out and RCLK_out pins at Port y are not available.

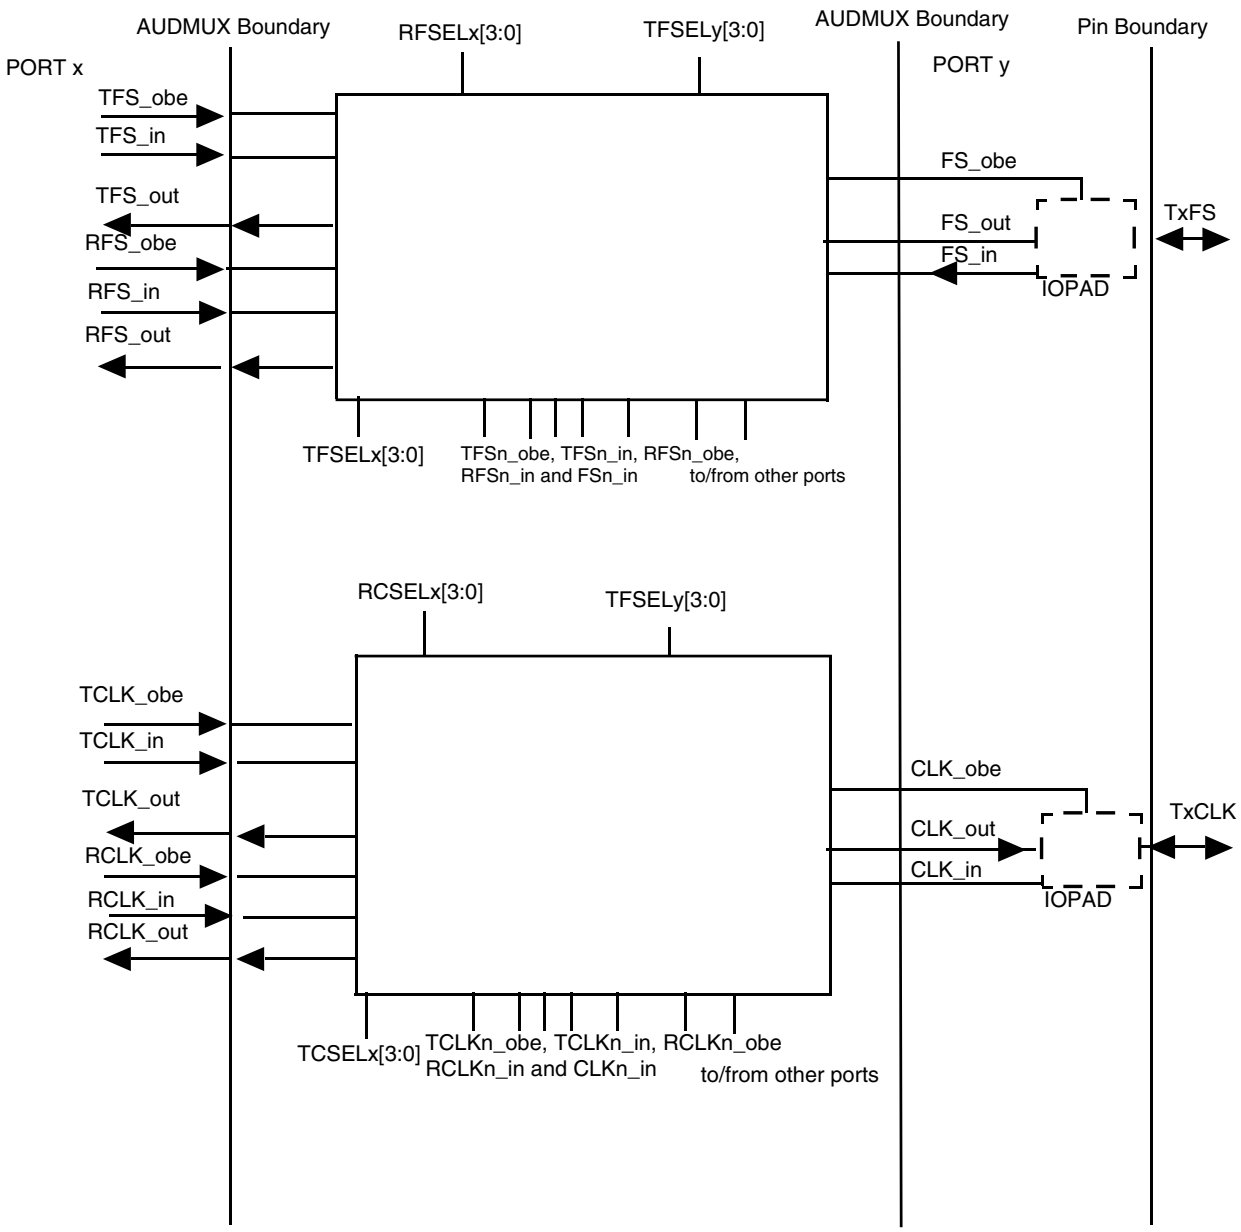

Figure 12-10. Frame Sync and Clock Routing When External Port Is 4-Wire

12.4.1.3.2 Asynchronous Mode (6-Wire Interface)

In Asynchronous mode, the port has a 6-wire interface (meaning RxD, TxD, TxCLK, TxFS, RxCLK, RxFS). This mode has additional receive clock (RxCLK) and frame sync (RxFS) signals as compared to the synchronous or 4-wire interface.

As shown in the figures below, Port x signals can be routed to Port y, producing 6-wire to 6-wire port connectivity.

TFS_in, RFS_in, TCLK_in, and RCLK_in are input frame sync and bit clocks from the serial interface (Port x) with their corresponding output buffer enable signals (_obe). TFS_out, RFS_out, TCLK_out, and RCLK_out are the frame sync and bit clocks that are transmitted to the serial interface from the other ports.

TFS_out and TCLK_out are selected by the TFSEL and TCSEL mux settings, respectively. RFS_out and RCLK_out are selected by the RFSEL and RCSEL mux settings, respectively. Similarly, in the external direction, the TFSEL selects the TxFS_obe and TxFS_out signals and TCSEL selects the TxCLK_obe and TxClk_out signals. The RFSEL selects the RxFS_obe and RxFS_out signals and RCSEL selects the RxCLK_obe and RxCLK_out signals.

NOTE

Because FS_in and CLK_in from external interfaces are also routed to the TFSEL and TCSEL muxes of the external ports, these signals do not have corresponding buffer enable signals. Consequently, their corresponding inputs to the TFSEL and TCSEL mux of the external ports have to be tied high.

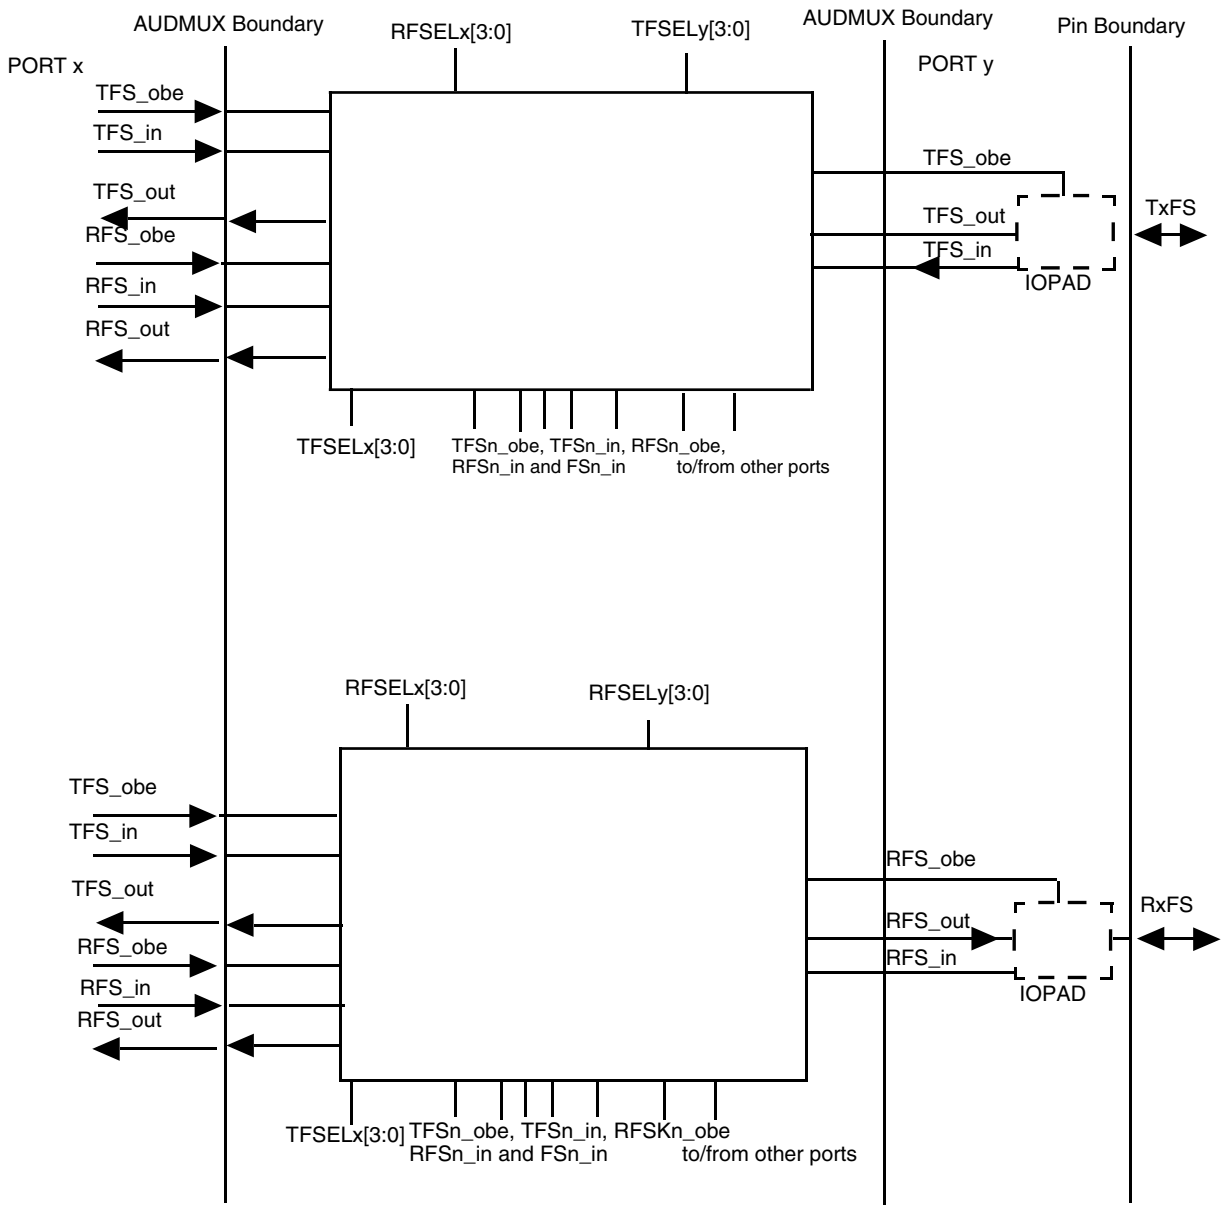

Figure 12-11. Frame Sync Routing When External Port Is 6-Wire

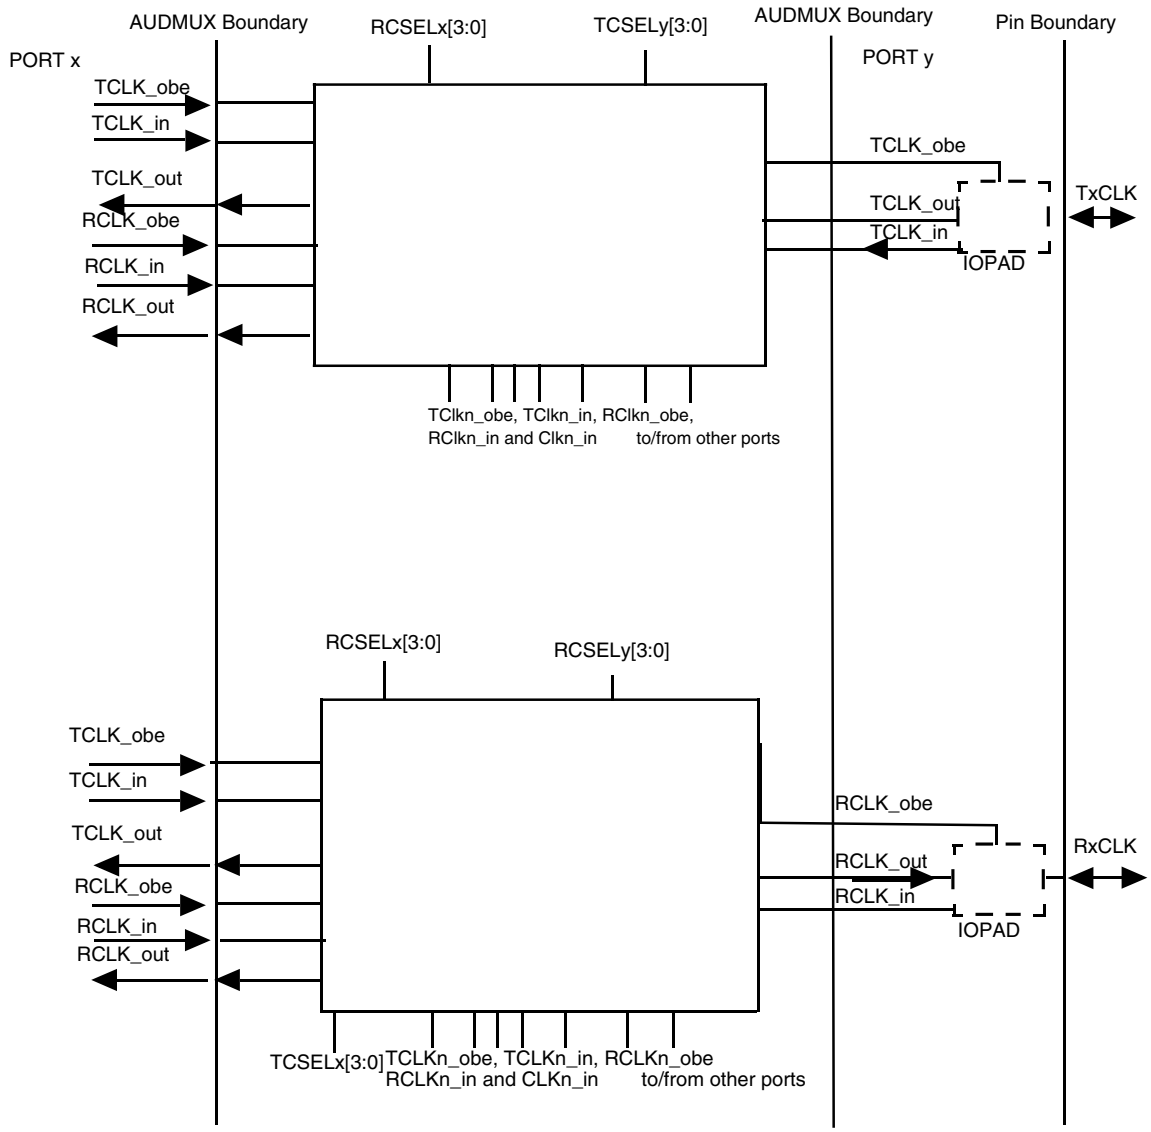

Figure 12-12. Clock Routing When External Port Is 6 Wire

12.4.2 Connectivity Between Ports

Four basic types of connections are provided by the AUDMUX:

- Internal port to external port
- External port to external port
- Internal port to internal port
- Loopback

The corresponding data connections are described in the following sections.

12.4.2.1 Internal Port to External Port Connectivity

The internal port is connected to a processor's serial interface. TxD_obe is the buffer enable signal from the serial interface, TxD_in is the input transmit data from the serial interface to the AUDMUX, and RxD_out is the receive data output from the AUDMUX to the serial interface.

RXDSEL[2:0] of the external port selects the buffer enable signal (TxD_obe) and transmit data output (TxD_out) signal from the TxD_obe and RxD_in signals. RXDSEL[2:0] is a common signal to both selection muxes.

NOTE

Because buffer TxD_in signals from external interfaces do not have corresponding buffer enable signals, their buffer enable signals into the selection mux are tied high. This will ensure that selection of TxD_in, as RxD_out will also drive the RxD_obe output high.

Transmit Data from the serial interface goes into the RXDSEL data mux and comes out as RxD_out. RxD_out is routed to Da_TxRx when TXRXEN is disabled and to D_RxTx when TXRXEN is enabled. Similarly, D_RxTx is routed to TxD_in when TXRXEN is disabled and D_TxRx is routed to TxD_in when TXRXEN is enabled. The routing of frame syncs is shown in Figure 12-11and the routing of interface clocks is shown in Figure 12-9.

If internal network mode is disabled, then RXDSEL selects the TxD_in, which is sent from the AUDMUX to the serial interface connected at Port x. When the internal network mode is selected, RxD_out is constructed by ANDing selected TxD_in signals from the ports (as determined by INMMASK).

If there is more than one device attached to the external port at D_TxRx and D_RxTx and one of the devices is a network master, then two conditions must be noted:

1. When the external master is enabled in network mode, then the serial interface at Port x must be configured as a slave (normal or network mode). No Tx/Rx switching is required.
2. When the external master is disabled and the serial interface at Port x and other slave devices must communicate, then the serial interface at Port x must be configured as a network mode master and the Tx/Rx switch at Port y must be enabled (TXRXEN=1). This will ensure that the transmit and receive paths are connected appropriately.

To communicate with more than one port, internal network mode can be enabled at Port x. In internal network mode, it is possible to communicate with any device attached to the other ports. Internal network mode shall be enabled at the port that is the SSI network mode master.

12.4.2.2 External Port to External Port Connectivity

External ports can communicate with external ports directly.

External ports can communicate together in three ways:

1. Each port's receive logic is configured in normal mode (MODE = 0) . Each port's RXDSEL[2:0] field is configured to select the other port's transmit data. Bit fields associated with clock/frame sync selection and direction are configured for each port. Either port can be the master.
2. One port is configured in internal network mode (MODE = 1) . All desired data lines are combined by the AND gate as determined by INMMASK[7:0]. Since an external port is being used as the internal network mode master, all other devices on the same AUDMUX port as the internal network mode master must be disabled. This configuration can be used with a combination of internal and external ports. All external ports must have a pull-up resistor on its RxDATA pin. Bit fields associated with clock/frame sync selection and direction are configured for each port. Any port can be the master.

12.4.2.3 Internal Port to Internal Port Connectivity

Internal ports can communicate with other internal ports directly.

Internal ports can communicate together in two ways:

1. Each port's receive logic is configured in normal mode (MODE = 0) . Each port's RXDSEL[2:0] field is configured to select the other port's transmit data. Bit fields associated with clock/frame sync selection and direction are configured for each port. Either port can be the master.
2. One port is configured in internal network mode (MODE = 1) . All desired data lines are combined by the AND gate as determined by INMMASK[7:0]. This configuration can be used with a combination of internal and external ports. All external ports must have a pull-up resistor on its RxDATA pin. Bit fields associated with clock/frame sync selection and direction are configured for each port. Any port can be the master.

12.4.2.4 Loopback Connectivity

AUDMUX ports can communicate with themselves in order to provide loopback functionality. Port x can route its TxDATA signal to its own RxD_out signal by setting RXDSELx[2:0] to its own port number. This is supported by all ports in the AUDMUX.

In addition, ports can provide loopback support in internal network mode. With internal network mode, the internal network mode master can loop its TxDATA signal (combined with those of other ports, if desired) back into its RxD_out signal. Port x's INMMASK should be set such that bit (x - 1) is clear in order to enable the loopback.

12.4.3 AUDMUX Clocking

This section provides information about AUDMUX clocking including clock inputs and the clock diagram.

12.4.3.1 AUDMUX Clock Inputs

The IP Bus read/write clock-peripheral clock-is an input to the AUDMUX. It is used for all AUDMUX register accesses. It is driven only when there is an AUDMUX access on the IP Bus.

12.4.3.2 AUDMUX Clock Diagram

The figure below shows the clocking used in the AUDMUX.

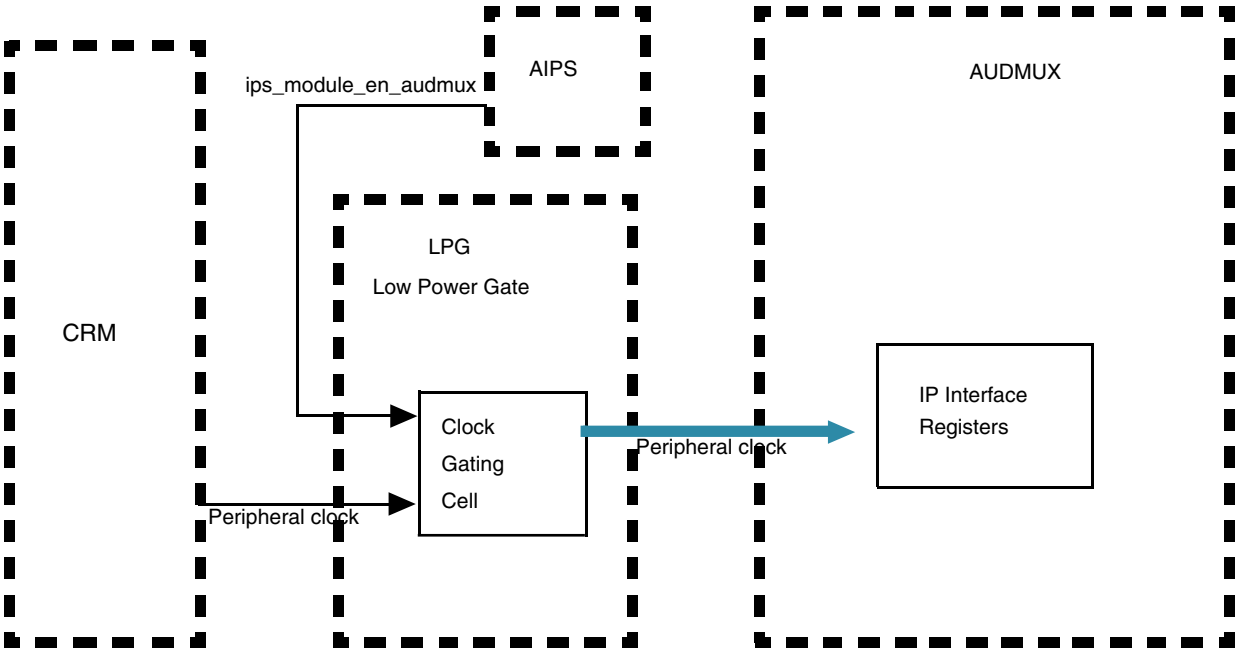

Figure 12-13. AUDMUX Clocking Scheme

12.4.3.3 Clocking Restrictions

- Since the AUDMUX requires only peripheral clock, the AUDMUX places no restrictions on the bus frequency.
- All registers in the AUDMUX are control registers so their values will not change frequently. Their values will be programmed when changing between use cases (not during use cases).

12.5 Programmable Registers

This section includes the block memory map and detailed descriptions of all registers. For the base address of a specific sub-block instantiation, see the system memory map in this manual.

The AUDMUX memory map is shown in the following table.

AUDMUX memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
63FD_0000	Port Timing Control Register 1 (AUDMUX_PTCR1)	32	R/W	AD40_0800h	12.5.1/ 658
63FD_0004	Port Data Control Register 1 (AUDMUX_PDCR1)	32	R/W	0000_A000h	12.5.2/ 660

AUDMUX_PTCR1 field descriptions

Field	Description
31 TFS DIR	Transmit Frame Sync Direction Control. This bit sets the direction of the TxFS pin of the interface as an output or input. When set as an input, the TFSEL settings are ignored. When set as an output, the TFSEL settings determine the source port of the frame sync. 0 TxFS is an input. 1 TxFS is an output.
30–27 TFSEL[3:0]	Transmit Frame Sync Select. Selects the source port from which TxFS is sourced. 0xxx Selects TxFS from port. 1xxx Selects RxFS from port. x000 Port 1 x101 Port 6 x11x Reserved
26 TCLKDIR	Transmit Clock Direction Control. This bit sets the direction of the TxClk pin of the interface as an output or input. When set as an input, the TCSEL settings are ignored. When set as an output, the TCSEL settings determine the source port of the clock. 0 TxClk is an input. 1 TxClk is an output.
25–22 TCSEL[3:0]	Transmit Clock Select. Selects the source port from which TxClk is sourced. 0xxx Selects TxClk from port. 1xxx Selects RxClk from port. x000 Port 1 x101 Port 6 x11x Reserved
21 RFS DIR	Receive Frame Sync Direction Control. This bit sets the direction of the RxFS pin of the interface as an output or input. When set as an input, the RFSEL settings are ignored. When set as an output, the RFSEL settings determine the source port of the frame sync. 0 RxFS is an input. 1 RxFS is an output.
20–17 RFSEL[3:0]	Receive Frame Sync Select. Selects the source port from which RxFS is sourced. RxFS can be sourced from TxFS and RxFS from other ports. 0xxx Selects TxFS from port. 1xxx Selects RxFS from port. x000 Port 1 x101 Port 6 x11x Reserved
16 RCLKDIR	Receive Clock Direction Control. This bit sets the direction of the RxClk pin of the interface as an output or input. When set as an input, the RCSEL settings are ignored. When set as an output, the RCSEL settings determine the source port of the clock. **NOTE:** RCLKDIR and SYN should not be changed at the same time. 0 RxClk is an input. 1 RxClk is an output.

Table continues on the next page...

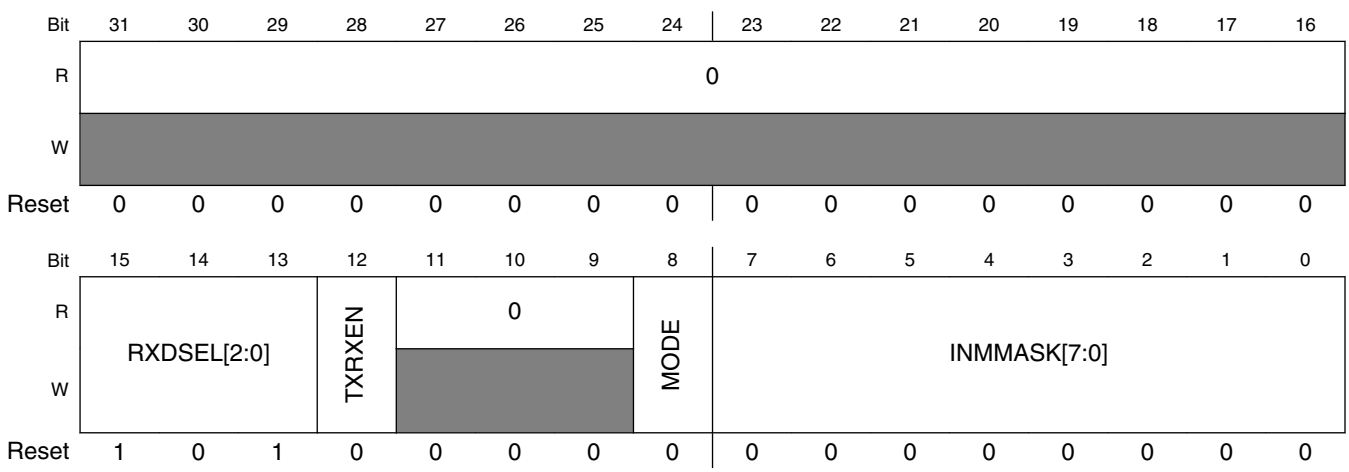
AUDMUX_PTCR1 field descriptions (continued)

Field	Description
15–12 RCSEL[3:0]	Receive Clock Select. Selects the source port from which RxClk is sourced. RxClk can be sourced from TxClk and RxClk from other ports. 0xxx Selects TxClk from port. 1xxx Selects RxClk from port. x000 Port 1 x101 Port 6 x11x Reserved
11 SYN	Synchronous/Asynchronous Select. When SYN is set, synchronous mode is chosen and the transmit and receive sections use common clock and frame sync signals (that is, the port is a 4-wire interface). When SYN is cleared, asynchronous mode is chosen and separate clock and frame sync signals are used for the transmit and receive sections (that is, the port is a 6-wire interface). **NOTE:** RCLKDIR and SYN should not be changed at the same time. 0 Asynchronous mode 1 Synchronous mode (default)
10–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

12.5.2 Port Data Control Register 1 (AUDMUX_PDCR1)

PDCR1 is the Port Data Control Register for Port 1.

Address: AUDMUX_PDCR1 is 63FD_0000h base + 4h offset = 63FD_0004h



AUDMUX_PDCR1 field descriptions

Field	Description

AUDMUX_PDCR1 field descriptions (continued)

Field	Description
15–13 RXDSEL[2:0]	Receive Data Select. Selects the source port for the RxD data. RXDSEL is ignored if MODE = 1 (that is, Internal Network Mode is enabled). xxx Port number for RxD 000 Port 1 101 Port 6 11x Reserved
12 TXRXEN	Transmit/Receive Switch Enable. Swaps the transmit and receive signals. 0 No switch (Transmit Pin = Transmit, Receive Pin = Receive) 1 Switch (Transmit Pin = Receive, Receive Pin = Transmit)
11–9 Reserved	This read-only field is reserved and always has the value zero. Reserved
8 MODE	Mode Select. This field selects the mode in which the port is to operate. The modes of operation include the following: • Normal mode, in which the RxD from the port selected by RXDSEL is routed to the port. • Internal Network mode in which RxD from other ports are ANDed together. RXDSEL is ignored. INMMASK determines which RxD signals are ANDed together. 0 Normal mode 1 Internal Network mode
7–0 INMMASK[7:0]	Internal Network Mode Mask. Bit mask that selects the ports from which the RxD signals are to be ANDed together for internal network mode. Bit 6 represents RxD from Port 6 and bit0 represents RxD from Port 1. 0 Includes RxDn for ANDing 1 Excludes RxDn from ANDing

12.5.3 Port Timing Control Register 2 (AUDMUX_PTCR2)

PTCR2 is the Port Timing Control Register for Port 2.

Address: AUDMUX_PTCR2 is 63FD_0000h base + 8h offset = 63FD_0008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

Reset	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0

AUDMUX_PTCR2 field descriptions

Field	Description
31 TFS DIR	Transmit Frame Sync Direction Control. This bit sets the direction of the TxFS pin of the interface as an output or input. When set as an input, the TFSEL settings are ignored. When set as an output, the TFSEL settings determine the source port of the frame sync. 0 TxFS is an input. 1 TxFS is an output.
30–27 TFSEL[3:0]	Transmit Frame Sync Select. Selects the source port from which TxFS is sourced. 0xxx Selects TxFS from port. 1xxx Selects RxFS from port. x000 Port 1 x101 Port 6 x11x Reserved
26 TCLKDIR	Transmit Clock Direction Control. This bit sets the direction of the TxClk pin of the interface as an output or input. When set as an input, the TCSEL settings are ignored. When set as an output, the TCSEL settings determine the source port of the clock. 0 TxClk is an input. 1 TxClk is an output.
25–22 TCSEL[3:0]	Transmit Clock Select. Selects the source port from which TxClk is sourced. 0xxx Selects TxClk from port. 1xxx Selects RxClk from port. x000 Port 1 x101 Port 6 x11x Reserved
21 RFS DIR	Receive Frame Sync Direction Control. This bit sets the direction of the RxFS pin of the interface as an output or input. When set as an input, the RFSEL settings are ignored. When set as an output, the RFSEL settings determine the source port of the frame sync. 0 RxFS is an input. 1 RxFS is an output.
20–17 RFSEL[3:0]	Receive Frame Sync Select. Selects the source port from which RxFS is sourced. RxFS can be sourced from TxFS and RxFS from other ports. 0xxx Selects TxFS from port. 1xxx Selects RxFS from port. x000 Port 1 x101 Port 6 x11x Reserved
16 RCLKDIR	Receive Clock Direction Control. This bit sets the direction of the RxClk pin of the interface as an output or input. When set as an input, the RCSEL settings are ignored. When set as an output, the RCSEL settings determine the source port of the clock. **NOTE:** RCLKDIR and SYN should not be changed at the same time. 0 RxClk is an input. 1 RxClk is an output.

Chapter 13
AHB to IP Bridge (AIPSTZ)

13.1 Introduction

This section provides an overview of the AHB to IP Bridge (AIPSTZ). The peripheral bridge acts as an interface between the system bus and lower bandwidth IP Slave (IPS) bus peripherals.

NOTE

Although we use the mnemonic "AIPSTZ," the AHB to IP Bridge in this chip does not support TrustZone.

13.1.1 Features

The following list summarizes the key features of the bridge:

- The bridge supports the IPS slave bus signals. This interface is only meant for slave peripherals.
- The bridge supports 8-, 16-, and 32-bit IPS peripherals. (Accesses larger than the size of a peripheral are not supported, except to 32-bit memory.)
- The bridge supports a pair of IPS accesses for 64-bit and certain misaligned AHB transfers to 32-bit memory in 64-bit platforms.
- The bridge directly supports up to 32 16-Kbyte external IPS peripherals, and 2 global external IPS peripheral spaces. The bridge occupies 64 MBytes of total address space.
- The bridge provides configurable per-block and per-master access protections.
- Peripheral read transactions require a minimum of 2 hclk clocks, and unbuffered write transactions require a minimum of 3 hclk clocks.
- The bridge uses one single asynchronous reset and one global clock.

13.2 General Operation

The AHB to IP bridge is the interface between the AHB and on-chip IPS peripherals, which are sub-blocks containing readable/writable control and status registers.

The AHB master reads and writes these registers through the AIPSTZ. The bridge generates block enables, the block address, transfer attributes, byte enables and write data as inputs to the IPS peripherals. The bridge captures read data from the IPS interface and drives it on the AHB.

It occupies a 64-Mbyte portion of the address space. 63.5 Mbytes are available for off-platform devices. The register maps of the IPS peripherals are located on 16-Kbyte boundaries. Each IPS peripheral is allocated one 16K-byte block of the memory map, and is activated by one of the block enables from the bridge. Up to thirty-two 16-Kbyte external IPS peripherals may be implemented, occupying contiguous blocks of 16 Kbytes. Two global external IPS block enables are available for the remaining 63 Mbytes of address space to allow for customization and expansion of addressed peripheral devices. In addition, a single "non-global" block enable is also asserted whenever any of the thirty-two non-global block enables is asserted.

The bridge is responsible for indicating to IPS peripherals if an access is in supervisor or user mode. It may block user mode accesses to certain IPS peripherals or it may allow the individual IPS peripherals to determine if user mode accesses are allowed. In addition, peripherals may be designated as write-protected.

All peripheral devices are expected to only require aligned accesses equal to or smaller in size than the peripheral size. An exception to this rule is supported for 32-bit peripherals to allow memory to be placed on the IPS.

13.2.1 AIPSTZ Registers

This section provides information on the registers of the AIPS bridge.

13.2.2 Overview

There are eleven registers that control the AIPS bridge. All registers are 32-bit registers and can only be accessed in supervisor mode by specifically configured bus masters such as the core processor. Additionally, these registers must only be read from or written to by a 32-bit aligned access. The bridge registers are mapped into the PACR0 address space.

Two system clocks are required for read accesses and three system clocks are required for write accesses to the bridge registers.

13.2.3 Control Registers

The memory map for the AIPS program-visible registers is shown in the table below.

The MPROT fields of the AIPSTZ_MPR and the AIPSTZ_PACR and AIPSTZ_OPACR registers are 4 bits in width. Some bits may be reserved depending on device.

Table 13-1. AIPSTZ Register Memory Map

PACR0_ Offset	[31:28]	[27:24]	[23:20]	[19:16]	[15:12]	[11:8]	[7:4]	[3:0]

13.3 Register Descriptions

13.3.1 Master Privilege Registers

Each AIPSTZ_MPR specifies eight 4-bit fields defining the access privilege level associated with a bus master in the platform, as well as specifying whether write accesses from this master are bufferable.

The registers provide one field per bus master, where field 15 corresponds to master 15, field 14 to master 14,... field 0 to master 0 (typically the processor core). The master index allocation is shown in Table 13-4.

Table 13-2. MPROT Field

Bit	3	2	1	0
Field	MBW	-	-	MPL
Reset	*	*	*	*
Read/Write	Read/Write			

Table 13-3. Master Protection Field Descriptions

Name	Description	Settings
3 **(MBW)**	**Master Buffer Writes** - This bit determines whether the AIPSTZ is enabled to buffer writes from this master.	0 Write accesses from this master are not bufferable 1 Write accesses from this master are allowed to be buffered
2 -	Reserved	0
1 -	Reserved	0
0 **(MPL)**	**Master Privilege Level** - This bit determines how the privilege level of the master is determined.	0 Accesses from this master are forced to user-mode (**ips_supervisor_access** is forced to zero) regardless of the **hprot[1]** access attribute. 1 Accesses from this master are not forced to user-mode. The **hprot[1]** access attribute is used directly to determine **ips_supervisor_access**.

Table 13-4. Master index allocation

Master index	Master name	Comments
Master 0	All masters excluding ARM core, SDMA and CAAM	Share the same number allocation.
Master 1	ARM CORE	
Master 2	CAAM	

Table continues on the next page...

Table 13-4. Master index allocation (continued)

Master index	Master name	Comments
Master 3	SDMA	
Master 4-15	Reserved	

13.3.2 Off-Platform Peripheral Access Control Registers (AIPSTZ_OPACRs)

Each of the off-platform peripherals have an Off-platform Peripheral Access Control Register (AIPSTZ_OPACR) which defines the access levels supported by the given block.

Each AIPSTZ_PACR has the following format:

Table 13-5. AIPSTZ_OPACR Fields

Field	BW	SP	WP	-
Reset	0	1	0	0
Read/Write	Read/Write			

Table 13-6. Peripheral Access Control Register Field Descriptions

Name	Description	Settings
3 **(BW)**	**Buffer Writes** - This bit determines whether write accesses to this peripheral are allowed to be buffered.[1]	0 Write accesses to this peripheral are not bufferable by the AIPSTZ. 1 Write accesses to this peripheral are allowed to be buffered by the AIPSTZ.
2 **(SP)**	**Supervisor Protect** - This bit determines whether the peripheral requires supervisor privilege level for access.	0 This peripheral does not require supervisor privilege level for accesses. 1 This peripheral requires supervisor privilege level for accesses. The master privilege level must indicate supervisor via the hprot[1] access attribute, and the MPROTx[MPL] control bit for the master must be set. If not, the access is terminated with an error response and no peripheral access is initiated on the IPS bus.
1 (WP)	**Write Protect** - This bit determines whether the peripheral allows write accesses	0 This peripheral allows write accesses. 1 This peripheral is write protected. If a write access is attempted, the access is terminated with an error response and no peripheral access is initiated on the IPS bus.
0 -	Reserved	0

1. Buffered writes are not available for AIPSTZ. This bit should be set to '0'.

13.4 Functional Description

The AIPS bridge serves as a protocol translator between the AHB system bus and the IP bus. Support is provided for generating a pair of 32-bit IP bus accesses when targeted by a 64-bit system bus access, or a misaligned access which crosses a 32-bit boundary. No other bus-sizing access support is provided.

13.5 Access Protections

The AIPS bridge provides programmable access protections for both masters and peripherals. It allows the privilege level of a master to be overridden, forcing it to user-mode privilege. Peripherals may require supervisor privilege level for access and may be write-protected.

13.6 Access Support

Aligned 64-bit accesses, aligned and misaligned word and half word accesses, as well as byte accesses are supported for 32-bit peripherals. Misaligned accesses are supported to allow memory to be placed on the IPS. Peripheral registers must not be misaligned, although no explicit checking is performed by the AIPS bridge.

The bridge will perform two IPS transfers for 64-bit accesses, word accesses with byte offsets of 1, 2, or 3, and for half word accesses with a byte offset of 3. All other accesses will be performed with a single IPS transfer.

Only aligned half word and byte accesses are supported for 16-bit peripherals. All other accesses types are unsupported, and results of such accesses are undefined. They are not terminated with an error response.

Only byte accesses are supported for 8-bit peripherals. All other accesses types are unsupported, and results of such accesses are undefined. They are not terminated with an error response.

13.7 Initialization Information

The AIPS bridge should be programmed before use. The following registers should be initialized: the Master Privilege Registers (AIPSTZ_MPRs), the Peripheral Access Control registers (AIPSTZ_PACRs), and the Off-platform Peripheral Access Control registers (AIPSTZ_OPACRs) described in 3.2 Control Registers.

Chapter 14
32-Bit Correcting ECC Accelerator (BCH)

14.1 Introduction

This chapter describes the hardware Bose Ray-Choudhury Hocquenghem (BCH) ECC accelerator. It provides detailed descriptions of how to use the accelerator and programmable registers (described in the Programmable Registers section).

From a programming standpoint, all data transfer to/from memory is handled by the BCH block directly instead of using DMA for data write operations. DMA is still used in programming the GPMI control registers.

14.2 Overview

The hardware ECC accelerator provides a forward error-correction function for improving the reliability of various storage media that may be attached to the chip. For example, modern high-density NAND flash devices presume the existence of forward error-correction algorithms to correct some soft and/or hard bit errors within the device, allowing for higher device yields and, therefore, lower NAND device costs.

The Bose, Ray-Chaudhuri, Hocquenghem (BCH) Encoder and Decoder module is capable of correcting from 2 to 32 single bit errors within a block of data no larger than about 1900 bytes for GF(2^14) (1024 bytes is typical), and about 900 bytes for GF(2^13) (512 bytes is typical). BCH is capable of correcting these errors in applications such as protecting data and resources stored on modern NAND flash devices. The correction level in the BCH block is programmable to provide flexibility for varying applications and configurations of flash page size. The design can be programmed to encode protection of 2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 26, 28, 30, or 32-bit errors when writing flash and to correct the corresponding number of errors on decode. The correction level when decoding MUST be programmed to the same correction level as was used during the encode phase.

BCH-codes are a type of block-code, which implies that all error-correction is performed over a block of N-symbols. The BCH operation will be performed over GF(2^{13} = 8192) or GF(2^{14} = 16384), which is the Galois Field consisting of 8191 or 16383 one-bit symbols. BCH-encoding (or encode for any block-code) can be performed by two algorithms: systematic encoding or multiplicative encoding. Systematic encoding is the process of reading all the symbols which constitute a block, dividing continuously these symbols by the generator polynomial for the GF(8192) or GF(16384) and appending the resulting *t* parity symbols to the block to create a BCH codeword (where *t* is the number of correctable bits).

The BCH encode process creates *t**13 (or *t**14)-bit parity symbols for each data block when the data is written to the flash device. The parity symbols are written to the flash device after the corresponding data block, and together these are collectively called the codeword. The codeword can be used during the decode process to correct errors that occur in either the data or parity blocks.

The BCH decoder processes codewords in a 4-step fashion:

- Syndrome Calculation (SC): This is the process of reading in all of the symbols of the codeword and continuously dividing by the generator polynomial for the field. 2**t* syndromes must be calculated for each codeword and inspection of the syndromes determines if there are errors: a non-zero set of syndromes indicates one or more errors. This process is implemented parallel hardware to minimize processing time since it must be done every time the decode is performed.
- Key Equation Solver (KES): The syndromes represent 2t-linear equations with 2t-unknown variables. The process of solving these equations and selecting from the numerous solutions constitutes the KES module. When the KES block completes its operations, it generates an error locator polynomial (sigma) that is used in the proceeding block to determine the locations and values of the errors.
- Chien Search (CS): This block takes input from the KES block and uses the Chien Algorithm for finding the locations of the errors based on the error locator polynomial. The method basically involves substituting all 8191 symbols from the GF(8192) or 16383 symbols from the GF(16383) into the locator polynomial. All evaluations that produce a zero solution indicate locations of the various errors. Since each located error corresponds to a single bit, the bit in the original data may be corrected by simply flipping the polarity of the incorrect location.
- Correction: this block has to convert the symbol index and mask information to memory byte indexes and masks.

The BCH block was designed to operate in a pipelined fashion to maximize throughput. Aside from the initial latency to fill the pipeline stages, the BCH throughput is about 7/4 cycles/byte. Thus, the bottleneck in performing NAND reads and error corrections is the BCH rate. Current GPMI read rates are approximately 1/2 cycles/byte maximally for the

current generation of NANDs. Fortunately, BCH has a different master clock from GPMI, this gives some flexibity to match the throughput rate. The ARM platform is not directly involved in generating parity symbols, checking for errors, or correcting them.

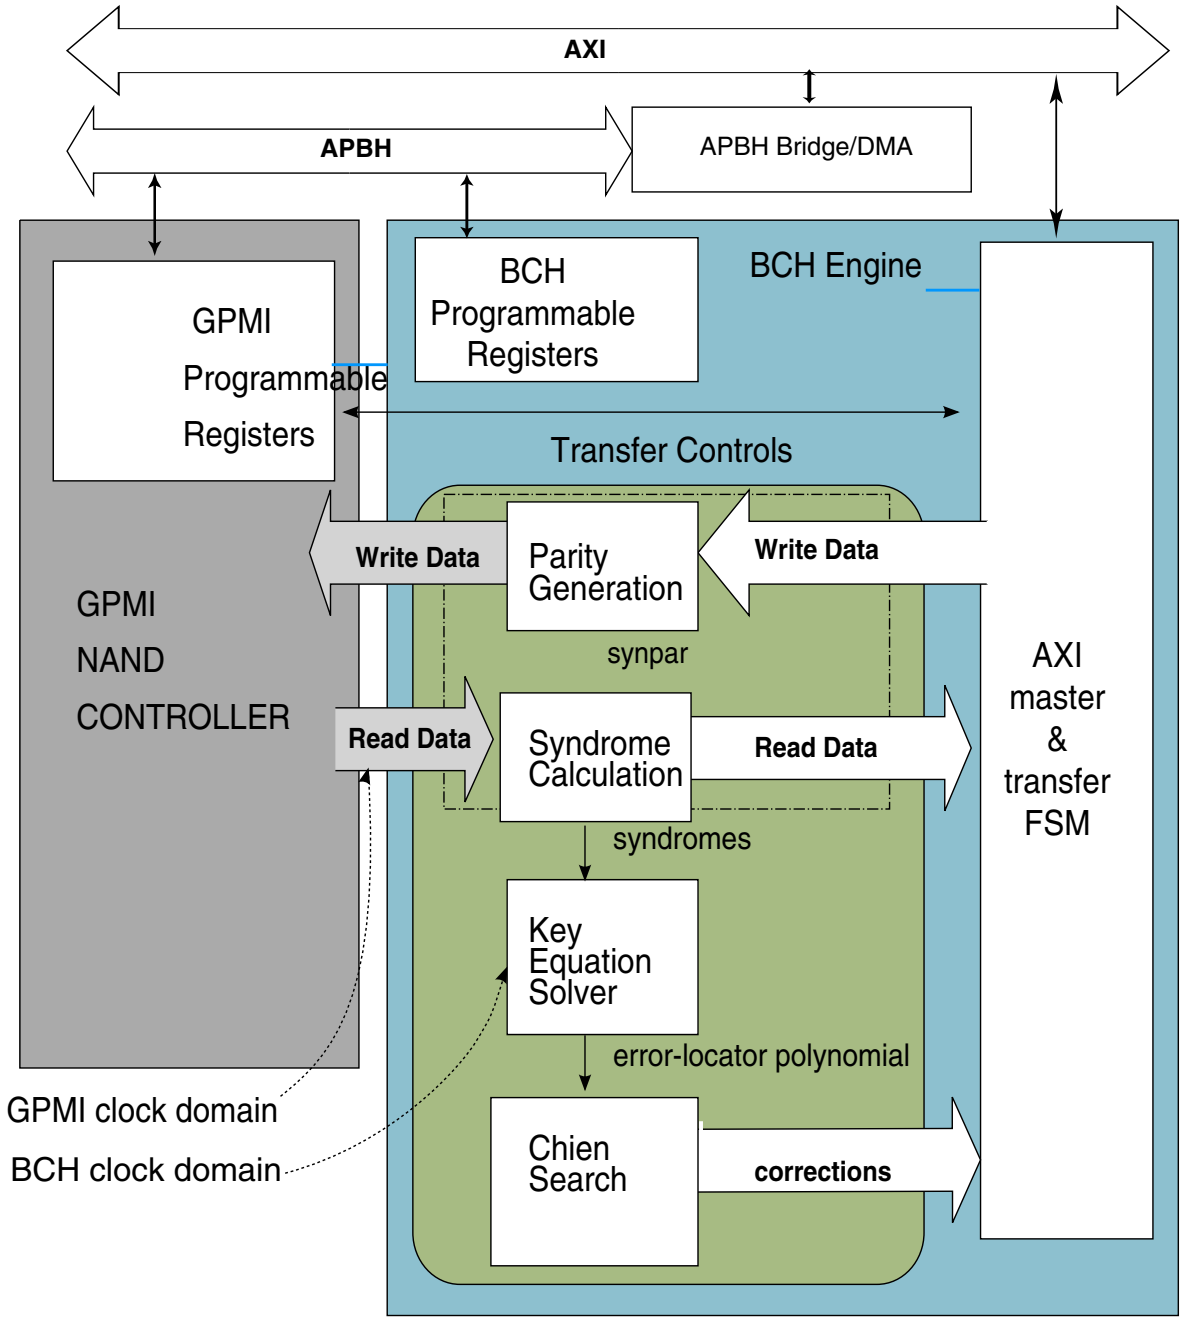

Figure 14-1. Hardware BCH Accelerator

14.3 Operation

Before performing any NAND flash read or write operations, software should first program the BCH's flash layout registers (see Flash Page Layout) to specify how data is to be formatted on the flash device. The BCH hardware allows full programmability over the flash page layout to enable users flexibility in balancing ECC correction levels and ever-changing flash page sizes.

To initiate a NAND flash write, software will program a GPMI DMA operation. The DMA need only program the GPMI control registers (and handle the requisite flash addressing handshakes) since the BCH will handle all data operations using its AXI bus interface. The BCH will then send the data to the GPMI controller to be written to flash as it computes the parity symbols. At the end of each data block the BCH will insert the parity symbols into the data stream so that the GPMI sees only a continuous stream of data to be written.

NAND flash read operations operate in a similar manner. As the GPMI controller reads the device, all data is sent to the BCH hardware for error detection/correction. The BCH controller writes all incoming read data to system memory and in parallel computes the syndromes used to detect bit errors. If errors are detected within a block, the BCH hardware activates the error correction logic to determine where bit errors have occurred and ultimately correct them in the data buffer in system memory. After an entire flash page has been read and corrected, the BCH will signal an interrupt to the ARM platform.

Figure 14-2 indicates how data read from the GPMI is operated on within the BCH hardware. As the BCH receives data from the GPMI (top row) it is written to memory by the BCH's Bus Interface Unit (BIU) (second row). For blocks requiring correction, the KES logic will be activated after the entire block has been received. Once the error locator polynomial has been computed, the corrections are determined by the Chien Search and fed back to the BIU, which performs a read/modify/write operation on the buffer in memory to correct the data

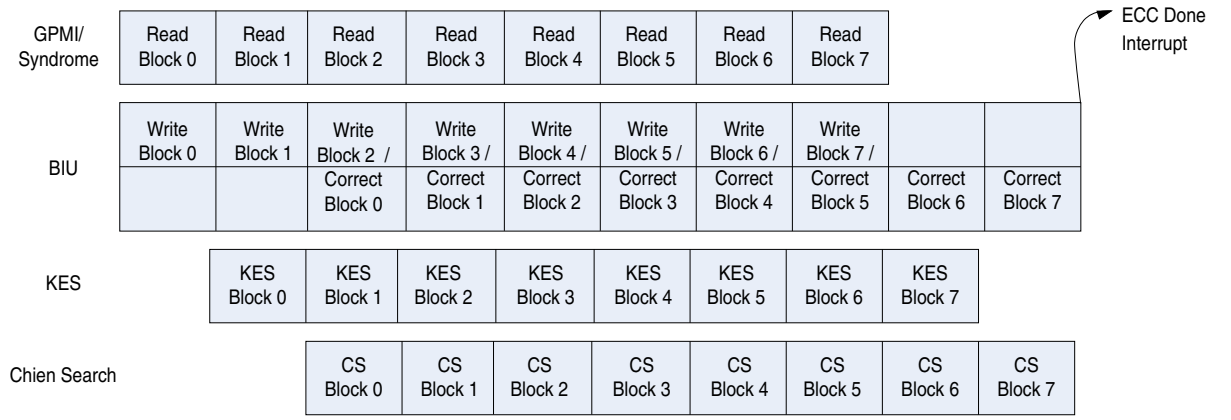

Figure 14-2. Block Pipeline while Reading Flash

14.3.1 BCH Limitations and Assumptions

BCH limitations and assumptions are as follows:

- The BCH is programmable to support 2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 26, 28, 30, and 32-bit error correction. ECC0 is supported as a passthrough, non-correcting mode.
- Data block sizes must be a multiple of 4 bytes and be aligned in system memory.
- The BCH supports a programmable number of metadata/auxiliary data bytes, from 0 to 255.
- Metadata will be written at the beginning of the flash page to facilitate fast access for filesystem operations.
- Metadata may be treated as an independent block for ECC purposes or combined with the first data block to conserve bits in the flash.
- The BCH does not support a partial page write (this can be accomplished by programming the BCH layout registers such that the BCH only sees a portion of the page).
- Flash read operations can read the entire page or the first block on the page.
- The BCH also supports a memory-to-memory mode of operation that does not require the use of DMA or the GPMI.

14.3.2 Flash Page Layout

The BCH supports a fully programmable flash page layout. The BCH maintains 4 independent layout registers that can describe four completely different NAND devices or layouts. When the BCH initiates an operation, it selects one of the layouts by using the chip select as an index into the BCH_LAYOUTSELECT register that determines which layout should be used for the operation.

Three possible (generic) flash layout schemes are supported, as indicated in Figure 14-3. (In each case, the metadata size may also be programmed to 0 bytes). Metadata may either be combined with the first block of data or the size of the first data block can be programmed to 0 to allow the metadata to be protected by its own ECC parity bits.

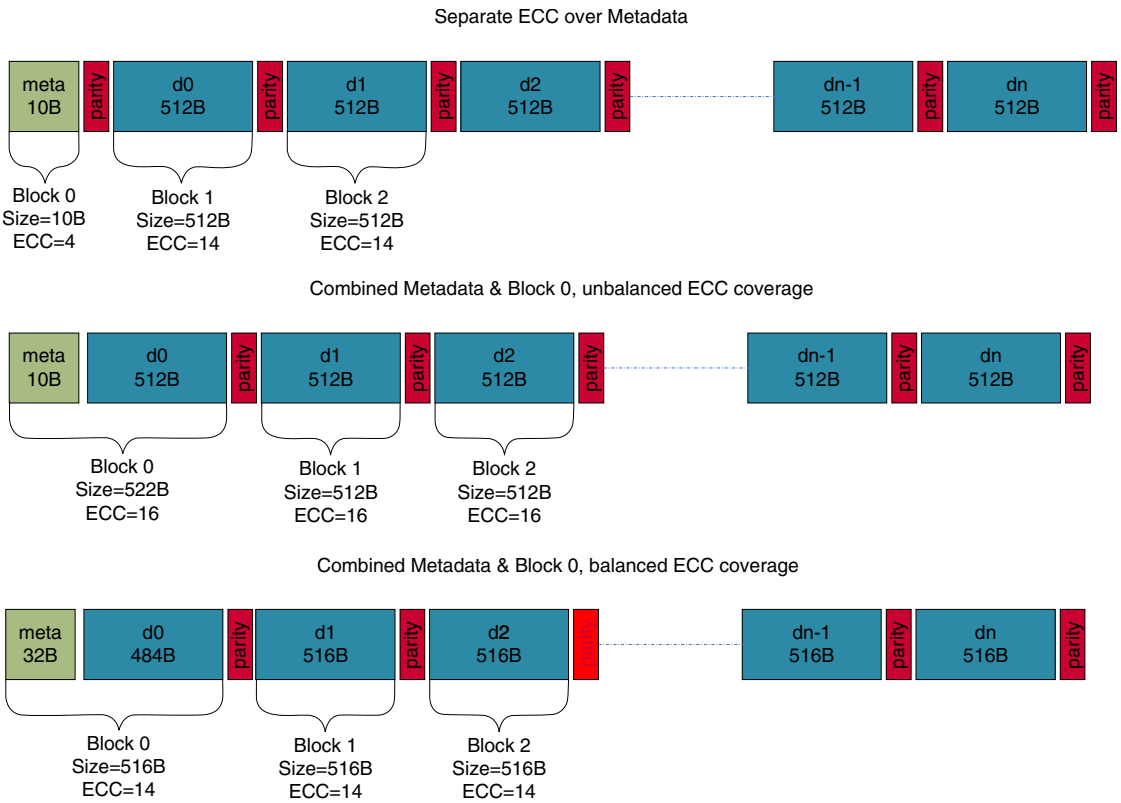

Figure 14-3. FLASH Page Layout Options

Each layout is determined by a pair of registers that define the following parameters:

- DATA0_SIZE: Indicates the number of data bytes in the first block on the page (this should not include parity or metadata bytes). This should be set to 0 when the metadata is to be covered separately with its own ECC. This MUST be a multiple of 4 bytes.
- ECC0: Indicates the ECC level to be used for the first block on the flash (data0+metadata).
- META_SIZE: indicates the number of bytes (from 0-255) that are stored as metadata.
- NBLOCKS: Indicates the number of subsequent "DATAN" blocks on the flash, or the number of blocks following the DATA0 block.
- DATAN_SIZE: Indicates the number of data bytes in all subsequent data blocks. This MUST be a multiple of 4 bytes.
- ECCN: Indicates the ECC level to be used for the subsequent data blocks.

- GF0 or GFN: Indicates the Galois field the meta / data blocks are using.
- PAGE_SIZE: Indicates the total number of bytes available per page on the physical flash device. This includes the spare area and is typically 4096 + 128, 4096 + 218, or 2048 + 64 bytes.

14.3.3 Determining the ECC layout for a Device

Since the BCH is programmable, a system can trade off ECC levels for flash size and layout configurations. The following examples indicate how to determine a valid layout based on the required storage space and flash size. For all cases, the size of the parity will be 13 (or 14 for GF(2^{14}))*ECC level *bits*-- thus for ECC8, 13 (or 14) bytes are required (per block).

14.3.3.1 4K + 218 Flash, 10 bytes Metadata, 512 byte Data Blocks, Separate Metadata, Assuming GF(2^13)

In this case, we have 8 data blocks each consisting of 512 bytes. Since the flash has 218 "spare" bytes (1744 bits), we first estimate an ECC level for the data blocks by first subtracting the number of metadata bytes from the spare bytes (218 - 10 = 208 bytes = 1664 bits) then dividing the number of bits by 8 (number of blocks) and then by 13 (bits per ECC level).

$$(218 - 10) \times 8 = \frac{1664}{13(8)} = 16$$

Thus all the data blocks could be covered by ECC16 if the metadata had no parity. This isn't acceptable, so assume ECC14 for all the data blocks. We now calculate the number of free bits for the metadata parity as

$$1664 - (14) \times 13 \times 8 = 208$$

Thus 208 bits remain for metadata parity. Dividing by 13 (bits/ECC) gives 16, thus the metadata can be covered with ECC16. The settings for this device would then be

Table 14-1. Settings for 4K+218 FLASH

Setting	Value
PAGE_SIZE	4096+218=4314=0x10DA
META_SIZE	10=0x0A

Table continues on the next page...

Table 14-1. Settings for 4K+218 FLASH (continued)

Setting	Value
DATA0_SIZE	0
ECC0	16=0x10
GF0	GF(2^13)
DATAN_SIZE	512=0x200 (in register interface, assigned as 0x80)
ECCN	14=0x0E
GFN	GF(2^13)
NBLOCKS	8

14.3.3.2 4K + 128 flash, 10 bytes Metadata, 1024 byte Data Blocks, Separate Metadata, Assuming GF(2^14) for Data and GF(2^13) for Metadata

This flash will have 118 bytes available for ECC (after subtracting the metadata size), thus 944 bits. Dividing by 4 x 14 (number of blocks x ECC level) we get 17.75, thus we can support ECC16 on the data blocks. The number of free spare bits becomes 944 - 16 x 4 x 14 = 944 - 896 = 48, divided by 13 = 3.69, thus the metadata can be covered by ECC2.

Table 14-2. Settings for 4K + 128 FLASH

Setting	Value
PAGE_SIZE	4096+128=4224=0x1080
META_SIZE	10=0x0A
DATA0_SIZE	0
ECC0	2
GF0	GF(2^13)
DATAN_SIZE	1024=0x400 (in register interface, assigned as 0x100)
ECCN	16
GFN	GF(2^14)
NBLOCKS	4

In this case, there will be additional unused spare bits, with the BCH will pad out with zeros.

14.3.4 Data buffers in System Memory

While the data on the flash is interleaved with parity symbols, the BCH assumes that the data buffers in memory are contiguous. Metadata read from the flash will be stored to the location pointed to by the GPMI_AUXILIARY register and data will be written to the address specified in the GPMI_PAYLOAD register as is shown in Figure 14-4 where the block length is 512 bytes for example. Since the number of blocks on a flash page is programmable, the BCH also writes individual block correction status to the auxiliary pointer at the word-aligned address following the end of the metadata. Optionally, the computed syndromes may also be written to the auxiliary area if the BCH_CTRL[DEBUGSYNDROME] bit is set in the control register.

As blocks complete processing, the bus master will accumulate the status for each block and write it to the auxiliary data buffer following the metadata. The metadata area will be padded with 0's until the next word boundary and the status for blocks 0-3 will be written to the next word. Status for subsequent blocks will then be written to the buffer. Status for the first block (metadata block) is also stored in the BCH_STATUS[STATUS_BLK0] bit field. The completion codes for the blocks are indicated in the Table 14-3. Note that the definition of the bytes and their ordering in the auxiliary and payload storage areas are user defined. When this data is read back from the flash and put into memory, it will resemble the original buffer that was written out to the flash.

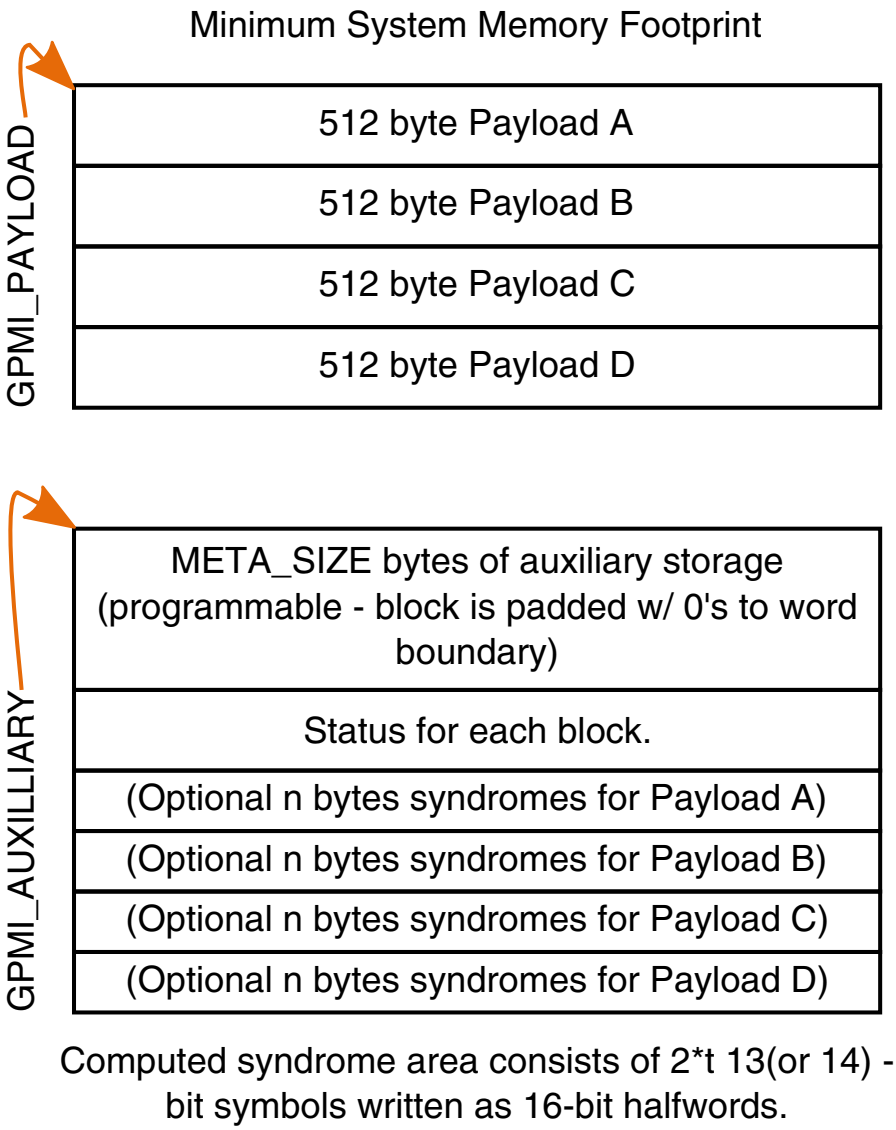

Figure 14-4. BCH Data Buffers in Memory

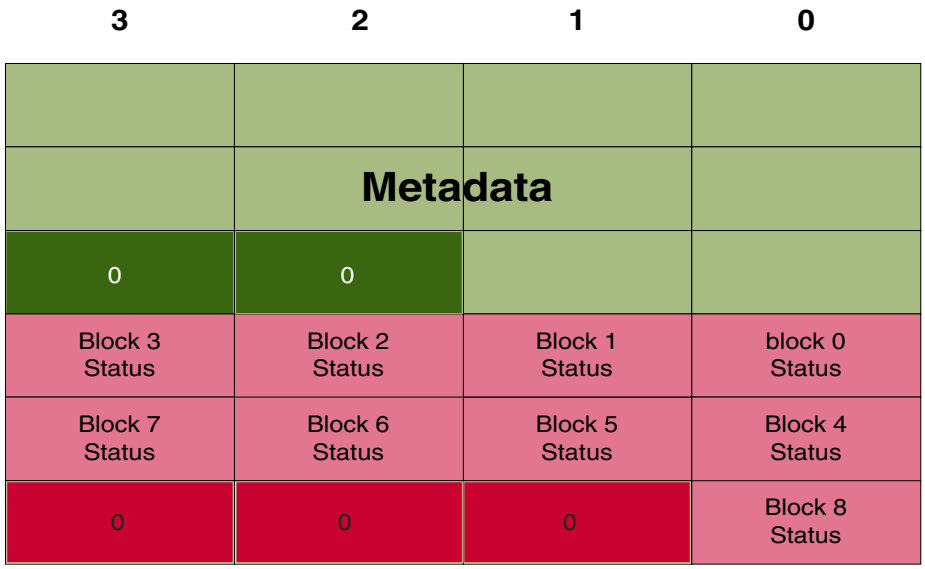
Table 14-3. Status Block Completion Codes

Code	Description
0xFF	Block is erased
0xFE	Block is uncorrectable
0x00	No errors found
0x01-0x20	Number of errors corrected

Figure 14-5 shows the layout of the bytes within the status field.



Status bytes are allocated based on the NBLOCKS programmed into the flash format register. The number of status bytes will be computed by the NBLOCKS+1. The status area will be padded with zeros to the next word boundary.

Syndrome data written for debug purposes will follow the end of the status block.

Figure 14-5. Memory-to-Memory Operations

14.4 Memory to Memory (Loopback) Operation

The BCH supports a memory-to-memory mode of operation where both the encoded and decoded buffers reside in system memory. This can be useful for applications where data must be protected by ECC, but the storage device does not reside on the GPMI bus.

The BCH operation in memory to memory mode is much simpler than in GPMI mode since DMAs are not required to manage the operation. Instead software simply writes the BCH_DATAPTR and BCH_METAPTR with the addresses of the data and metadata (auxiliary) buffers and the BCH_ENCODEPTR with the address of the buffer for encoded data. To initiate the operation, software simply sets the M2M_ENCODE and M2M_ENABLE bits in the control register. The BCH can be programmed to either issue an interrupt at the end of the operation or software may poll the status bits for completion.

Memory to memory decode operations work in a similar manner. The encoded data address is written to the BCH_ENCODEPTR and the data and meta pointers are written to buffers that correspond to the desired decoded data addresses. To initiate a decode, software must set the M2M_ENCODE bit to 0 while writing the M2M_ENABLE bit.

Note that the addresses written to the BCH_DATAPTR, BCH_METAPTR and BCH_ENCODEPTR registers should always be aligned on a 4 byte boundary, one should note that the address appearing in the interface registers are already removed the 2 always-zero LSBs.

14.5 Programming the BCH/GPMI Interfaces

Programming the BCH for NAND operations consists largely of disabling the soft reset and clock bits (SFTRST and CLKGATE) from the BCH_CTRL register and then programming the flash layout registers to correspond to the format of the attached NAND device(s). The BCH_LAYOUTSELECT register should also be programmed to map the chip select of each attached device into one of the four layout registers.

The bulk of the programming is actually applied to the GPMI via PIO operations embedded in DMA command structures. The DMA will perform all the requisite handshaking with the GPMI interface to negotiate the address portion of the transfer, then the BCH will handle all the movement of data from memory to the GPMI (writes) or the GPMI to memory (reads). The BCH will direct all data blocks to the buffer pointed to by the PAYLOAD_BUFFER and the metadata will be written to the AUXILIARY_BUFFER. Both of these registers are located in the GPMI PIO data space and are communicated to the BCH hardware at the beginning of the transfer. Thus, the normal multi-NAND DMA based device interleaving is preserved, i.e., four NANDs on four separate chip selects can be scheduled for read or write operations using the BCH. Whichever channel finishes its ready wait first and enters the DMA arbiter with its lock bit set will "own" the GPMI command interface and through it will own the BCH resources for the duration of its processing.

14.5.1 BCH Encoding for NAND Writes

The BCH encoder flowchart in Figure 14-6 shows the detailed steps involved in programming and using the BCH encoder. This flowchart shows how to use the BCH block with the GPMI.

To use the BCH encoder with the GPMI's DMA, create a DMA command chain containing ten descriptor structures, as shown in Figure 14-8 and detailed in the DMA structure code example that follows it in DMA Structure Code Example 1. The ten descriptors perform the following tasks:

1. Disable the BCH block (in case it was enabled) and issue NAND write setup command byte (under "CLE") and address bytes (under "ALE").
2. Configure and enable the BCH and GPMI blocks to perform the NAND write.

3. Disable the BCH block and issue NAND write execute command byte (under "CLE").
4. Wait for the NAND device to finish writing the data by watching the ready signal.
5. Check for NAND timeout through "PSENSE".
6. Issue NAND status command byte (under "CLE").
7. Read the status and compare against expected.
8. If status is incorrect/incomplete, branch to error handling descriptor chain.
9. Otherwise, write is complete and emit GPMI interrupt.

```

14.5.1.2 Using the BCH Encoder

To use the BCH encoder, first turn off the module-wide soft reset bit in both the GPMI and BCH blocks before starting any DMA activity. Note that turning off the soft reset must take place by itself, prior to programming the rest of the control registers. Turn off the BCH bus master soft reset bit. Turn off the clock gate bits.

Program the remainder of the GPMI, BCH and APBH DMA as follows:

```
// bring APBH out of reset
HW_APBH_CTRL0_CLR(BM_APBH_CTRL0_SFRST);
HW_APBH_CTRL0_CLR(BM_APBH_CTRL0_CLKGATE);
// bring BCH out of reset
HW_BCH_CTRL_CLR(BM_BCH_CTRL_SFTRST);
HW_BCH_CTRL_CLR(BM_BCH_CTRL_CLKGATE);
// bring gpmi out of reset
HW_GPMI_CTRL0_CLR(BM_GPMI_CTRL0_SFTRST);
HW_GPMI_CTRL0_CLR(BM_GPMI_CTRL0_CLKGATE);
HW_GPMI_CTRL1_SET(BM_GPMI_CTRL1_DEV_RESET | // deassert reset
             BM_GPMI_CTRL1_BCH_MODE  ); // enable BCH mode

// enable pinctrl
HW_PINCTRL_CTRL_WR(0x00000000);
// enable gpmi pins
HW_PINCTRL_MUXSEL0_CLR(0x0000ffff); // data bits
HW_PINCTRL_MUXSEL1_CLR(0x03ffffff); // control bits
HW_PINCTRL_MUXSEL8_CLR(0x0003f3ff); // control bits
HW_PINCTRL_MUXSEL8_SET(0x00015155); // control bits
```

Note that for writing NANDs (ECC encoding), only GPMI DMA command complete interrupts are used. The BCH engine is used for writing to the NAND but may optionally produces an interrupt. From the sample code in DMA Structure Code Example 1.

- DMA descriptor 1 prepares the NAND for data write by using the GPMI to issue a write setup command byte under "CLE", then sends a 5-byte address under "ALE". The BCH engine is disabled and not used for these commands.
- DMA descriptor 2 enables the BCH engine for encoding to begin the initial writing of the NAND data by specifying where the data and auxiliary payload are coming from in system memory.

- DMA descriptor 3 issues the write commit command byte under "CLE" to the NAND.
- DMA descriptor 4 waits for the NAND to complete the write commit/transfer by watching the NAND's ready line status. This descriptor relinquishes the NANDLOCK on the GPMI to enable the other DMA channels to initiate NAND transactions on different NAND CS lines.
- DMA descriptor 6 issues a NAND status command byte under "CLE" to check the status of the NAND device following the page write.
- DMA descriptor 7 reads back the NAND status and compares the status with an expected value. If there are differences, then the DMA processing engine follows an error-handling DMA descriptor path.
- DMA descriptor 8 disables the BCH engine and emits a GPMI interrupt to indicate that the NAND write has been completed.

14.5.2 BCH Decoding for NAND Reads

When a page is read from NAND flash, BCH syndromes will be computed and, if correctable errors are found, they will be corrected on a per block basis within the NAND page. This decoding process is fully overlapped with other NAND data reads and with ARM platform execution. The BCH decoder flowchart in Figure 14-9 shows the steps involved in programming the decoder. The hardware flow of reading and decoding a 4096-byte page is shown in Figure 14-10.

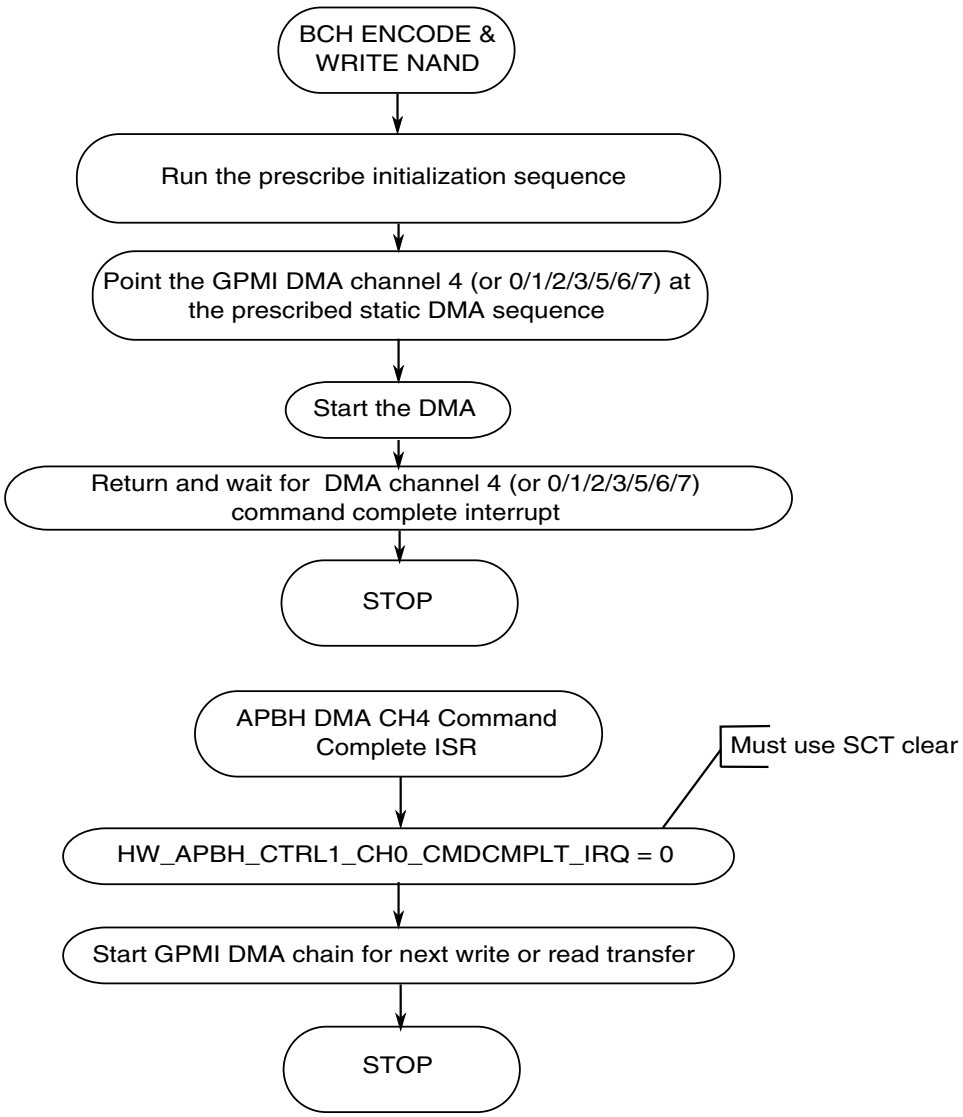

Figure 14-9. BCH Decode Flowchart

Conceptually, an APBH DMA Channel 0, 1, 2, 3, 4, 5, 6, or 7 command chain with seven command structures linked together is used to perform the BCH decode operation (as shown in Figure 14-10). NOTE: The GPMI's DMA command structures controls the BCH decode operation.

To use the BCH decoder with the GPMI's DMA, create a DMA command chain containing seven descriptor structures, as shown in Figure 14-10 and detailed in the DMA structure code example that follows it in DMA Structure Code Example 2. The seven DMA descriptors perform the following tasks:

1. Issue NAND read setup command byte (under "CLE") and address bytes (under "ALE").
2. Issue NAND read execute command byte (under "CLE").

3. Wait for the NAND device to complete accessing the block data by watching the ready signal.
4. Check for NAND timeout through "PSENSE".
5. Configure and enable the BCH block and read the NAND block data.
6. Disable the BCH block.
7. Descriptor NOP to allow NANDLOCK in the previous descriptor to the thread-safe.

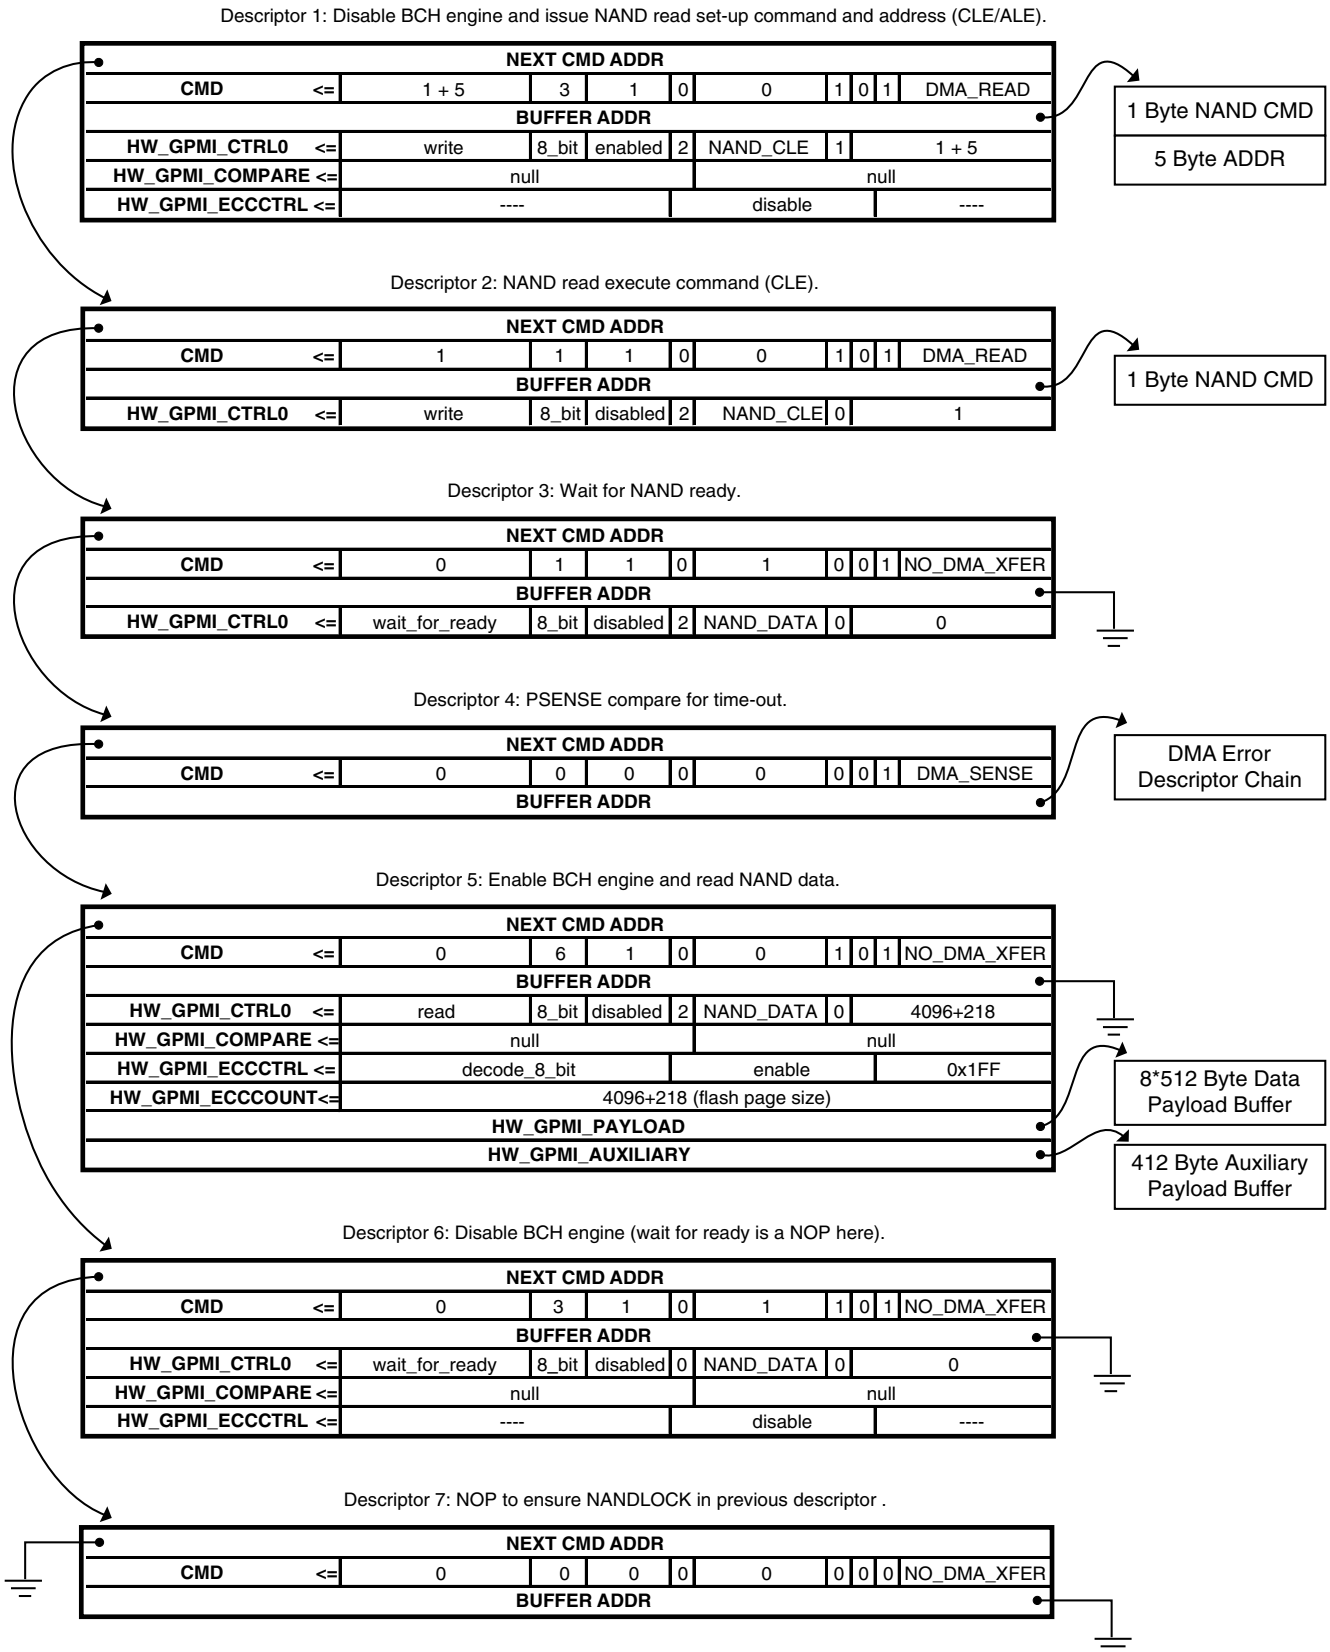

Figure 14-10. BCH Decode DMA Descriptor Chain

NOTE

To interpret the fields in this diagram, see Figure 14-7 for the descriptor legend.

14.5.2.1 DMA Structure Code Example 2

The following sample code illustrates the coding for one read transaction, consisting of a seven DMA command structure chain for reading all 4096 bytes of payload data (eight 512-byte blocks) and 65 bytes of metadata with the associative parity bytes (8 x (18) + 9) from a 4K NAND page sitting on GPMI CS2.

                  BF_APBH_CHn_CMD_SEMAPHORE     (0)    |
                  BF_APBH_CHn_CMD_NANDWAIT4READY(0)    |
                  BF_APBH_CHn_CMD_NANDLOCK      (0)    |    // relinquish nand lock
                  BF_APBH_CHn_CMD_IRQONCMPLT    (0)    |    // BCH engine generates interrupt
                  BF_APBH_CHn_CMD_CHAIN         (0)    |    // terminate DMA chain processing
                  BV_FLD(APBH_CHn_CMD, COMMAND, NO_DMA_XFER);      // no dma transfer
read[6].dma_bar = NULL;                                             // field not used
```

14.5.2.2 Using the Decoder

As illustrated in Figure 14-10 and the sample code in DMA Structure Code Example 2 :

- DMA descriptor 1 prepares the NAND for data read by using the GPMI to issue a NAND read setup command byte under "CLE", then sends a 5-byte address under "ALE". The BCH engine is not used for these commands.

- DMA descriptor 2 issues a one-byte read execute command to the NAND device that triggers its read access. The NAND then goes not ready.
- DMA descriptor 3 performs a wait for ready operation allowing the DMA chain to remain dormant until the NAND device completes its read access time.
- DMA descriptor 5 handles the reading and error correction of the NAND data. This command's PIOs activate the BCH engine to write the read NAND data to system memory and to process it for any errors that need to be corrected. This DMA descriptor contains two PIO values that are system memory addresses pointing to the PAYLOAD data area and to the AUXILIARY data area. These addresses are used by the BCH engine's bus master to move data into system memory and to correct it. While this example is reading an entire 4K page-payload plus metadata-it is equally possible to read just one 512-byte payload block or just the uniquely protected metadata block in a single 7 DMA structure transfer.
- DMA descriptor 6 disables the BCH engine with the NANDLOCK asserted. This is necessary to ensure that the GPMI resource is not arbitrated to another DMA channel when multiple DMA channels are active concurrently.
- DMA descriptor 7 deasserts the NANDLOCK to free up the GPMI resource to another channel.

As the BCH block receives data from the GPMI:

- The decoder transforms the read NAND data block into an BCH code word and computes the codeword syndrome.
- If no errors are present, then the BCH block can immediately report back to firmware. This report is passed as the BCH_CTRL_COMPLETE_IRQ interrupt status bit and the associated status registers in BCH_STATUS0/1 registers.
- If an error is present, then the BCH block corrects the necessary data block or parity block bytes, if possible (not all errors are correctable).

As the BCH decoder reads the data and parity blocks, it records a special condition, that is, that all of the bits of a payload data block or metadata block are one, including any associated parity bytes. The "all-ones" case for both parity and data indicates an erased block in the NAND device.

The BCH_STATUS0 register contains a 4-bit field that indicates the final status of the auxiliary block. A value of 0x0 indicates no errors found for a block.

- A value of 1 to 20 inclusive indicates that many correctable errors were found and fixed.
- A value of 0xFE indicates uncorrectable errors detected on the block.
- A value of 0xFF indicates that the block was in the special ALL ONES state and is therefore considered to be an ERASED block.
- All other values are disallowed by the hardware design.

Recall that up to eight NAND devices can have DMA chains in-flight at once, that is, they can all be contending for access to the GPMI data bus. It is impossible to predict which NAND device will enter the BCH engine with a transfer first, because each chain includes a wait4ready command structure. As a result, firmware should look at the BCH_STATUS0_COMPLETED_CE bit field to determine which block is being reported in the status register. There is also a 16 bit HANDLE field in the GPMI_ECCCTRL register that is passed down the pipeline with each transaction. This handle field can be used to speed firmware's detection of which transaction is being reported.

These examples of reading and writing have focused on full page transfers of 4 K page NAND devices. Other device configurations can be specified by changing the ECCOUNT field in the GPMI registers and reprogramming the BCH's FLASHnLAYOUTm registers.

The BCH and GPMI blocks are designed to be very efficient at reading single 512(or 1024)-byte pages in one transaction. With no errors, the transaction takes less than 20 HCLKs longer than the time to read the raw data from the NAND.

To summarize, the APBH DMA command chain for a BCH decode operation is shown in Figure 14-10. Seven DMA command structures must be present for each NAND read transaction decoded by the BCH. The seven DMA command structures for multiple NAND read transaction blocks can be chained together to make larger units of work for the BCH, and each will produce an appropriate error report in the BCH PIO space. Multiple NAND devices can have such multiple chains scheduled. The results can come back out of order with respect to the multiple chains.

14.5.3 Interrupts

There are two interrupt sources used in processing BCH protected NAND read and write transfers. Since all BCH operations are initiated by GPMI DMA command structures, the DMA completion interrupt for the GPMI is an important ISR. Both of the flow charts of the Programmable Registers section and Programming the BCH/GPMI Interfaces show the GPMI DMA complete ISR skeleton. In both reads and writes, the GPMI DMA completion interrupt is used to schedule work *INTO* the error correction pipeline. As the front end processing completes, the DMA interrupt is generated and additional work, i.e. DMA chains, are passed to the GPMI DMA to keep it "*fed*". For write operations, this is the only interrupt that will be generated for processing the NAND write transfer.

For reads, however, two interrupts are needed. Every read is started by a GPMI DMA command chain and the front end queue is fed as described above. The back end of the read pipeline is "drained" by monitoring the BCH completion interrupt found int BCH_CTRL_COMPLETE_IRQ.

An BCH transaction consists of reading or writing all of the blocks requested in the GPMI_ECCCTRL_BUFFER_MASK bit field. As every read transaction completes, it posts the status of all of the blocks to the BCH_STATUS0 register and sets the completion interrupt. The five stages of the BCH read pipeline completes, one in the GPMI and four in the BCH, are independently stalled as they complete and try to deliver to the next stage in the data flow. Several of these stages can be skipped if no-errors are found or once an uncorrectable error is found in a block.

In any case, the final stage will stall if the status register is busy waiting for the ARM platform to take status register results. The hardware monitors the state of the BCH_CTRL_COMPLETE_IRQ bit. If it is still set when the last pipeline stage is ready to post data, then the stage will stall. It follows that the next previous stage will stall when it is ready to hand off work to the final stage, and so on up the pipeline.

WARNING: It is important that firmware read the STATUS0/1 results and save them before clearing the interrupt request bit otherwise a transaction and its results could be completely lost.

14.6 Behavior During Reset

A soft reset (SFTRST) can take multiple clock periods to complete, so do NOT set CLKGATE when setting SFTRST. The reset process gates the clocks automatically. The examplary code is shown below:

```
// A soft reset can take multiple clocks to complete, so do NOT gate the
// clock when setting soft reset. The reset process will gate the clock
// automatically. Poll until this has happened before subsequently
// preparing soft-reset and clock gate
  HW_BCH_CTRL_CLR(BM_BCH_CTRL_SFTRST);
  HW_BCH_CTRL_CLR(BM_BCH_CTRL_CLKGATE);
// asserting soft-reset
  HW_BCH_CTRL_SET(BM_BCH_CTRL_SFTRST);
// waiting for confirmation of soft-reset
  while (!HW_BCH_CTRL.B.CLKGATE)
  {
// busy wait
  }
// Done.
  HW_BCH_CTRL_CLR(BM_BCH_CTRL_SFTRST);
  HW_BCH_CTRL_CLR(BM_BCH_CTRL_CLKGATE);
```

14.7 Programmable Registers

BCH Hardware Register Format Summary

BCH memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4100_8000	Hardware BCH ECC Accelerator Control Register (BCH_CTRL)	32	R/W	C000_0000h	14.7.1/ 715
4100_8004	Hardware BCH ECC Accelerator Control Register (BCH_CTRL_SET)	32	R/W	C000_0000h	14.7.1/ 715
4100_8008	Hardware BCH ECC Accelerator Control Register (BCH_CTRL_CLR)	32	R/W	C000_0000h	14.7.1/ 715
4100_800C	Hardware BCH ECC Accelerator Control Register (BCH_CTRL_TOG)	32	R/W	C000_0000h	14.7.1/ 715

14.7.1 Hardware BCH ECC Accelerator Control Register (BCH_CTRL*n*)

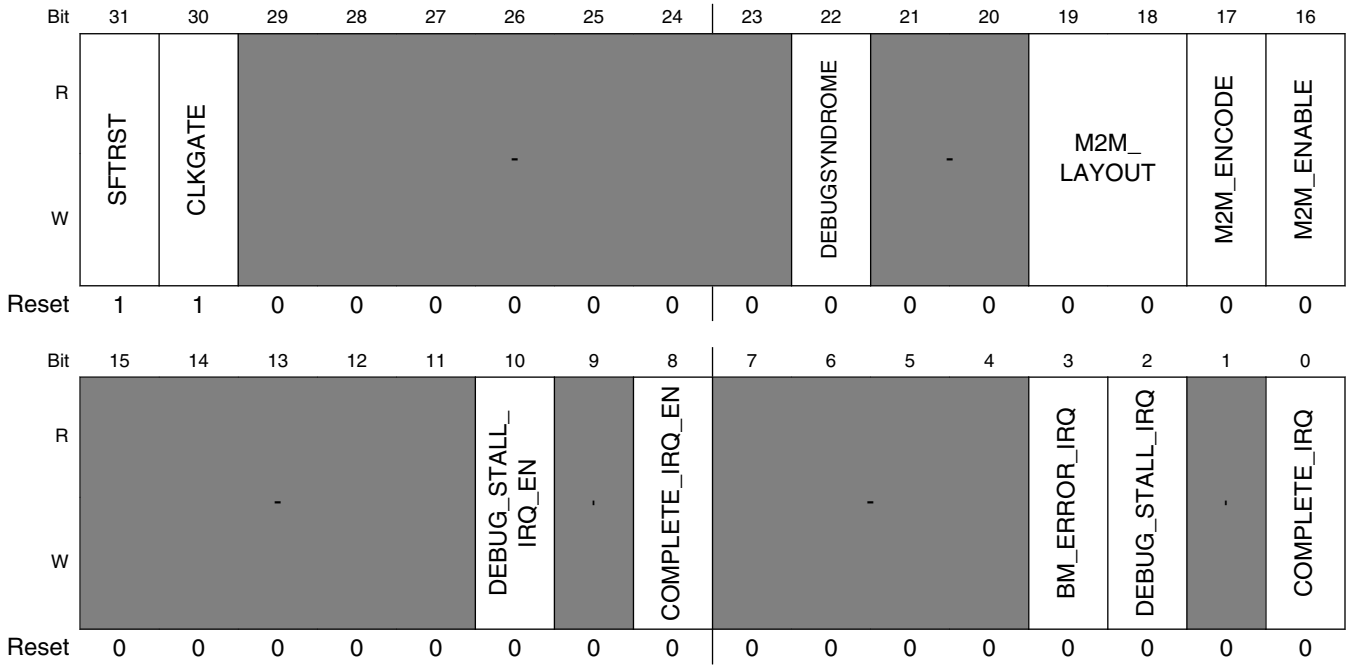
The BCH CTRL provides overall control of the hardware ECC accelerator

Addresses: BCH_CTRL is 4100_8000h base + 0h offset = 4100_8000h

BCH_CTRL_SET is 4100_8000h base + 4h offset = 4100_8004h

BCH_CTRL_CLR is 4100_8000h base + 8h offset = 4100_8008h

BCH_CTRL_TOG is 4100_8000h base + Ch offset = 4100_800Ch



BCH_CTRL*n* field descriptions

Field	Description
31 SFTRST	Set this bit to zero to enable normal BCH operation. Set this bit to one (default) to disable clocking with the BCH and hold it in its reset (lowest power) state. This bit can be turned on and then off to reset the BCH block to its default state. This bit resets all state machines except for the AHB master state machine 0x0 **RUN** — Allow BCH to operate normally. 0x1 **RESET** — Hold BCH in reset.
30 CLKGATE	This bit must be set to zero for normal operation. When set to one it gates off the clocks to the block. 0x0 **RUN** — Allow BCH to operate normally. 0x1 **NO_CLKS** — Do not clock BCH gates in order to minimize power consumption.
29–23 -	Reserved, always set this bit to zero.
22 DEBUGSYNDROME	(For debug purposes only). Enable write of computed syndromes to memory on BCH decode operations. Computed syndromes will be written to the auxiliary buffer after the status block. Syndromes will be written as padded 16-bit values.
21–20 -	Reserved, always set these bits to zero.
19–18 M2M_LAYOUT	Selects the flash page format for memory-to-memory operations.
17 M2M_ENCODE	Selects encode (parity generation) or decode (correction) mode for memory-to-memory operations.

Table continues on the next page...

BCH_CTRL*n* field descriptions (continued)

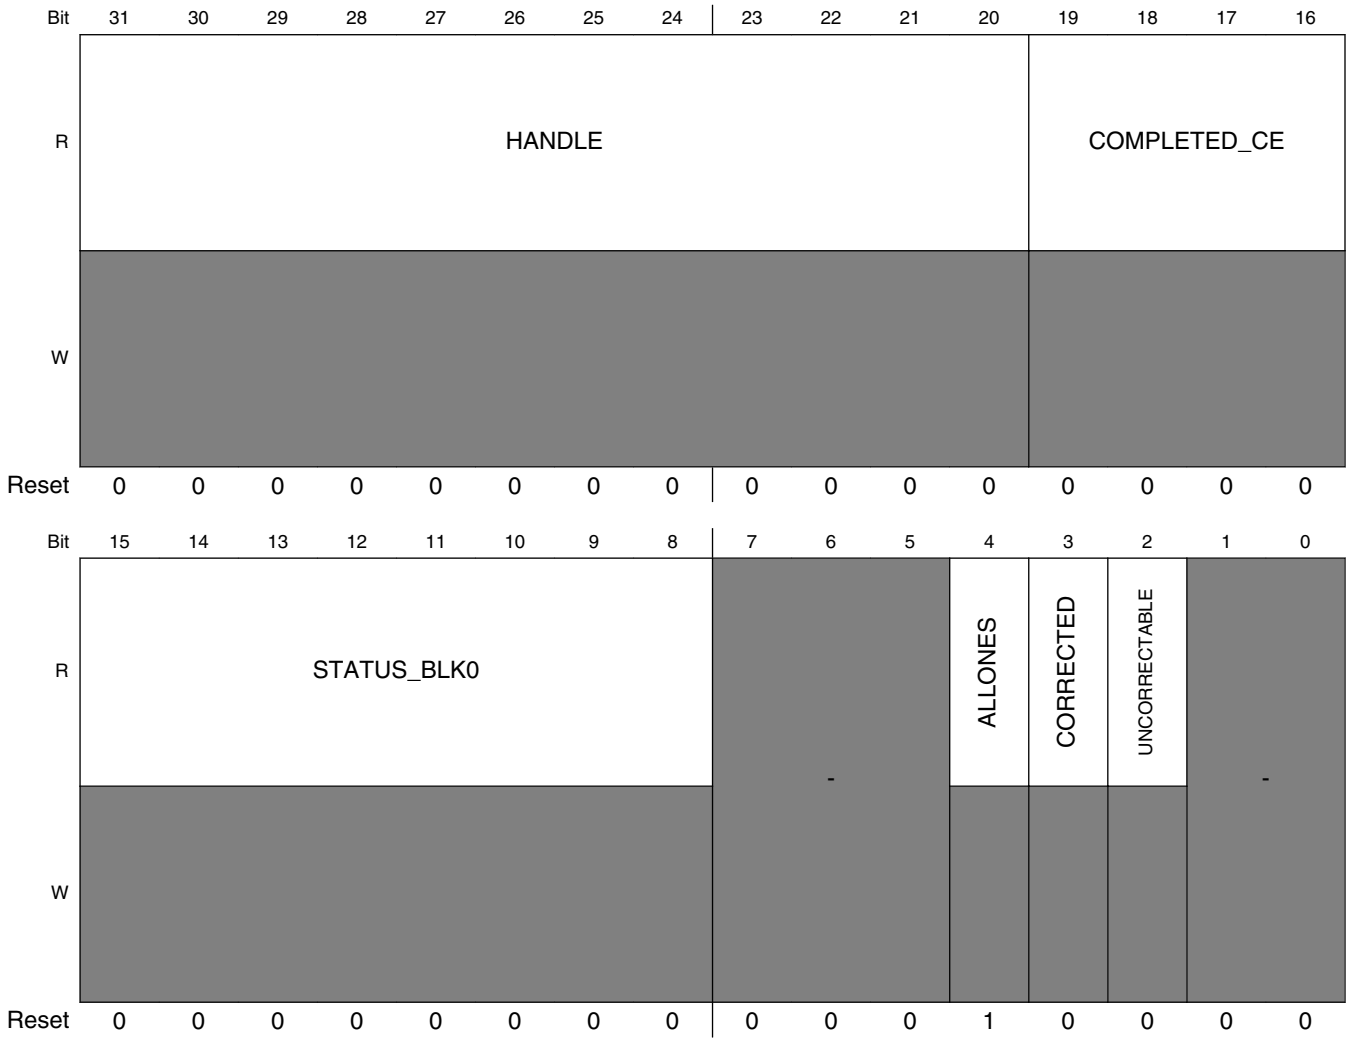
Field	Description
16 M2M_ENABLE	WARNING! WRITING THIS BIT INITIATES A MEMORY-TO-MEMORY OPERATION. The BCH module must be inactive (not processing data from the GPMI) when this bit is set. The M2M_ENCODE and M2M_LAYOUT bits as well as the ENCODEPTR, DATAPTR, and METAPTR registers are used for memory-to-memory operations and must be correctly programmed before writing this bit.
15–11 -	Reserved, always set these bits to zero.
10 DEBUG_STALL_IRQ_EN	1 = interrupt on debug stall mode is enabled. The irq is raised on every block
9 -	Reserved, always set these bits to zero.
8 COMPLETE_IRQ_EN	1 = interrupt on completion of correction is enabled.
7–4 -	Reserved, always set these bits to zero.
3 BM_ERROR_IRQ	AHB Bus interface Error Interrupt Status. Write a one to the SCT clear address to clear the interrupt status bit.
2 DEBUG_STALL_IRQ	DEBUG STALL Interrupt Status. Write a one to the SCT clear address to clear the interrupt status bit.
1 -	Reserved, always set these bits to zero.
0 COMPLETE_IRQ	This bit indicates the state of the external interrupt line. Write a one to the SCT clear address to clear the interrupt status bit. NOTE: subsequent ECC completions will be held off as long as this bit is set. Be sure to read the data from BCH_STATUS0,1 before clearing this interrupt bit.

14.7.2 Hardware ECC Accelerator Status Register 0 (BCH_STATUS0)

The BCH STAT provides overall status of the hardware ECC accelerator

The BCH STAT register provides visibility into the run-time status of the BCH and status information when processing is complete.

Address: BCH_STATUS0 is 4100_8000h base + 10h offset = 4100_8010h



BCH_STATUS0 field descriptions

Field	Description
31–20 HANDLE	Software supplies a 12 bit handle for this transfer as part of the GPMI DMA PIO operation that started the transaction. That handle passes down the pipeline and ends up here at the time the BCH interrupt is signaled.
19–16 COMPLETED_CE	This is the chip enable number corresponding to the NAND device from which this data came.
15–8 STATUS_BLK0	Count of symbols in error during processing of first block of flash (metadata block). The number of errors reported will be in the range of 0 to the ECC correction level for block 0. 0x00 **ZERO** — No errors found on block. 0x01 **ERROR1** — One error found on block. 0x02 **ERROR2** — One errors found on block. 0x03 **ERROR3** — One errors found on block. 0x04 **ERROR4** — One errors found on block. 0xFE **UNCORRECTABLE** — Block exhibited uncorrectable errors. 0xFF **ERASED** — Page is erased.

Table continues on the next page...

BCH_STATUS0 field descriptions (continued)

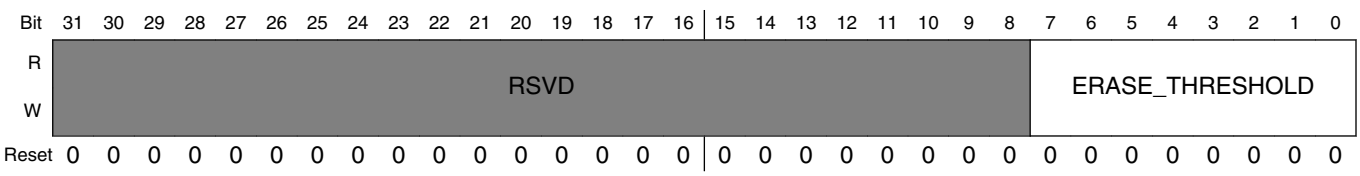
Field	Description
7–5 -	Reserved, always set these bits to zero.
4 ALLONES	1 = All data bits of this transaction are ONE.
3 CORRECTED	1 = At least one correctable error encountered during last processing cycle.
2 UNCORRECTABLE	1 = Uncorrectable error encountered during last processing cycle.
1–0 -	Reserved, always set these bits to zero.

14.7.3 Hardware ECC Accelerator Mode Register (BCH_MODE)

The BCH MODE register provides additional mode controls.

Contains additional global mode controls for the BCH engine.

Address: BCH_MODE is 4100_8000h base + 20h offset = 4100_8020h



BCH_MODE field descriptions

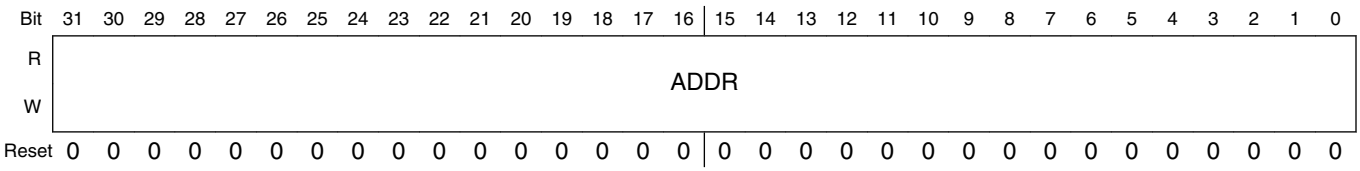
Field	Description
31–8 RSVD	Reserved, always set these bits to zero.
7–0 ERASE_ THRESHOLD	This value indicates the maximum number of zero bits on a flash page for it to be considered erased. For SLC NAND devices, this value should be programmed to 0 (meaning that the entire page should consist of bytes of 0xFF. For MLC NAND devices, bit errors may occur on reads (even on blank pages), so this threshold can be used to tune the erased page checking algorithm.

14.7.4 Hardware BCH ECC Loopback Encode Buffer Register (BCH_ENCODEPTR)

When performing memory to memory operations, indicates the address of the encode buffer. This register should be programmed before writing a 1 to the M2M_ENABLE bit in the CTRL register.

For memory to memory operations, this register is used as the pointer to the encoded data, which is an output when encoding and an input while decoding.

Address: BCH_ENCODEPTR is 4100_8000h base + 30h offset = 4100_8030h



BCH_ENCODEPTR field descriptions

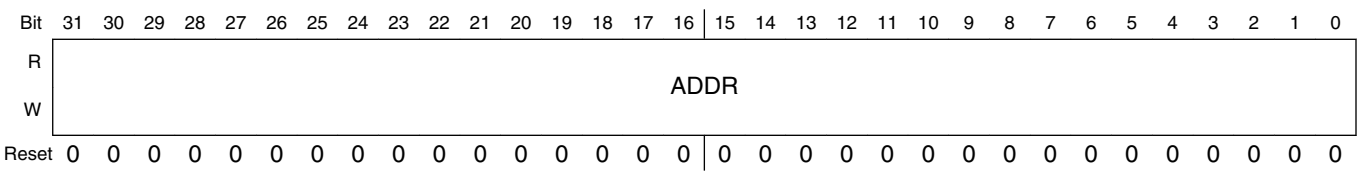
Field	Description
31–0 ADDR	Address pointer to encode buffer. This is the source for decode operations and the destination for encode operations. This value must be aligned on a 4 byte boundary.

14.7.5 Hardware BCH ECC Loopback Data Buffer Register (BCH_DATAPTR)

When performing memory to memory operations, indicates the address of the data buffer.

For memory to memory operations, this register is used as the pointer to the data to encode or the destination buffer for decode operations.

Address: BCH_DATAPTR is 4100_8000h base + 40h offset = 4100_8040h



BCH_DATAPTR field descriptions

Field	Description
31–0 ADDR	Address pointer to data buffer. This is the source for encode operations and the destination for decode operations. This register should be programmed before writing a 1 to the M2M_ENABLE bit in the CTRL register. This value must be aligned on a 4 byte boundary.

14.7.6 Hardware BCH ECC Loopback Metadata Buffer Register (BCH_METAPTR)

When performing memory to memory operations, indicates the address of the metadata buffer.

For memory to memory operations, this register is used as the pointer to the metadata to encode or the extracted metadata for decode operations.

Address: BCH_METAPTR is 4100_8000h base + 50h offset = 4100_8050h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

BCH_METAPTR field descriptions

Field	Description
31–0 ADDR	Address pointer to metadata buffer. This is the source for encode metadata read operations and the destination for metadata decode operations. This register should be programmed before writing a 1 to the M2M_ENABLE bit in the CTRL register. This value must be aligned on a 4 byte boundary.

14.7.7 Hardware ECC Accelerator Layout Select Register (BCH_LAYOUTSELECT)

The BCH LAYOUTSELECT register provides a mapping of chip selects to layout registers.

When the BCH engine receives a request to process a data block from the GPMI interface, it will use this register to map the incoming chip select to one of the four possible flash layout registers

Address: BCH_LAYOUTSELECT is 4100_8000h base + 70h offset = 4100_8070h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

BCH_LAYOUTSELECT field descriptions

Field	Description
31–30 CS15_SELECT	Selects which layout is used for chip select 15.
29–28 CS14_SELECT	Selects which layout is used for chip select 14.
27–26 CS13_SELECT	Selects which layout is used for chip select 13.

Table continues on the next page...

BCH_LAYOUTSELECT field descriptions (continued)

Field	Description
25–24 CS12_SELECT	Selects which layout is used for chip select 12.
23–22 CS11_SELECT	Selects which layout is used for chip select 11.
21–20 CS10_SELECT	Selects which layout is used for chip select 10.
19–18 CS9_SELECT	Selects which layout is used for chip select 9.
17–16 CS8_SELECT	Selects which layout is used for chip select 8.
15–14 CS7_SELECT	Selects which layout is used for chip select 7.
13–12 CS6_SELECT	Selects which layout is used for chip select 6.
11–10 CS5_SELECT	Selects which layout is used for chip select 5.
9–8 CS4_SELECT	Selects which layout is used for chip select 4.
7–6 CS3_SELECT	Selects which layout is used for chip select 3.
5–4 CS2_SELECT	Selects which layout is used for chip select 2.
3–2 CS1_SELECT	Selects which layout is used for chip select 1.
1–0 CS0_SELECT	Selects which layout is used for chip select 0.

14.7.8 Hardware BCH ECC Flash 0 Layout 0 Register (BCH_FLASH0LAYOUT0)

The flash format register contains a description of the logical layout of data on the flash device. This register is used in conjuction with the FLASH0LAYOUT1 register to control the format for the devices selecting layout 0 in the LAYOUTSELECT register.

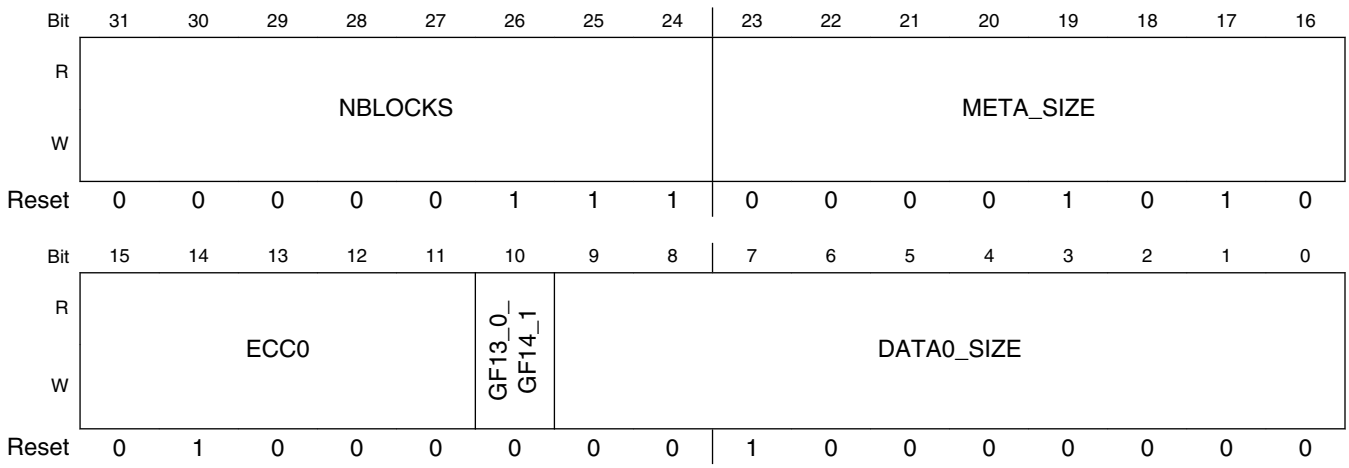
Each pair of layout registers describes one of four supported flash configurations. Software should program the LAYOUTSELECT register for each supported GPMI chip select to select from one of the fourlayout values. Each pair of registers contains settings that are used by the BCH block while reading/writing the flash page to control data, metadata, and flash page sizes as well as the ECC correction level. The first block written to flash can be programmed to have different ECC, metadata, and data sizes from subsequent data blocks on the device. In addition, the number of blocks stored on a page

of flash is not fixed, but instead is determined by the number of bytes consumed by the initial (block 0) and subsequent data blocks. See the BCH programming reference manual for more information on setting up the flash layout registers.

EXAMPLE

```
BCH_FLASH0LAYOUT0_WR(0x020C8000);
BCH_FLASH0LAYOUT1_WR(0x04408200);
```

Address: BCH_FLASH0LAYOUT0 is 4100_8000h base + 80h offset = 4100_8080h



BCH_FLASH0LAYOUT0 field descriptions

Field	Description
31–24 NBLOCKS	Number of subsequent blocks on the flash page (excluding the data0 block). A value of 0 indicates that only the DATA0 block is present and a value of 8 indicates that 8 subsequent blocks are present for a total of 9 blocks on the flash (including the DATA0 block). Any values from 0 to 255 are supported by the hardware.
23–16 META_SIZE	Indicates the size of the metadata (in bytes) to be stored on a flash page. The BCH design support from 0 to 255 bytes for metadata -- if set to zero, no metadata will be stored. Metadata is stored before the associated data in block 0. If the DATA0_SIZE field is programmed to a zero, then metadata effectively be stored with its own parity. When both the metadata and data0 fields are programmed with non-zero values, the first block will contain both portions of data and will be covered by a single parity block.
15–11 ECC0	Indicates the ECC level for the first block on the flash page. The first block covers metadata plus the associated data from the DATA0_SIZE field. 0x0 **NONE** — No ECC to be performed 0x1 **ECC2** — ECC 2 to be performed 0x2 **ECC4** — ECC 4 to be performed 0x3 **ECC6** — ECC 6 to be performed 0x4 **ECC8** — ECC 8 to be performed 0x5 **ECC10** — ECC 10 to be performed 0x6 **ECC12** — ECC 12 to be performed 0x7 **ECC14** — ECC 14 to be performed 0x8 **ECC16** — ECC 16 to be performed 0x9 **ECC18** — ECC 18 to be performed

Table continues on the next page...

BCH_FLASH0LAYOUT0 field descriptions (continued)

Field	Description
	0xA **ECC20** — ECC 20 to be performed 0xB **ECC22** — ECC 22 to be performed 0xC **ECC24** — ECC 24 to be performed 0xD **ECC26** — ECC 26 to be performed 0xE **ECC28** — ECC 28 to be performed 0xF **ECC30** — ECC 30 to be performed 0x10 **ECC32** — ECC 32 to be performed
10 GF13_0_GF14_1	Select GF13 or GF14: 0-GF13; 1-GF14
9–0 DATA0_SIZE	Indicates the size of the data 0 block (in DWORDS/four bytes) to be stored on the flash page. If set to zero, the first block will only contain metadata.

14.7.9 Hardware BCH ECC Flash 0 Layout 1 Register (BCH_FLASH0LAYOUT1)

The flash format register contains a description of the logical layout of data on the flash device. This register is used in conjuction with the FLASH0LAYOUT0 register to control the format for the device selecting layout 0 in the LAYOUTSELECT register.

EXAMPLE

```
BCH_FLASH0LAYOUT0_WR(0x020C8000);
BCH_FLASH0LAYOUT1_WR(0x04408200);
```

Address: BCH_FLASH0LAYOUT1 is 4100_8000h base + 90h offset = 4100_8090h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	PAGE_SIZE															
Reset	0	0	0	1	0	0	0	0	1	1	0	1	1	0	1	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ECCN					GF13_0_GF14_1	DATAN_SIZE									
Reset	0	1	0	0	0	0	0	0	1	0	0	0	0	0	0	0

BCH_FLASH0LAYOUT1 field descriptions

Field	Description
31–16 PAGE_SIZE	Indicates the total size of the flash page (in bytes). This should be set to the page size including spare area. The page size is programmable to accomodate different flash configurations that may be available in the future.
15–11 ECCN	Indicates the ECC level for the subsequent blocks on the flash page (blocks 1-n). Subsequent blocks only contain data (no metadata). 0x0 **NONE** — No ECC to be performed 0x1 **ECC2** — ECC 2 to be performed 0x2 **ECC4** — ECC 4 to be performed 0x3 **ECC6** — ECC 6 to be performed 0x4 **ECC8** — ECC 8 to be performed 0x5 **ECC10** — ECC 10 to be performed 0x6 **ECC12** — ECC 12 to be performed 0x7 **ECC14** — ECC 14 to be performed 0x8 **ECC16** — ECC 16 to be performed 0x9 **ECC18** — ECC 18 to be performed 0xA **ECC20** — ECC 20 to be performed 0xB **ECC22** — ECC 22 to be performed 0xC **ECC24** — ECC 24 to be performed 0xD **ECC26** — ECC 26 to be performed 0xE **ECC28** — ECC 28 to be performed 0xF **ECC30** — ECC 30 to be performed 0x10 **ECC32** — ECC 32 to be performed
10 GF13_0_GF14_1	Select GF13 or GF14: 0-GF13; 1-GF14
9–0 DATAN_SIZE	Indicates the size of the subsequent data blocks (in DWORDS/four bytes) to be stored on the flash page. The size of subsequent data blocks does not have to match the data size for block 0, which is important when metadata is stored separately or for balancing the amount of data stored in each block.

14.7.10 Hardware BCH ECC Flash 1 Layout 0 Register (BCH_FLASH1LAYOUT0)

The flash format register contains a description of the logical layout of data on the flash device. This register is used in conjuction with the FLASH1LAYOUT1 register to control the format for the devices selecting layout 1 in the LAYOUTSELECT register.

Each pair of layout registers describes one of four supported flash configurations. Software should program the LAYOUTSELECT register for each supported GPMI chip select to select from one of the fourlayout values. Each pair of registers contains settings that are used by the BCH block while reading/writing the flash page to control data, metadata, and flash page sizes as well as the ECC correction level. The first block written to flash can be programmed to have different ECC, metadata, and data sizes from subsequent data blocks on the device. In addition, the number of blocks stored on a page

of flash is not fixed, but instead is determined by the number of bytes consumed by the initial (block 0) and subsequent data blocks. See the BCH programming reference manual for more information on setting up the flash layout registers.

EXAMPLE

```
BCH_FLASH1LAYOUT0_WR(0x020C8000);
BCH_FLASH1LAYOUT1_WR(0x04408200);
```

Address: BCH_FLASH1LAYOUT0 is 4100_8000h base + A0h offset = 4100_80A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	NBLOCKS								META_SIZE							
Reset	0	0	0	0	0	1	1	1	0	0	0	0	1	0	1	0

R W	ECC0					GF13_0_GF14_1	DATA0_SIZE									
Reset	0	1	0	0	0	0	0	0	1	0	0	0	0	0	0	0

BCH_FLASH1LAYOUT0 field descriptions

Field	Description
31–24 NBLOCKS	Number of subsequent blocks on the flash page (excluding the data0 block). A value of 0 indicates that only the DATA0 block is present and a value of 8 indicates that 8 subsequent blocks are present for a total of 9 blocks on the flash (including the DATA0 block). Any values from 0 to 255 are supported by the hardware.
23–16 META_SIZE	Indicates the size of the metadata (in bytes) to be stored on a flash page. The BCH design support from 0 to 255 bytes for metadata -- if set to zero, no metadata will be stored. Metadata is stored before the associated data in block 0. If the DATA0_SIZE field is programmed to a zero, then metadata effectively be stored with its own parity. When both the metadata and data0 fields are programmed with non-zero values, the first block will contain both portions of data and will be covered by a single parity block.
15–11 ECC0	Indicates the ECC level for the first block on the flash page. The first block covers metadata plus the associated data from the DATA0_SIZE field. 0x0 **NONE** — No ECC to be performed 0x1 **ECC2** — ECC 2 to be performed 0x2 **ECC4** — ECC 4 to be performed 0x3 **ECC6** — ECC 6 to be performed 0x4 **ECC8** — ECC 8 to be performed 0x5 **ECC10** — ECC 10 to be performed 0x6 **ECC12** — ECC 12 to be performed 0x7 **ECC14** — ECC 14 to be performed 0x8 **ECC16** — ECC 16 to be performed 0x9 **ECC18** — ECC 18 to be performed

The size of subsequent data blocks does not have to match the data size for block 0, which is important when metadata is stored separately or for balancing the amount of data stored in each block.

14.7.12 Hardware BCH ECC Flash 2 Layout 0 Register (BCH_FLASH2LAYOUT0)

The flash format register contains a description of the logical layout of data on the flash device. This register is used in conjuction with the FLASH2LAYOUT1 register to control the format for the devices selecting layout 2 in the LAYOUTSELECT register.

Each pair of layout registers describes one of four supported flash configurations. Software should program the LAYOUTSELECT register for each supported GPMI chip select to select from one of the fourlayout values. Each pair of registers contains settings that are used by the BCH block while reading/writing the flash page to control data, metadata, and flash page sizes as well as the ECC correction level. The first block written to flash can be programmed to have different ECC, metadata, and data sizes from subsequent data blocks on the device. In addition, the number of blocks stored on a page

of flash is not fixed, but instead is determined by the number of bytes consumed by the initial (block 0) and subsequent data blocks. See the BCH programming reference manual for more information on setting up the flash layout registers.

EXAMPLE

```
BCH_FLASH2LAYOUT0_WR(0x020C8000);
BCH_FLASH2LAYOUT1_WR(0x04408200);
```

Address: BCH_FLASH2LAYOUT0 is 4100_8000h base + C0h offset = 4100_80C0h

BCH_FLASH3LAYOUT1 field descriptions

Field	Description
31–16 PAGE_SIZE	Indicates the total size of the flash page (in bytes). This should be set to the page size including spare area. The page size is programmable to accomodate different flash configurations that may be available in the future.
15–11 ECCN	Indicates the ECC level for the subsequent blocks on the flash page (blocks 1-n). Subsequent blocks only contain data (no metadata). 0x0 **NONE** — No ECC to be performed 0x1 **ECC2** — ECC 2 to be performed 0x2 **ECC4** — ECC 4 to be performed 0x3 **ECC6** — ECC 6 to be performed 0x4 **ECC8** — ECC 8 to be performed 0x5 **ECC10** — ECC 10 to be performed 0x6 **ECC12** — ECC 12 to be performed 0x7 **ECC14** — ECC 14 to be performed 0x8 **ECC16** — ECC 16 to be performed 0x9 **ECC18** — ECC 18 to be performed 0xA **ECC20** — ECC 20 to be performed 0xB **ECC22** — ECC 22 to be performed 0xC **ECC24** — ECC 24 to be performed 0xD **ECC26** — ECC 26 to be performed 0xE **ECC28** — ECC 28 to be performed 0xF **ECC30** — ECC 30 to be performed 0x10 **ECC32** — ECC 32 to be performed
10 GF13_0_GF14_1	Select GF13 or GF14: 0-GF13; 1-GF14
9–0 DATAN_SIZE	Indicates the size of the subsequent data blocks (in DWORDS/four bytes) to be stored on the flash page. The size of subsequent data blocks does not have to match the data size for block 0, which is important when metadata is stored separately or for balancing the amount of data stored in each block.

14.7.16 Hardware BCH ECC Debug Register0 (BCH_DEBUG0*n*)

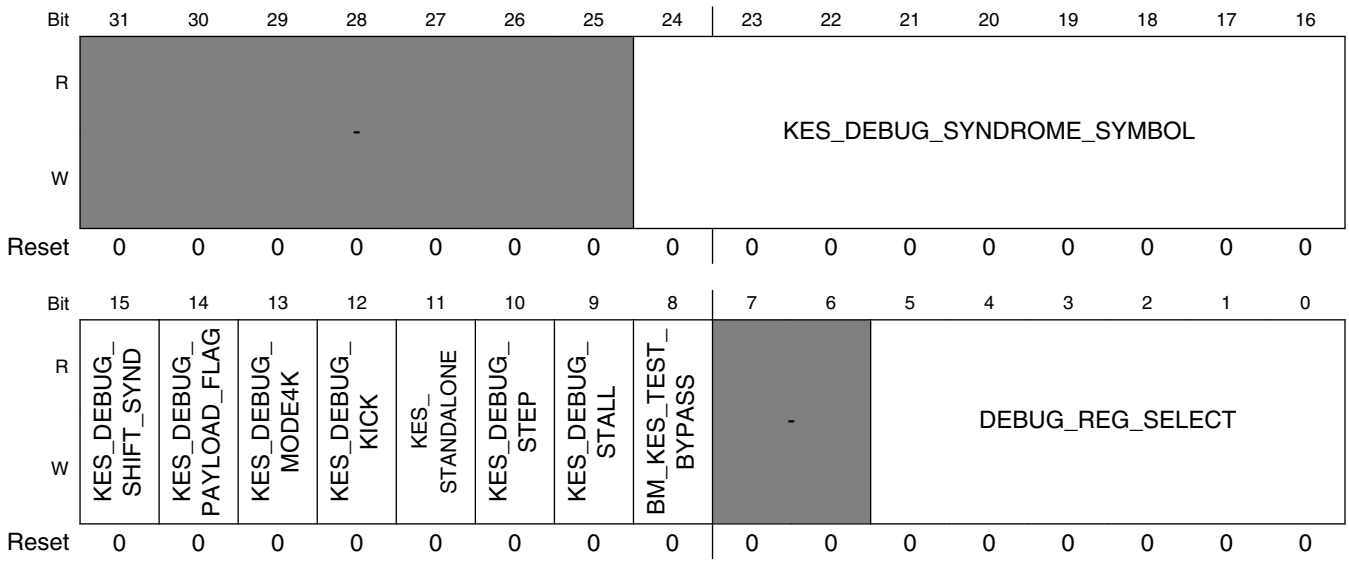
The hardware BCH accelerator internal state machines and signals can be seen in the ECC debug register.The BCH_DEBUG0 register provides access to various internal state information which might prove useful during hardware debug and validation.

Addresses: BCH_DEBUG0 is 4100_8000h base + 100h offset = 4100_8100h

BCH_DEBUG0_SET is 4100_8000h base + 104h offset = 4100_8104h

BCH_DEBUG0_CLR is 4100_8000h base + 108h offset = 4100_8108h

BCH_DEBUG0_TOG is 4100_8000h base + 10Ch offset = 4100_810Ch



BCH_DEBUG0*n* field descriptions

Field	Description
31–25 -	Reserved, always set these bits to zero.
24–16 KES_DEBUG_SYNDROME_SYMBOL	The 9 bit value in this bit field will be shifted into the syndrome register array at the input of the KES engine whenever BCH_DEBUG0_KES_DEBUG_SHIFT_SYND is toggled. 0x0 **NORMAL** — Bus master address generator for synd_gen writes operates normally. 0x1 **TEST_MODE** — Bus master address generator always addresses last four bytes in Auxilliary block.
15 KES_DEBUG_SHIFT_SYND	Toggling this bit causes the value in BCH_DEBUG0_KES_SYNDROME_SYMBOL to be shift into the syndrome register array at the input to the KES engine. After shifting in 16 symbols, one can kick off both KES and CF cycles by toggling BCH_DEBUG0_KES_DEBUG_KICK. Be sure to set KES_BCH_DEBUG0_KES_STANDALONE mode to 1 before kicking.
14 KES_DEBUG_PAYLOAD_FLAG	When running the stand alone debug mode on the error calculator, the state of this bit is presented to the KES engine as the input payload flag. 0x1 **DATA** — Payload is set for 512 byte data block. 0x1 **AUX** — Payload is set for 65 or 19 byte auxilliary block.

Table continues on the next page...

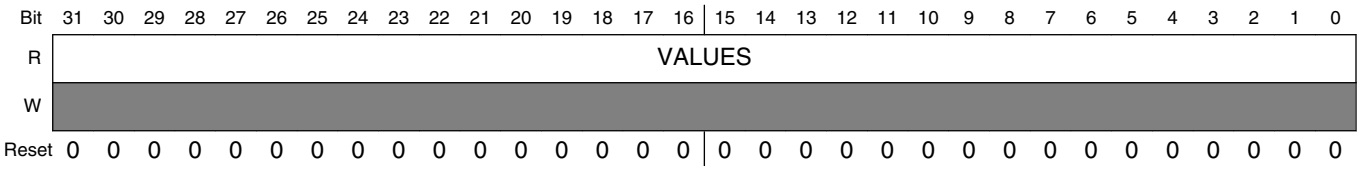
BCH_DEBUG0*n* field descriptions (continued)

Field	Description
13 KES_DEBUG_ MODE4K	When running the stand alone debug mode on the error calculator, the state of this bit is presented to the KES engine as the input mode (4K or 2K pages). 0x1 **4k** — Mode is set for 4K NAND pages. 0x1 **2k** — Mode is set for 2K NAND pages.
12 KES_DEBUG_ KICK	Toggling causes KES engine FSM to start as if kick by the Bus Master. This allows stand alone testing of the KES and Chien Search engines. Be sure to set KES_BCH_DEBUG0_KES_STANDALONE mode to 1 before kicking.
11 KES_ STANDALONE	Set to one to cause the KES engine to suppress toggling the KES_BM_DONE signal to the bus master and to suppress toggling the CF_BM_DONE signal by the CF engine. 0x0 **NORMAL** — Bus master address generator for synd_gen writes operates normally. 0x1 **TEST_MODE** — Bus master address generator always addresses last four bytes in Auxilliary block.
10 KES_DEBUG_ STEP	Toggling this bit causes the KES FSM to skip passed the stall state if it is in DEBUG_STALL mode and it has completed processing a block.
9 KES_DEBUG_ STALL	Set to one to cause KES FSM to stall after notifying Chien search engine to start processing its block but before notifying the bus master that the KES computation is complete. This allows a diagnostic to stall the FSM after each blocks key equations are solved. This also has the effect of stalling the CSFE search engine so it's state can be examined after it finishes processing the KES stalled block. 0x0 **NORMAL** — KES FSM proceeds to next block supplied by bus master. 0x1 **WAIT** — KES FSM waits after current equations are solved and the search engine is started.
8 BM_KES_ TEST_BYPASS	1 = Point all synd_gen writes to dummy area at the end of the AUXILLIARY block so that diagnostics can preload all payload, parity bytes and computed syndrome bytes for test the KES engine. 0x0 **NORMAL** — Bus master address generator for synd_gen writes operates normally. 0x1 **TEST_MODE** — Bus master address generator always addresses last four bytes in Auxilliary block.
7–6 -	Reserved, always set these bits to zero.
5–0 DEBUG_REG_ SELECT	The value loaded in this bit field is used to select the internal register state view of KES engine or the Chien search engine.

14.7.17 KES Debug Read Register (BCH_DBGKESREAD)

The hardware BCH ECC accelerator key equation solver internal state machines and signals can be seen in the ECC debug registers.

Address: BCH_DBGKESREAD is 4100_8000h base + 110h offset = 4100_8110h



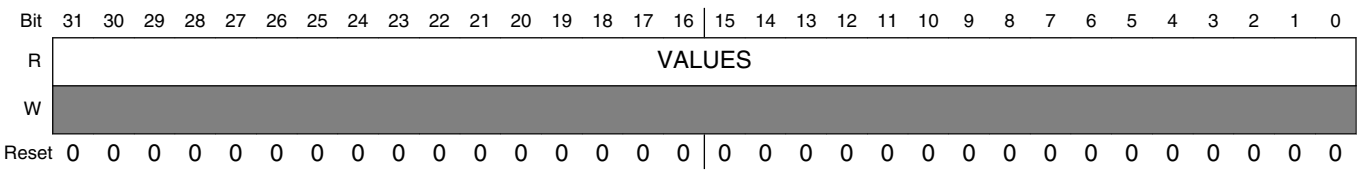
BCH_DBGKESREAD field descriptions

Field	Description
31–0 VALUES	This register will return the KES debug value.

14.7.18 Chien Search Debug Read Register (BCH_DBGCSFEREAD)

The hardware BCH ECC accelerator Chien Search internal state machines and signals can be seen in the ECC debug registers.

Address: BCH_DBGCSFEREAD is 4100_8000h base + 120h offset = 4100_8120h



BCH_DBGCSFEREAD field descriptions

Field	Description
31–0 VALUES	Reserved

14.7.19 Syndrome Generator Debug Read Register (BCH_DBGSYNDGENREAD)

The hardware BCH ECC accelerator syndrome generator internal state machines and signals can be seen in the ECC debug registers.

Address: BCH_DBGSYNDGENREAD is 4100_8000h base + 130h offset = 4100_8130h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

BCH_DBGAHBMREAD field descriptions

Field	Description
31–0 VALUES	Reserved

14.7.21 Block Name Register (BCH_BLOCKNAME)

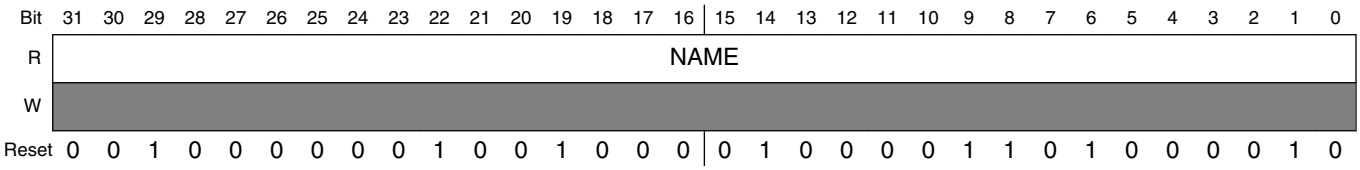
Read only view of the block name string BCH.

Fixed pattern read only value for test puposes. Can be read as an ASCII string with the zero termination coming from the first byte of the BLOCKVERSION register.

EXAMPLE

```
char *cp = ((char *)BCH_BLOCKNAME_ADDR);   reads back "BCH ".
```

Address: BCH_BLOCKNAME is 4100_8000h base + 150h offset = 4100_8150h



BCH_BLOCKNAME field descriptions

Field	Description
31–0 NAME	Should be the ascii characters "BCH " (0x20, H, C, B).

14.7.22 BCH Version Register (BCH_VERSION)

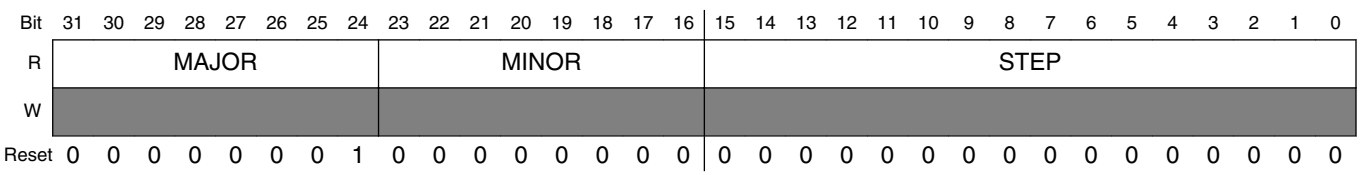
This register always returns a known read value for debug purposes it indicates the version of the block.

This register indicates the RTL version in use.

EXAMPLE

```
if (BCH_VERSION.B.MAJOR != 1) Error();
```

Address: BCH_VERSION is 4100_8000h base + 160h offset = 4100_8160h



BCH_VERSION field descriptions

Field	Description
31–24 MAJOR	Fixed read-only value reflecting the MAJOR field of the RTL version.
23–16 MINOR	Fixed read-only value reflecting the MINOR field of the RTL version.
15–0 STEP	Fixed read-only value reflecting the stepping of the RTL version.

Chapter 15
Clock Amplifier (CAMP)

15.1 Introduction

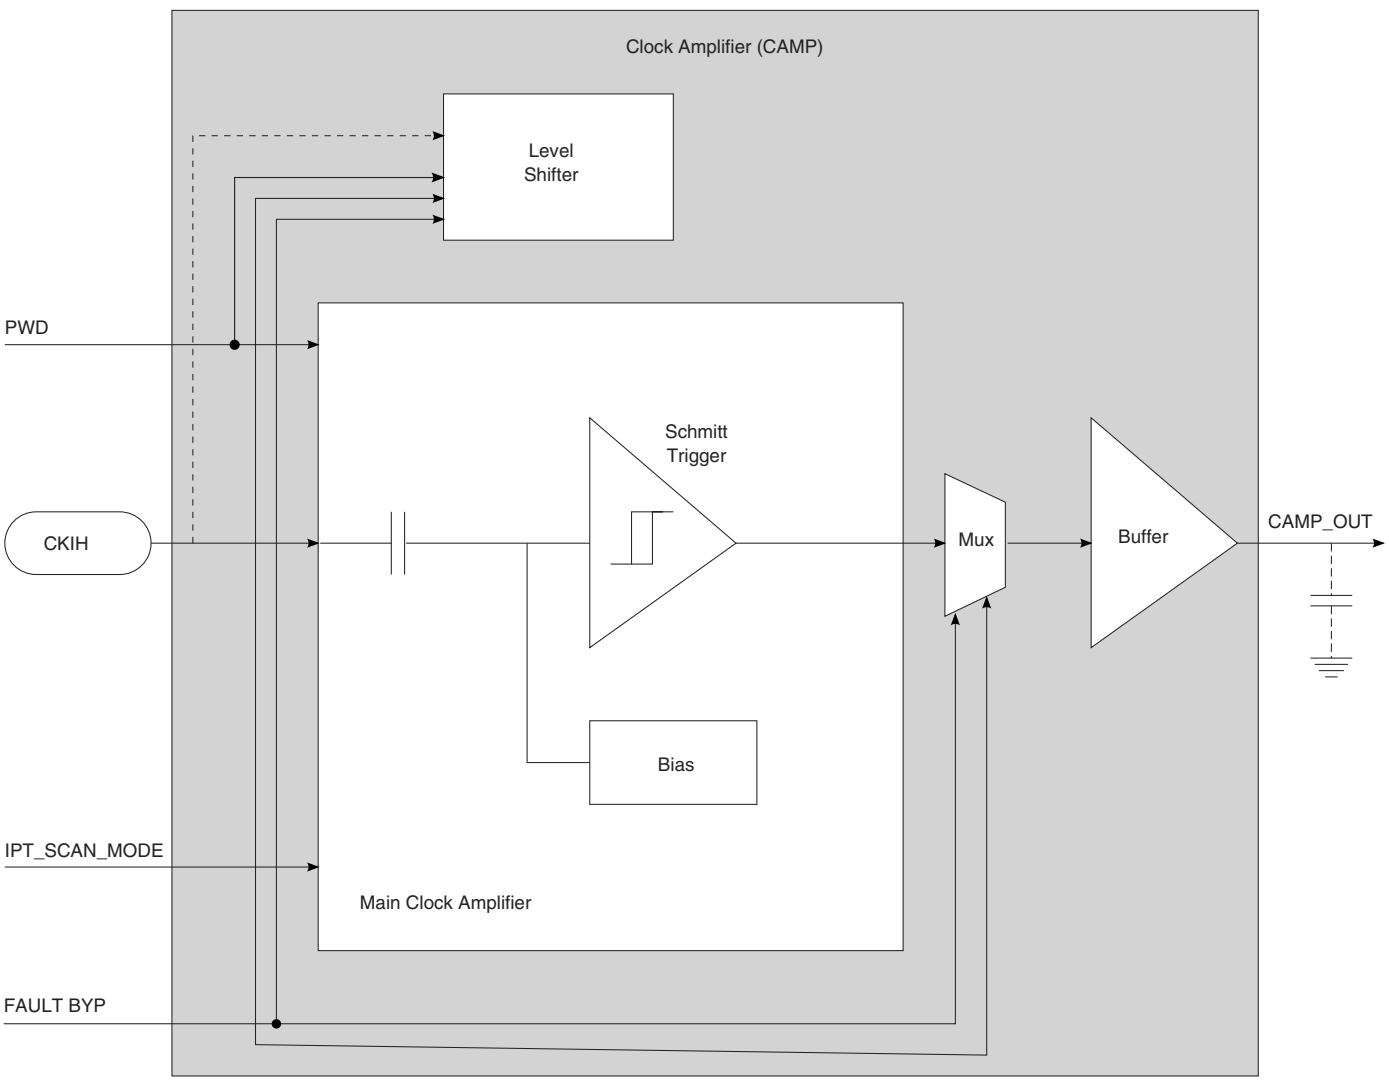


Figure 15-1. Clock Amplifier Block Diagram

15.1.1 Overview

The Clock Amplifier converts a square wave/sinusoidal input of frequency range 8-40 MHz, into a rail to rail square wave (CAMP supply voltage).

The input of the CAMP block is CKIH and the output is CAMP_OUT. The input to CAMP is internally AC coupled (in normal mode); no external coupling is required.

15.1.2 Features

The CAMP includes the following features:

- Converts sinusoidal input to square wave.
- Can accept a square wave of amplitude greater than the supply voltage of the block.

15.1.3 Modes of Operation

The CAMP supports three modes of operation.

15.1.3.1 Normal Mode

In this mode of operation, the Clock Amplifier accepts a sinusoidal/square wave as input and gives a rail to rail square wave output.

15.1.3.2 Power Down Mode

In this mode the CAMP is disabled and put in the low power state. CAMP_OUT remains at logic'0' level during power down.

15.1.3.3 Test Mode (Fault Bypass or Scan)

The Test mode is to be used for testing purpose or during scan. The MAIN CLOCK AMPLIFIER is bypassed in this mode.

15.2 External Signal Description

15.2.1 Signals Overview

Table 15-1. CAMP External Signal Properties

Name	Direction	Function
CKIH	Input	Input clock

Table 15-2. CAMP Interface Signal Properties

Name	Direction	Function
VDD	Input	Power supply
VSS	Input	Ground
PWD	Input	Power down signal
FAULT_BYP	Input	Test mode control signal
IPT_SCAN_MODE	Input	Scan mode signal
CAMP_OUT	Output	Output clock from CAMP

15.2.2 Detailed Signal Description

15.2.2.1 CKIH - External Clock Input

The signal CKIH is the clock input signal to the CAMP. It can be a sinusoidal input with a minimum swing of 400mV p-p or a square wave. It comes directly from the pad.

15.2.2.2 VDD - Power supply

The VDD is the power supply for the CAMP. It supplies the main clock amplifier, buffer and level shifter.

15.2.2.3 VSS - Ground

The VSS input is the ground for the CAMP.

15.2.2.4 IPT_SCAN_MODE - Scan Signal

This signal is active high. When this signal is asserted CAMP is forced to "Test Mode" irrespective of states of fault_byp or pwd signals.

15.2.2.5 PWD - Power Down Signal

This signal when asserted (and ipt_scan_mode = 0), puts the CAMP in the low power mode. This signal is active high.

15.2.2.6 FAULT_BYP - Control Signal for Test Mode

This signal when asserted puts CAMP in test mode. This signal is active high. When this signal is low (and ipt_scan_mode = 0) CAMP works in normal mode.

15.2.2.7 CAMP_OUT - Clock Output from CAMP

This signal is the output of the CAMP.

15.3 Memory Map/Register Definition

The CAMP gets its control signals PWD and FAULT_BYP from registers residing in the CRM. It gets its control signal IPT_SCAN_MODE from TSCM (Test and Scan Control sub-block).

15.4 Functional Description

This section provides a functional description of the Clock Amplifier. The block can be divided into three parts. First the Main Clock Amplifier, second the Output Buffer and third the Level Shifter.

15.4.1 CAMP Sub-Blocks

This section describes the Main Clock amplifier, the Output Buffer and Level Shifter of CAMP. (See Figure 15-1).

15.4.1.1 Main Clock Amplifier

The input clock is ac coupled to the input of a Schmitt trigger. A dc bias generation circuit is used to provide a fixed dc to the input of the Schmitt trigger. The Schmitt trigger converts a sinusoidal signal to a square wave.

15.4.1.2 Output Buffer

The output of the main clock amplifier is buffered by the output buffer.

15.4.1.3 Level Shifter

This is activated in the test mode. It level shifts the input signal to CAMP supply.

15.4.2 CAMP Modes of Operation

Table 15-3. Truth Table for CAMP

IPT_SCAN_MODE	PWD	FAULT_BYP	CAMP_OUT	Main Clock Amplifier Path	Level Shifter Path
0	0	0	Square Wave	Enabled	Disabled
0	0	1	Square Wave	Disabled	Enabled
0	1	X	Logic'0'	Disabled	Disabled
1	X	X	Square Wave	Disabled	Enabled

15.4.2.1 Normal Mode

In this mode of operation the IPT_SCAN_MODE, PWD and FAULT_BYP signals are de-asserted. The sinusoidal (or square wave) clock input (with peak to peak amplitude not exceeding 3 Volts) is converted to square wave with amplitude equal to the Camp supply.

15.4.2.2 Power Down Mode

In this mode of operation, the CAMP is powered down. The supply to Main Clock Amplifier and level shifter is turned off by power gating. The CAMP_OUT is a t logic '0' level.

15.4.2.3 Test Mode

In this mode the MAIN CLOCK AMPLIFIER is bypassed via a level shifter. It accepts only square wave input with voltage swing greater than or equal to CAMP supply voltage. There is no guarantee of output clock duty cycle in this mode. To obtain 45%-55% duty cycle output from CAMP in this mode, the input must be a square wave at CAMP's supply level with slews less than or equal to 2ns.

15.5 Initialization/Application Information

During initialization it has to be ensured that PWD and IPT_SCAN_MODE remain de-asserted.

Chapter 16
Configurable Serial Peripheral Interface (CSPI)

16.1 Overview

This chapter describes a block integrated into an SoC. The chapter is intended for a block driver software developer. It describes block-level operation and programming. To understand how the block is integrated at the SoC level, a system software developer should see discussions of the block in the appropriate SoC-level chapter(s).

The Configurable Serial Peripheral Interface (CSPI) block is a full-duplex, synchronous, four-wire serial communication block. The CSPI block contains an 8 x 32 receive buffer (RXFIFO) and an 8 x 32 transmit buffer (TXFIFO). With data FIFOs, the CSPI allows rapid data communication with fewer software interrupts. Figure 16-1 shows a block diagram of the CSPI.

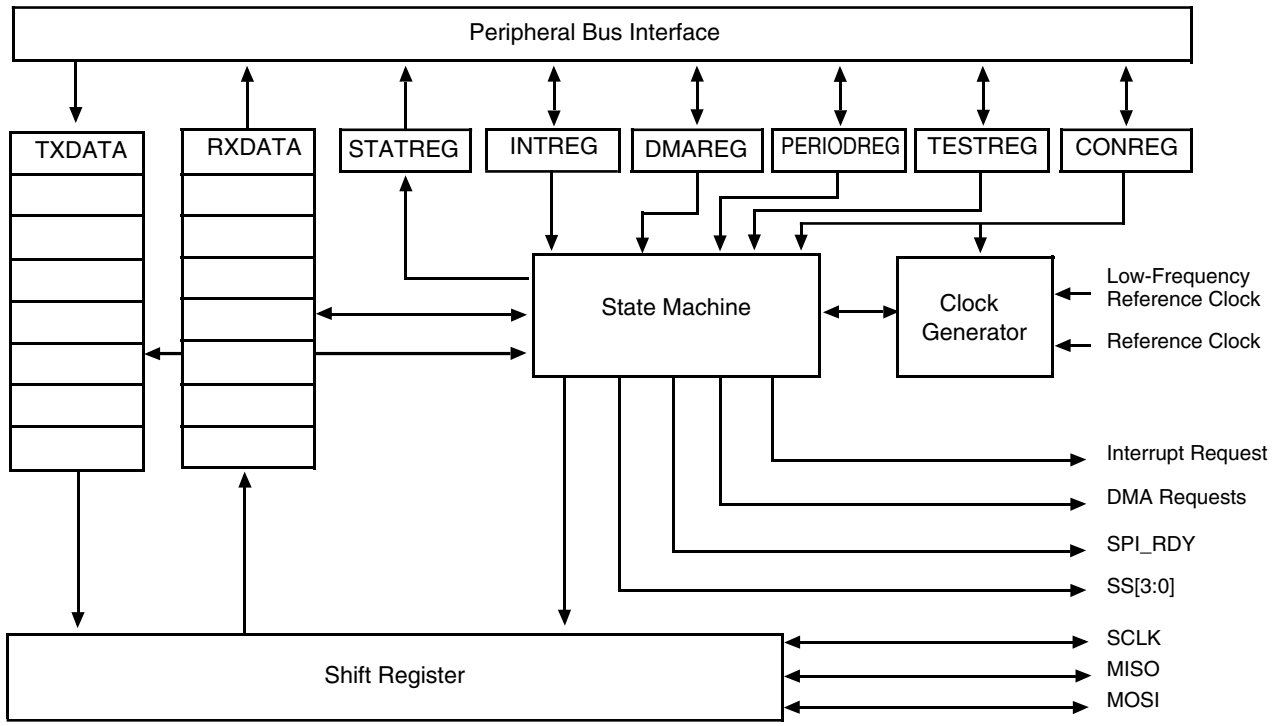

Figure 16-1. CSPI Block Diagram

16.1.1 Features

Key features of the CSPI include:

- Full-duplex synchronous serial interface
- Master/Slave configurable
- Four Chip Select (SS) signals to support multiple peripherals
- Transfer continuation function allows unlimited length data transfers
- 32-bit wide by 8 -entry FIFO for both transmit and receive data
- Polarity and phase of the Chip Select (SS) and SPI Clock (SCLK) are configurable
- Direct Memory Access (DMA) support
- Max operation frequency up to one-quarter of the reference clock frequency.

16.1.2 Modes and Operations

The CSPI supports the modes described in the indicated sections:

- Operating Modes
  - Master Mode
  - Slave Mode
- Low Power Modes

As described in Operations, the CSPI supports the operations described in the indicated sections:

- Typical Master Mode
  - Master Mode with SPI_RDY
  - Master Mode with Wait States
  - Master Mode with SSCTL Control
  - Master Mode with Phase Control
- Typical Slave Mode

16.2 External Signals

The following table lists conventions for representing signals.

Table 16-1. Block Signal Conventions

Category	Convention	Example(s)
Off-chip signal	Uppercase (all capital letters)	TXD
Internal signal[1]	Lowercase italics	*core_int*
Active low signal	_B (_b) suffix or overbar	RESET_EN_B or $\overline{\text{RESET\_EN}}$
Range of bussed or commonly named signals	Beginning and end points of the range are: • Separated by a colon. • Surrounded by square brackets.	ADDR[31:0] CSE_B[7:0] or $\overline{\text{CSE}}$[7:0]
Individual signal in a range of bussed or commonly named signals	Individual number in the range appears without a colon or square brackets	ADDR31 CSE0_B or $\overline{\text{CSE0}}$

1. Internal signals are for reference only in descriptions of internal block or SoC functionality.

The following table describes all CSPI signals that connect off-chip.

Table 16-2. Off-Chip Block Signals

Signal	I/O	Description	Reset State[1]	Pull-Up/ Down[1]
$\overline{\text{SS}}$[3:0]	I/O	Chip selects	1	-
SCLK	I/O	SPI clock	0	Active
MISO	I/O	Master data in; slave data out	0	Passive
MOSI	I/O	Master data out; slave data in	0	-
SPI_RDY	I	Master data out; slave data in	0	Active

1. The reset state values and pull-up/down requirements provided in this table are from the block-level perspective. To understand how the block is integrated at the SoC level, the system software developer must see discussions of the block in the appropriate SoC-level chapter(s). For example, a block signal that requires a pull-up could be integrated with a pull-up option built into the SoC. In this case, the system software developer must ensure the proper programming at the SoC level.

The following figure shows the CSPI in master mode connected to four external devices in a one-way communication link.

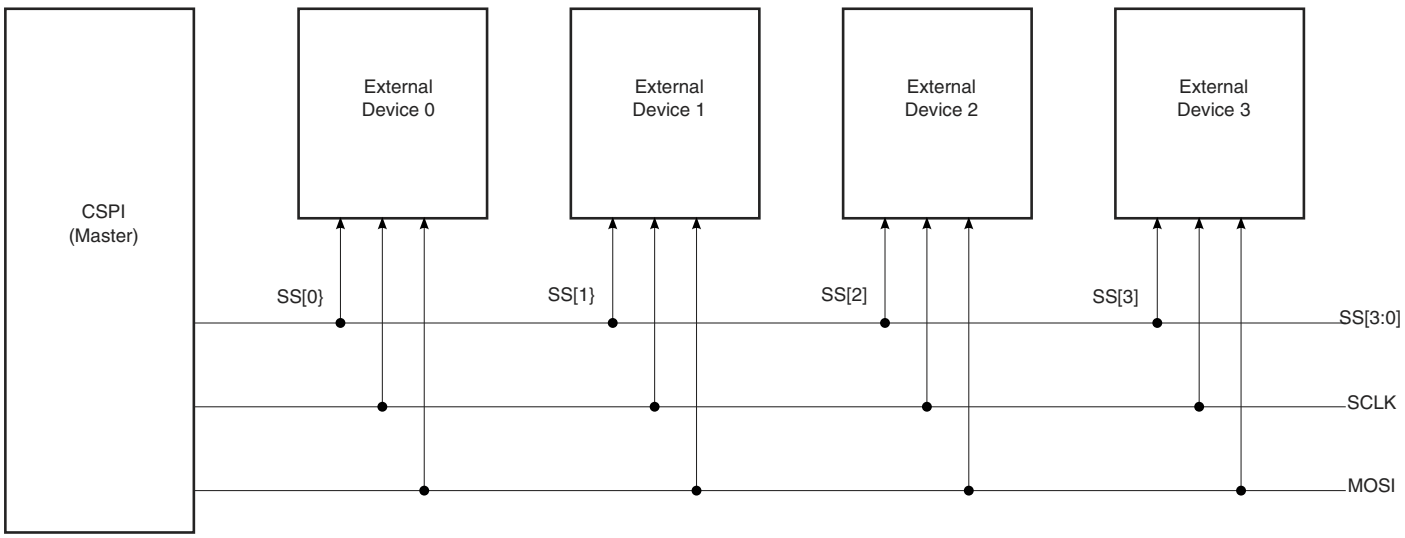

Figure 16-2. Example Connection Diagram

16.3 Functional Description

This section provides a complete functional description of the CSPI. The following figure shows the relationship of SCLK and data lines while CSPI has been configured with different POL and PHA settings.

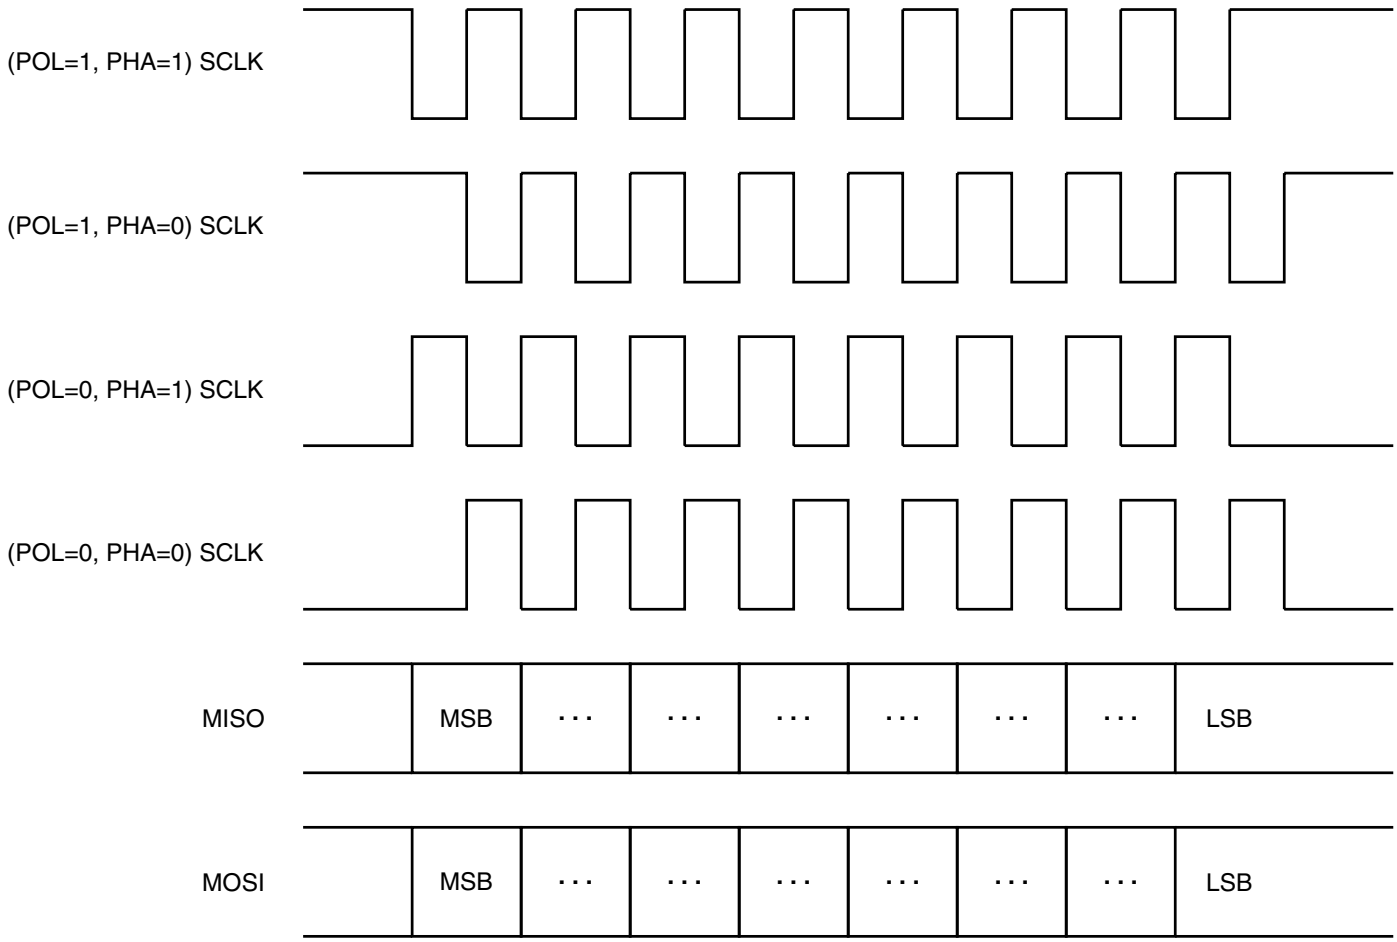

Figure 16-3. CSPI SCLK, MISO, and MOSI Relationship

16.3.1 Operating Modes

CSPI has two operating modes, master mode and slave mode. This section describes all functional operation modes of the CSPI.

16.3.1.1 Master Mode

When the CSPI is configured as a master, it uses a serial link to transfer data between the CSPI and an external slave device. One of the Chip Select (SS) signals and the clock signal (SCLK) are used to transfer data between two devices. If the external device is a transmit-only device, the CSPI master's output port can be ignored and used for other purposes. In order to use the internal TXFIFO and RXFIFO, two auxiliary output signals,

Chip Select (SS) and CSPI_CONREG[DRCTL], are used for data transfer rate control. Software can also configure the sample period control register to a fixed data transfer rate.

16.3.1.2 Slave Mode

When the CSPI is configured as a slave, software can configure the CSPI Control register to match the external SPI master's timing. In this configuration, Chip Select ($\overline{SS}$) becomes an input signal, and is used to control data transfers through the Shift register, as well as to load/store the data FIFO.

16.3.2 Low Power Modes

The CSPI does not operate under low power mode. It holds its operation when its clock is gated off in master mode. In slave mode, the CSPI does not respond when its clock is gated off.

16.3.3 Operations

This section describes the CSPI's operations.

16.3.3.1 Typical Master Mode

The CSPI master uses the Chip Select (SS) signal to enable an external SPI device, and uses the SCLK signal to transfer data in and out of the Shift register. The SPI_RDY enables fast data communication with fewer software interrupts. By programming the CSPI_PERIODREG register accordingly, the CSPI can be used for a fixed data transfer rate.

When the CSPI is in Master mode the SS, SCLK, and MOSI are output signals, and the MISO signal is an input. The following figure shows a typical SPI burst.

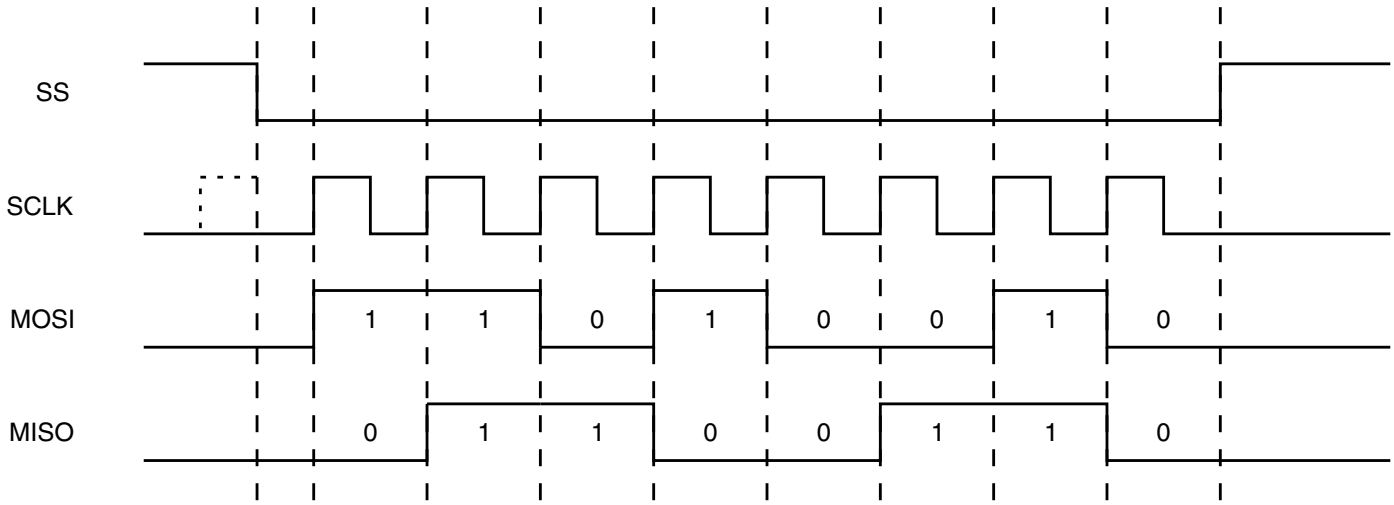

Figure 16-4. Typical SPI Burst (8-bit Transfer)

The Chip Select (SS) signal enables the selected external SPI device, and the SCLK synchronizes the data transfer. The MOSI and MISO signals change on rising edge of SCLK and the MISO signal is latched on the falling edge of the SCLK. The above figure shows a data of 0xD2 is shifted out, and a data of 0x66 is shifted in.

16.3.3.1.1 Master Mode with SPI_RDY

By default, the CSPI does not use the SPI_RDY signal in master mode (MODE =1). A SPI burst begins when the following events happen:

- The CSPI is enabled, TXFIFO has data in it, and CONREG[XCH] bit or the CONREG[SMC] bit is set.
- When the SPI Data Ready Control (CONREG[DRCTL]) bits contains either 01 or 10, the SPI_RDY signal controls when a SPI burst starts.

A SPI burst is defined as a bus transaction that starts when the slave select is asserted and ends when the slave select is negated. The Chip Select (SS) signal will remain asserted until all the bits in a SPI burst are shifted out.

If CONREG[DRCTL] is set to 01, the SPI burst can be triggered only if a falling edge of the SPI_RDY signal from CSPI_CONREG[DRCTL] register has been detected. The following figure shows the relationship between a SPI burst and the falling edge of SPI_RDY signal.

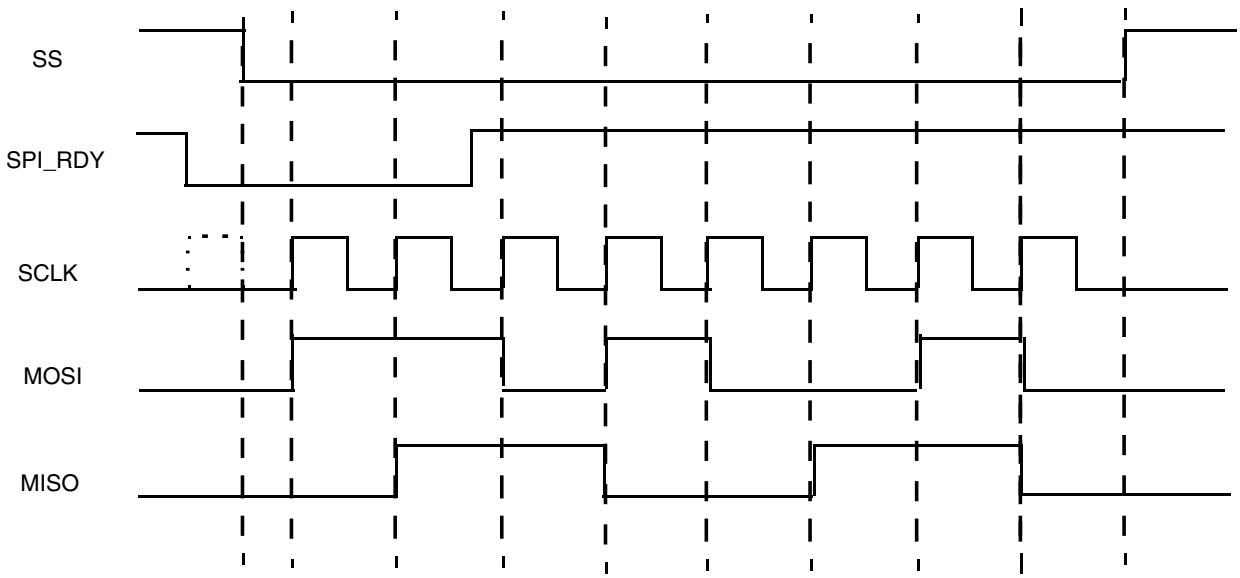

Figure 16-5. Relationship Between a SPI Burst and SPI_RDY: Falling-Edge Triggered

A SPI burst does not start until the falling edge of the SPI_RDY signal is detected. The next SPI burst starts when the next SPI_RDY falling edge is detected, after the last burst has finished.

If SPI Data Ready Control (CONREG[DRCTL]) is set to 10, the SPI burst can be triggered only if the SPI_RDY signal is low. The following figure shows the relationship between a SPI burst and the SPI_RDY signal. The SPI burst does not begin until the SPI_RDY signal goes low. The CSPI will keep transmitting SPI burst if the SPI_RDY signal remains low.

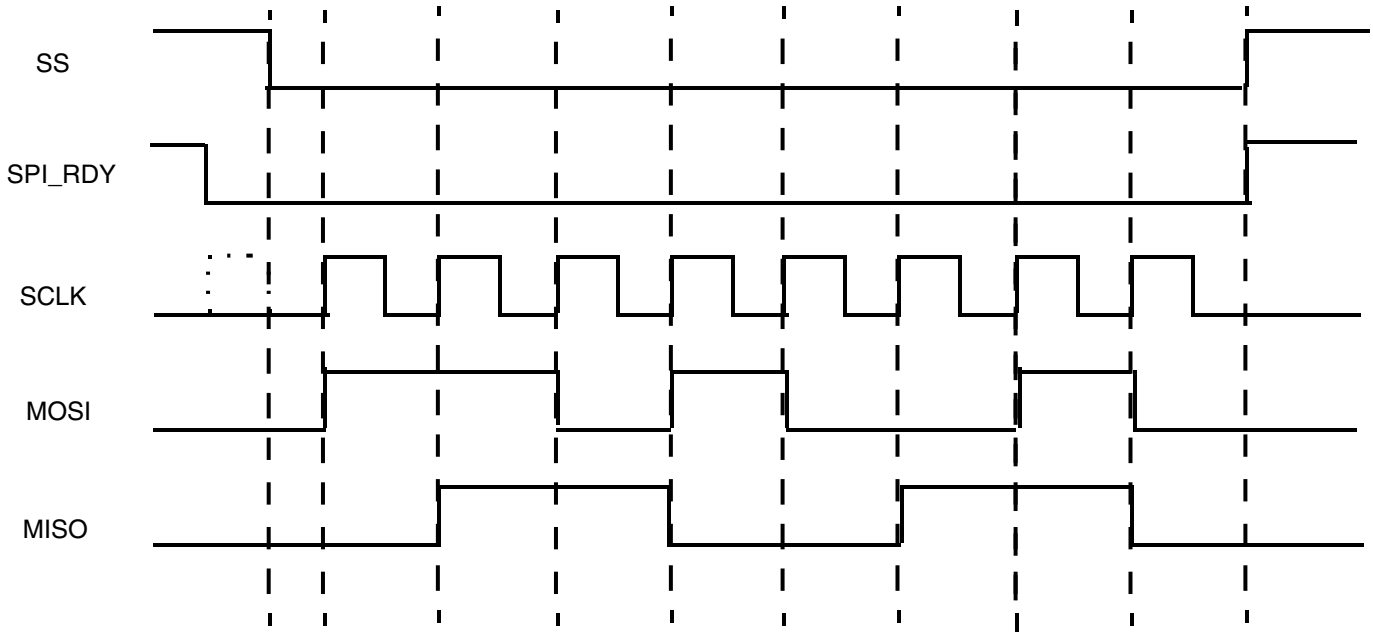

Figure 16-6. Relationship Between a SPI Burst and SPI_RDY: Low-Level Triggered

16.3.3.1.2 Master Mode with Wait States

Wait states can be inserted between SPI bursts. This provides a way for software to slow down the SPI burst to meet the timing requirements of a slower SPI device. The following figure shows wait states inserted between SPI bursts.

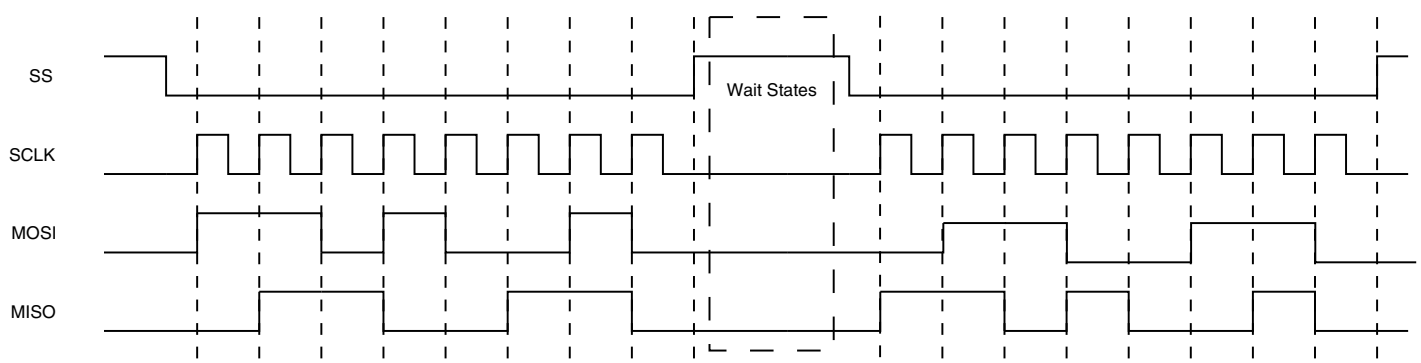

Figure 16-7. SPI Bursts with Wait States

In this case, the number of wait states is controlled by PERIODREG[SAMPLE PERIOD] and the wait states' clock source is selected by PERIODREG[CSRC].

16.3.3.1.3 Master Mode with SSCTL Control

The SPI SS Control (SSCTL) bit controls whether the current operation is single burst or multiple bursts. When the SPI SS Wave Form Select (SSCTL) bit is set, the current operation is multiple bursts transfer. When the SPI SS Wave Form Select (SSCTL) bit is cleared, the current operation is single burst transfer. A SPI burst can contains multiple words as defined in the BURST LENGTH field of the CSPI_CONREG register.

The following figure shows one SPI burst while SSCTL is clear.

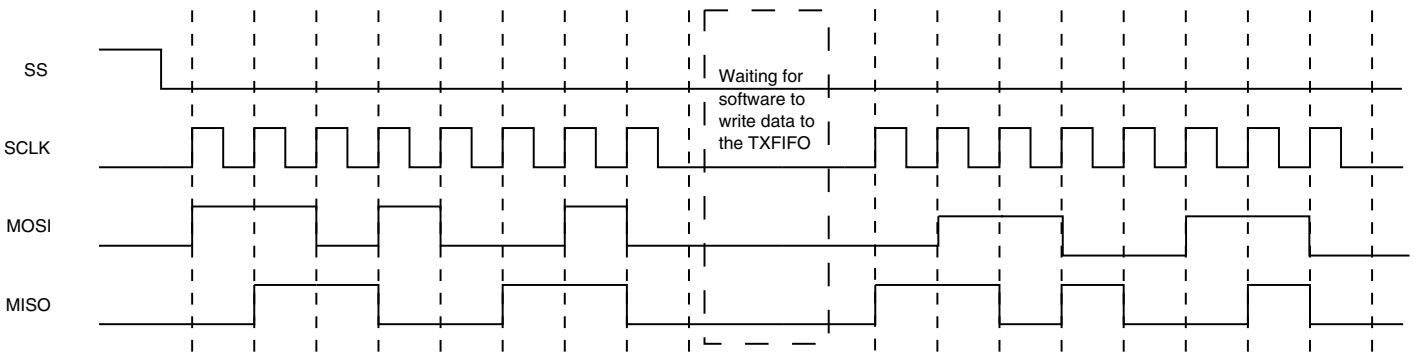

Figure 16-8. SPI Burst While SSCTL is Clear

Two 8-bit bursts in the TXFIFO have been combined and transmitted in one SPI burst. The maximum length of a single SPI burst is defined in the BURST LENGTH field of the CONREG control register. (The above figure corresponds to a BURST LENGTH of 8.) This provides a way for transferring a longer SPI burst by writing data into TXFIFO while the CSPI is transmitting.

The following figure shows two SPI bursts are transmitted while SSCTL is set.

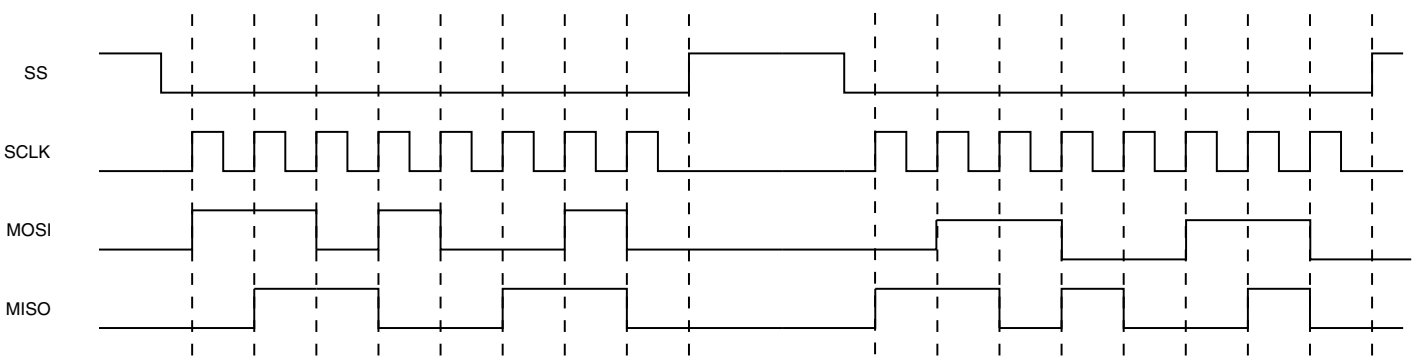

Figure 16-9. SPI Bursts While SSCTL is Set

Two FIFO entries are transmitted, one entry with each SPI burst. The CSPI will continue to transmit SPI bursts until the TXFIFO is empty. When wait states can be inserted between SPI bursts, the SS will negate between SPI bursts until the wait states finish.

16.3.3.1.4 Master Mode with Phase Control

The Phase Control (CSPI_CONREG[PHA]) bit controls how the transmit data shifts out and the receive data shifts in.

When the Phase control (CSPI_CONREG[PHA]) bit is set, the transmit data will shift out on the rising edge of SCLK, and the receive data is latched on the falling edge of SCLK. The most-significant bit is output on the first rising SCLK edge.

When CSPI_CONREG[PHA] is cleared, the transmit data is shifted out on the falling edge of SCLK and the receive data is latched on the rising edge of SCLK. The MSB is output when the host processor loads the transmitted data.

Inverting the SCLK polarity does not impact the edge-triggered operations because they are internal to the serial peripheral interface master.

The following figure shows a SPI burst using different POL and PHA configurations.

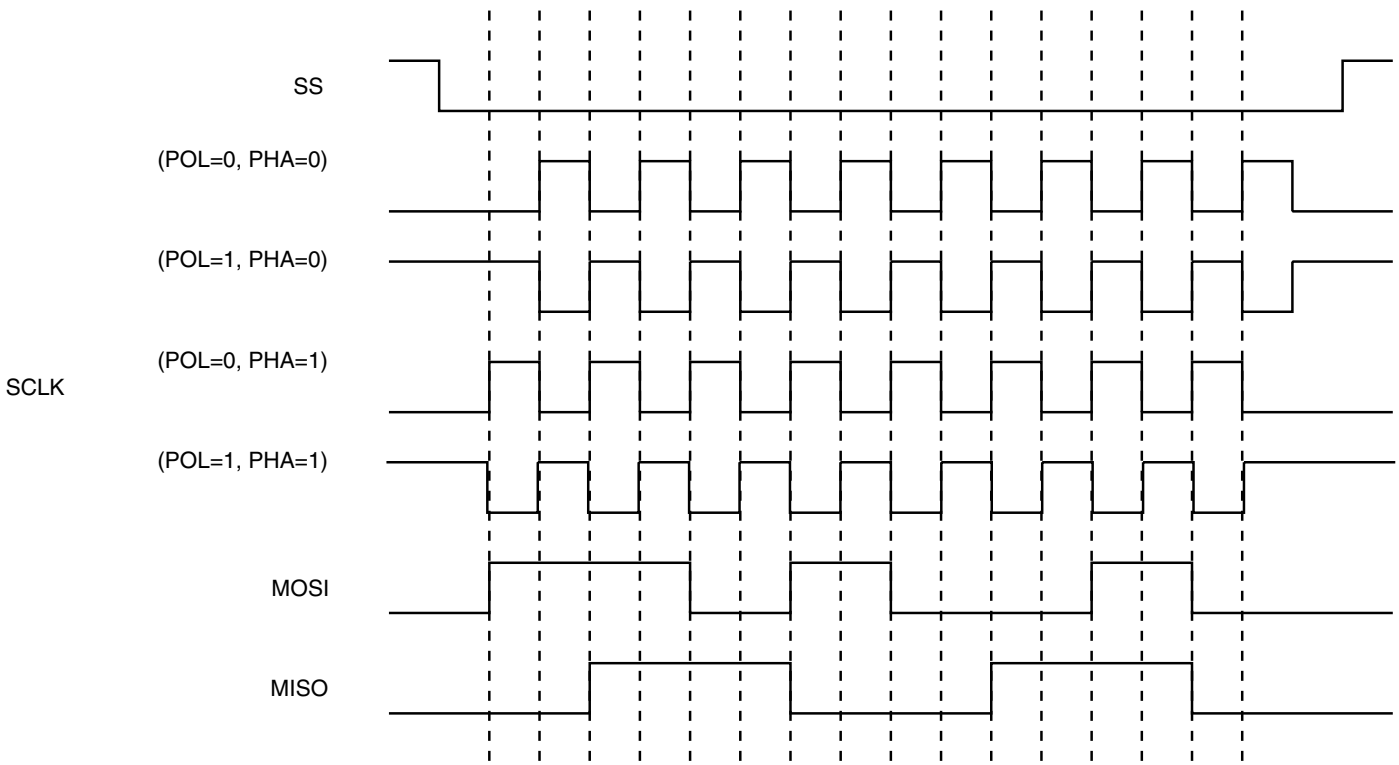

Figure 16-10. SPI Burst with Different POL and PHA Configurations

16.3.3.2 Typical Slave Mode

When the CSPI is configured as a slave (Mode = 0), software can configure the CSPI Control register to match the external SPI master's timing. In this configuration, SS becomes an input signal, and is used to latch data in and out of the internal data Shift registers, as well as to advance the data FIFO.

The SS, SCLK, and MOSI are inputs and MISO is output. Most of the timing diagrams are similar to the diagrams shown previously for the SPI in Master mode (Mode = 1), because the inputs come from a SPI master device.

However, the timing is different when SS is used to advance the data FIFO. When the SSCTL is set while the CSPI is configured in Slave mode, the data FIFO will advance on the rising edge of the SS signal. When the polarity is reversed (SSPOL = 1), the data FIFO will advance on the falling edge of the SS signal.

The following figure shows a SPI burst in which the data FIFO is advanced by the rising edge of the SS signal.

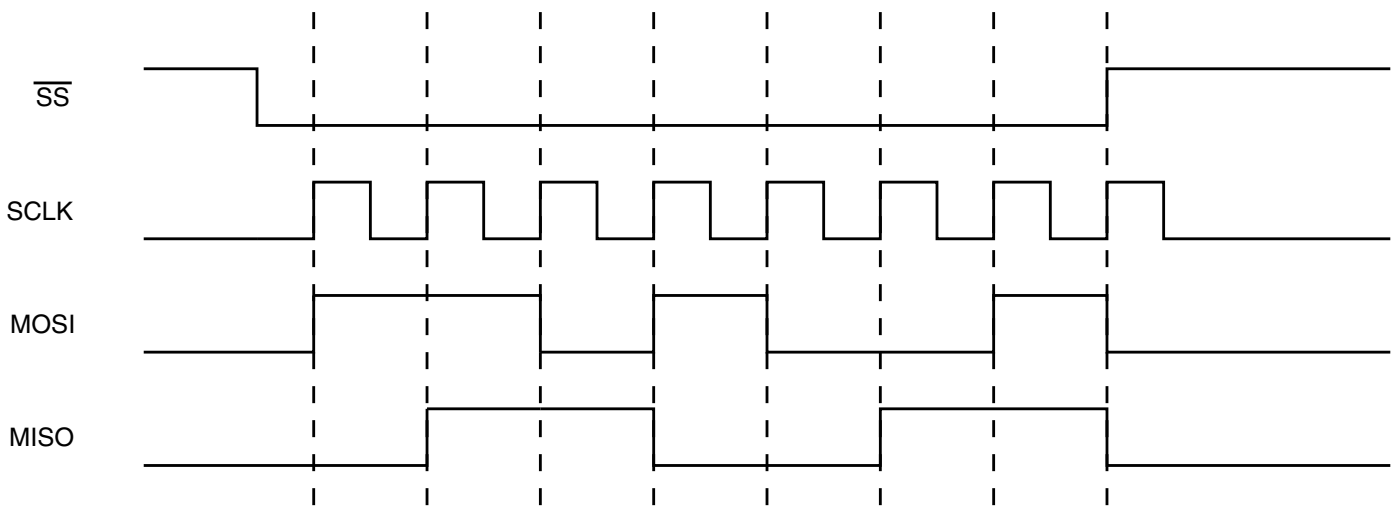

Figure 16-11. Advancing the Data FIFO on the Rising Edge of SS

In the above case, only the most significant 7 bits are loaded to the RXFIFO.

16.3.4 Clocks

This section describes clocks and special clocking requirements of the block.

CSPI has the following clock inputs:

- Reference Clock is the reference clock.
- Low-Frequency Reference Clock is a 32KHz input clock optionally used for counting wait states.

16.3.5 Reset

Whenever a device reset occurs, a reset is performed on the CSPI, resetting all registers to their default values.

Software can reset the block using the CONREG[EN] bit; see Control Register (CSPI_CONREG).

16.3.6 Interrupts

Interrupt control provides a way to manage the CSPI FIFOs:

- For transmitting data, software can enable the TXFIFO empty, TXFIFO half , and TXFIFO full interrupts to maintain the TXFIFO using an interrupt service routine.
- For receiving data, software can enable the RXFIFO ready, RXFIFO half , and RXFIFO full interrupts to retrieve data from the RXFIFO using an interrupt service routine.

Other interrupt sources can be used to control or debug the SPI bursts:

- The transfer-completed interrupt means that there is no data left in the TXFIFO and that the data in the Shift register has been shifted out.
- The RXFIFO overflow interrupt means that the RXFIFO received more than 8 words and will not accept any other words.

The following figure shows a program sequence of SPI bursts using interrupt control.

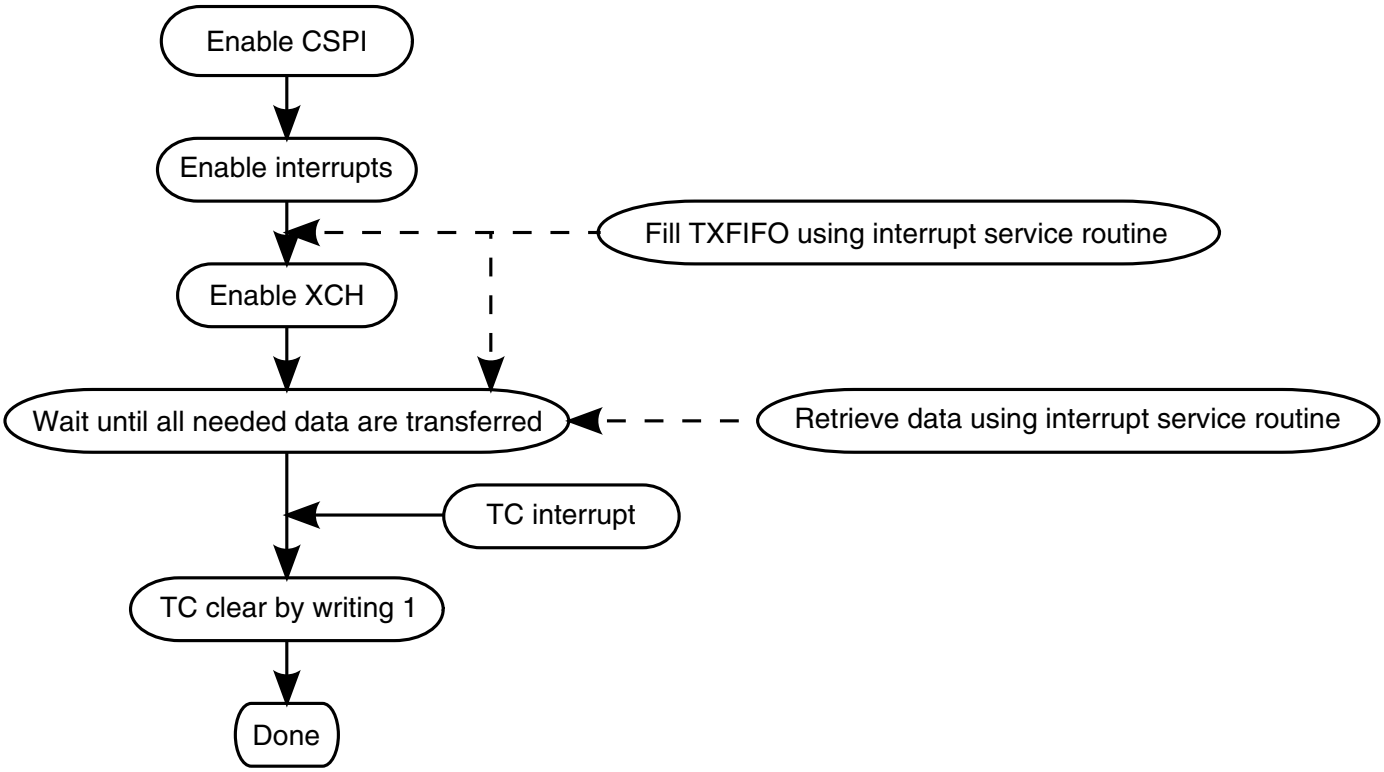

Figure 16-12. Program Sequence of SPI Burst Using Interrupt Control

16.3.7 DMA

DMA control provides another method to utilize the FIFOs in the CSPI. By using DMA request and acknowledge signals, larger amounts of data can be transferred, and will reduce interrupts and host processor loading. When the appropriate conditions are matched, the block will send out a DMA request, and the DMA can deal with the following conditions:

- TXFIFO empty
- TXFIFO half
- RXFIFO half
- RXFIFO full

The following figure shows a program sequence of SPI bursts using DMA control.

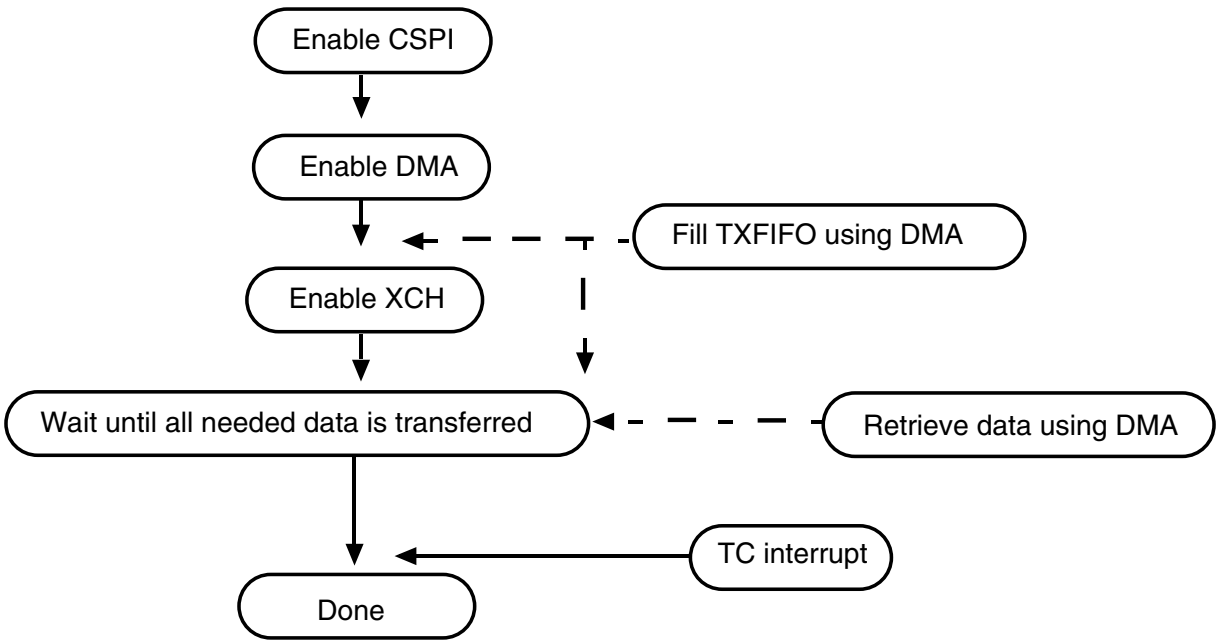

Figure 16-13. Program Sequence of SPI Burst Using DMA

16.3.8 Byte Order

Software can swap bytes for receive data using the TESTREG[SWAP] bit. See Test Control Register (CSPI_TESTREG).

16.4 Initialization

This section provides initialization information for CSPI.

To initialize the block:

1. Clear the EN bit in CSPI_CONREG to reset the block.
2. Enable the clocks for CSPI.
3. Set the EN bit in CSPI_CONREG to put CSPI out of reset.
4. Configure corresponding IOMUX for CSPI external signals.
5. Configure registers of CSPI properly according to the specifications of the external SPI device.

16.5 Applications

The following figure shows two flowcharts for the master and slave mode of operations supported by the CSPI.

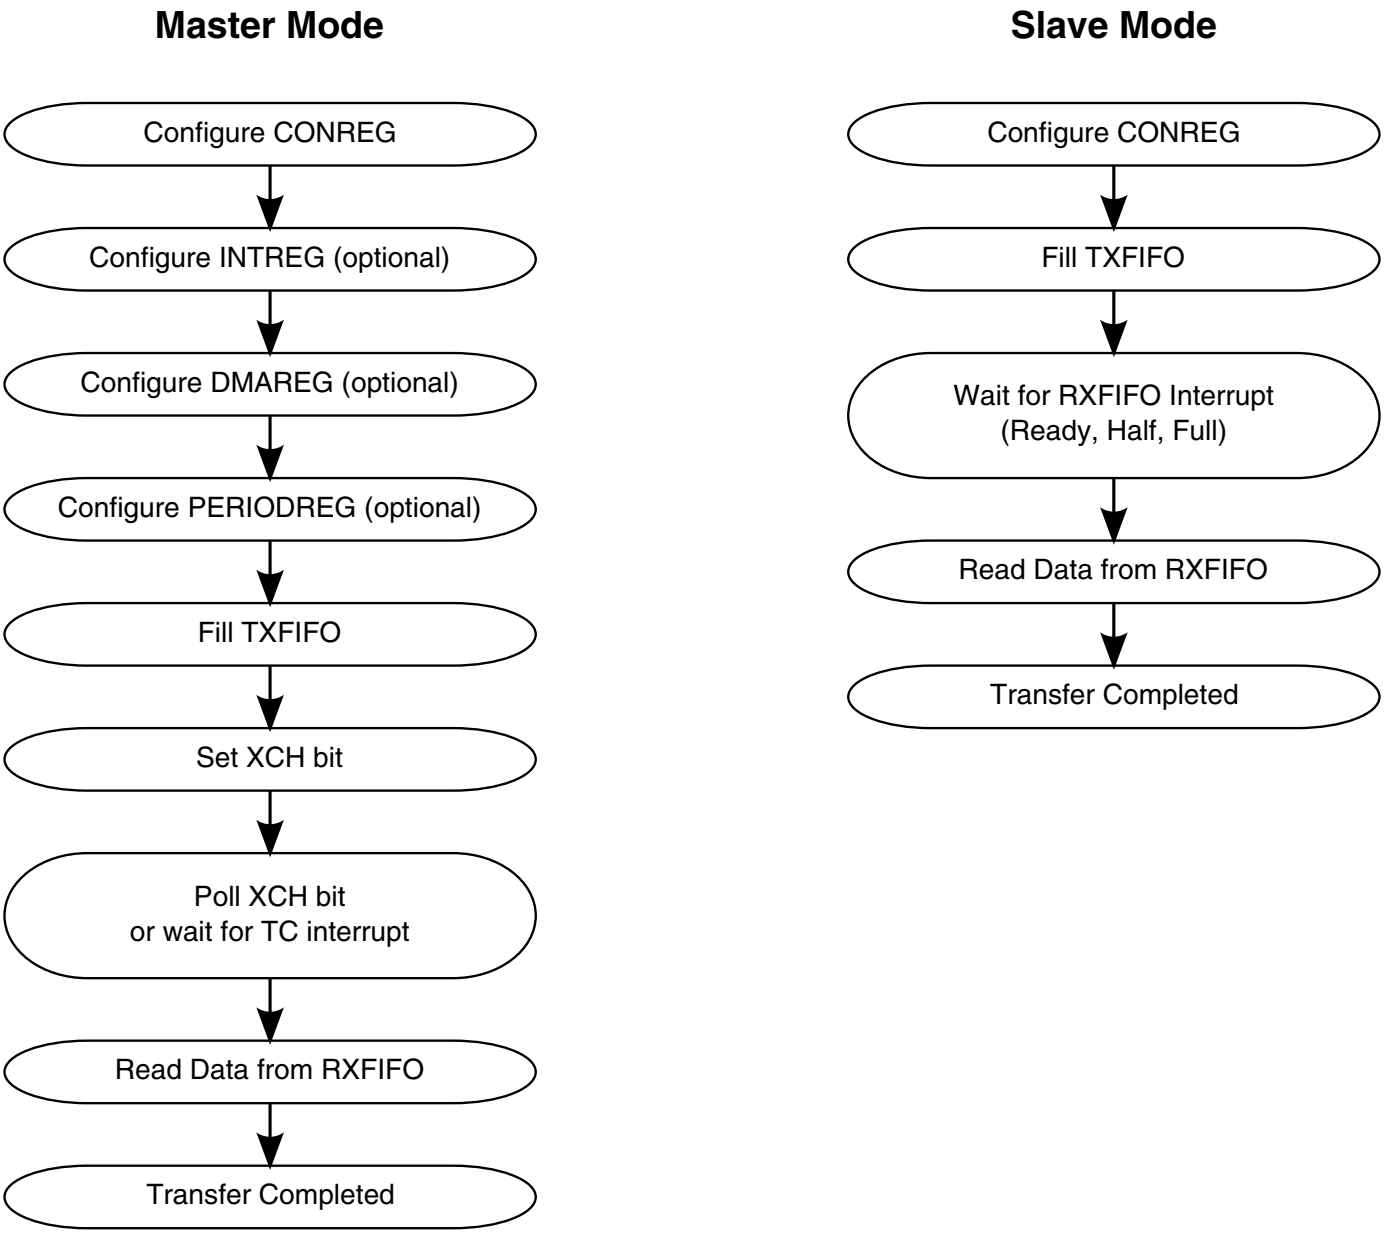

Figure 16-14. Flowchart of the CSPI Operation

The following example shows example code of CSPI operation using ARM instructions.

CSPI Operation using ARM Instructions

```
          LDR R0, =CSPI_BASE_ADDRESS                    ; Load CSPI Base Address to R0

interrupt)

          LDR R5, =0x05                                 ; R5 as number of words to be
transferred.

          LDR R1, =0x11111111                           ; R1 as increment to generate the
data.

          LDR R2, =0x12345678                           ; R2 load the data to be transferred.

Loop_00

          STR R2, [R2,#0x04]                               ; Store data into TXFIFO.

          ADD R2, R2, R1                                ; Generating next data to be
transferred.

          SUB R5, R5, #1                                ; Decrease the R5.

          CMP R5, #0x00                                 ; Check R5 if it is zero.

          BNE Loop_00                                  ; Loop until R5 is zero.

          LDR R1, =0x01F00007                             ; set XCH bit to start transaction.

          STR R1, [R0, #0x08]

Loop_01

          LDR R1, [R0, #0x08]                              ; check XCH bit if it is cleared.

          LDR R2, =0x00000004

          AND R1, R2, R1

          CMP R1, #0x00

          BEQ PASS_00                                  ; if XCH bit is cleared then finish.

          B Loop_01                                    ; if it isn't cleared then continue loop

          LDR R1, [R0, #0x00]                              ; Read data from RXFIFO.
```

16.6 Programmable Registers

This section includes the block memory map and detailed descriptions of all registers. For the base address of a particular block instantiation, see the system memory map.

CSPI memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
63FC_0000	Receive Data Register (CSPI_RXDATA)	32	R	0000_0000h	16.6.1/ 764
63FC_0004	Transmit Data Register (CSPI_TXDATA)	32	W (always reads zero)	0000_0000h	16.6.2/ 765

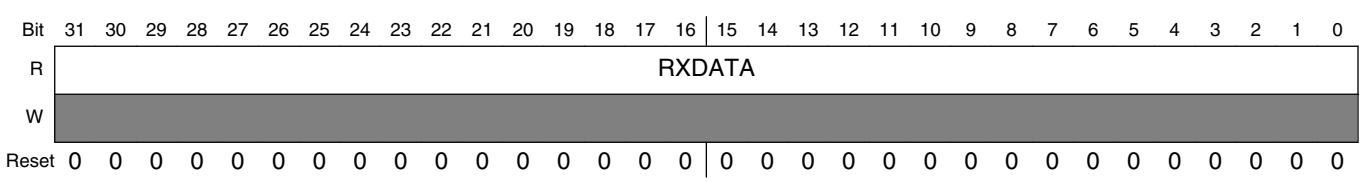
16.6.1 Receive Data Register (CSPI_RXDATA)

The Receive Data register (CSPI_RXDATA) is a read-only register that forms the top word of the 8 x 32 receive FIFO. This register holds the data received from an external SPI device during a data transaction. Only word-sized read operations are allowed.

Address: CSPI_RXDATA is 63FC_0000h base + 0h offset = 63FC_0000h



CSPI_RXDATA field descriptions

Field	Description
31–0 RXDATA	Receive Data. This register holds the top word of the receive data FIFO. The FIFO is advanced for each read of this register. The data read is undefined when the Receive Data Ready (RR) bit in the Interrupt Control/Status register is cleared. Zeros are read when CSPI is disabled.

16.6.2 Transmit Data Register (CSPI_TXDATA)

The Transmit Data (CSPI_TXDATA) register is a write-only data register that forms the bottom word of the 8 x 32 TXFIFO. The TXFIFO can be written to as long as it is not full, even when the SPI Exchange bit (XCH) in CSPI_CONREG is set. This allows software to write to the TXFIFO during a SPI data exchange process. Writes to this register are ignored when the CSPI block is disabled (CSPI_CONREG[EN] bit is cleared).

Address: CSPI_TXDATA is 63FC_0000h base + 4h offset = 63FC_0004h

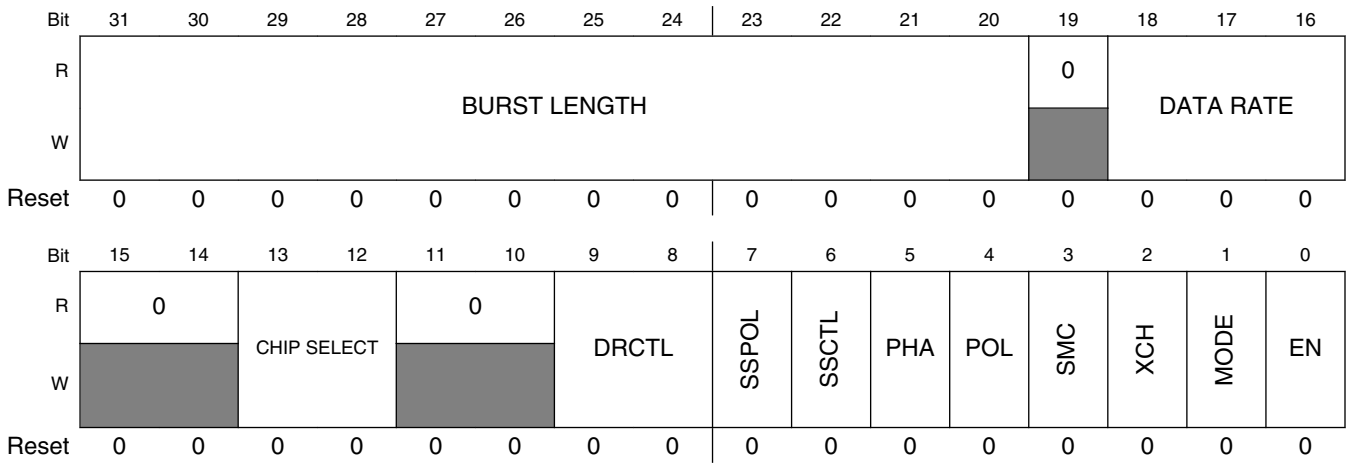
CSPI_TXDATA field descriptions

Field	Description
31–0 TXDATA	Transmit Data. This register holds the top word of data loaded into the FIFO. Data written to this register must be a word operation. The number of bits actually transmitted is determined by the BIT_COUNT field of the corresponding SPI Control register. If this field contains more bits than the number specified by BIT_COUNT, the extra bits are ignored. For example, to transfer 10 bits of data, a 32-bit word must be written to this register. Bits 9-0 are shifted out and bits 31-10 are ignored. When the CSPI is operating in Slave mode, zeros are shifted out when the FIFO is empty. Zeros are read when CSPI is disabled.

16.6.3 Control Register (CSPI_CONREG)

The Control Register (CSPI_CONREG) allows software to enable the CSPI, configure its operating modes, specify the divider value, phase, and polarity of the clock, configure the Chip Select (SS) and SPI_RDY (CSPI_CONREG[DRCTL]) control signal, and define the transfer length.

Address: CSPI_CONREG is 63FC_0000h base + 8h offset = 63FC_0008h



CSPI_CONREG field descriptions

Field	Description
31–20 BURST LENGTH	Burst Length. This field defines the length of a SPI burst to be transferred. The Chip Select (SS) will remain asserted until all bits in a SPI burst are shifted out. A maximum of 2^12 bits can be transferred in a single SPI burst. In master mode, it controls the number of bits per SPI burst. Since the shift register always loads 32-bit data from transmit FIFO, only the n least-significant (n = BURST LENGTH + 1) will be shifted out. The remaining bits will be ignored. In slave mode, only when SSCTL is cleared, this field will take effect in the transfer. Number of Valid Bits in a SPI burst. 0x000 A SPI burst contains the 1 LSB in a word. 0x001 A SPI burst contains the 2 LSB in a word. 0x002 A SPI burst contains the 3 LSB in a word. 0x01F A SPI burst contains all 32 bits in a word. 0x020 A SPI burst contains the 1 LSB in first word and all 32 bits in second word. 0x021 A SPI burst contains the 2 LSB in first word and all 32 bits in second word. 0xFFE A SPI burst contains the 31 LSB in first word and 2^7 -1 words. 0xFFF A SPI burst contains 2^7 words.
19 Reserved	This read-only field is reserved and always has the value zero. Reserved
18–16 DATA RATE	SPI Data Rate Control. This field selects the baud rate of the SCLK based on a division of the reference clock.

Table continues on the next page...

CSPI_CONREG field descriptions (continued)

Field	Description
	These bits allow the CSPI to synchronize with different external SPI devices. The max frequency is one quarter of the reference clock. The divide ratio is determined according to the following table using the equation: $2^{(n+2)}$. SPI Data Rate Control (Master Mode only) 000 Divide by 4. 001 Divide by 8. 010 Divide by 16. 011 Divide by 32. 100 Divide by 64. 101 Divide by 128. 110 Divide by 256. 111 Divide by 512.
15–14 Reserved	This read-only field is reserved and always has the value zero. Reserved
13–12 CHIP SELECT	CHIP SELECT. Select one of four external SPI Master/Slave Devices. In master mode, these two bits select the external slave devices by asserting the Chip Select (SSn) outputs. Only the selected Chip Select (SSn) signal can be active at a given time; the remaining three signals will be negated. Chip Select 00 Chip Select 0 (SS0) will be asserted. 01 Chip Select 1 (SS1) will be asserted. 10 Chip Select 2 (SS2) will be asserted. 11 Chip Select 3 (SS3) will be asserted.
11–10 Reserved	This read-only field is reserved and always has the value zero. Reserved
9–8 DRCTL	SPI Data Ready Control. This field selects the utilization of the $\overline{\text{SPI\_RDY}}$ signal in master mode. CSPI checks this field before it starts an SPI burst. 00 The $\overline{\text{SPI\_RDY}}$ signal is a don't care. 01 Burst will be triggered by the falling edge of the SPI_RDY signal (edge-triggered). 10 Burst will be triggered by a low level of the SPI_RDY signal (level-triggered). 11 Reserved.
7 SSPOL	SPI SS Polarity Select. In both Master and Slave modes, this bit selects the polarity of the Chip Select (SS) signal. 0 Active low. 1 Active high.
6 SSCTL	SPI SS Wave Form Select. In master mode, this bit controls the output wave form of the Chip Select (SS) signal when SMC is cleared. The SSCTL bit will be ignored if the SMC (Start Mode Control) bit is set. In slave mode, this bit controls when the SPI burst is completed. 0 Only one SPI burst will be transmitted. 1 Negate Chip Select (SS) signal between SPI bursts. Multiple SPI bursts will be transmitted. The SPI transfer will automatically stop when the TXFIFO is empty.

Table continues on the next page...

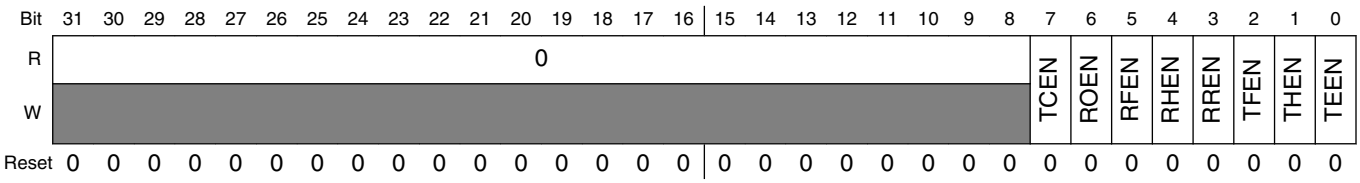
CSPI_CONREG field descriptions (continued)

Field	Description
	0 (slave mode) A SPI burst is completed when the number of bits received in the shift register is equal to BURST LENGTH + 1. Only n least-significant bits (n = BURST LENGTH[4:0] + 1) of the first received word are valid. All bits subsequent to the first received word in RXFIFO are valid. 1 (slave mode) A SPI burst is completed by the Chip Select (SS) signal edges. (SSPOL = 0: rising edge; SSPOL = 1: falling edge) The RXFIFO is advanced whenever a Chip Select (SS) signal edge is detected or the shift register contains 32-bits of valid data.
5 PHA	SPI Clock/Data Phase Control. This bit controls the clock/data phase relationship. See Typical Slave Mode for more information. 0 Phase 0 operation. 1 Phase 1 operation.
4 POL	SPI Clock Polarity Control. This bit controls the polarity of the SCLK signal. See Typical Slave Mode for more information. 0 Active high polarity (0 = Idle). 1 Active low polarity (1 = Idle).
3 SMC	Start Mode Control. This bit applies only when the block is configured in Master mode (MODE = 1). It controls how the CSPI starts a SPI burst, either through the SPI exchange bit, or immediately when the TXFIFO is written to. 0 SPI Exchange Bit (XCH) controls when a SPI burst can start. Setting the XCH bit will start a SPI burst or multiple bursts. This is controlled by the SPI SS Wave Form Select (SSCTL) bit. Refer to XCH and SSCTL bit descriptions. 1 Immediately starts a SPI burst when data is written in TXFIFO.
2 XCH	SPI Exchange Bit. This bit applies only when the block is configured in Master mode (MODE = 1). If the Start Mode Control (SMC) bit is cleared, writing a 1 to this bit starts one SPI burst or multiple SPI bursts according to the SPI SS Wave Form Select (SSCTL bit). The XCH bit remains set while either the data exchange is in progress, or when the CSPI is waiting for an active input if SPIRDY is enabled through DRCTL. This bit is cleared automatically when all data in the TXFIFO and the shift register has been shifted out. 0 Idle. 1 Initiates exchange (write) or busy (read).
1 MODE	SPI Function Mode Select. This bit selects the operating mode of the CSPI. 0 Slave mode. 1 Master mode.
0 EN	SPI Module Enable Control. This bit enables the CSPI. This bit must be set before writing to other registers or initiating an exchange. Writing zero to this bit disables the block and resets the internal logic with the exception of the CONREG. The block's internal clocks are gated off whenever the block is disabled. 0 Disable the block. 1 Enable the block.

16.6.4 Interrupt Control Register (CSPI_CSPI_INTREG)

The Interrupt Control Register (CSPI_INTREG) enables the generation of interrupts to the host processor. If the CSPI is disabled, this register reads zero.

Address: CSPI_CSPI_INTREG is 63FC_0000h base + Ch offset = 63FC_000Ch



CSPI_CSPI_INTREG field descriptions

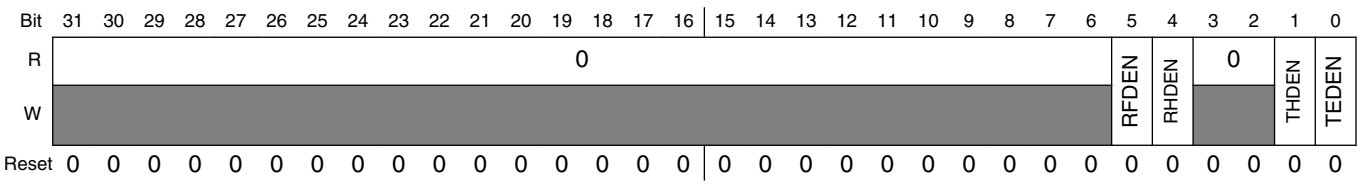
Field	Description
31–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7 TCEN	Transfer Completed Interrupt enable. This bit enables the Transfer Completed Interrupt. 0 Disable 1 Enable
6 ROEN	RXFIFO Overflow Interrupt enable. This bit enables the RXFIFO Overflow Interrupt. 0 Disable 1 Enable
5 RFEN	RXFIFO Full Interrupt enable. This bit enables the RXFIFO Full Interrupt. 0 Disable 1 Enable
4 RHEN	RXFIFO Half Full Interrupt enable. This bit enables the RXFIFO Half Full Interrupt. 0 Disable 1 Enable
3 RREN	RXFIFO Ready Interrupt enable. This bit enables the RXFIFO Ready Interrupt. 0 Disable 1 Enable
2 TFEN	TXFIFO Full Interrupt enable. This bit enables the TXFIFO Full Interrupt. 0 Disable 1 Enable
1 THEN	TXFIFO Half Empty Interrupt enable. This bit enables the TXFIFO Half Empty Interrupt. 0 Disable 1 Enable
0 TEEN	TXFIFO Empty Interrupt enable. This bit enables the TXFIFO Empty Interrupt. 0 Disable 1 Enable

16.6.5 DMA Control Register (CSPI_CSPI_DMAREG)

The Direct Memory Access Control Register (CSPI_DMAREG) provides software a way to use an on-chip DMA controller for CSPI data. Internal DMA request signals enable direct data transfers between the CSPI FIFOs and system memory. The CSPI sends out DMA requests when the appropriate FIFO conditions are matched.

If the CSPI is disabled, this register is read as 0.

Address: CSPI_CSPI_DMAREG is 63FC_0000h base + 10h offset = 63FC_0010h



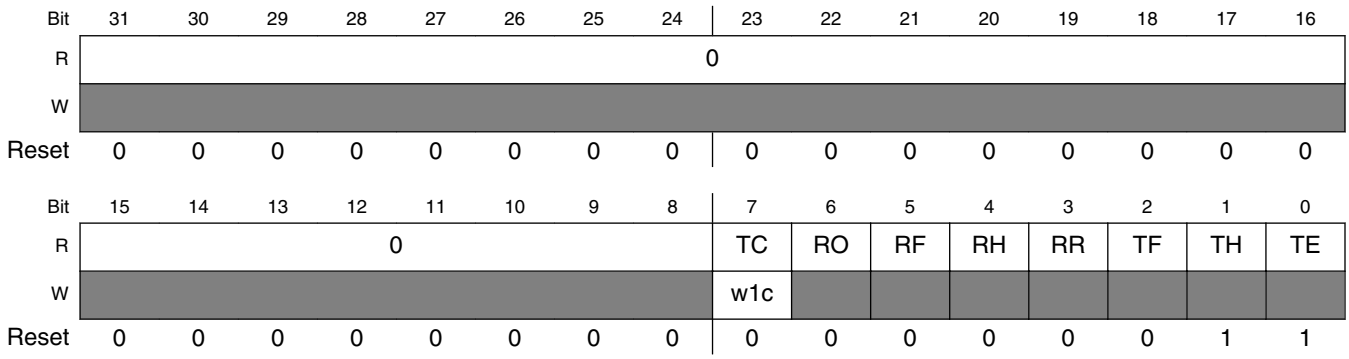
CSPI_CSPI_DMAREG field descriptions

Field	Description
31–6 Reserved	This read-only field is reserved and always has the value zero. Reserved
5 RFDEN	RXFIFO Full DMA Request Enable. This bit enables/disables the RXFIFO Full DMA Request. 0 Disable 1 Enable
4 RHDEN	RXFIFO Half Full DMA Request Enable. This bit enables/disables the RXFIFO Half Full DMA Request. 0 Disable 1 Enable
3–2 Reserved	This read-only field is reserved and always has the value zero. Reserved
1 THDEN	TXFIFO Half Empty DMA Request Enable. This bit enables/disables the TXFIFO Half Empty DMA Request. 0 Disable 1 Enable
0 TEDEN	TXFIFO Empty DMA Request Enable. This bit enables/disables the TXFIFO Empty DMA Request. 0 Disable 1 Enable

16.6.6 Status Register (CSPI_CSPI_STATREG)

The CSPI Status Register (CSPI_STATREG) reflects the status of the CSPI block's operating condition. If the CSPI is disabled, this register reads 0x0000_0003.

Address: CSPI_CSPI_STATREG is 63FC_0000h base + 14h offset = 63FC_0014h



CSPI_CSPI_STATREG field descriptions

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7 TC	Transfer Completed Status bit. Writing 1 to this bit clears it. 0 Transfer in progress. 1 Transfer completed.
6 RO	RXFIFO Overflow. When set, this bit indicates that RXFIFO has overflowed. 0 RXFIFO has no overflow. 1 RXFIFO has overflowed.
5 RF	RXFIFO Full. This bit is set when the RXFIFO is full. 0 Not Full. 1 Full.
4 RH	RXFIFO Half Full. This bit is set when the RXFIFO reaches half full. 0 Less than 4 words are stored in RXFIFO. 1 Four or more words are available in RXFIFO.
3 RR	RXFIFO Ready. This bit is set when one or more words are stored in the RXFIFO. 0 No valid data in RXFIFO. 1 More than 1 word in RXFIFO.
2 TF	TXFIFO Full. This bit is set when if the TXFIFO is full. 0 TXFIFO is not Full. 1 TXFIFO is Full.
1 TH	TXFIFO Half empty. This bit is set when the TXFIFO reaches half empty.

Table continues on the next page...

CSPI_CSPI_STATREG field descriptions (continued)

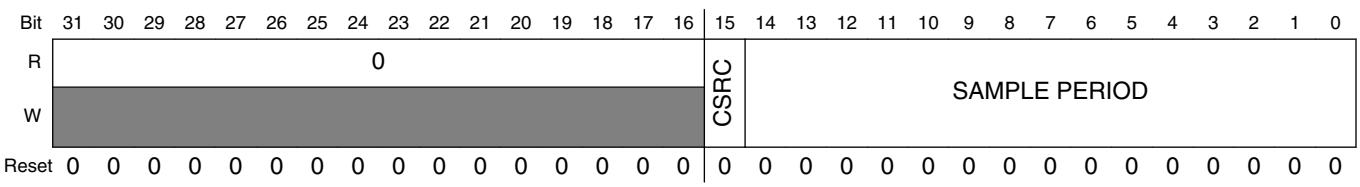
Field	Description
	0 TXFIFO holds more than 4 words. 1 TXFIFO holds 4 or fewer words.
0 TE	TXFIFO Empty. This bit is set if the TXFIFO is empty. 0 TXFIFO contains one or more words. 1 TXFIFO is empty.

16.6.7 Sample Period Control Register (CSPI_PERIODREG)

The Sample Period Control Register (CSPI_PERIODREG) provides software a way to insert delays (wait states) between consecutive SPI transfers. Control bits in this register select the clock source for the sample period counter and the delay count indicating the number of wait states to be inserted between data transfers.

The delay counts apply only when the block is configured in Master mode (CONREG[MODE] = 1).

Address: CSPI_PERIODREG is 63FC_0000h base + 18h offset = 63FC_0018h



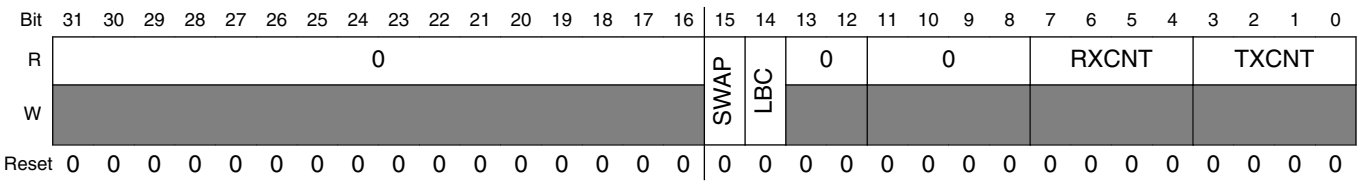
CSPI_PERIODREG field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15 CSRC	Clock Source Control. This bit selects the clock source for the sample period counter. 0 SPI Clock (SCLK) 1 Low-Frequency Reference Clock (32.768 KHz)
14–0 SAMPLE PERIOD	Sample Period Control. These bits control the number of wait states to be inserted in data transfers. During the idle clocks, the state of the SS output will operate according to the SSCTL control field in the CSPI_CONREG register. 0x00000 wait states inserted 0x00011 wait state inserted 0x7FFE32766 wait states inserted 0x7FFF32767 wait states inserted

16.6.8 Test Control Register (CSPI_TESTREG)

The Test Control Register (CSPI_TESTREG) provides software a mechanism to internally connect the receive and transmit devices of the CSPI, swap the byte order for receive data, and monitor the contents of the receive and transmit FIFO.

Address: CSPI_TESTREG is 63FC_0000h base + 1Ch offset = 63FC_001Ch



CSPI_TESTREG field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15 SWAP	Data Swap. This bit is used to swap data as it is read from the RXFIFO. When this bit is set, data read from RXFIFO is swapped. RXDATA[31:0] is swapped as follows: {RXDATA[7:0],RXDATA[15:8], RXDATA[23:16],RXDATA[31:24]} 0 Data read from RXFIFO is unchanged. 1 Data read from RXFIFO is swapped.
14 LBC	Loop Back Control. This bit is used in Master mode only. When this bit is set, the CSPI connects the transmitter and receiver sections internally, and the data shifted out from the most-significant bit of the shift register is looped back into the least-significant bit of the Shift register. In this way, a self-test of the complete transmit/receive path can be made. The output pins are not affected, and the input pins are ignored. 0 Not connected. 1 Transmitter and receiver sections internally connected for Loopback.
13–12 Reserved	This read-only field is reserved and always has the value zero. Reserved
11–8 Reserved	This read-only field is reserved and always has the value zero. Reserved, all bits should be ignored.
7–4 RXCNT	RXFIFO Counter. These bits indicate the number of words in RXFIFO. RXFIFO Counter 0000 0 word in RXFIFO 0001 1 word in RXFIFO 0111 7 words in RXFIFO 1000 8 words in RXFIFO
3–0 TXCNT	TXFIFO Counter. These bits indicate the number of words in TXFIFO. TXFIFO Counter

Table continues on the next page...

CSPI_TESTREG field descriptions (continued)

Field	Description
	0000 0 word in TXFIFO 0001 1 word in TXFIFO 0111 7 words in TXFIFO 1000 8 words in TXFIFO

Chapter 17
Data Co-Processor (DCP)

17.1 Overview

This chapter describes the data co-processor (DCP) block included on the i.MX50 and how to use it. It includes sections on memory copy functionality, Advanced Encryption Standard (AES), hashing, and arbitration. Sections on programming channel operations and example code are also provided. Programmable registers are described in DCP.

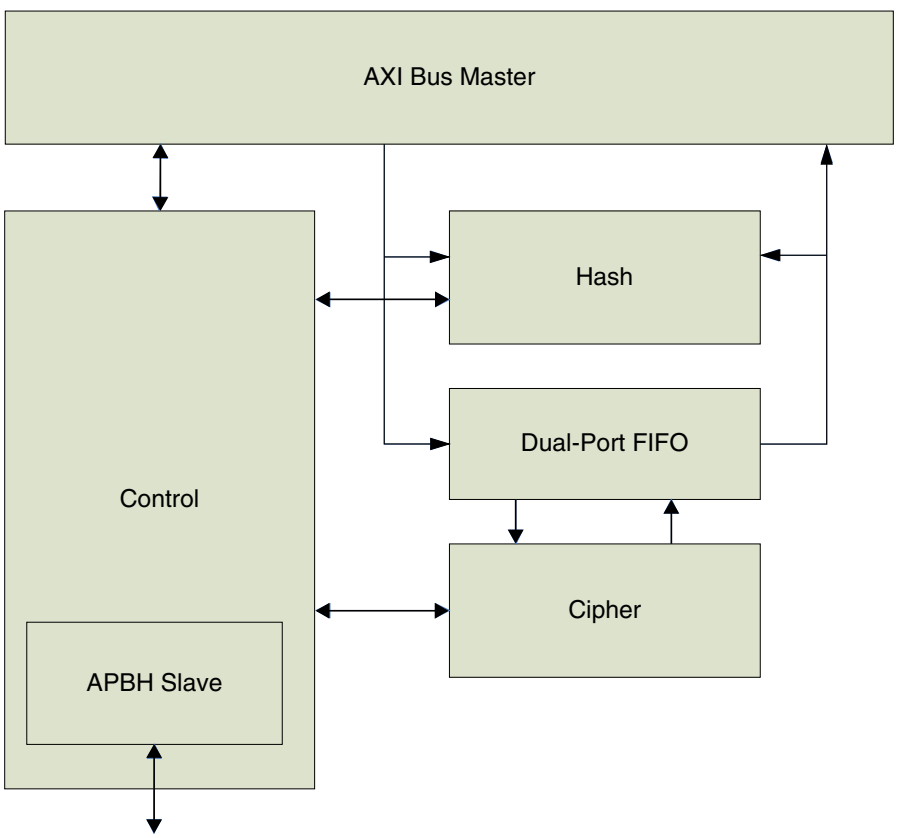


Figure 17-1. Data Co-Processor (DCP) Block Diagram

The DCP module provides support for general encryption and hashing functions typically used for security functions. Because its basic job is moving data from memory to memory, it also incorporates memory-copy (memcopy) function for both debugging and as a more efficient method of copying data between memory blocks than the DMA-based approach. The memcopy function also has a "blit" mode of operation where it can transfer a rectangular block of data to a video frame buffer.

The DCP has been designed to support a wide variety of encryption and hashing algorithms, and the control structures have been designed to allow flexibility in adding additional algorithms and modes in the future. It supports up to 16 encryption algorithms (for example DES, TDEA, AES-128, and so on) with 16 different modes of operation (ECB, CBC, and so on) as well as 16 hashing algorithms (for example MD5, SHA-1, SHA-2, and so on). While the DCP module has been designed to support numerous algorithms, only a subset may be implemented in any given implementation (see the Capability Register).

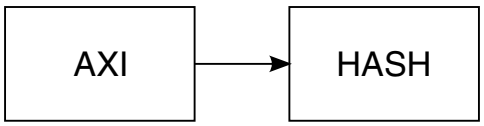
The DCP module processes data based on chained command structures written to system memory by software (in a manner similar to the DMA engine). The control block maintains registers to support four independent and concurrent chains, allowing software to virtualize access to the DCP block. Each command in a chain represents a work unit that the module will process to completion. At the end of each work unit, the control logic arbitrates among chains with outstanding commands and processes a command from that chain. Arbitration among the channels is round-robin, allowing all active channels equal access to the data engine. Each channel also supports a "high-priority" mode that allows it to have priority over the remaining channels. If multiple channels are selected as high-priority, the channel arbiter selects among the high-priority channels in round-robin fashion.

The data flow through the DCP module can be configured in one of five fashions, depending on the functionality activated by the control packet:

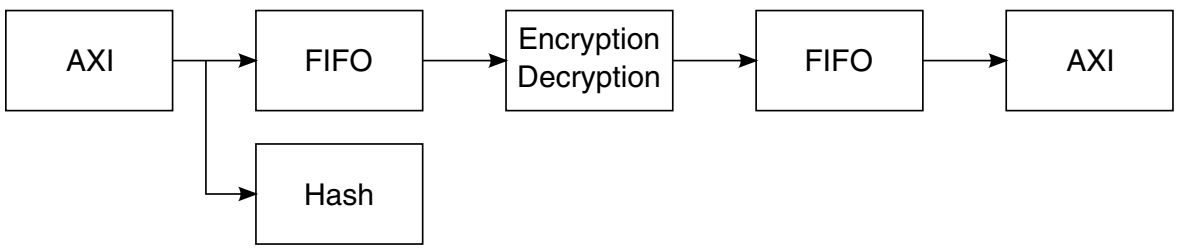
- **Memcopy/Blit Mode-**Data is moved unchanged from one memory buffer to another.

- **Encryption Only-**Data from source buffer is encrypted/decrypted into the destination buffer

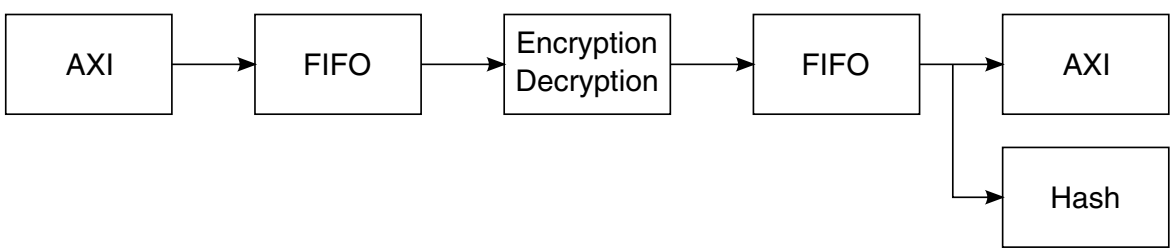
- **Hashing Only-**Data from source buffer is read, and a hash is generated.



- **Encryption and Input Hashing-**Data from source buffer is encrypted/decrypted into destination, and source buffer is hashed.



- **Encryption and Output Hashing-**Data from source buffer is encrypted/decrypted into destination, and output data is hashed.



17.1.1 DCP Limitations for Software

While the DCP module has been designed to be as flexible as possible, there are a few limitations to which software must adhere:

- Buffer sizes for all operations MUST be aligned to the natural size of the transfer algorithm used. Memcopy operations can transfer any number of bytes (one-byte granularity) and AES operations must be multiples of 16 bytes (four-word granularity). For all operations, if the byte count is not a word granularity, the hardware rounds up to the next word. Hashing is supported at a byte granularity.

- The DCP module supports buffer operations to any byte alignment, but performance will be improved if buffers are aligned to a four-byte boundary, since fetch/store operations can be performed without having to do byte operations to accommodate the misaligned addresses.
- Hash operations are limited to a 512 Mbyte buffer size. The hardware only implements a 32-bit hash length counter instead of the 64-bit counter supported by the SHA-1/SHA-256 algorithm (counter counts bits, not bytes, therefore a total of 512 Mbytes).
- For chained hashing operations (operations involving multiple descriptors), every descriptor except the last must have a byte count that is a 16-word multiple (granularity of the hash algorithm).
- Key values cannot be written while the AES block is active. This limitation exists because the key RAM is in use while AES is operational. Any writes from the APB cannot be held in wait states; therefore, the RAM must be accessible during key writes.
- The byte-swap controls can only be used with modulo-4 length buffers. For non-modulo-4 lengths, the final partial word will contain incorrect data. Any address alignment can be used with byte swapping, however.
- The word-swap controls are only useful with cipher operations, because the logic forms the 128-bit cipher data from four words from system memory. The word-swap controls are ignored for memcopy or hashing operations.
- DCP only supports writes to word boundaries to OCRAM. This is not required for DRAM MC address.

17.2 Operation

The top-level DCP module contains the AXI master, APB slave bus interface units, the main control block and FIFO, and any encryption or hashing blocks included with the design.

The controller manages the fetching of work blocks, the fetching/storing of context information when switching between chain pointers, and the managing of the data flow through the FIFO, SHA, and AES blocks. Data entering the block from the AXI master is placed in the FIFO for consumption by the cipher block. After the cipher module has finished its operation, data is placed back into the FIFO and stored back to memory via the AXI master. When hashing is enabled, the SHA block takes its inputs from the bus side of the FIFO to allow it to operate without waiting for the cipher block to complete. The APB slave provides all register controls and interfaces mainly with the control block.

17.2.1 Memory Copy, Blit, and Fill Functionality

In its most basic operation, the DCP supports moving unmodified data from one place in system memory to another. This functionality is referred to as "memcopy", because it operates only on memory and it copies data from one place to another. Typical uses for memcopy might be for fast virtual memory page moves or repositioning data blocks in memory. Memcopy buffers can be aligned to any memory address and can be of any length (byte granularity). For best performance, buffers should be word-aligned, although the DCP includes enhancements to improve performance for unaligned cases.

The DCP also has the ability to do basic "blit" operations that are typical in graphics operations. To specify a blit, the control packet must have the ENABLE_BLIT bit set in the packet control register. Blit source buffers must be contiguous. The output destination buffer for a blit operation is defined as a "M runs of N bytes" that define a rectangular region in a frame buffer. For blit operations, each line of the blit may consist of any number of bytes. After performing a "run", the DCP updates the destination pointer such that the next destination address falls on the pixel below the start of the previous run operation. This is done by incrementing the starting pointer by the frame buffer width, which is specified in the Control field.

In addition to being able to copy data within memory, the DCP also provides a "fill" operation, where source data comes not from another memory location, but from an internal register (the source buffer address in the control packet). This is done whenever the DCP_Control0[CONSTANT_FILL] flag is set in the packet control register (see Control1 Field). This feature may be used with memcopy to prefill memory with a specified value or during a blit operation to fill a rectangular region with a constant color.

17.2.2 Advanced Encryption Standard (AES)

The AES block implements a 128-bit key/data encryption/decryption block as defined by the National Institute of Standards and Technology (NIST) as US FIPS PUB 197, dated November 2001 (see references for specifications and toolkits).

The AES core used in the design was derived from the AES design available from OpenCores.org under a modified BSD license as described here: *http://www.opencores.org/projects.cgi/web/aes_core/overview. The license for this code is documented on page 60 for compliance.*

There are three variations of AES, each corresponding to the key size used: AES-128, AES-192 or AES-256. AES always operates on 128 bits of data at a time. Only the AES-128 algorithm is implemented at this time.

17.2.2.1 Key Storage

The DCP implements four SRAM-based keys that may be used by software to securely store keys on a semi-permanent basis. The keys may be written via the PIO interface by specifying a key index to specify which key to load and a subword pointer that indicates which word to write within the key. After a subword is written, the logic automatically increments the subword pointer so that software can program the higher-order words of the key without rewriting the key index. Keys written into the key storage are not readable.

To use a key in the key storage, the cipher descriptor packet should select the key by setting the DCP_Control1[KEY_SELECT] field in the Control1 descriptor field without setting the OTP_KEY or PAYLOAD_KEY fields in the Control0 register. See Control0 Field and Control1 Field.

17.2.2.2 AES OTP Key

After a system reset, the OTP controller reads the e-fuse devices and provides OTP key information to the DCP over a static 128-bit data bus input called otp_crypto_key_data. The DCP internally generates the control logic signals to capture this key into the key RAM. The system reset controller coordinates the deassertion of reset such that the OTP key is stable before the DCP reads it.

To use the OTP key, the descriptor packet should set the OTP_KEY field in the Control1 register (see Control1 Field).

17.2.2.3 Encryption Modes

The most basic form of encryption is the Electronic Code Book (ECB) mode. In this mode, the encryption output is a function only of the key and the plaintext, thus it can be visualized as a giant lookup table. While this provides a great deal of security, there are a few limitations. For instance, if the same plaintext appears more than once in a block of data, the same ciphertext will also appear. This can be very evident if the plaintext contains large blocks of constant data (0s for example) and can be used to formulate attacks against a key.

In order to make ciphers stronger, several modes of operation can be implemented around the basic ECB cipher to provide additional security. One such mode is CBC mode (Cipher Block Chaining), which takes the previous encrypted data and logically XORs it

with the next incoming plaintext before performing the encryption. During decryption, the process is reversed and the previous encrypted data is XORed with the decrypted ECB data to provide the plaintext again.

The AES engine supports handling the various modes of operation. The core AES block supports ECB mode, and other algorithms are handled in the wrapper around the encryption blocks. The DCP module supports Cipher Block Chaining (CBC), which chains the data blocks by XORing the previously encrypted data with the plaintext before encryption. Cipher block chaining encryption is illustrated in Figure 17-2.

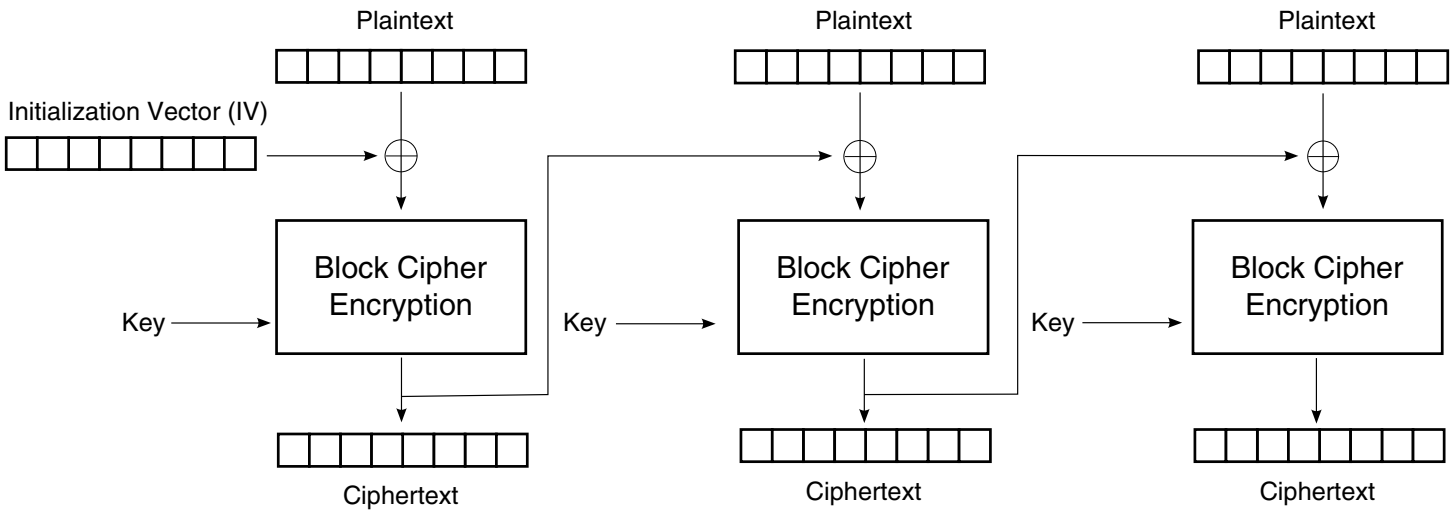


Figure 17-2. Cipher Block Chaining (CBC) Mode Encryption

Decryption (shown in Figure 17-3) works in a similar manner, where the cipher text is first decrypted and then XORed with the previous ciphertext. For the first encryption/ decryption operation, an initialization vector (IV) is used to seed the operation. The IV must be the same for both the encryption and decryption steps; otherwise, decrypted data will not match the original plaintext.

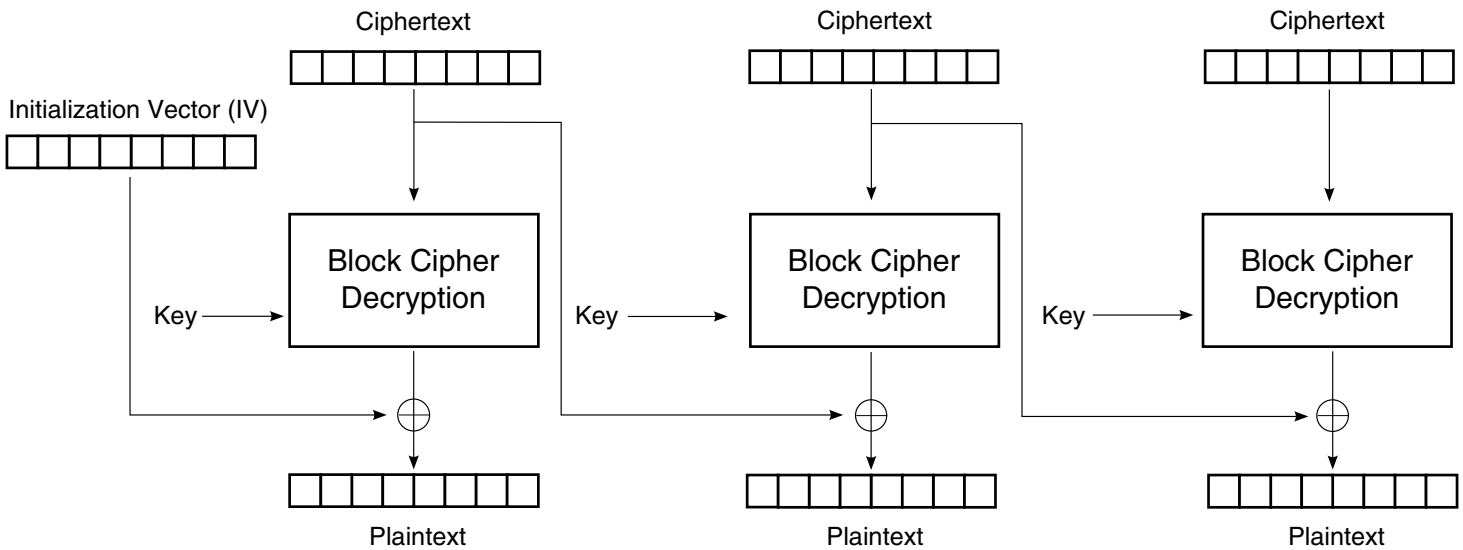

Figure 17-3. Cipher Block Chaining (CBC) Mode Decryption

17.2.3 Hashing

The hashing module implements the SHA-1 and SHA-256 hashing algorithms and a modified CRC-32 checksum algorithm. These algorithms produce a signature for a block of data that can be used to determine whether the data is intact.

The CRC-32 algorithm implements a 32-bit CRC algorithm similar to the one used by Ethernet and many other protocols. The CRC differs from the Unix cksum() function in three ways:

- The CRC is initialized as 0xFFFFFFFF instead of 0x00000000.
- Logic pads zeros to a 32-bit boundary for trailing bytes.
- Logic does not post-pend the file length.

The SHA-1 block implements a 160-bit hashing algorithm that operates on 512-bit (64-byte) blocks as defined by US FIPS PUB 180-1 in 1995. The SHA-256 mode implements a 256-bit hashing algorithm that operates on 512-bit (64-byte) blocks as defined by US FIPS PUB 180-2 in 2002. The purpose of the hashing module is to generate a unique signature for a block of data that can be used to validate the integrity of the data by comparing the resulting "digest" with the original digest.

Results from hash operations are written to the beginning of the payload for the descriptor. The DCP also has the ability to check the resulting hash against a value in the payload and issue an interrupt if a mismatch occurs.

17.2.4 One Time Programmable (OTP) Key

After a system reset, the One Time Programmable (OTP) controller will read the e-fuse devices and provide OTP key information to the DCP through the 128-bit wide otp_crypto_key_data input data bus and the 64 bit wide otp_unique_key_data unique key input that come directly from the OTP controller. These bus input values are held constant and originate from the eFuse shadow registers after reset. (Note that the shadow registers for these bits can be changed in the OTP block if they are unlocked.) They will only be loaded by the DCP once after the deassertion of system reset. After reset, the DCP automatically loads these wide keys 32 bits at the time into the internal key RAM.

While OTP key is normally not available to read operations, the module will allow the key to be read if the otp_crypto_key_ren (read-enable) input is active (high). This allows verification of the key after it has been programmed into the eFuse device. After programming has been validated, another fuse will be set to disable the read capability.

The OTP key (crypto key) may be selected using the DCP_Control1[OTP_KEY] bit in the control field of the packet descriptor or by using key select 0xFF in the CTRL1 field of the descriptor. DCP also supports a second hardware key called the UNIQUE_KEY which is generated from the OTP KEY and key modifier bits from other OTP fuse fields. This key is unique to the device and may be used for encrypting private data stored on the NAND. This key may be selected by writing 0xFE to the KEY_SELECT field in the CTRL1 packet data.

17.2.5 Managing DCP Channel Arbitration and Performance

The DCP can have four channels all competition for DCP resources to complete their operations. Depending on the situation, critical operations may need to be prioritized above less important operations to ensure smooth system operation. To help software achieve this goal, the DCP implements a programmable arbiter for internal DCP operations and provides "recovery" timers on each channel to throttle channel activity.

17.2.5.1 DCP Arbitration

The DCP implements a multi-tiered arbitration policy that allows software a lot of flexibility in scheduling DCP operations. Figure 17-4 illustrates the arbitration levels and where each channel fit into the arbitration scheme.

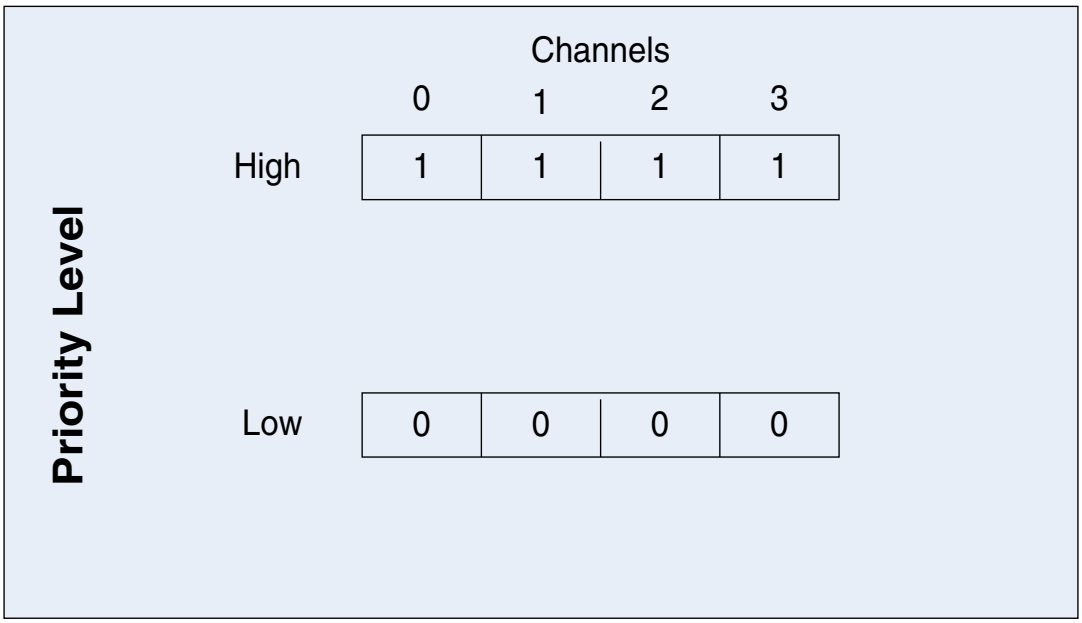

Figure 17-4. DCP Arbitration

Each channel can be programmed as being in either the high-priority or low-priority arbitration pool, depending on the setting in the HIGH_PRIORITY_CHANNEL field of the DCP_CHANNELCTRL register. When the corresponding bit is programmed as a 1, the channel arbitrates in the high-priority pool; otherwise it arbitrates in the low-priority pool. Once a channel has been selected, it completes one packet and then the arbiter re-arbitrates. The channel that just completed participates in the new arbitration round.

17.2.5.2 Channel Recovery Timers

Each channel also contains a channel recovery timer in its DCP_CHnOPTS register. The purpose of the recovery timer is to keep the channel inactive for a period of time after it completes an operation. This capability could be used for a high-priority channel to ensure that at least some lower-priority requests get serviced between packets or to simply allow more timeslices for other channels to perform operations. The value programmed into the recovery timers register delays the channel from operations until 16 times the programmed value. Any non-zero value should prevent the channel from participating in the next arbitration cycle.

17.2.6 Programming Channel Operations

The control logic block maintains the channel pointers and manages arbitration and context switching between the different channels. It also manages the fetching of work packets and data fetch/store operations from the AXI master interface and coordinates the actions of the hashing and encryption blocks.

The control logic maintains four channels that allow software to effectively create four independent work sets for the DCP module. Software can construct chained control packets in memory that describe encryption/hashing/memcopy operations to the hardware unit. The address for this first control packet can be written to one of the four virtual channels and enabled. When one or more of the channels is enabled, the controller fetches the control packet pointed to by that channel and initiate data fetches from the source buffer. Data is then processed as described in the control packet and stored back to system memory.

Once the processing for a control packet is complete, the controller writes completion status information back to the control packet, and optionally stores relevant state information to the context buffer. If the control packet specifies a subsequent control packet, the channel's pointer is updated to the address for the next packet and an optional interrupt can be issued to the processor.

At this point, the DCP module arbitrates among the virtual channels for the next operation and processes its control packet. If a subsequent operation is continued from a previous operation, the controller automatically loads the context from the previous session into the working registers before resuming operation for that channel.

17.2.6.1 Virtual Channels

The DCP module processes data via work packets stored in memory. Each of the channels contains a pointer to the current work packet and enough control logic to determine whether the channel is active and to provide status to the processor. Each channel also provides a recovery timer to help throttle processing by a particular channel. After processing a packet, the channel enables its 16-bit recovery timer (if the recovery time is set to a non-zero value). The channel will not become active again until its recovery timer has expired. The recovery timer timebase is 16 HCLK cycles, so the timer acts as a 20-bit timer with the bottom four bits implicitly tied to 0. This provides an effective range of zero to 2^{20-1} clocks or 0 ns to 7.8 ms at 133 MHz.

A channel is activated any time its semaphore is non-zero and its recovery timer is cleared. The semaphore can be incremented by software to indicate that the chain pointer has been loaded with a valid pointer. As the hardware completes the work packets, it decrements the semaphore if the Decrement Semaphore flag in the Control 0 field set.

Work packets may be chained together using the CHAIN or CHAIN_CONTIGUOUS bits in the Control0 field, which causes the channel to automatically update the work packet pointer to the value in the NEXT_COMMAND_ADDRESS field at the end of the current work packet.

17.2.6.2 Context Switching

The control logic maintains four virtual channels that allow the DCP block to time-multiplex encryption, hashing, and memcopy operations, it must also retain state information when changing channels so that when a channel is resumed, it can resume the operation from where it left off. This process is called context-switching.

To minimize the number of registers used in the design, the controller saves context information from each channel into a private context area in system memory. When initializing the DCP module, software must allocate memory for the context buffer and write the address into the Context Buffer Pointer register. As the DCP module processes packets, it saves the context information for each channel to the buffer after completing each control packet. When the channel is subsequently activated, the DCP module's internal registers are then reloaded with the proper context before resuming the operation.

Each channel reserves one-fourth of the context buffer area for its context storage. The context buffer consumes 208 bytes of system memory and is formatted as shown in Table 17-1.

Table 17-1. DCP Context Buffer Layout

Range	Channel	Data	Size
0x00-0x0C	3	Cipher Context	16 bytes
0x10-0x30	-	Hash Context	36 bytes
0x34-0x40	2	Cipher Context	16 bytes
0x44-0x64	-	Hash Context	36 bytes
0x68-0x74	1	Cipher Context	16 bytes
0x78-0x98	-	Hash Context	36 bytes
0x9C-0xA8	0	Cipher Context	16 bytes
0xAC-0xCC	-	Hash Context	36 bytes

The control logic writes to the context buffer only if the function is being used. This effectively means that the cipher context is stored for CBC encryption/decryption operations only, and the hash context is written only if SHA-1/SHA-256 is utilized. If neither of these modes are used for a given channel, the memory for the context buffer need not be allocated by software.

Since channel 0 is likely to be used for VMI in an SDRAM-based system-to-page data from the SDRAM to on-chip SRAM, the buffer allocation table has been organized so that the *highest* numbered channel uses the *lowest* area in the context buffer. For this reason, software should allocate the higher numbered channels for encryption/hashing operations and the lower numbered channels for memcopy operations to reduce the size of the context buffer.

If only a single channel is used for CBC mode operations or hashing operations, the controller provides a bit in the control register to disable context switching. In this scenario, context switching is not required, because other channels will not corrupt the state of the hashing or cipher modes. Thus, when the channel resumes, a context load is not required.

Additionally, the control logic monitors the use of CBC/hashing, so that a context reload is not done if the previous channel resumes an operation without an intermediate operation from another channel.

17.2.6.3 Working with Semaphores

Each channel has a semaphore register to indicate that control packets are ready to be processed. Several techniques can be used when programming the semaphores to control the execution of packets within a channel. The channel will continue to execute packets as long as the semaphore is non-zero, a chain bit is set in the descriptor, and no error has occurred.

- Software can write the number of pending packets into the semaphore register with the Decrement Semaphore bit in each control packet set. In this scenario, the channel simply decrements the semaphore for each packet set and terminates at the end of the packet chain. The benefit of this method is that software can easily determine how many packets have executed by reading the semaphore status register.
- Software can create a packet chain with the Decrement Semaphore bit set only in the last packet. In this case, software would write a 1 to the semaphore register to start the chains and the DCP will terminate after executing the last packet.
- Software can create a packet chain with the Decrement Semaphore bit set for each packet and write either a 1 or a number less than the number of packets to the semaphore register. This can be useful when debugging, because it allows the channel to execute only a portion of the packets and software can inspect intermediate values before restarting the channel again.

If an error occurs, the channel issues an interrupt and clears the semaphore register. The channel does not perform any further operations until the error bits in the status register have been cleared. Software can manually clear a non-zero semaphore by writing 0xFF to the CLR (clear) address of the semaphore register.

17.2.6.4 Work Packet Structure

Work packets for the DCP module are created in memory by the processor. Each work packet includes all information required for the hardware to process the data. The general structure of the packet is shown in Figure 17-5.

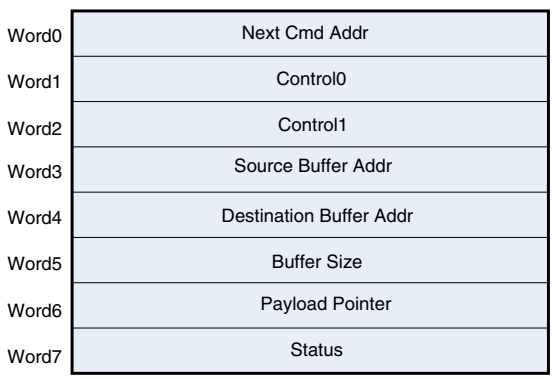

Figure 17-5. DCP Work Packet Structure

For some operations, additional information is required to process the data in the packet. This additional information is provided in the variable-sized payload buffer, which can be found at the address specified in the payload pointer field. When encryption is specified, the payload may include the encryption key (if the key selected resides in the packet), an initialization vector (for modes of operation such as CBC), and expected hash values when data hashing is indicated. The hardware can automatically compare the expected hash with the actual hash and interrupt the processor only on a mismatch. The payload area is used by software to store the calculated hash value at the end of hashing operations (when the HASH_TERM control bit in DCP_Control0 is set).

17.2.6.4.1 Next Command Address Field

The NEXT_COMMAND_ADDRESS field (as shown in Table 17-2) is used to point to the next work packet in the chain. This field is loaded into the channel's command pointer after the current packet has completed processing if the CHAIN bit in the CONTROL0

field (see Table 17-3) is set. The Next Command Address field should be programmed to a non-zero value when the CHAIN bit is set; otherwise, the channel will flag an invalid setup error.

Table 17-2. DCP Next Command Address Field

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	09	08	07	06	05	04	03	02	01	00
NEXT_COMMAND_ADDRESS																															

17.2.6.4.2 Control0 Field

The main functions of the DCP module are enabled with the ENABLE_MEMCOPY, ENABLE_BLIT, ENABLE_CIPHER, and ENABLE_HASH bits from the Control0 field in the work packet. The combinations of these bits determine the function performed by the DCP. Table 17-4 summarizes the function performed for each combination.

Table 17-3. DCP Control0 Field

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	09	08	07	06	05	04	03	02	01	00
TAG								OUTPUT_WORDSWAP	OUTPUT_BYTESWAP	INPUT_WORDSWAP	INPUT_BYTESWAP	KEY_WORDSWAP	KEY_BYTESWA	TEST_SEMA_IRQ	CONSTANT_FILL	HASH_OUTPUT	HASH_CHECK	HASH_TERM	HASH_INIT	PAYLOAD_KEY	OTP_KEY	CIPHER_INIT	CIPHER_ENCRYP	ENABLE_BLIT	ENABLE_HASH	ENABLE_CIPHE	ENABLE_MEMCOPY	CHAIN_CONTINUOUS	CHAIN	DECR_SEMAPHOR	INTERRUPT_ENABLE

Table 17-4. DCP Function Enable Bits

Hash	Cipher	Blit	Memcopy	Description
0	0	0	X	Simple memcopy operation.
0	0	1	0	Blit operation.
0	1	0	0	Simple encrypt/decrypt operation.
1	0	0	0	Simple hash. Only reads performed.
1	0	0	1	Memcopy and hash operation.
1	1	0	0	Hash with encryption/decryption.
All Others				Invalid setup.

The CHAIN bit should be set if the NEXT_COMMAND_ADDRESS field has a valid pointer to the next work packet. When set, this bit causes the channel to update its pointer to the next packet. The CHAIN_CONTINUOUS bit is similar, but it indicates that the

next packet follows immediately after the current packet. This allows software to generate templates of operations without regard to the actual physical addresses used, which makes programming easier, especially in a virtual memory environment.

If the INTERRUPT_ENABLE bit is set, the channel generates an interrupt to the processor after completing the work for this packet. When the interrupt is issued, the packet will have been completely processed, including the update of the status/payload fields in the work packet.

Each channel contains an eight-bit counting semaphore that controls whether it is in the run or idle state. When the semaphore in non-zero, the channel is ready to run and process commands. Whenever a command finishes its operation, it checks the DECR_SEMAPHORE bit. If set, it decrements the counting semaphore. If the semaphore goes to 0 as a result, then the channel enters the idle state and remains there until the semaphore is incremented by software. When the semaphore goes to non-zero and the channel is in its idle state, it then uses the value in the NEXT_COMMAND_ADDRESS field to begin processing.

If the ENABLE_CIPHER bit is set, the data is encrypted or decrypted based on the CIPHER_ENCRYPT bit using the key/encryption settings from the Control1 field. The OTP_KEY and PAYLOAD_KEY indicate the source of the keys for the operation. If the OTP_KEY value is set, the KEY_SELECT field from the Control1 register indicates which OTP key is to be used. If the PAYLOAD_KEY bit is set, the first entry in the payload is the key to be used for the operation. If neither bit is set, the KEY_SELECT field indicates an index in the key RAM that contains the key to be used. (For cases when both the OTP_KEY and PAYLOAD_KEY bits are set, the PAYLOAD_KEY takes precedence.)

The HASH_ENABLE enables hashing of the data with the HASH_OUTPUT bit controlling whether the input data (HASH_OUTPUT=0) or output data (HASH_OUTPUT=1) is hashed. In addition, the hardware can be programmed to automatically check the hashed data if the HASH_CHECK bit is set. If the hash does not match, an interrupt is generated and the channel terminates operation on the current chain. The hashing algorithms also require two additional fields in order to operate properly. The HASH_INIT bit should be set for the first block in a hashing pass to properly initialize the hashing function. The HASH_TERM bit must be set on the final block of a hash to notify the hardware that the hashing operation is complete so that it can properly pad the tail of the buffer according to the hashing algorithm. This flag also triggers the write-back of the hash output to the work packet's payload area.

The CONSTANT_FILL flag may be used for both memcopy and blit operations. When this is set, the source address field is used instead as a constant that is written to all locations in the output buffer.

The WORDSWAP and BYTESWAP bits enable muxes around the FIFO to swap data to handle little-endian and big-endian storage of data in system memory. When these bits are cleared, data is assumed to be in little-endian format. When all bits are set, data is assumed to be in big-endian format.

The TAG field is used to identify the work packet and the associated completion status. As each packet is completed, the channel provides the status and tag information for the last packet processed.

17.2.6.4.3 Control1 Field

The Control1 field (shown in Table 17-5) provides additional values used when hashing or encrypting/decrypting data. For blit operations, this field indicates the number of bytes in a frame buffer line, which is used to calculate the address for successive lines in each blit operation.

Table 17-5. DCP Control1 Field

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	09	08	07	06	05	04	03	02	01	00
CIPHER_CONFIG												HASH_ SELECT				KEY_SELECT								CIPHER_ MODE				CIPHER_ SELECT			
																FRAMEBUFFER_LENGTH (in bytes, blit mode)															

The CIPHER_SELECT field selects from one of sixteen possible encryption algorithms (0=AES128). The CIPHER_MODE selects the mode of operation for that cipher (0=ECB, 1=CBC).

The KEY_SELECT field allows key selection for one of several sources. Keys can be included in the packet payload or may come from OTP or write-only registers.

The HASH_SELECT field selects a hashing algorithm for the operation (0=SHA-1, 1=CRC32, 2=SHA-256).

The CIPHER_CONFIG field provides optional configuration information for the selected cipher. An example would be a key length for the RC4 algorithm.

17.2.6.4.4 Source Buffer

The SOURCE_BUFFER pointer (shown in Table 17-6) specifies the location of the source buffer in memory. The buffer may reside at any byte alignment and should refer to an on-chip SRAM of off-chip SDRAM location. For optimal performance, buffers should be word aligned. When the CONSTANT_FILL flag is set in the Control0 field, the value in this field is used as the data written to all destination buffer locations.

Table 17-6. DCP Source Buffer Field

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	09	08	07	06	05	04	03	02	01	00
SOURCE_BUFFER																															
CONSTANT (CONSTANT_FILL mode)																															

17.2.6.4.5 Destination Buffer

The DESTINATION_BUFFER (shown in Table 17-7) specifies the location of the destination buffer in on-chip SRAM or off-chip SDRAM memory and may be set to any byte alignment. For in-place encryption, the destination buffer and source buffer should be the same value. For optimal performance, the buffer location should be word-aligned.

Table 17-7. DCP Destination Buffer Field

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	09	08	07	06	05	04	03	02	01	00
DESTINATION_BUFFER																															

17.2.6.4.6 Buffer Size Field

The BUFFER_SIZE field (shown in Table 17-8) indicates the size of the buffers for memcopy, encryption, and hashing modes. For memcopy and hashing operations, the value may be any number of bytes (byte granularity), and for encryption modes, the length must be a multiple of the selected encryption algorithm's natural data size (16 bytes for AES).

Table 17-8. DCP Buffer Size Field

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	09	08	07	06	05	04	03	02	01	00
NUMBER_LINES (blit mode)																BLIT_WIDTH (in bytes, blit mode)															
BUFFER_SIZE (in bytes, memcopy, encryption, hashing modes)																															

For blit operations, the buffer size field is split into two portions, a BLIT_WIDTH value, which specifies the number of bytes in each "line" of the blit operation, and a NUMBER_LINES value, which specifies how many vertical rows of pixels are in the image buffer.

17.2.6.4.7 Payload Pointer

Some operations require additional control values that are stored in a Payload Buffer (shown in Table 17-9), which is pointed to by this field. After the DCP reads the control packet, it examines the Control0 register and determines whether any payload information is required. If so, the DCP loads the payload from the address specified in this field. (See Payload for more details.)

Table 17-9. DCP Payload Buffer Pointer

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	09	08	07	06	05	04	03	02	01	00
PAYLOAD_POINTER																															

The payload area is also written to by the DCP at the completion of a hash operation (when the HASH_TERM) bit is set. Software must allocate the appropriate amount of storage (20 bytes for SHA-1 and 4 bytes for CRC32) in the payload or risk having the DCP write to an unallocated address.

17.2.6.4.8 Status

After the DCP engine has completed processing of a descriptor, it writes the packet status (shown in Table 17-10) back to the descriptor In the Status field. The packet status is the value of the channel status register at the time the packet completed processing.

Table 17-10. DCP Status Field

31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	09	08	07	06	05	04	03	02	01	00
TAG								ERROR_CODE																		ERROR_DS	ERROR_SR	ERROR_PACKET	ERROR_SETU	HASH_MISMATCH	COMPLETE

For various error conditions, the DCP encodes additional error information in the ERROR_CODE field. See DCP for more details on assignments of error codes. For any completion codes besides the COMPLETE flag, the channel suspends processing of the command chain until the error status values are cleared in the channel status register.

The format for this field is the same as for the channel status register, with the exception that the COMPLETE bit is written to the payload status but is not present in the channel status register.

17.2.6.4.9 Payload

The payload is a variable-length field that is used to provide key, initialization values, and expected results from hashing operations. The payload may consist of the data fields listed in Table 17-11.

Table 17-11. DCP Payload Field

Field Name	Size	Description	Condition
Cipher Key	16 bytes	AES key	Cipher enable with PAYLOAD_KEY
Cipher IV	16 bytes	CBC initialization vector	Cipher enable with CBC mode.
Hash Check	20 bytes	Hash completion value	Hash enabled with HASH_TERM fields set.

If fields are not used, they do not appear in the payload and the other payload values move upwards in the payload area. For instance, if only hashing is used, then the HASH_CHECK value would appear at offset 0 in the payload area. Table 17-12 should be used by software to determine the amount of payload to allocate and initialize.

Table 17-12. DCP Payload Allocation by Software

Control Bits Present			Payload Size
Hash_Check	Cipher_Init	Payload_Key	
0	0	0	0 words / 0 bytes
0	0	1	4 words / 16 bytes
0	1	0	4 words / 16 bytes
0	1	1	8 words / 32 bytes
1	0	0	SHA-1: 5 words / 20 bytes SHA-2: 8 words / 32 bytes
1	0	1	SHA-1: 9 words / 36 bytes SHA-2:12 words / 48 bytes
1	1	0	SHA-1: 9 words / 36 bytes SHA-2: 12 words / 48 bytes
1	1	1	SHA-1: 13 words / 52 bytes SHA-2: 16 words / 64 bytes

For hashing operations, the DCP module writes the final hash value back to the start of the payload area for descriptors with the HASH_TERM bit set in the control packet. It is important that software allocate the required payload space, even though it is not required to set up the payload for control purposes.

17.2.7 Programming DCP Functions

17.2.7.1 Basic Memory Copy Programming Example

To perform a basic memcopy operation, only a single descriptor is required. The DCP simply copies data from the source to the destination buffer. This process is illustrated in Figure 17-6.

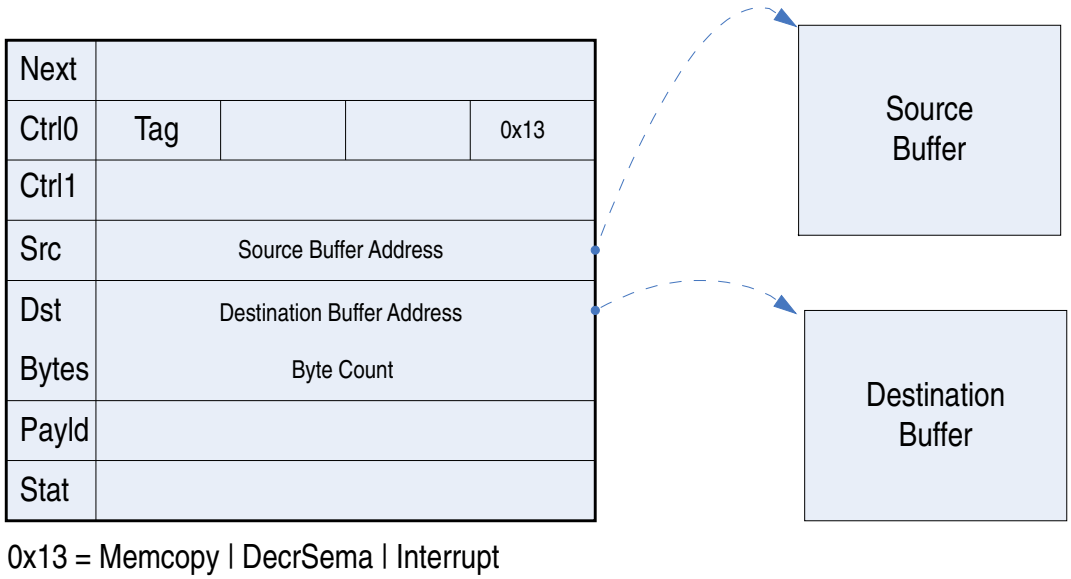

Figure 17-6. Basic Memory Copy Operation

```
<code>
typedef struct _dcp_descriptor
{
    u32              *next;
    hw_dcp_packet1_t  ctrl0;
    hw_dcp_packet2_t  ctrl1;
    u32              *src,
                     *dst,
                      buf_size,
                     *payload,
                      stat;
}  DCP_DESCRIPTOR;
  DCP_DESCRIPTOR dcp1;
  u32 *srcbuffer, *dstbuffer;
  // set up control packet
  dcp1.next = 0;                    // single packet in chain
  dcp1.ctrl0.U = 0;                 // clear ctrl0 field
  dcp1.ctrl0.B.ENABLE_MEMCOPY = 1; // enable memcopy
  dcp1.ctrl0.B.DECR_SEMAPHORE = 1; // decrement semaphore
  dcp1.ctrl0.B.INTERRUPT = 1;       // interrupt
  dcp1.ctrl1.U = 0;                 // clear ctrl1
  dcp1.src = srcbuffer;             // source buffer
  dcp1.dst = dstbuffer;             // destination buffer
  dcp1.buf_size = 512;              // 512 bytes
  dcp1.payload = NULL;              // not required
  dcp1.status = 0;                  // clear status
  // Enable channel 0
  HW_DCP_CHnCMDPTR_WR(0, dcp1);     // write packet address to pointer register
  HW_DCP_CHnSEMA_WR(0, 1);          // increment semaphore by 1
  // now wait for interrupt or poll
  // polling code
  while ( (HW_DCP_STAT_RD() & 0x01) == 0x00 );
```

```
  // now check/clear channel status
  if ( (HW_DCP_CHnSTAT_RD(0) & 0xFF) != 0 ) {
    // an error occurred
    HW_DCP_CHnSTAT_CLR(0, 0xff);
  }
  // clear interrupt register
  HW_DCP_STAT_CLR(1);
</code>
```

17.2.7.2 Basic Hash Operation Programming Example

To perform a basic hash operation, only a single descriptor is required. The DCP simply reads data from the source buffer and computes the hash value on the contents. This process is illustrated in Figure 17-7.

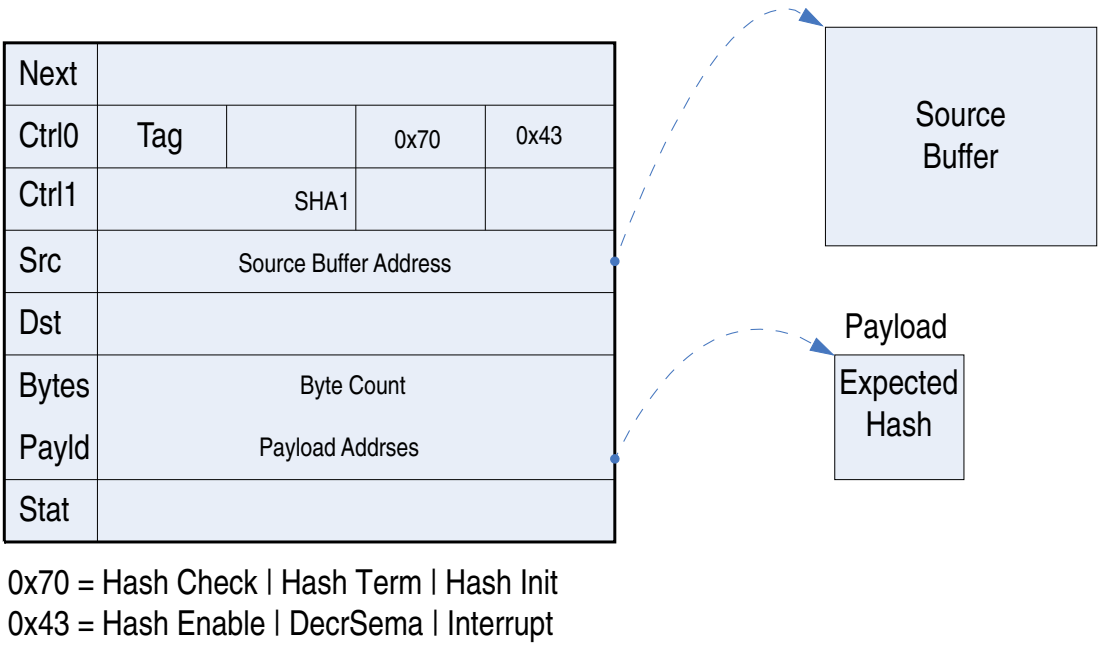

Figure 17-7. Basic Hash Operation

```
<code>
typedef struct _dcp_descriptor
{
    u32              *next;
    hw_dcp_packet1_t  ctrl0;
    hw_dcp_packet2_t  ctrl1;
    u32              *src,
                     *dst,
                      buf_size,
                     *payload,
                      stat;
}  DCP_DESCRIPTOR;
  DCP_DESCRIPTOR dcp1;
  u32 *srcbuffer;
  u32 payload[5];
  // set up expected hash check value
  payload[0]=0x01234567;
  payload[1]=0x89ABCDEF;
  payload[2]=0x00112233;
  payload[3]=0x44556677;
  payload[4]=0x8899aabb;
```

```
  // set up control packet
  dcp1.next = 0;                    // single packet in chain
  dcp1.ctrl0.U = 0;                 // clear ctrl0 field
  dcp1.ctrl0.B.HASH_CHECK = 1;      // check hash when complete
  dcp1.ctrl0.B.HASH_INIT = 1;       // initialize hash with this block
  dcp1.ctrl0.B.HASH_TERM = 1;       // terminate hash with this block
  dcp1.ctrl0.B.ENABLE_HASH = 1;     // enable hash
  dcp1.ctrl0.B.DECR_SEMAPHORE = 1; // decrement semaphore
  dcp1.ctrl0.B.INTERRUPT = 1;       // interrupt
  dcp1.ctrl1.U = 0;                 // clear ctrl1
  dcp1.src = srcbuffer;             // source buffer
  dcp1.dst = 0;                     // no destination buffer
  dcp1.buf_size = 512;              // 512 bytes
  dcp1.payload = payload;           // holds expected hash value
  dcp1.status = 0;                  // clear status
  // Enable channel 0
  HW_DCP_CHnCMDPTR_WR(0, dcp1);     // write packet address to pointer register
  HW_DCP_CHnSEMA_WR(0, 1);          // increment semaphore by 1
  // now wait for interrupt or poll
  // polling code
  while ( (HW_DCP_STAT_RD() & 0x01) == 0x00 );
  // now check/clear channel status
  if ( (HW_DCP_CHnSTAT_RD(0) & 0xFF) != 0 ) {
    // an error occurred
    HW_DCP_CHnSTAT_CLR(0, 0xff);
  }
  // clear interrupt register
  HW_DCP_STAT_CLR(1);
</code>
```

17.2.7.3 Basic Cipher Operation Programming Example

To perform a basic cipher operation, only a single descriptor is required. The DCP reads data from the source buffer, encrypts it, and writes it to the destination buffer. For this example, the key is provided in the payload and the algorithm uses the AES CBC mode of operation. This requires a payload with both the key and CBC initialization value. This process is illustrated in Figure 17-8.

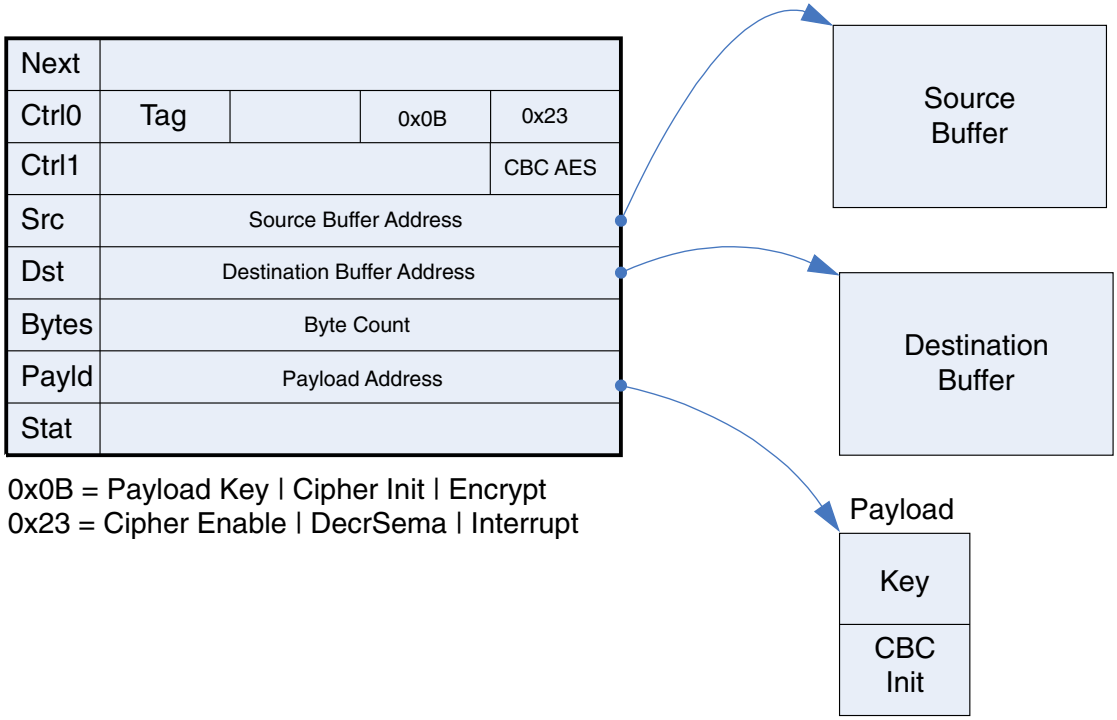

Figure 17-8. Basic Cipher Operation

```
<code>
typedef struct _dcp_descriptor
{
    u32              *next;
    hw_dcp_packet1_t  ctrl0;
    hw_dcp_packet2_t  ctrl1;
    u32              *src,
                     *dst,
                      buf_size,
                     *payload,
                      stat;
}  DCP_DESCRIPTOR;
  DCP_DESCRIPTOR dcp1;
  u32 *srcbuffer;
  u32 *dstbuffer;
  u32 payload[8];
  // set up key/CBC init in the payload
  payload[0]=0x01234567;           // key
  payload[1]=0x89ABCDEF;
  payload[2]=0xfedcba98;
  payload[3]=0x76543210;
  payload[4]=0x00112233;           // CBC initialization
  payload[5]=0x44556677;
  payload[6]=0x8899aabb;
  payload[7]=0xccddeeff;
  // set up control packet
  dcp1.next = 0;                   // single packet in chain
  dcp1.ctrl0.U = 0;                // clear ctrl0 field
  dcp1.ctrl0.B.PAYLOAD_KEY = 1;    // key is located in payload
  dcp1.ctrl0.B.CIPHER_ENCRYPT = 1; // encryption operation
  dcp1.ctrl0.B.CIPHER_INIT = 1;    // init CBC for this block (from payload)
  dcp1.ctrl0.B.ENABLE_CIPHER = 1;  // enable cipher
  dcp1.ctrl0.B.DECR_SEMAPHORE = 1; // decrement semaphore
  dcp1.ctrl0.B.INTERRUPT = 1;      // interrupt
  dcp1.ctrl1.U = 0;                // clear ctrl1
  dcp1.ctrl1.B.CIPHER_MODE = 1;    // select CBC mode of operation
  dcp1.src = srcbuffer;            // source buffer
  dcp1.dst = dstbuffer;            // destination buffer
```

```
  dcp1.buf_size = 512;              // 512 bytes
  dcp1.payload = payload;           // holds key/CBC init
  dcp1.status = 0;                  // clear status
  // Enable channel 0
  HW_DCP_CHnCMDPTR_WR(0, dcp1);     // write packet address to pointer register
  HW_DCP_CHnSEMA_WR(0, 1);          // increment semaphore by 1
  // now wait for interrupt or poll
  // polling code
  while ( (HW_DCP_STAT_RD() & 0x01) == 0x00 );
  // now check/clear channel status
  if ( (HW_DCP_CHnSTAT_RD(0) & 0xFF) != 0 ) {
    // an error occurred
    HW_DCP_CHnSTAT_CLR(0, 0xff);
  }
  // clear interrupt register
  HW_DCP_STAT_CLR(1);
</code>
```

17.2.7.4 Multi-Buffer Scatter/Gather Cipher and Hash Operation Programming Example

For this example, three separate buffers are encrypted and hashed with the results being directed to a unified buffer (gather operation). Three descriptors are used for the operation because there are three separate source buffer pointers. The DCP reads data from the source buffer and computes a hash on the unencrypted data. It then encrypts the data and writes it to the destination buffer. For this example, the key is located in the key RAM, and the algorithm uses the AES CBC mode of operation with a SHA-1 hash. The payload for the first operation contains the CBC initialization value, and the payload for the last packet contains the expected hash value. The middle packet requires no payload. This process is illustrated in Figure 17-9.

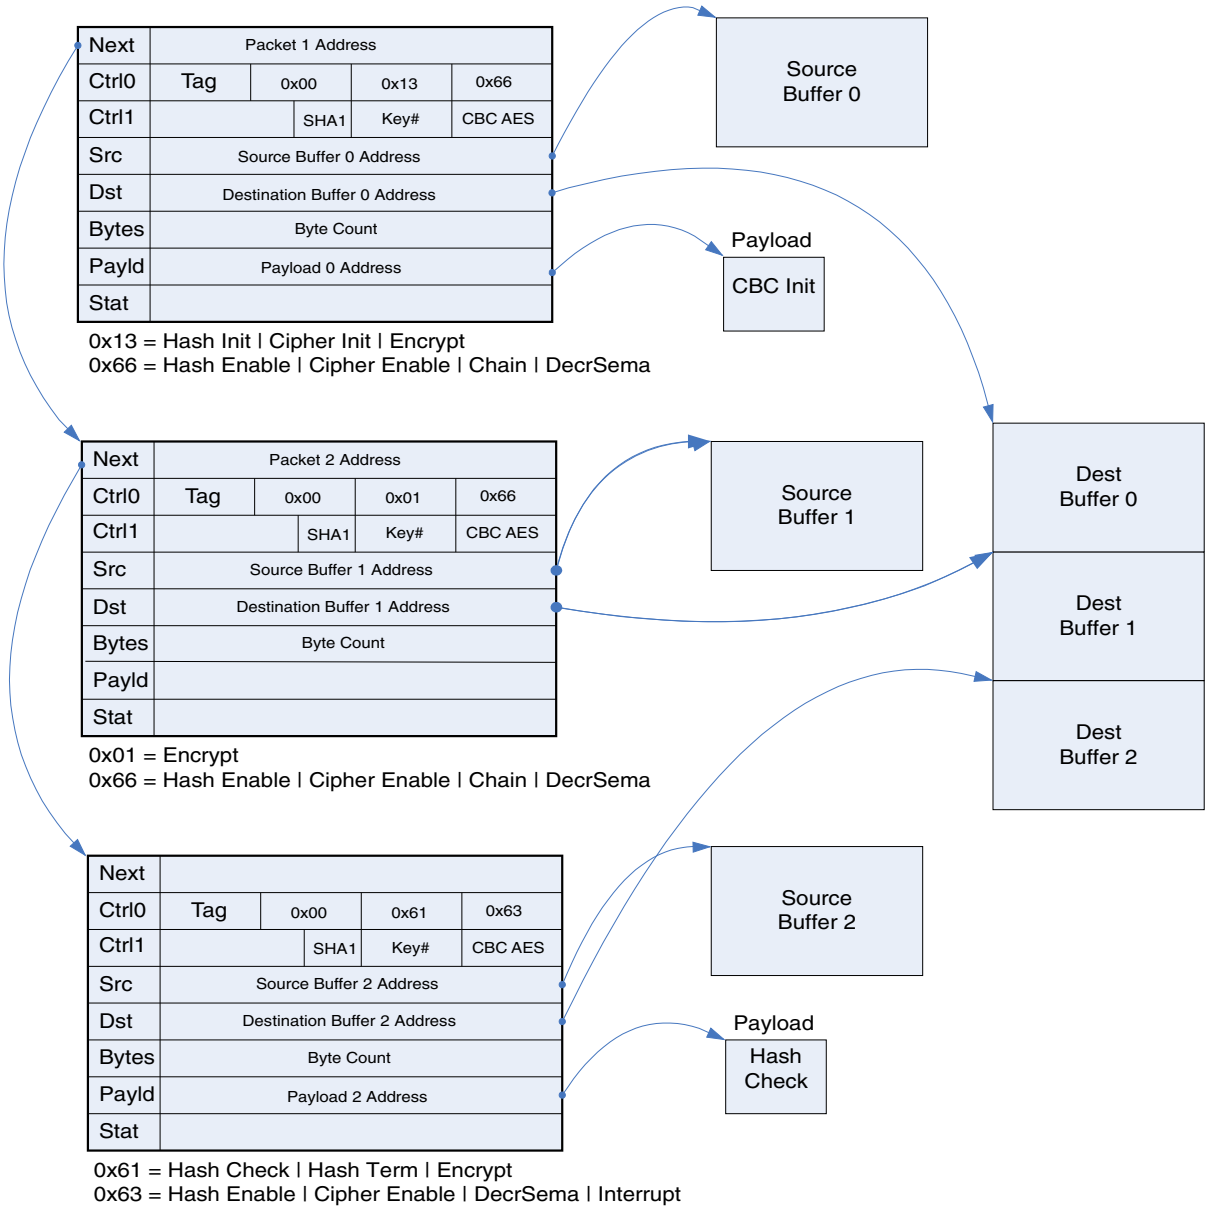

Figure 17-9. Multi-Buffer Scatter/Gather Cipher and Hash Operation

```
<code>
typedef struct _dcp_descriptor
{
    u32              *next;
    hw_dcp_packet1_t  ctrl0;
    hw_dcp_packet2_t  ctrl1;
    u32              *src,
                     *dst,
                      buf_size,
                     *payload,
                      stat;
}  DCP_DESCRIPTOR;
  DCP_DESCRIPTOR dcp1, dcp2, dcp3;
  u32 *srcbuffer0, *srcbuffer2, *srcbuffer3;
  u32 *dstbuffer;
  u32 payload0[4], payload2[5];
  // set up CBC init in the payload
  payload0[0]=0x01234567;           // key
  payload0[1]=0x89ABCDEF;
```

```
  payload0[2]=0xfedcba98;
  payload0[3]=0x76543210;
  payload2[0]=0x00112233;           // CBC initialization
  payload2[1]=0x44556677;

17.3.1 DCP Control Register 0 (DCP_CTRL)

The CTRL register contains controls for the DCP module.

CTRL: 0x000

CTRL_SET: 0x004

CTRL_CLR: 0x008

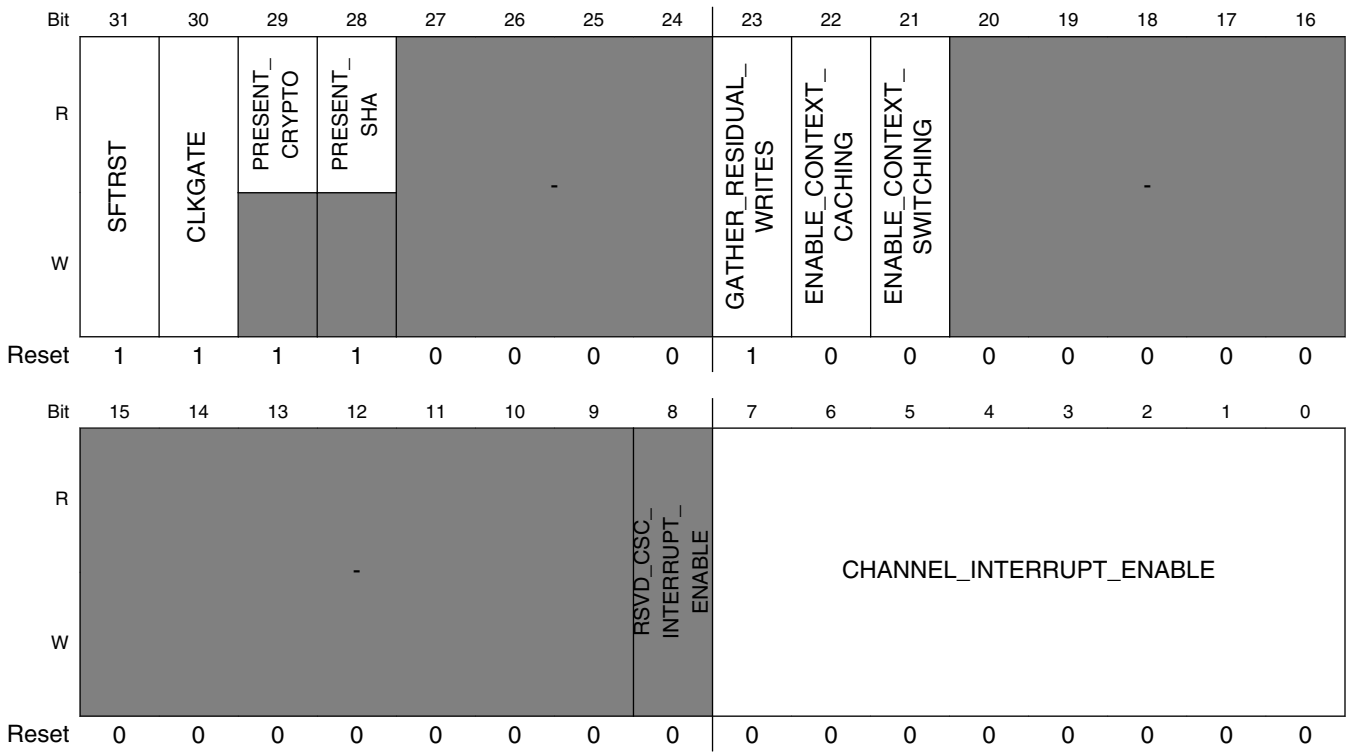
CTRL_TOG: 0x00C

The Control register contains the primary controls for the DCP block. The present bits indicate which of the sub-features of the block are present in the hardware. The context control bits control how the DCP utilizes it's context buffer and the gather residual writes bit controls how the master handles writing misaligned data to the bus. Each channel and the color-space converter contains an independent interrupt enable.

EXAMPLE

```
DCP_CTRL_SET(BM_DCP_CTRL_SFTRST);
DCP_CTRL_CLR(BM_DCP_CTRL_SFTRST | BM_DCP_CTRL_CLKGATE);
```

Address: DCP_CTRL is 0h base + 0h offset = 0000_0000h



DCP_CTRL field descriptions

Field	Description
31 SFTRST	Set this bit to zero to enable normal DCP operation. Set this bit to one (default) to disable clocking with the DCP and hold it in its reset (lowest power) state. This bit can be turned on and then off to reset the DCP block to its default state.
30 CLKGATE	This bit must be set to zero for normal operation. When set to one it gates off the clocks to the block.
29 PRESENT_ CRYPTO	Indicates whether the crypto (Cipher/Hash) functions are present. 0x1 **Present** — 0x0 **Absent** —
28 PRESENT_SHA	Indicates whether the SHA1/SHA2 functions are present. 0x1 **Present** — 0x0 **Absent** —
27–24 -	Reserved, always set to zero.
23 GATHER_ RESIDUAL_ WRITES	Software should set this bit to enable ragged writes to unaligned buffers to be gathered between multiple write operations. This improves performance by removing several byte operations between write bursts. Trailing byte writes are held in a residual write data buffer and combined with a subsequent write to the buffer to form a word write.
22 ENABLE_ CONTEXT_ CACHING	Software should set this bit to enable caching of contexts between operations. If only a single channel is used for encryption/hashing, enabling caching causes the context to not be reloaded if the channel was the last to be used.

Table continues on the next page...

DCP_CTRL field descriptions (continued)

Field	Description
21 ENABLE_ CONTEXT_ SWITCHING	Enable automatic context switching for the channels. Software should set this bit if more than one channel is doing hashing or cipher operations that require context to be saved (for instance, when CBC mode is enabled). By disabling context switching, software can save the 208 bytes used for the context buffer.
20–9 -	Reserved, always set to zero.
8 RSVD_CSC_ INTERRUPT_ ENABLE	Reserved, always set to zero.
7–0 CHANNEL_ INTERRUPT_ ENABLE	Per-channel interrupt enable bit. When set, the channel's interrupt will get routed to the interrupt controller. Channel 0 is routed to the dcp_vmi_irq signal and the other channels are combined (along with the CRC interrupt) into the dcp_irq signal. 0x01 **CH0** — 0x02 **CH1** — 0x04 **CH2** — 0x08 **CH3** —

17.3.2 DCP Status Register (DCP_STAT)

The DCP Interrupt Status register provides channel interrupt status information.

STAT: 0x010

STAT_SET: 0x014

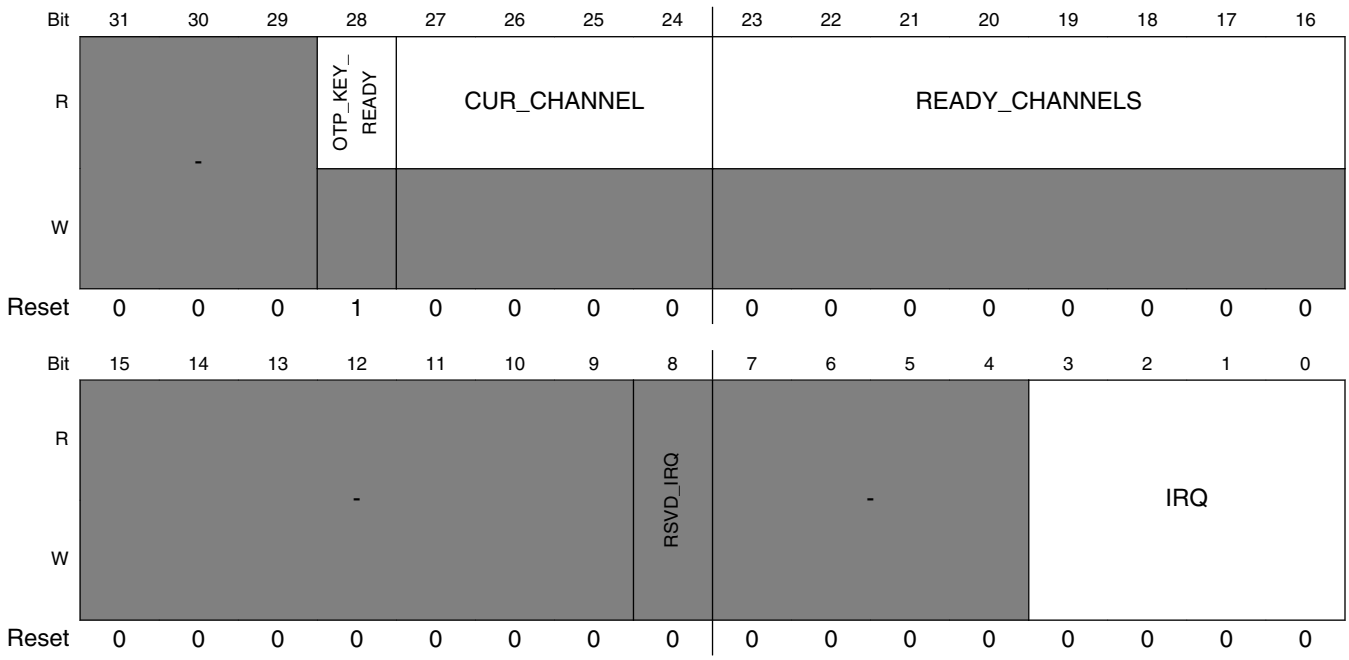
STAT_CLR: 0x018

STAT_TOG: 0x01C

This register provides status feedback indicating the channel currently performing an operation and which channels have pending operations.

EXAMPLE

Address: DCP_STAT is 0h base + 10h offset = 0000_0010h



DCP_STAT field descriptions

Field	Description
31–29 -	Reserved, always set to zero.
28 OTP_KEY_READY	When set, indicates that the OTP key has been shifted from the fuse block and is ready for use.
27–24 CUR_CHANNEL	Current (active) channel (encoded). 0x0 **None** — 0x1 **CH0** — 0x2 **CH1** — 0x3 **CH2** — 0x4 **CH3** —
23–16 READY_CHANNELS	Indicates which channels are ready to proceed with a transfer (active channel also included). Each bit is a one-hot indicating the request status for the associated channel. 0x01 **CH0** — 0x02 **CH1** — 0x04 **CH2** — 0x08 **CH3** —
15–9 -	Reserved, always set to zero.
8 RSVD_IRQ	Reserved, always set to zero.
7–4 -	Reserved, always set to zero.

Table continues on the next page...

DCP_STAT field descriptions (continued)

Field	Description
3–0 IRQ	Indicates which channels have pending interrupt requests. Channel 0's interrupt is routed through the dcp_vmi_irq and the other interrupt bits are routed through the dcp_irq.

17.3.3 DCP Channel Control Register (DCP_CHANNELCTRL)

The DCP Channel Control register provides controls for channel arbitration and channel enables.

CHANNELCTRL: 0x020

CHANNELCTRL_SET: 0x024

CHANNELCTRL_CLR: 0x028

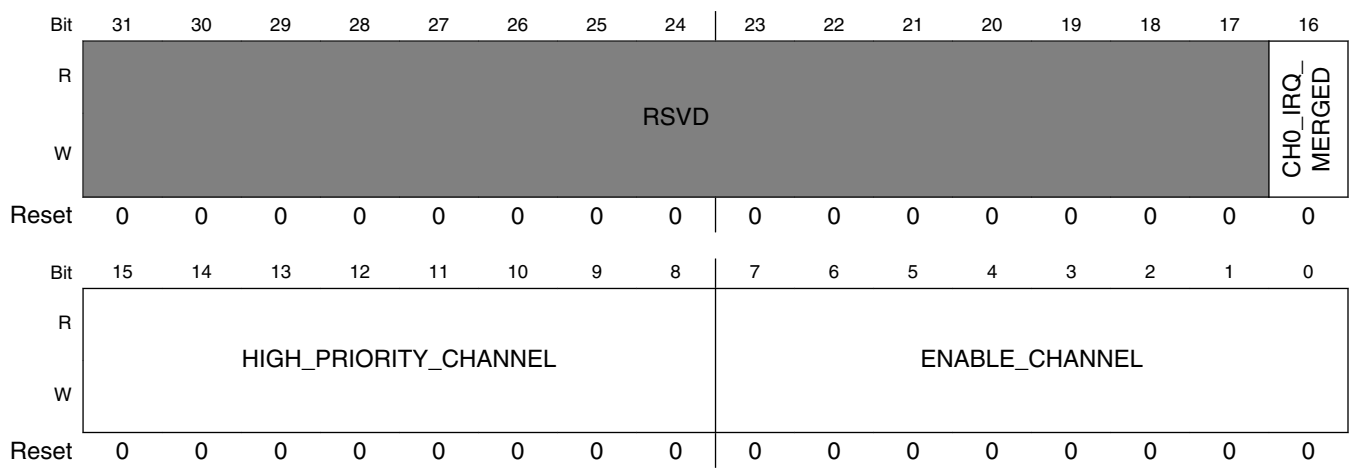
CHANNELCTRL_TOG: 0x02C

This register provides status feedback indicating the channel currently performing an operation and which channels have pending operations.

EXAMPLE

```
        BW_DCP_CHANNELCTRL_ENABLE_CHANNEL(BV_DCP_CHANNELCTRL_ENABLE_CHANNEL__CH0);  //
enable channel 0
```

Address: DCP_CHANNELCTRL is 0h base + 20h offset = 0000_0020h



DCP_CHANNELCTRL field descriptions

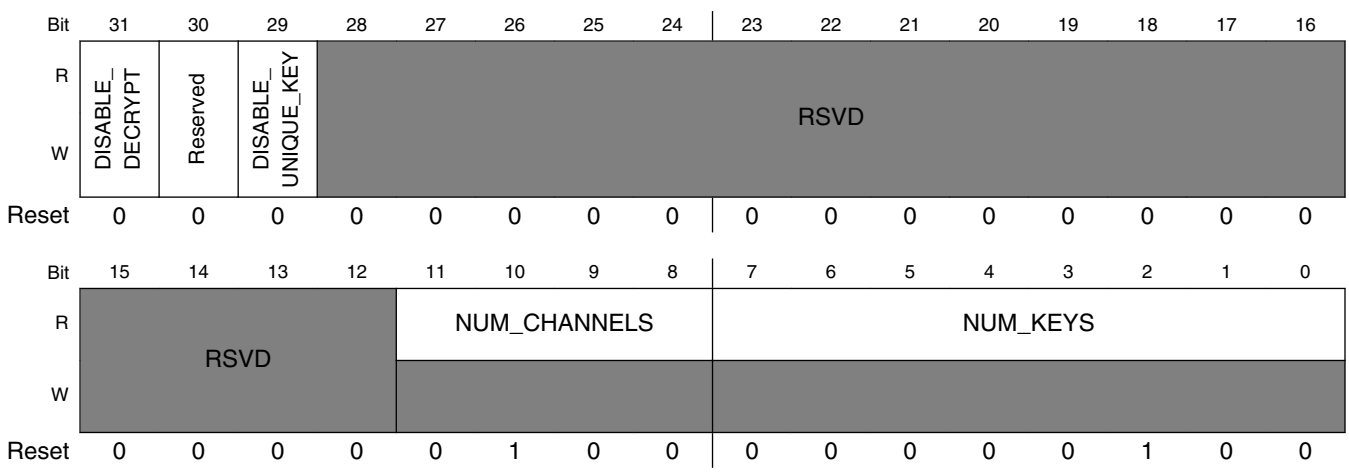
Field	Description
31–17 RSVD	Reserved, always set to zero.
16 CH0_IRQ_ MERGED	Indicates that the interrupt for channel 0 should be merged with the other interrupts on the shared dcp_irq interrupt. When set to 0, channel 0's interrupt will be routed to the separate dcp_vmi_irq. When set to 1, the interrupt will be routed to the shared DCP interrupt.
15–8 HIGH_ PRIORITY_ CHANNEL	Setting a bit in this field causes the corresponding channel to have high-priority arbitration. High priority channels will be arbitrated round-robin and will take precedence over other channels that are not marked as high priority. 0x01 **CH0** — 0x02 **CH1** — 0x04 **CH2** — 0x08 **CH3** —
7–0 ENABLE_ CHANNEL	Setting a bit in this field will enabled the DMA channel associated with it. This field is a direct input to the DMA channel arbiter. When not enabled, the channel is denied access to the central DMA resources. 0x01 **CH0** — 0x02 **CH1** — 0x04 **CH2** — 0x08 **CH3** —

17.3.4 DCP Capability 0 Register (DCP_CAPABILITY0)

This register contains additional information about the DCP module implementation parameters.

This register provides capability information for the DCP block. It indicates the number of channels implemented as well as the number of key storage locations available for software use.

Address: DCP_CAPABILITY0 is 0h base + 30h offset = 0000_0030h



DCP_CAPABILITY0 field descriptions

Field	Description
31 DISABLE_ DECRYPT	Write to a 1 to disable decryption. This bit can only be written by secure software and the value can only be cleared by a reset.
30 Reserved	This field is reserved. -
29 DISABLE_ UNIQUE_KEY	Write to a 1 disable the per-device unique key. The device-specific hardware key may be selected by using a value of 0xFE in the key select field.
28–12 RSVD	Reserved, always set to zero.
11–8 NUM_ CHANNELS	Encoded value indicating the number of channels implemented in the design.
7–0 NUM_KEYS	Encoded value indicating the number of key storage locations implemented in the design.

17.3.5 DCP Capability 1 Register (DCP_CAPABILITY1)

This register contains information about the algorithms available on the implementation.

This register provides capability information for the DCP block. It contains two fields indicating which encryption and hashing algorithms are present in the design. Each bit set indicates that support for the associated function is present.

Address: DCP_CAPABILITY1 is 0h base + 40h offset = 0000_0040h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	1	1	1	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1

DCP_CAPABILITY1 field descriptions

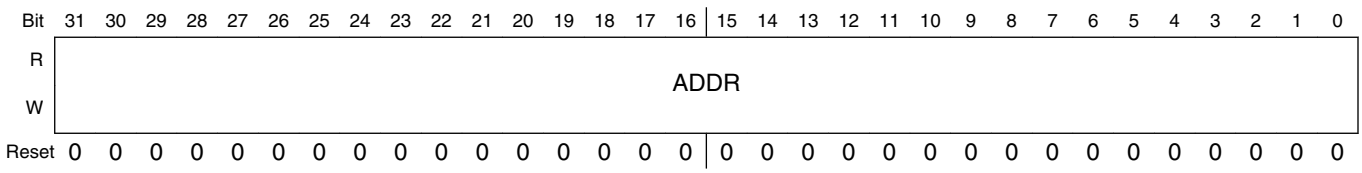
Field	Description
31–16 HASH_ ALGORITHMS	One-hot field indicating which hashing features are implemented in HW. 0x0001 **SHA1** — 0x0002 **CRC32** — 0x0004 **SHA256** —
15–0 CIPHER_ ALGORITHMS	One-hot field indicating which cipher algorithms are available. 0x0001 **AES128** —

17.3.6 DCP Context Buffer Pointer (DCP_CONTEXT)

This register contains a pointer to the memory region to be used for DCP context swap operations.

This register contains a pointer to the start of the context pointer memory in on-chip SRAM or off-chip SDRAM. This buffer will be used to store state information when the DCP module changes from one channel to another.

Address: DCP_CONTEXT is 0h base + 50h offset = 0000_0050h



DCP_CONTEXT field descriptions

Field	Description
31–0 ADDR	Context pointer address. Address should be located in system RAM and should be word-aligned for optimal performance.

17.3.7 DCP Key Index (DCP_KEY)

This register contains a pointer to the key location to be written.

The DCP module maintains a set of write-only keys that may be used by software. To write a key, software must first write the desired key index/subword to this register and then write the key values to the key registers (below). After each write to the key data register, the SUBWORD field will increment to allow software to write the subsequent key to be written without having to rewrite the key index.

EXAMPLE

```
// write key 0 to 0x00112233_44556677_8899aabb_ccddeeff
DCP_KEY_WR(BF_DCP_KEY_INDEX(0) | BF_DCP_KEY_SUBWORD(0));  // set key index to key 0, subword
0
DCP_KEYDATA_WR(0xccddeeff);  // write key values (subword 0)
DCP_KEYDATA_WR(0x8899aabb);  // write key values (subword 1)
DCP_KEYDATA_WR(0x44556677);  // write key values (subword 2)
DCP_KEYDATA_WR(0x00112233);  // write key values (subword 3)
```

Address: DCP_KEY is 0h base + 60h offset = 0000_0060h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	RSVD															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	RSVD								RSVD_INDEX		INDEX		RSVD_ SUBWORD		SUBWORD	
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DCP_KEY field descriptions

Field	Description
31–8 RSVD	Reserved, always set to zero.
7–6 RSVD_INDEX	Reserved, always set to zero.
5–4 INDEX	Key index pointer. Valid indices are 0-[number_keys].
3–2 RSVD_ SUBWORD	Reserved, always set to zero.
1–0 SUBWORD	Key subword pointer. Valid indices are 0-3. After each write to the key data register, this field will increment.

17.3.8 DCP Key Data (DCP_KEYDATA)

This register provides write access to the key/key subword specified by the Key Index Register.

Writing this location updates the selected subword for the key located at the index specified by the Key Index Register. A write also triggers the SUBWORD field of the KEY register to increment to the next higher word in the key.

EXAMPLE

```
// write key 0 to 0x00112233_44556677_8899aabb_ccddeeff
DCP_KEY_WR(BF_DCP_KEY_INDEX(0) | BF_DCP_KEY_SUBWORD(0));  // set key index to key 0, subword
0
DCP_KEYDATA_WR(0xccddeeff);  // write key values (subword 0)
DCP_KEYDATA_WR(0x8899aabb);  // write key values (subword 1)
DCP_KEYDATA_WR(0x44556677);  // write key values (subword 2)
DCP_KEYDATA_WR(0x00112233);  // write key values (subword 3)
```

Address: DCP_KEYDATA is 0h base + 70h offset = 0000_0070h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DCP_KEYDATA field descriptions

Field	Description
31–0 DATA	Word 0 data for key. This is the least-significant word.

17.3.9 DCP Work Packet 0 Status Register (DCP_PACKET0)

This register displays the values for the current work packet offset 0x00 (Next Command) field.

The Work Packet Status Registers show the contents of the currently executing packet. When the channels are inactive, the packet status register return 0. The register bits are fully documented here to document the packet structure in memory.

Address: DCP_PACKET0 is 0h base + 80h offset = 0000_0080h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DCP_PACKET0 field descriptions

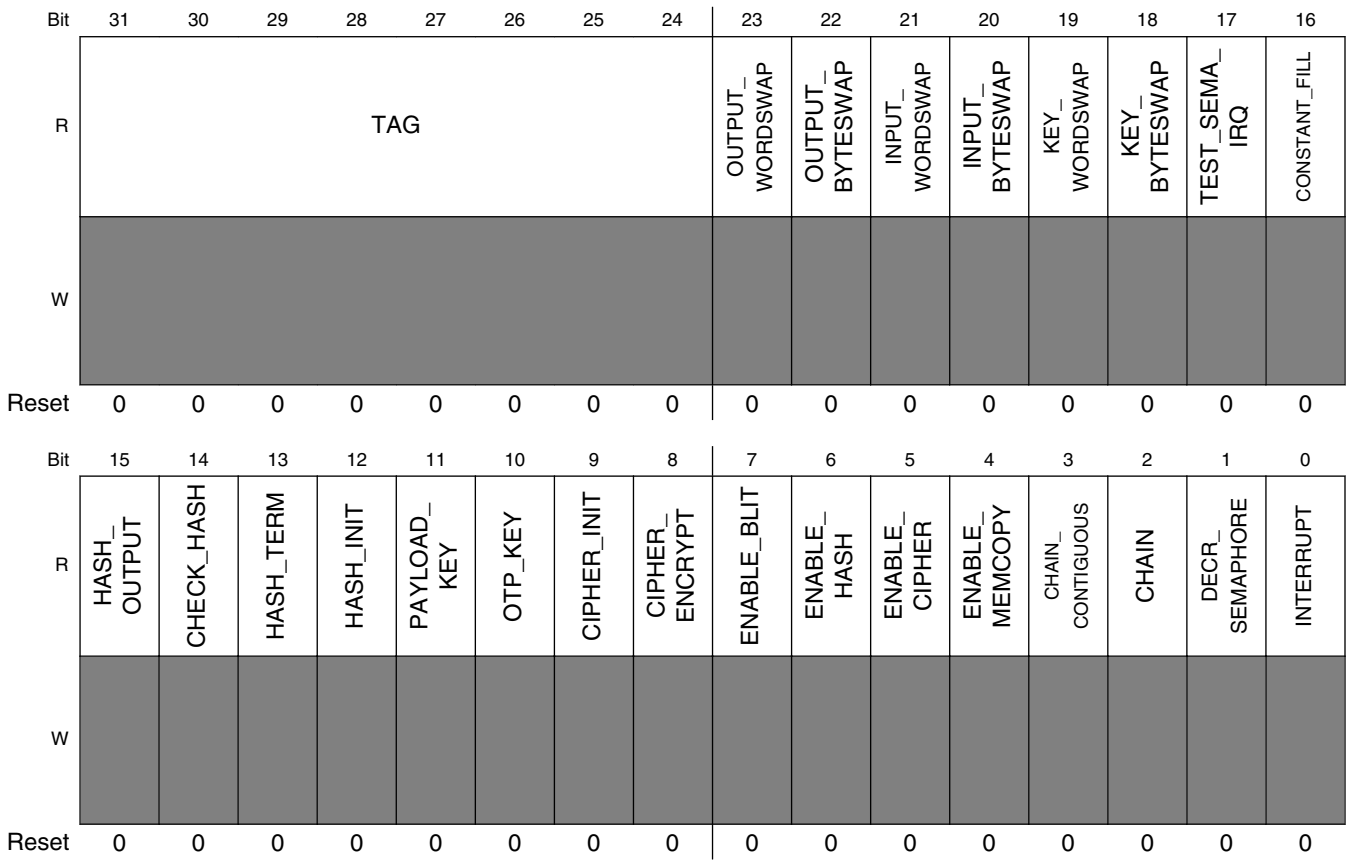
Field	Description
31–0 ADDR	Next Pointer Register,

17.3.10 DCP Work Packet 1 Status Register (DCP_PACKET1)

This register displays the values for the current work packet offset 0x04 (control) field.

This register shows the contents of the Control0 register from the packet being processed.

Address: DCP_PACKET1 is 0h base + 90h offset = 0000_0090h



DCP_PACKET1 field descriptions

Field	Description
31–24 TAG	Packet Tag
23 OUTPUT_ WORDSWAP	Reflects whether the DCP engine will wordswap output data (big-endian data).
22 OUTPUT_ BYTESWAP	Reflects whether the DCP engine will byteswap output data (big-endian data).
21 INPUT_ WORDSWAP	Reflects whether the DCP engine will wordswap input data (big-endian data).
20 INPUT_ BYTESWAP	Reflects whether the DCP engine will byteswap input data (big-endian data).
19 KEY_ WORDSWAP	Reflects whether the DCP engine will swap key words (big-endian key).
18 KEY_ BYTESWAP	Reflects whether the DCP engine will swap key bytes (big-endian key).

Table continues on the next page...

DCP_PACKET1 field descriptions (continued)

Field	Description
17 TEST_SEMA_ IRQ	This bit is used to test the channel semaphore transition to 0. FOR TEST USE ONLY!
16 CONSTANT_ FILL	When this bit is set (MEMCOPY and BLIT modes only), the DCP will simply fill the destination buffer with the value found in the Source Address field.
15 HASH_OUTPUT	When hashing is enabled, this bit controls whether the input or output data is hashed. 0 **INPUT** — 1 **OUTPUT** —
14 CHECK_HASH	Reflects whether the calculated hash value should be compared against the hash provided in the payload.
13 HASH_TERM	Reflects whether the current hashing block is the final block in the hashing operation, so the hash padding should be applied by hardware.
12 HASH_INIT	Reflects whether the current hashing block is the initial block in the hashing operation, so the hash registers should be initialized before the operation.
11 PAYLOAD_KEY	When set, indicates the payload contains the key. This bit takes precedence over the OTP_KEY control
10 OTP_KEY	Reflects whether a hardware-based key should be used. The KEY_SELECT field from the Control1 field is used to select from multiple hardware keys. The PAYLOAD_KEY bit takes precedence over the OTP_KEY bit.
9 CIPHER_INIT	Reflects whether the cipher block should load the initialization vector from the payload for this operation.
8 CIPHER_ ENCRYPT	When the cipher block is enabled, this bit indicates whether the operation is encryption or decryption. 1 **ENCRYPT** — 0 **DECRYPT** —
7 ENABLE_BLIT	Reflects whether the DCP should perform a blit operation. Source data is always continuous and the destination buffer is written in run/stride format. When set, the BUFFER_SIZE field is treated as two 16-bit values for the X-Y extents of the blit operation.
6 ENABLE_HASH	Reflects whether the selected hashing function should be enabled for this operation.
5 ENABLE_ CIPHER	Reflects whether the selected cipher function should be enabled for this operation.
4 ENABLE_ MEMCOPY	Reflects whether the selected hashing function should be enabled for this operation.
3 CHAIN_ CONTIGUOUS	Reflects whether the next packet's address is located following this packet's payload.
2 CHAIN	Reflects whether the next command pointer register should be loaded into the channel's current descriptor pointer.

Table continues on the next page...

DCP_PACKET1 field descriptions (continued)

Field	Description
1 DECR_ SEMAPHORE	Reflects whether the channel's semaphore should be decremented at the end of the current operation. When the semaphore reaches a value of zero, no more operations will be issued from the channel.
0 INTERRUPT	Reflects whether the channel should issue an interrupt upon completion of the packet.

17.3.11 DCP Work Packet 2 Status Register (DCP_PACKET2)

This register displays the values for the current work packet offset 0x08 (Control1) field.

This register shows the contents of the Control0 register from the packet being processed.

Address: DCP_PACKET2 is 0h base + A0h offset = 0000_00A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	CIPHER_CFG								RSVD				HASH_SELECT

R	KEY_SELECT								CIPHER_MODE				CIPHER_SELECT			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DCP_PACKET2 field descriptions

Field	Description
31–24 CIPHER_CFG	Cipher configuration bits. Optional configuration bits required for ciphers
23–20 RSVD	Reserved, always set to zero.
19–16 HASH_SELECT	Hash Selection Field 0x00 **SHA1** — 0x01 **CRC32** — 0x02 **SHA256** —
15–8 KEY_SELECT	Key Selection Field. The value here reflects the key index for the cipher operation. Values 0-3 refer to the software keys that can be written to the key RAM. The OTP key or the unique device-specific key may also be selected with a value of 0xFF (OTP key) or 0xFE (unique key). 0x00 **KEY0** — 0x01 **KEY1** — 0x02 **KEY2** — 0x03 **KEY3** —

Table continues on the next page...

DCP_PACKET2 field descriptions (continued)

Field	Description
	0xFE **UNIQUE_KEY** — 0xFF **OTP_KEY** —
7–4 CIPHER_MODE	Cipher Mode Selection Field. Reflects the mode of operation for cipher operations. 0x00 **ECB** — 0x01 **CBC** —
3–0 CIPHER_ SELECT	Cipher Selection Field 0x00 **AES128** —

17.3.12 DCP Work Packet 3 Status Register (DCP_PACKET3)

This register displays the values for the current work packet offset 0x0C (Source Address) field.

This register shows the contents of the Source Address register from the packet being processed. When the CONSTANT_FILL bit in the Control 0 field is set, this field contains the data written to the destination buffer.

Address: DCP_PACKET3 is 0h base + B0h offset = 0000_00B0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DCP_PACKET3 field descriptions

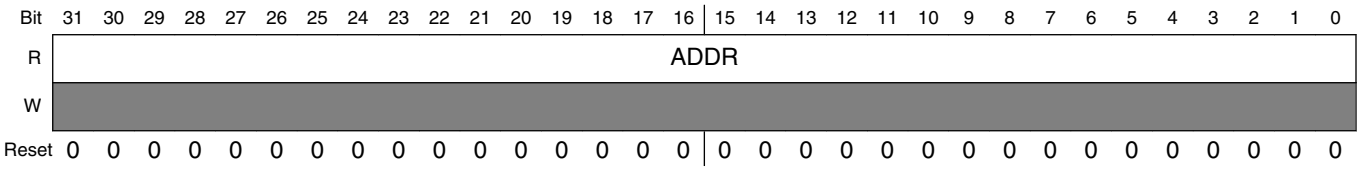
Field	Description
31–0 ADDR	Source Buffer Address Pointer. This value is the working value and will update as the operation proceeds.

17.3.13 DCP Work Packet 4 Status Register (DCP_PACKET4)

This register displays the values for the current work packet offset 0x10 (Destination Address) field.

This register shows the contents of the Destination Address register from the packet being processed.

Address: DCP_PACKET4 is 0h base + C0h offset = 0000_00C0h



DCP_PACKET4 field descriptions

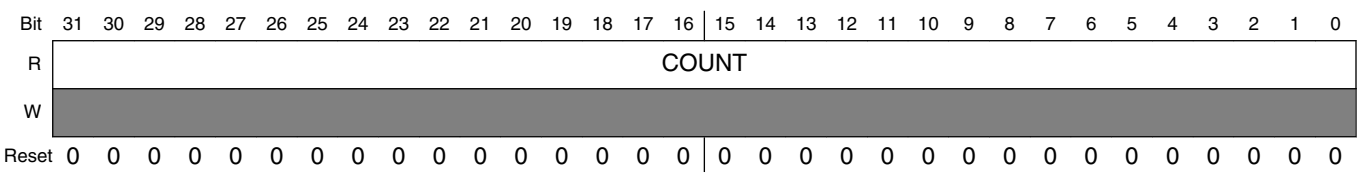
Field	Description
31–0 ADDR	Destination Buffer Address Pointer. This value is the working value and will update as the operation proceeds.

17.3.14 DCP Work Packet 5 Status Register (DCP_PACKET5)

This register displays the values for the current work packet offset 0x14 (Buffer Size) field.

This register shows the contents of the bytecount register from the packet being processed. The field can be considered either a byte count or a buffer size. The logic treats this as a decrmenting count of bytes from the buffer size programmed into the field. As the transaction proceeds, the logic will decrement the bytecount as data is written to the destination buffer. For blit operations, the top 16-bits of this field represents the number of lines (y size) in the blit and the lower 16-bits represent the number of bytes in a line (x size).

Address: DCP_PACKET5 is 0h base + D0h offset = 0000_00D0h



DCP_PACKET5 field descriptions

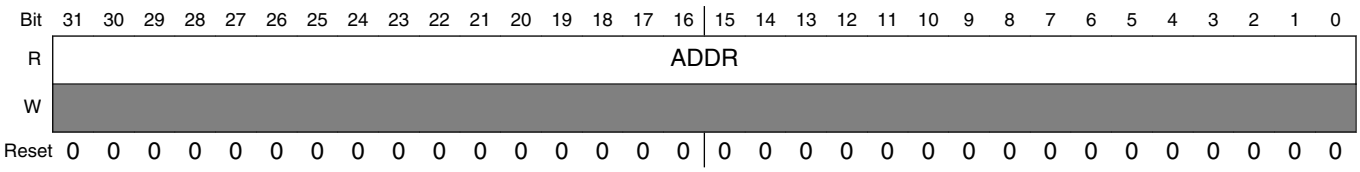
Field	Description
31–0 COUNT	Byte Count register. This value is the working value and will update as the operation proceeds.

17.3.15 DCP Work Packet 6 Status Register (DCP_PACKET6)

This register displays the values for the current work packet offset 0x1C (Payload Pointer) field.

This register shows the contents of the payload pointer fieldr from the packet being processed.

Address: DCP_PACKET6 is 0h base + E0h offset = 0000_00E0h



DCP_PACKET6 field descriptions

Field	Description
31–0 ADDR	This regiser reflects the payload pointer for the current control packet.

17.3.16 DCP Channel 0 Command Pointer Address Register (DCP_CH0CMDPTR)

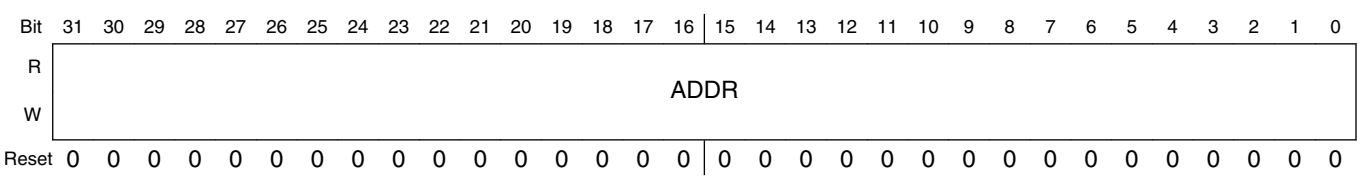
The DCP channel 0 current command address register points to the multiword descriptor that is to be executed (or currently being executed). The channel may be activated by writing the command pointer address to a valid descriptor in memory and then updating the semaphore to a non-zero value. After the engine completes processing of a descriptor, the "next_ptr" field from the descriptor is moved into this register to enable processing of the next descriptor. All channels with a non-zero semaphore value will arbitrate for access to the engine for the subsequent operation.

DCP Channel 0 is controlled by a variable sized command structure. This register points to the command structure to be executed.

EXAMPLE

```
            DCP_CHnCMDPTR_WR(0, v);   // Write channel 0 command pointer
            pCurptr = (DCP_chncmdptr_t *) DCP_CHnCMDPTR_RD(0);  // Read current command
pointer
```

Address: DCP_CH0CMDPTR is 0h base + 100h offset = 0000_0100h



DCP_CH0CMDPTR field descriptions

Field	Description
31–0 ADDR	Pointer to descriptor structure to be processed for channel 0.

17.3.17 DCP Channel 0 Semaphore Register (DCP_CH0SEMA)

The DCP Channel 0 semaphore register is used to synchronize the ARM platform instruction stream and the DMA chain processing state. After a command chain has been generated in memory, software should write the address of the first command descriptor to the CMDPTR register and then write a non-zero value to the semaphore register to indicate that the channel is active. Each command packet has a chaining bit which indicates that another descriptor should be loaded into the channel upon completion of the current descriptor. If the chaining bit is not set, the next address will not be loaded into the CMDPTR register. Each packet also contains a "decrement semaphore" bit, which indicates that the counting semaphore should be decremented after the operation. A channel is considered active when the semaphore is a non-zero value. When programming a series operations, software must properly program the semaphore values in conjuction with the "decrement_semaphore" bits in the control packets to ensure that the proper number of descriptors are activated. A semaphore may be cleared by software by writing 0xFF to the DCP_CHnSEMA_CLR register. The logic will also clear the semaphore if an error has occurred.

Each DCP channel has an 8 bit counting semaphore that is used to synchronize between the program stream and and the DCP chain processing. After processing each control packet, the DCP decrements the semaphore if it is non-zero. The channel will continue processing packets as long as the semaphore contains a non-zero value and the CHAIN or CHAIN_CONTIGOUS control bits in the Control0 field are set.

Address: DCP_CH0SEMA is 0h base + 110h offset = 0000_0110h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	-								VALUE								-								INCREMENT							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DCP_CH0SEMA field descriptions

Field	Description
31–24 -	Reserved, always set to zero.

Table continues on the next page...

DCP_CH0SEMA field descriptions (continued)

Field	Description
23–16 VALUE	This read-only field shows the current (instantaneous) value of the semaphore counter.
15–8 -	Reserved, always set to zero.
7–0 INCREMENT	The value written to this field is added to the semaphore count in an atomic way such that simultaneous software adds and DCP hardware substracts happening on the same clock are protected. This bit field reads back a value of 0x00. Writing a value of 0x02 increments the semaphore count by two, unless the DCP channel decrements the count on the same clock, then the count is incremented by a net one. The semaphore may be cleared by writing 0xFF to the DCP_CHnSEMA_CLR register.

17.3.18 DCP Channel 0 Status Register (DCP_CH0STAT)

The DCP Channel 0 Interrupt Status register contains the interrupt status bit and the tag of the last completed operation from the command chain. If an error occurs during processing, the ERROR bit is set and an interrupt is generated.

DCP_CH0STAT: 0x120

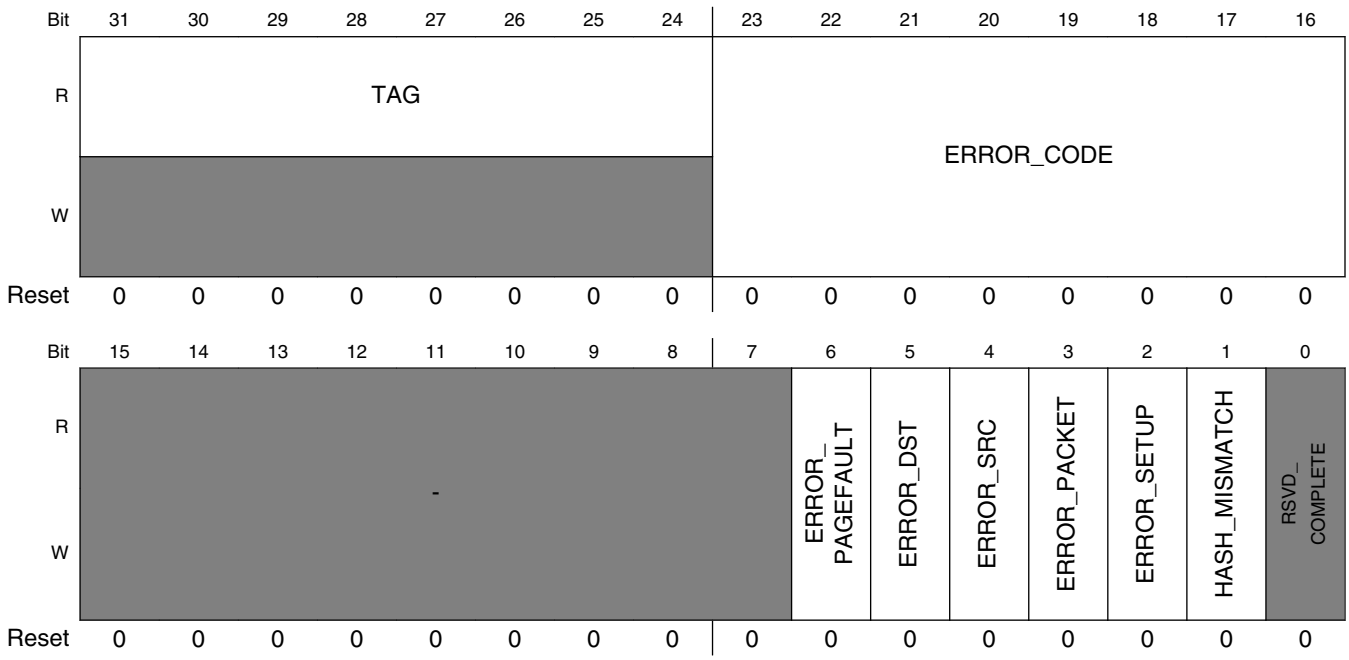
CH0STAT_SET: 0x124

CH0STAT_CLR: 0x128

CH0STAT_TOG: 0x12C

The interrupt status register is updated at the end of each work packet. If the interrupt bit is set in the command packet's command field, an interrupt will be generated once the packet has completed. In addition, the tag value from the command is stored in the TAG field so that software can identify which command structure was the last to complete. If an error occurs, the ERROR bit is set and processing of the command chain is halted.

Address: DCP_CH0STAT is 0h base + 120h offset = 0000_0120h



DCP_CH0STAT field descriptions

Field	Description
31–24 TAG	Indicates the tag from the last completed packet in the command structure
23–16 ERROR_CODE	Indicates additional error codes for some error conditions. 0x01 **NEXT_CHAIN_IS_0** — Error signalled because the next pointer is 0x00000000 0x02 **NO_CHAIN** — Error signalled because the semaphore is nonzero and neither chain bit is set 0x03 **CONTEXT_ERROR** — Error signalled because an error was reported reading/writing the context buffer 0x04 **PAYLOAD_ERROR** — Error signalled because an error was reported reading/writing the payload 0x05 **INVALID_MODE** — Error signalled because the control packet specifies an invalid mode select (for instance, blit + hash)
15–7 -	Reserved, always set to zero.
6 ERROR_ PAGEFAULT	This bit indicates a page fault occurred while converting a virtual address to a physical address.. When an error is detected, the channel's processing will stop until the error handled by software.
5 ERROR_DST	This bit indicates a bus error occurred when storing to the destination buffer. When an error is detected, the channel's processing will stop until the error handled by software.
4 ERROR_SRC	This bit indicates a bus error occurred when reading from the source buffer. When an error is detected, the channel's processing will stop until the error handled by software.
3 ERROR_ PACKET	This bit indicates that a a bus error occurred when reading the packet or payload or when writing status back to the packet payload. When an error is detected, the channel's processing will stop until the error is handled by software.

Table continues on the next page...

DCP_CH0STAT field descriptions (continued)

Field	Description
2 ERROR_SETUP	This bit indicates that the hardware has detected an invalid programming configuration such as a buffer length that is not a multiple of the natural data size for the operation. When an error is detected, the channel's processing will stop until the error is handled by software.
1 HASH_ MISMATCH	The bit indicates that a hashing check operation mismatched for control packets that enable the HASH_CHECK bit. When an error is detected, the channel's processing will stop until the error is handled by software.
0 RSVD_ COMPLETE	This bit will always read 0 in the status register, but will be set to 1 in the packet status field after processing of the packet has completed. This was done so that software can verify that each packet completed properly in a chain of commands for cases when an interrupt is issued only for the last item in a packet. The completion bit for the channel is effectively the channel interrupt status bit.

17.3.19 DCP Channel 0 Options Register (DCP_CH0OPTS)

The DCP Channel 0 Options Status register contains optional control information that may be used to further tune the behavior of the channel.

DCP_CH0OPTS: 0x130

CH0OPTS_SET: 0x134

CH0OPTS_CLR: 0x138

CH0OPTS_TOG: 0x13C

The options register can be used to control optional features of the channels.

Address: DCP_CH0OPTS is 0h base + 130h offset = 0000_0130h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	RSVD																RECOVERY_TIMER															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DCP_CH0OPTS field descriptions

Field	Description
31–16 RSVD	Reserved, always set to zero.
15–0 RECOVERY_ TIMER	This field indicates the recovery time for the channel. After each operation, the recover timer for the channel is initiallized with this value and then decremented until the timer reaches zero. The channel will not initiate another operation for the next packet in the chain until the recovery time has been satisfied. The timebase for the recovery timer is 16 HCLK clock cycles, providing a range of 0ns to 8.3ms at 133 MHz operation.

17.3.20 DCP Channel 1 Command Pointer Address Register (DCP_CH1CMDPTR)

The DCP channel 1 current command address register points to the multiword descriptor that is to be executed (or currently being executed). The channel may be activated by writing the command pointer address to a valid descriptor in memory and then updating the semaphore to a non-zero value. After the engine completes processing of a descriptor, the "next_ptr" field from the descriptor is moved into this register to enable processing of the next descriptor. All channels with a non-zero semaphore value will arbitrate for access to the engine for the subsequent operation.

DCP Channel 1 is controlled by a variable sized command structure. This register points to the command structure to be executed.

EXAMPLE

```
            DCP_CHn_CMDPTR_WR(1, v);   // Write channel 1 command pointer
            pCurptr = (DCP_chn_cmdptr_t *) DCP_CHn_CMDPTR_RD(1);  // Read current command
pointer
```

Address: DCP_CH1CMDPTR is 0h base + 140h offset = 0000_0140h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DCP_CH1CMDPTR field descriptions

Field	Description
31–0 ADDR	Pointer to descriptor structure to be processed for channel 1.

17.3.21 DCP Channel 1 Semaphore Register (DCP_CH1SEMA)

The DCP Channel 1 semaphore register is used to synchronize the ARM platform instruction stream and the DMA chain processing state. After a command chain has been generated in memory, software should write the address of the first command descriptor to the CMDPTR register and then write a non-zero value to the semaphore register to indicate that the channel is active. Each command packet has a chaining bit which indicates that another descriptor should be loaded into the channel upon completion of the current descriptor. If the chaining bit is not set, the next address will not be loaded into the CMDPTR register. Each packet also contains a "decrement semaphore" bit, which indicates that the counting semaphore should be decremented after the operation. A channel is considered active when the semaphore is a non-zero value. When programming a series operations, software must properly program the semaphore values in conjuction with the "decrement_semaphore" bits in the control packets to ensure that the proper number of descriptors are activated. A semaphore may be cleared by software by writing 0xFF to the DCP_CHnSEMA_CLR register. The logic will also clear the semaphore if an error has occurred.

Each DCP channel has an 8 bit counting semaphore that is used to synchronize between the program stream and and the DCP chain processing. DCP processing continues until the engine attempts to decrement a semaphore that has already reached a value of zero. When the attempt is made, the DCP channel is stalled until software increments the semaphore count.

Address: DCP_CH1SEMA is 0h base + 150h offset = 0000_0150h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DCP_CH1SEMA field descriptions

Field	Description
31–24 -	Reserved, always set to zero.
23–16 VALUE	This read-only field shows the current (instantaneous) value of the semaphore counter.
15–8 -	Reserved, always set to zero.
7–0 INCREMENT	The value written to this field is added to the semaphore count in an atomic way such that simultaneous software adds and DCP hardware substracts happening on the same clock are protected. This bit field reads back a value of 0x00. Writing a value of 0x02 increments the semaphore count by two, unless the

Table continues on the next page...

DCP_CH1SEMA field descriptions (continued)

Field	Description
	DCP channel decrements the count on the same clock, then the count is incremented by a net one. The semaphore may be cleared by writing 0xFF to the DCP_CHnSEMA_CLR register.

17.3.22 DCP Channel 1 Status Register (DCP_CH1STAT)

The DCP Channel 1 Interrupt Status register contains the interrupt status bit and the tag of the last completed operation from the command chain. If an error occurs during processing, the ERROR bit is set and an interrupt is generated.

CH1STAT: 0x160

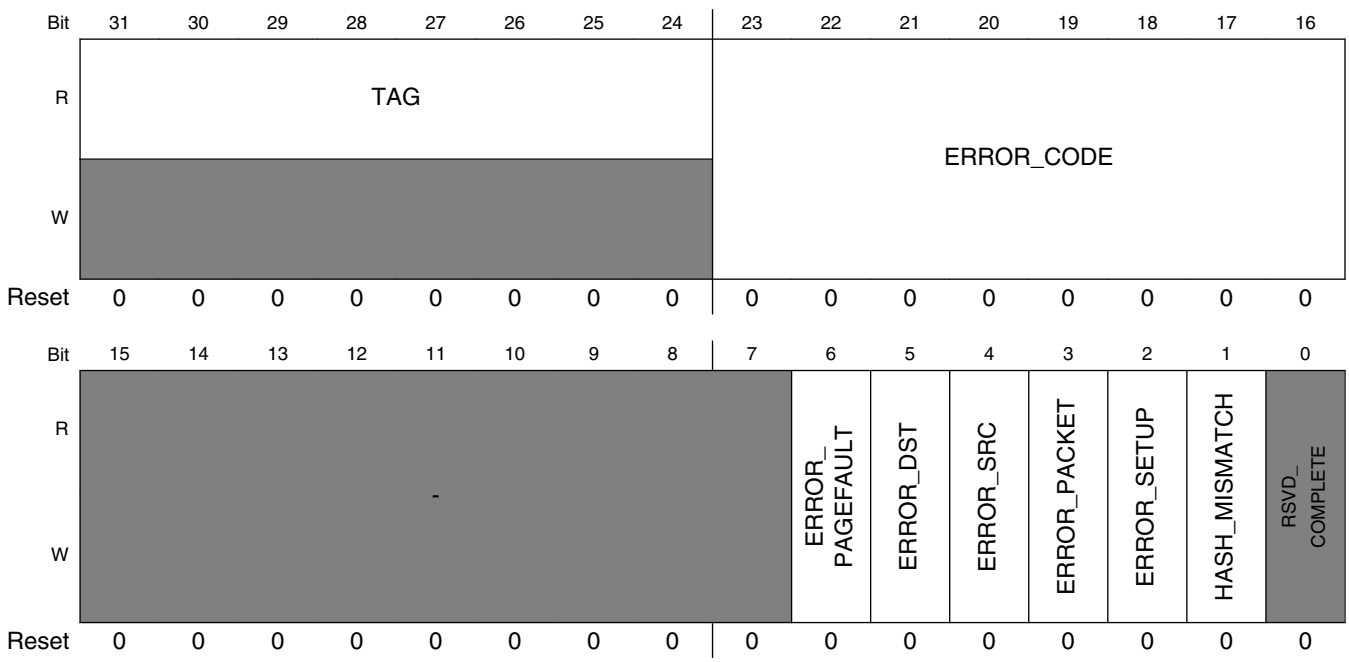
CH1STAT_SET: 0x164

CH1STAT_CLR: 0x168

CH1STAT_TOG: 0x16C

The interrupt status register is updated at the end of each work packet. If the interrupt bit is set in the command packet's command field, an interrupt will be generated once the packet has completed. In addition, the tag value from the command is stored in the TAG field so that software can identify which command structure was the last to complete. If an error occurs, the ERROR bit is set and processing of the command chain is halted.

Address: DCP_CH1STAT is 0h base + 160h offset = 0000_0160h



DCP_CH1STAT field descriptions

Field	Description
31–24 TAG	Indicates the tag from the last completed packet in the command structure
23–16 ERROR_CODE	Indicates additional error codes for some error conditions. 0x01 **NEXT_CHAIN_IS_0** — Error signalled because the next pointer is 0x00000000 0x02 **NO_CHAIN** — Error signalled because the semaphore is nonzero and neither chain bit is set 0x03 **CONTEXT_ERROR** — Error signalled because an error was reported reading/writing the context buffer 0x04 **PAYLOAD_ERROR** — Error signalled because an error was reported reading/writing the payload 0x05 **INVALID_MODE** — Error signalled because the control packet specifies an invalid mode select (for instance, blit + hash)
15–7 -	Reserved, always set to zero.
6 ERROR_ PAGEFAULT	This bit indicates a page fault occurred while converting a virtual address to a physical address.. When an error is detected, the channel's processing will stop until the error handled by software.
5 ERROR_DST	This bit indicates a bus error occurred when storing to the destination buffer. When an error is detected, the channel's processing will stop until the error handled by software.
4 ERROR_SRC	This bit indicates a bus error occurred when reading from the source buffer. When an error is detected, the channel's processing will stop until the error handled by software.
3 ERROR_ PACKET	This bit indicates that a bus error occurs when reading the packet or payload or when writing status back to the packet paylaod. When an error is detected, the channel's processing will stop until the error is handled by software.
2 ERROR_SETUP	This bit indicates that the hardware detected an invalid programming configuration such as a buffer length that is not a multiple of the natural data size for the operation. When an error is detected, the channel's processing will stop until the error is handled by software.
1 HASH_ MISMATCH	The bit indicates that a hashing check operation mismatched for control packets that enable the HASH_CHECK bit. When an error is detected, the channel's processing will stop until the error is handled by software.
0 RSVD_ COMPLETE	This bit will always read 0 in the status register, but will be set to 1 in the packet status field after processing of the packet has completed. This was done so that software can verify that each packet completed properly in a chain of commands for cases when an interrupt is issued only for the last item in a packet. The completion bit for the channel is effectively the channel interrupt status bit.

17.3.23 DCP Channel 1 Options Register (DCP_CH1OPTS)

The DCP Channel 1 Options Status register contains optional control information that may be used to further tune the behavior of the channel.

DCP_CH1OPTS: 0x170

DCP_CH1OPTS_SET: 0x174

CH1OPTS_CLR: 0x178

CH1OPTS_TOG: 0x17C

The options register can be used to control optional features of the channels.

Address: DCP_CH1OPTS is 0h base + 170h offset = 0000_0170h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DCP_CH1OPTS field descriptions

Field	Description
31–16 RSVD	Reserved, always set to zero.
15–0 RECOVERY_ TIMER	This field indicates the recovery time for the channel. After each operation, the recover timer for the channel is initiallized with this value and then decremented until the timer reaches zero. The channel will not initiate operation on the next packet in the chain until the recovery time has been satisfied. The timebase for the recovery timer is 16 HCLK clock cycles, providing a range of 0ns to 8.3ms at 133 MHz operation.

17.3.24 DCP Channel 2 Command Pointer Address Register (DCP_CH2CMDPTR)

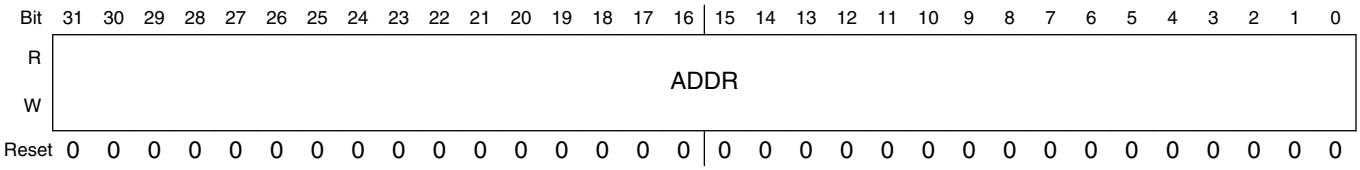
The DCP channel 2 current command address register points to the multiword descriptor that is to be executed (or currently being executed). The channel may be activated by writing the command pointer address to a valid descriptor in memory and then updating the semaphore to a non-zero value. After the engine completes processing of a descriptor, the "next_ptr" field from the descriptor is moved into this register to enable processing of the next descriptor. All channels with a non-zero semaphore value will arbitrate for access to the engine for the subsequent operation.

DCP Channel 2 is controlled by a variable sized command structure. This register points to the command structure to be executed.

EXAMPLE

```
            DCP_CHn_CMDPTR_WR(2, v);   // Write channel 2 command pointer
            pCurptr = (DCP_chn_cmdptr_t *) DCP_CHn_CMDPTR_RD(2);  // Read current command
pointer
```

Address: DCP_CH2CMDPTR is 0h base + 180h offset = 0000_0180h



DCP_CH2CMDPTR field descriptions

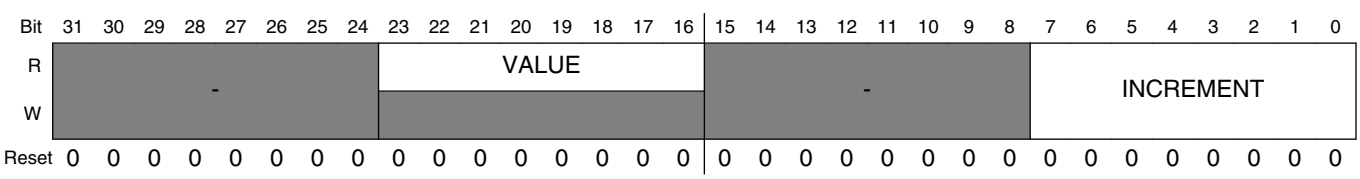
Field	Description
31–0 ADDR	Pointer to descriptor structure to be processed for channel 2.

17.3.25 DCP Channel 2 Semaphore Register (DCP_CH2SEMA)

The DCP Channel 2 semaphore register is used to synchronize the ARM platform instruction stream and the DMA chain processing state. After a command chain has been generated in memory, software should write the address of the first command descriptor to the CMDPTR register and then write a non-zero value to the semaphore register to indicate that the channel is active. Each command packet has a chaining bit which indicates that another descriptor should be loaded into the channel upon completion of the current descriptor. If the chaining bit is not set, the next address will not be loaded into the CMDPTR register. Each packet also contains a "decrement semaphore" bit, which indicates that the counting semaphore should be decremented after the operation. A channel is considered active when the semaphore is a non-zero value. When programming a series operations, software must properly program the semaphore values in conjuction with the "decrement_semaphore" bits in the control packets to ensure that the proper number of descriptors are activated. A semaphore may be cleared by software by writing 0xFF to the DCP_CHnSEMA_CLR register. The logic will also clear the semaphore if an error has occurred.

Each DCP channel has an 8 bit counting semaphore that is used to synchronize between the program stream and and the DCP chain processing. DCP processing continues until the engine attempts to decrement a semaphore that has already reached a value of zero. When the attempt is made, the DCP channel is stalled until software increments the semaphore count.

Address: DCP_CH2SEMA is 0h base + 190h offset = 0000_0190h



DCP_CH2SEMA field descriptions

Field	Description
31–24 -	Reserved, always set to zero.
23–16 VALUE	This read-only field shows the current (instantaneous) value of the semaphore counter.
15–8 -	Reserved, always set to zero.
7–0 INCREMENT	The value written to this field is added to the semaphore count in an atomic way such that simultaneous software adds and DCP hardware substracts happening on the same clock are protected. This bit field reads back a value of 0x00. Writing a value of 0x02 increments the semaphore count by two, unless the DCP channel decrements the count on the same clock, then the count is incremented by a net one. The semaphore may be cleared by writing 0xFF to the DCP_CHnSEMA_CLR register.

17.3.26 DCP Channel 2 Status Register (DCP_CH2STAT)

The DCP Channel 2 Interrupt Status register contains the interrupt status bit and the tag of the last completed operation from the command chain. If an error occurs during processing, the ERROR bit is set and an interrupt is generated.

CH2STAT: 0x1A0

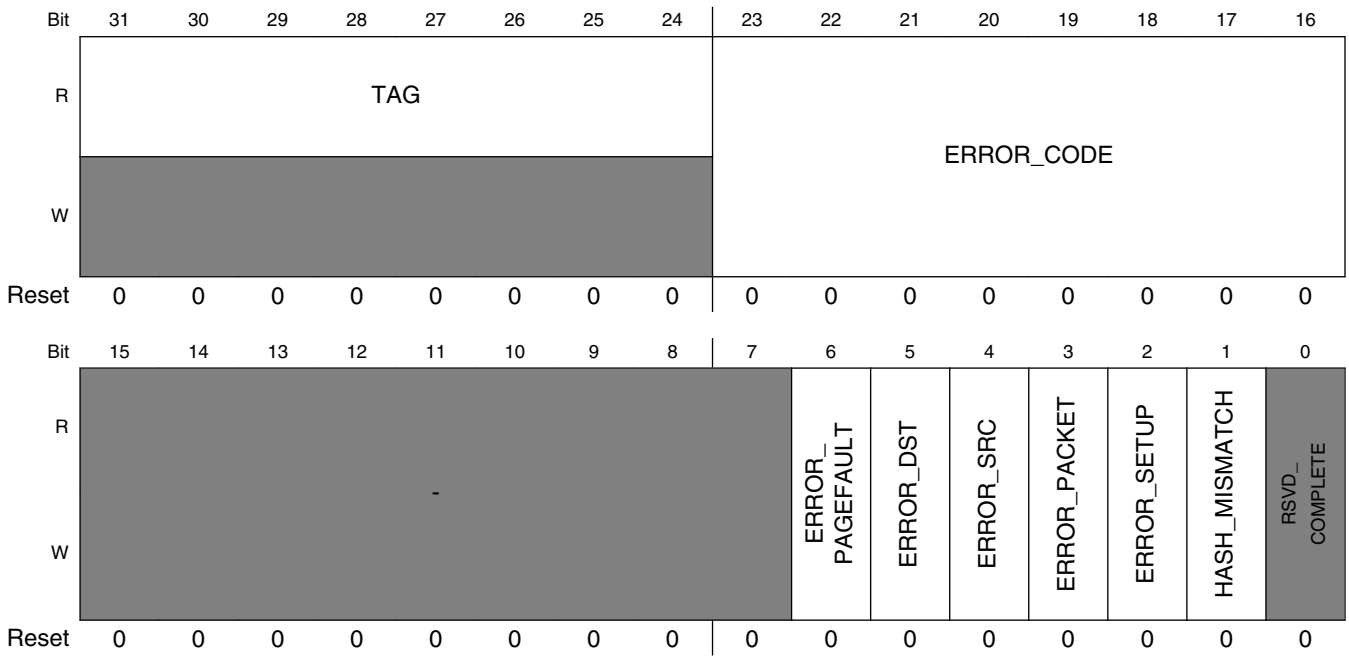
CH2STAT_SET: 0x1A4

CH2STAT_CLR: 0x1A8

CH2STAT_TOG: 0x1AC

The interrupt status register is updated at the end of each work packet. If the interrupt bit is set in the command packet's command field, an interrupt will be generated once the packet has completed. In addition, the tag value from the command is stored in the TAG field so that software can identify which command structure was the last to complete. If an error occurs, the ERROR bit is set and processing of the command chain is halted.

Address: DCP_CH2STAT is 0h base + 1A0h offset = 0000_01A0h



DCP_CH2STAT field descriptions

Field	Description
31–24 TAG	Indicates the tag from the last completed packet in the command structure
23–16 ERROR_CODE	Indicates additional error codes for some error conditions. 0x01 **NEXT_CHAIN_IS_0** — Error signalled because the next pointer is 0x00000000 0x02 **NO_CHAIN** — Error signalled because the semaphore is nonzero and neither chain bit is set 0x03 **CONTEXT_ERROR** — Error signalled because an error was reported reading/writing the context buffer 0x04 **PAYLOAD_ERROR** — Error signalled because an error was reported reading/writing the payload 0x05 **INVALID_MODE** — Error signalled because the control packet specifies an invalid mode select (for instance, blit + hash)
15–7 -	Reserved, always set to zero.
6 ERROR_ PAGEFAULT	This bit indicates a page fault occurred while converting a virtual address to a physical address.. When an error is detected, the channel's processing will stop until the error handled by software.
5 ERROR_DST	This bit indicates a bus error occurred when storing to the destination buffer. When an error is detected, the channel's processing will stop until the error handled by software.
4 ERROR_SRC	This bit indicates a bus error occurred when reading from the source buffer. When an error is detected, the channel's processing will stop until the error handled by software.
3 ERROR_ PACKET	This bit indicates that a bus error occurred when reading the packet or payload or when writing status back to the packet paylaod. When an error is detected, the channel's processing will stop until the error is handled by software.

Table continues on the next page...

DCP_CH2STAT field descriptions (continued)

Field	Description
2 ERROR_SETUP	This bit indicates that the hardware detected an invalid programming configuration such as a buffer length that is not a multiple of the natural data size for the operation. When an error is detected, the channel's processing will stop until the error is handled by software.
1 HASH_ MISMATCH	The bit indicates that a hashing check operation mismatched for control packets that enable the HASH_CHECK bit. When an error is detected, the channel's processing will stop until the error is handled by software.
0 RSVD_ COMPLETE	This bit will always read 0 in the status register, but will be set to 1 in the packet status field after processing of the packet has completed. This was done so that software can verify that each packet completed properly in a chain of commands for cases when an interrupt is issued only for the last item in a packet. The completion bit for the channel is effectively the channel interrupt status bit.

17.3.27 DCP Channel 2 Options Register (DCP_CH2OPTS)

The DCP Channel 2 Options Status register contains optional control information that may be used to further tune the behavior of the channel.

CH2OPTS: 0x1B0

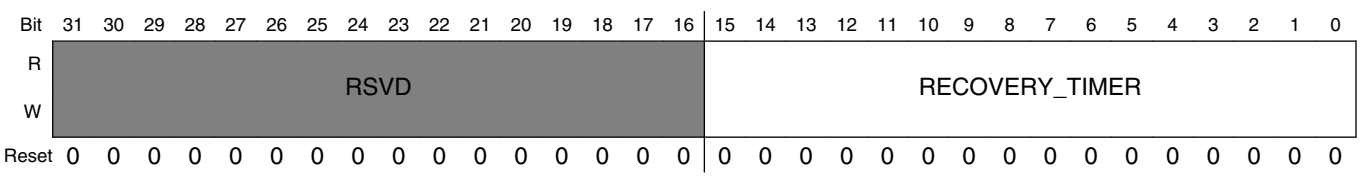
CH2OPTS_SET: 0x1B4

CH2OPTS_CLR: 0x1B8

CH2OPTS_TOG: 0x1BC

The options register can be used to control optional features of the channels.

Address: DCP_CH2OPTS is 0h base + 1B0h offset = 0000_01B0h



DCP_CH2OPTS field descriptions

Field	Description
31–16 RSVD	Reserved, always set to zero.
15–0 RECOVERY_ TIMER	This field indicates the recovery time for the channel. After each operation, the recover timer for the channel is initiallized with this value and then decremented until the timer reaches zero. The channel will not initiate operation on the next packet in the chain until the recovery time has been satisfied. The timebase for the recovery timer is 16 HCLK clock cycles, providing a range of 0ns to 8.3ms at 133 MHz operation.

17.3.28 DCP Channel 3 Command Pointer Address Register (DCP_CH3CMDPTR)

The DCP channel 3 current command address register points to the multiword descriptor that is to be executed (or currently being executed). The channel may be activated by writing the command pointer address to a valid descriptor in memory and then updating the semaphore to a non-zero value. After the engine completes processing of a descriptor, the "next_ptr" field from the descriptor is moved into this register to enable processing of the next descriptor. All channels with a non-zero semaphore value will arbitrate for access to the engine for the subsequent operation.

DCP Channel 3 is controlled by a variable sized command structure. This register points to the command structure to be executed.

EXAMPLE

```
            DCP_CHn_CMDPTR_WR(3, v);   // Write channel 3 command pointer
            pCurptr = (DCP_chn_cmdptr_t *) DCP_CHn_CMDPTR_RD(3);  // Read current command
pointer
```

Address: DCP_CH3CMDPTR is 0h base + 1C0h offset = 0000_01C0h

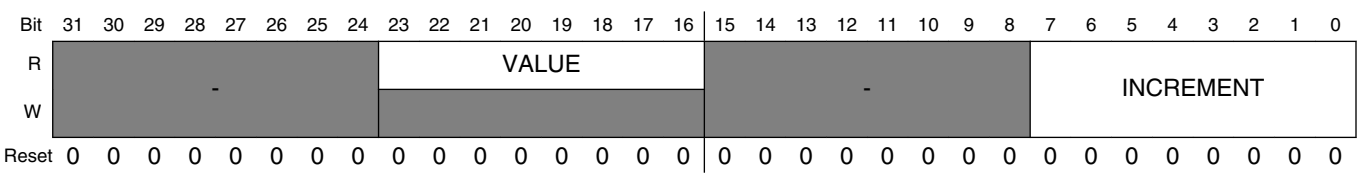
Field	Description
31–0 ADDR	Pointer to descriptor structure to be processed for channel 3.

17.3.29 DCP Channel 3 Semaphore Register (DCP_CH3SEMA)

The DCP Channel 3 semaphore register is used to synchronize the ARM platform instruction stream and the DMA chain processing state. After a command chain has been generated in memory, software should write the address of the first command descriptor to the CMDPTR register and then write a non-zero value to the semaphore register to indicate that the channel is active. Each command packet has a chaining bit which indicates that another descriptor should be loaded into the channel upon completion of the current descriptor. If the chaining bit is not set, the next address will not be loaded into the CMDPTR register. Each packet also contains a "decrement semaphore" bit, which indicates that the counting semaphore should be decremented after the operation. A channel is considered active when the semaphore is a non-zero value. When programming a series operations, software must properly program the semaphore values in conjuction with the "decrement_semaphore" bits in the control packets to ensure that the proper number of descriptors are activated. A semaphore may be cleared by software by writing 0xFF to the DCP_CHnSEMA_CLR register. The logic will also clear the semaphore if an error has occurred.

Each DCP channel has an 8 bit counting semaphore that is used to synchronize between the program stream and and the DCP chain processing. DCP processing continues until the engine attempts to decrement a semaphore that has already reached a value of zero. When the attempt is made, the DCP channel is stalled until software increments the semaphore count.

Address: DCP_CH3SEMA is 0h base + 1D0h offset = 0000_01D0h



DCP_CH3SEMA field descriptions

Field	Description
31–24 -	Reserved, always set to zero.
23–16 VALUE	This read-only field shows the current (instantaneous) value of the semaphore counter.
15–8 -	Reserved, always set to zero.
7–0 INCREMENT	The value written to this field is added to the semaphore count in an atomic way such that simultaneous software adds and DCP hardware substracts happening on the same clock are protected. This bit field reads back a value of 0x00. Writing a value of 0x02 increments the semaphore count by two, unless the

Table continues on the next page...

DCP_CH3SEMA field descriptions (continued)

Field	Description
	DCP channel decrements the count on the same clock, then the count is incremented by a net one. The semaphore may be cleared by writing 0xFF to the DCP_CHnSEMA_CLR register.

17.3.30 DCP Channel 3 Status Register (DCP_CH3STAT)

The DCP Channel 3 Interrupt Status register contains the interrupt status bit and the tag of the last completed operation from the command chain. If an error occurs during processing, the ERROR bit is set and an interrupt is generated.

DCP_CH3STAT: 0x1E0

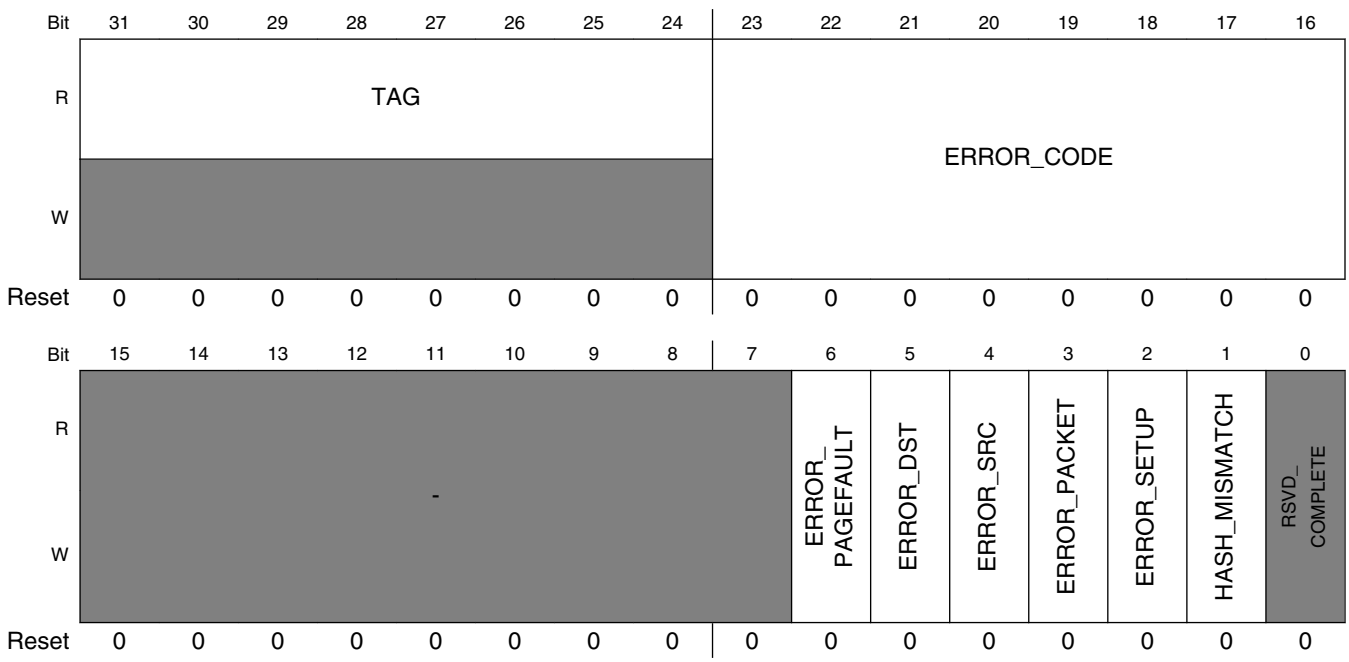
CH3STAT_SET: 0x1E4

CH3STAT_CLR: 0x1E8

CH3STAT_TOG: 0x1EC

The interrupt status register is updated at the end of each work packet. If the interrupt bit is set in the command packet's command field, an interrupt will be generated once the packet has completed. In addition, the tag value from the command is stored in the TAG field so that software can identify which command structure was the last to complete. If an error occurs, the ERROR bit is set and processing of the command chain is halted.

Address: DCP_CH3STAT is 0h base + 1E0h offset = 0000_01E0h



DCP_CH3STAT field descriptions

Field	Description
31–24 TAG	Indicates the tag from the last completed packet in the command structure
23–16 ERROR_CODE	Indicates additional error codes for some error conditions. 0x01 **NEXT_CHAIN_IS_0** — Error signalled because the next pointer is 0x00000000 0x02 **NO_CHAIN** — Error signalled because the semaphore is nonzero and neither chain bit is set 0x03 **CONTEXT_ERROR** — Error signalled because an error was reported reading/writing the context buffer 0x04 **PAYLOAD_ERROR** — Error signalled because an error was reported reading/writing the payload 0x05 **INVALID_MODE** — Error signalled because the control packet specifies an invalid mode select (for instance, blit + hash)
15–7 -	Reserved, always set to zero.
6 ERROR_ PAGEFAULT	This bit indicates a page fault occurred while converting a virtual address to a physical address.. When an error is detected, the channel's processing will stop until the error handled by software.
5 ERROR_DST	This bit indicates a bus error occurred when storing to the destination buffer. When an error is detected, the channel's processing will stop until the error handled by software.
4 ERROR_SRC	This bit indicates a bus error occurred when reading from the source buffer. When an error is detected, the channel's processing will stop until the error handled by software.
3 ERROR_ PACKET	This bit indicates that a bus error occurred when reading the packet or payload or when writing status back to the packet paylaod. When an error is detected, the channel's processing will stop until the error is handled by software.
2 ERROR_SETUP	This bit indicates that the hardware detected an invalid programming configuration such as a buffer length that is not a multiple of the natural data size for the operation. When an error is detected, the channel's processing will stop until the error is handled by software.
1 HASH_ MISMATCH	The bit indicates that a hashing check operation mismatched for control packets that enable the HASH_CHECK bit. When an error is detected, the channel's processing will stop until the error is handled by software.
0 RSVD_ COMPLETE	This bit will always read 0 in the status register, but will be set to 1 in the packet status field after processing of the packet has completed. This was done so that software can verify that each packet completed properly in a chain of commands for cases when an interrupt is issued only for the last item in a packet. The completion bit for the channel is effectively the channel interrupt status bit.

17.3.31 DCP Channel 3 Options Register (DCP_CH3OPTS)

The DCP Channel 3 Options Status register contains optional control information that may be used to further tune the behavior of the channel.

DCP_CH3OPTS: 0x1F0

CH3OPTS_SET: 0x1F4

CH3OPTS_CLR: 0x1F8

CH3OPTS_TOG: 0x1FC

The options register can be used to control optional features of the channels.

Address: DCP_CH3OPTS is 0h base + 1F0h offset = 0000_01F0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DCP_DBGSELECT field descriptions

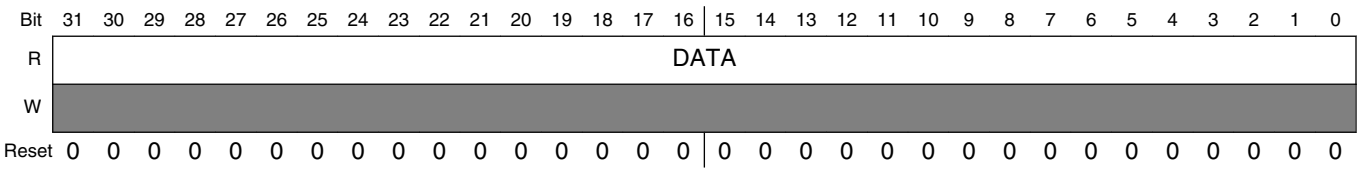
Field	Description
31–8 RSVD	Reserved, always set to zero.
7–0 INDEX	Selects a value to read via the debug data register. 0x01 **CONTROL** — 0x10 **OTPKEY0** — 0x11 **OTPKEY1** — 0x12 **OTPKEY2** — 0x13 **OTPKEY3** —

17.3.33 DCP Debug Data Register (DCP_DBGDATA)

Reading this register returns the debug data value from the selected index.

This register returns the debug data from the selected debug index source.

Address: DCP_DBGDATA is 0h base + 410h offset = 0000_0410h



DCP_DBGDATA field descriptions

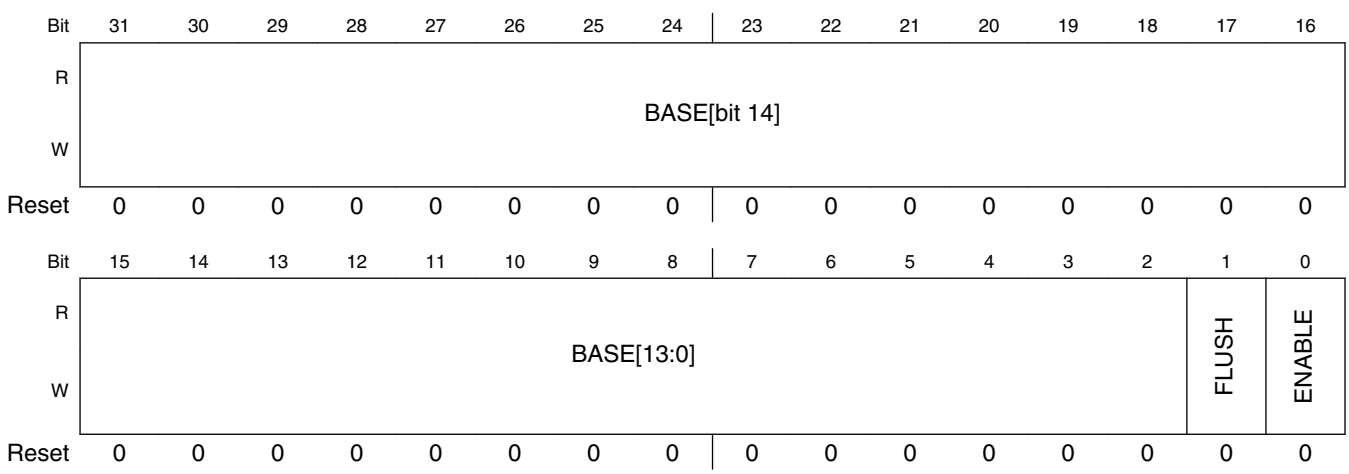
Field	Description
31–0 DATA	Debug Data

17.3.34 DCP Page Table Register (DCP_PAGETABLE)

The DCP Page Table register controls the virtual memory functionality of the DCP. It provides a base address for the page table as well as an enable/disable bit and the ability to flush the cached page table entries.

This register returns the debug data from the selected debug index source.

Address: DCP_PAGETABLE is 0h base + 420h offset = 0000_0420h



DCP_PAGETABLE field descriptions

Field	Description
31–2 BASE	Page Table Base Address. The page table must be word aligned and the pointer should reference a page table in the standard ARM format.
1 FLUSH	Page Table Flush control. To flush the TLB, write this bit to a 1 then back to a 0.
0 ENABLE	Page Table Enable control. Virtual addressing will only be used when this bit is set to a 1. Disabling the page table will not flush any cached entries, so software should write the FLUSH high and enable LOW when updating page tables.

17.3.35 DCP Version Register (DCP_VERSION)

Read-only register indicating implemented version of the DCP.

This register returns the debug data from the selected debug index source.

Address: DCP_VERSION is 0h base + 430h offset = 0000_0430h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

DCP_VERSION field descriptions

Field	Description
31–24 MAJOR	Fixed read-onlyl value reflecting the MAJOR version of the design implementation.
23–16 MINOR	Fixed read-onlyl value reflecting the MINOR version of the design implementation.
15–0 STEP	Fixed read-onlyl value reflecting the stepping of version of the design implementation.

Chapter 18
Digital Control (DIGCTL) and On-Chip RAM

18.1 Overview

The digital control block provides miscellaneous control within the top digital block of the chip, including:

- Specifies which version of the eSDHC block should be used. In i.MX50, use the default selected eSDHCv3 version.
- Read/Write delay control for On-Chip RAM
- Speed Sensor functionality control and status.

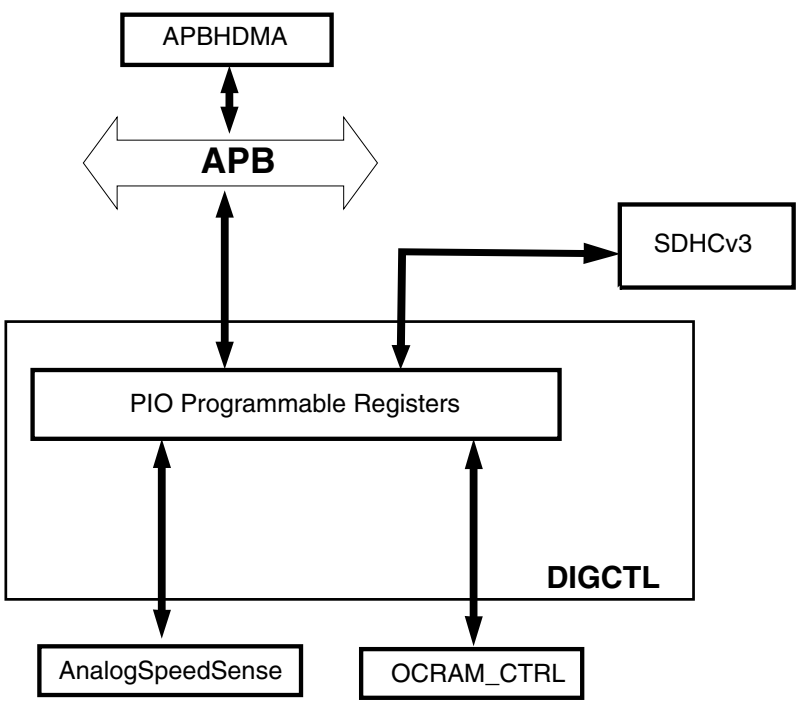

Figure 18-1. Block Diagram

18.2 eSDHC Version control

The ESDHC_VERSION bit of the DIGCTL_CTL register switches between two onboard versions of the SD/SDIO/MMC memory card interface controller, namely eSDHCv3 and uSDHC. By default v3 is set. This bit should only be set when the SDHC controller is idle.

18.3 OCRAM Pipeline Controls

The on-chip 128 Kbyte RAM is comprised of four physical banks of 16 K x 64-bit each. The bits in the DIGCTL_OCRAM register can be used to effect the pipeline delay for reading and writing this memory. These delays can be used to avoid memory timing violations when the OCRAM clock is programmed at high frequencies. Setting the *_EN bits will add 1 cycle of delay to the address or data phases of each read or write transaction to the memory. The corresponding status (STAT) bits indicate whether it is safe to change a delay bit. The enable bit should only be changed when its corresponding status bit is polled as not busy. Please refer to chapter entitled "On-Chip RAM" for a more detailed functional description.

18.4 Speed Sensor Controls

The SoC integrates three silicon speed sensors to measure the performance characteristics of an individual die at its ambient temperature and process parametrics. They each consist of a ring oscillator and a frequency counter. The frequency tracks the silicon performance as it changes in response to changes in operating voltage and temperature. The crystal oscillator is directly used as the precision time base for measuring the frequency of a ring oscillator. The ring oscillator is normally disabled. There is a 32-bit counter connected to each of the ring oscillators that performs the frequency measurement.

Thus, the counter holds the number of cycles the ring oscillator was able to generate during one crystal clock period. The natural frequency of the ring oscillator strongly tracks the silicon process parametrics, i.e., faster silicon processes yield ring oscillators that run faster and thereby yield larger count values. The natural frequency tracks junction temperature effects on silicon speed as well.

The information given by the speed sensor can be used with the silicon temperature and process parameters, which can also be monitored by system software. Freescale can provide a power management application note and firmware that takes full advantage of the on-chip monitoring functions to enable minimum-voltage operation.

To take a speed sensor measurement, first the DIGCTL_SPEEDCTL[SELECT] should be set to a value of either 0, 1 or 2 to select the desired sensor. Then the DIGCTL_SPEEDCTL[CTRL] field should be written three times writng it with the sequence of 00b, 01b and 11b. At this point the DIGCTL_SPEEDSTAT[STATUS] field can be read and will contain the speed sensor count value. This value is only valid when the DIGCTL_SPEEDCTL[CTRL] = 11b. For repeated sensor measurements, the sequence of 00b-01b-11b must be rewritten to the DIGCTL_SPEEDCTL [CTRL] field. For proper measurement, the back-to-back writes to the DIGCTL_SPEEDCTL register should not proceed faster than a frequency of 1.5 MHz.

18.5 Programmable Registers

i.MX50 DIGCTL Register Format Summary

DIGCTL memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page

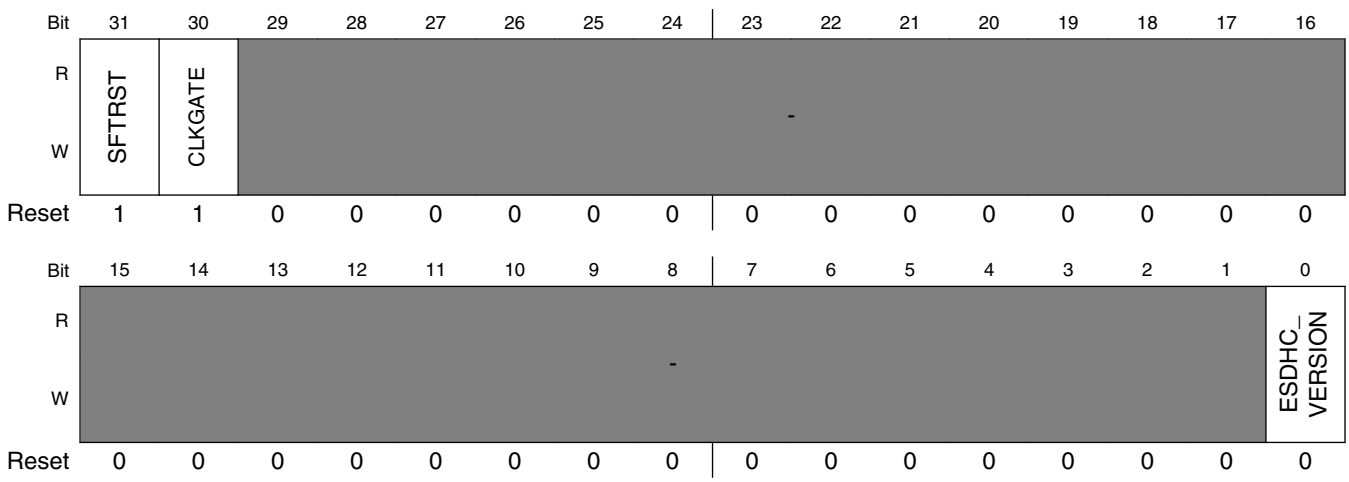
18.5.1 DIGCTL Control Register (DIGCTL_CTRL*n*)

The DIGCTL Control Register provides overall control of various functions throughout the digital portion of the chip. This register controls various functions throughout the digital portion of the chip.

Addresses: DIGCTL_CTRL is 4100_4000h base + 0h offset = 4100_4000h
DIGCTL_CTRL_SET is 4100_4000h base + 4h offset = 4100_4004h
DIGCTL_CTRL_CLR is 4100_4000h base + 8h offset = 4100_4008h
DIGCTL_CTRL_TOG is 4100_4000h base + Ch offset = 4100_400Ch



DIGCTL_CTRL*n* field descriptions

Field	Description
31 SFTRST	Set this bit to zero to enable normal DIGCTL operation. Set this bit to one (default) to disable clocking with the DIGCTL and hold it in its reset (lowest power) state. This bit can be turned on and then off to reset the DIGCTL block to its default state.
30 CLKGATE	This bit must be set to zero for normal operation. When set to one it gates off the clocks to the block.

Table continues on the next page...

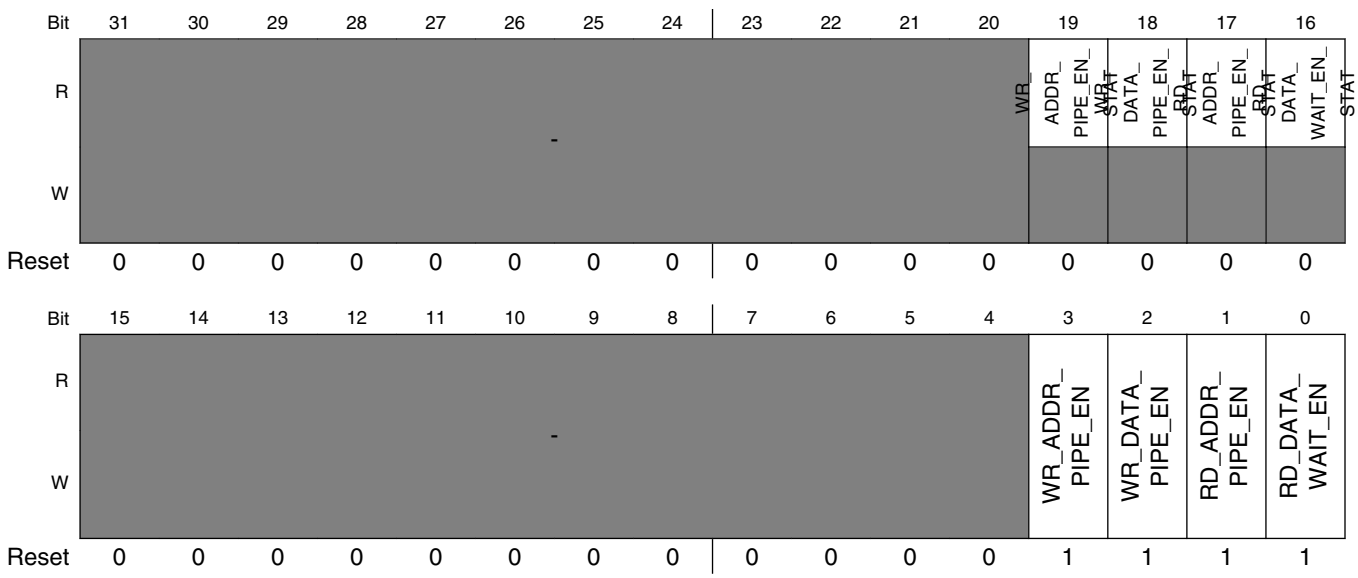
DIGCTL_CTRL*n* field descriptions (continued)

Field	Description
29–1 -	Reserved.
0 ESDHC_ VERSION	Specifies which version of the eSDHC block to use. This setting will enable the selected version's functionality and register access. 0x0 Use ESDHCv3 0x1 Use uSDHC

18.5.2 DIGCTL OCRAM Register (DIGCTL_OCRAM*n*)

The DIGCTL OCRAM Register contains control bits and reports read-only status for the OCRAM control block.

Addresses: DIGCTL_OCRAM is 4100_4000h base + 10h offset = 4100_4010h
DIGCTL_OCRAM_SET is 4100_4000h base + 14h offset = 4100_4014h
DIGCTL_OCRAM_CLR is 4100_4000h base + 18h offset = 4100_4018h
DIGCTL_OCRAM_TOG is 4100_4000h base + 1Ch offset = 4100_401Ch



DIGCTL_OCRAM*n* field descriptions

Field	Description
31–20 -	Reserved.
19 WR_ADDR_ PIPE_EN_STAT	Configuration status of OCRAM timing parameter: Write Address Pipeline Enable Status 0x0 NOT_BUSY 0x1 BUSY

Table continues on the next page...

DIGCTL_OCRAM*n* field descriptions (continued)

Field	Description
18 WR_DATA_ PIPE_EN_STAT	Configuration status of OCRAM timing parameter: Write Data Pipeline Enable Status 0x0 NOT_BUSY 0x1 BUSY
17 RD_ADDR_ PIPE_EN_STAT	Configuration status of OCRAM timing parameter: Read Address Pipeline Enable Status 0x0 NOT_BUSY 0x1 BUSY
16 RD_DATA_ WAIT_EN_STAT	Configuration status of OCRAM timing parameter: Read Data Wait Enable Status 0x0 NOT_BUSY 0x1 BUSY
15–4 -	Reserved.
3 WR_ADDR_ PIPE_EN	OCRAM timing parameter: Write Address Pipeline Enable 0x0 DISABLE 0x1 ENABLE
2 WR_DATA_ PIPE_EN	OCRAM timing parameter: Write Data Pipeline Enable 0x0 DISABLE 0x1 ENABLE
1 RD_ADDR_ PIPE_EN	OCRAM timing parameter: Read Address Pipeline Enable 0x0 DISABLE 0x1 ENABLE
0 RD_DATA_ WAIT_EN	OCRAM timing parameter: Read Data Wait Enable 0x0 DISABLE 0x1 ENABLE

18.5.3 Transistor Speed Control Register (DIGCTL_SPEEDCTL*n*)

This register contains the setup and controls needed to measure silicon speed.

Addresses: DIGCTL_SPEEDCTL is 4100_4000h base + 20h offset = 4100_4020h
DIGCTL_SPEEDCTL_SET is 4100_4000h base + 24h offset = 4100_4024h
DIGCTL_SPEEDCTL_CLR is 4100_4000h base + 28h offset = 4100_4028h
DIGCTL_SPEEDCTL_TOG is 4100_4000h base + 2Ch offset = 4100_402Ch

DIGCTL_DIGCTL_SPEEDSTAT field descriptions

Field	Description
31–0 STATUS	Result from the speed sensor. This result is only valid when SPEEDCTRL=0b11; otherwise this field contains debug information from the switching DC-DC converter.

Chapter 19
DPLL Controller (DPLLC)

19.1 Overview

The Digital Phase-Locked Loop Control (DPLLC) is the control interface to a DPLL. It generates the control signals required for the DPLL operations.

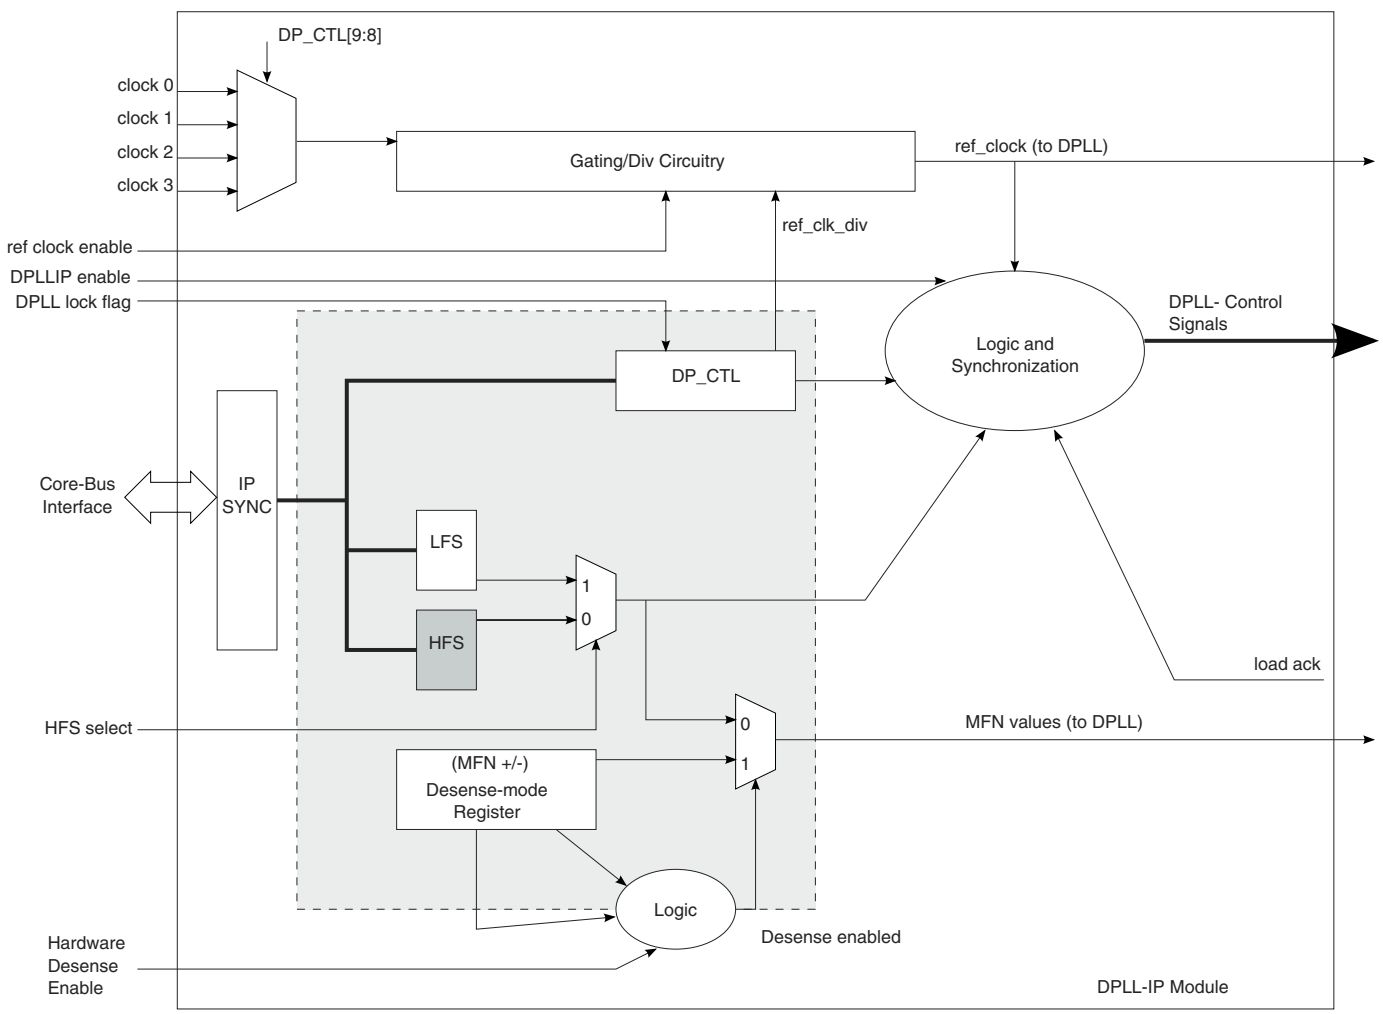

Figure 19-1. Block Diagram of the DPLLC

19.1.1 Feature Description

Key features of this module include:

- Controls the operation of DPLLs.
- Provides controlled phase modulation of clocks to reduce receiver desensitization using desense circuit for DPLLs.
- If auto restart is enabled (AREN bit of the DPLL Config Register is '1'), a restart sequence is issued automatically whenever one of the DPLL registers (DPLLC_DP_CTL, DP_OP, DPLLC_DP_MFD or DPLLC_DP_HFS_OP, DP_HFS_MFD) is written. Otherwise, software needs to set the restart bit of DPLL Control Register manually.

19.1.2 Modes and Operation

The DPLLC supports the following modes of operation:

- Normal Mode
- DPLL Desense Mode
- DVFS Support: HFS Mode

Refer to Operations for DPLLC operations.

19.2 Functional Description

The DPLLC module is mainly divided in the following blocks as shown in Figure 19-1.

- Register read/write: Core bus reads and writes the registers of the module.
- Reference clock selection circuitry: This circuitry comprises of clock selection mux, gating circuit and divide by 2 logic. The reference clock is selected from one of the four external input clocks based on register configuration. This reference clock goes to DPLL. See Figure 19-2 for more details.
- DPLL restart logic and synchronization of data: Based on input signal, registers corresponding to low frequency or high frequency modes are selected. Data goes to the DPLL port, is synchronized on the reference clock.
- Desense mode logic: Desense mode is enabled based on DPLLC configuration. The output to DPLL toggles between predefined values (configured in DPLLC registers)

which determines the DPLL reference clock frequency. See DPLL Desense Mode for mode details.

- Desense mode logic: Desense mode is enabled based on DPLLC configuration. The output to DPLL toggles between predefined values (configured in DPLLC registers) which determines the DPLL reference clock frequency. See DPLL Desense Mode for mode details.

19.2.1 Operating Modes

19.2.1.1 Normal Mode

In DPLLC normal mode out of the four external input clocks, one is selected depending upon DPLLC register configuration. This is followed by a divider circuitry and then by a gating circuitry as shown below. If reference clock enable signal is HIGH, the clock is passed, else it is gated to a value'1'. Refer to Figure 19-2 for details.

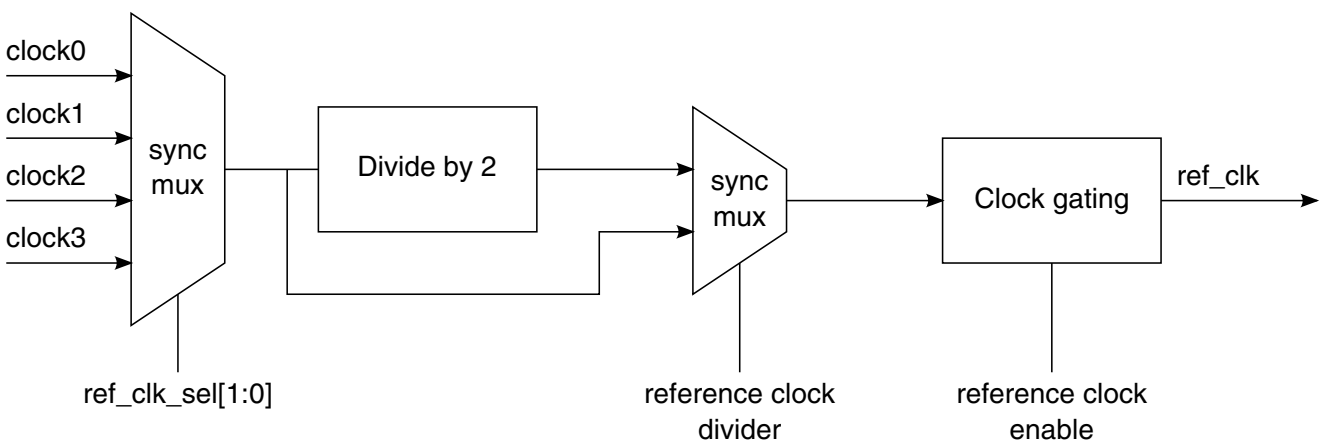

Figure 19-2. Clock MUXing and Gating/Divider Circuitry

19.2.1.2 DPLL Desense Mode

Radiation of clock harmonics causes receiver desensitization. Controlled phase modulation of the clocks coming out of the DPLL will reduce this desensitization. The desense circuit when enabled provides a MFN value that toggles between two programmed MFN_PLUS and MFN_MINUS values for a programmed toggle frequency. This will help achieve the phase modulation of the DPLL clocks.

The disable bit in the DPLLC_DP_MFN_TOGC register should be clear in order to enable the desense logic. Once the disable bit is cleared, desense can be enabled by programming the TOG_EN bit of the DPLLC_DP_MFN_TOGC register for the corresponding PLL. (The desense logic can be activated either by writing to TOG_EN, or by asserting hardware desense enable signal).

Once desense is enabled, the DPLLC module provides the DPLL with a MFN value that switches between MFN_PLUS and MFN_MINUS for n number of correct reference clock cycles. MFN_PLUS and MFN_MINUS are programmed by writing to DPLLC_DP_MFNPLUS and DPLLC_DP_MFNMINUS registers. TOG_CNT (Bits [15:0] of the DPLLC_DP_MFN_TOGC register) determines the toggle rate n. The ref_pll receives a MFN value equal to MFN_PLUS for the first n/2 cycles and MFN_MINUS value for the remaining n/2 cycles.

In the middle of the dither sequence, if the desense mode is disabled through toggle enable (disable) bit or desense hardware request, the circuit completes the ongoing MFN_PLUS, MFN_MINUS cycle before exiting the desense mode. PLL runs on normal MFN after the completion of desense mode. If desense disables and enables again in the middle of the sequence, toggle counter will not stop the current cycle. Only even values for the counter are allowed. If the counter is programmed to an odd value, the counter value will default to a value one less from the odd value.

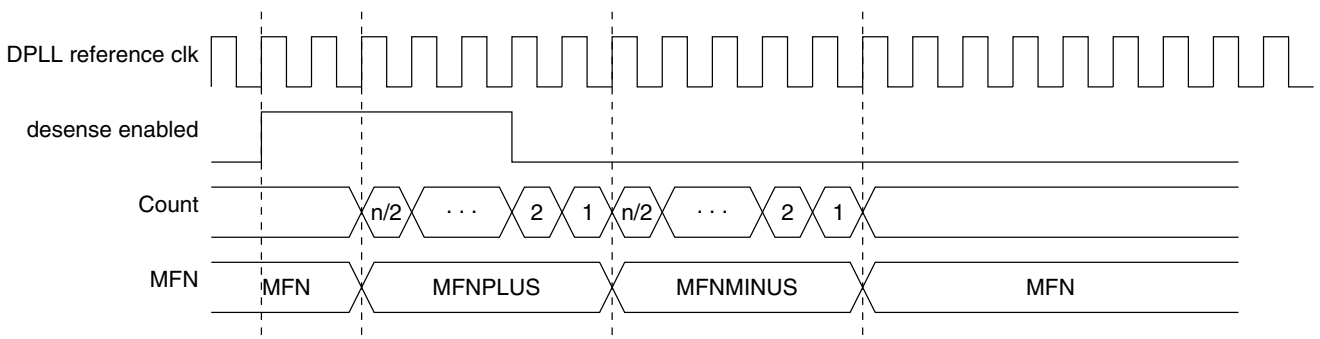

Figure 19-3. Desense Mode MFN Timing

When in desense mode, the DPLLC generates an automatic load request to the PLL whenever the MFN value changes. This signal stays asserted till the load acknowledge signal from the PLL is received. The load request asserts for a minimum of 3 reference clock cycles. Hence for a counter value of 6, where the MFN value toggles between MFN_PLUS and MFN_MINUS every 3 reference clock cycles, the load request may not reflect the updated MFN value and therefore, there is a possibility that the new MFN values are not loaded. Hence it is recommended that the counter be programmed for value greater than 8.

It is required that the toggle counter values not change after the toggle enable is asserted. If toggle counter value changes, the functioning of the desense circuit may be unpredictable.

When any of the 3 MFN values, that is, MFN_PLUS, MFN_MINUS, or MFN values change after the desense mode is enabled, they are buffered till the desense mode is disabled. Therefore to update the MFN_PLUS and MFN_MINUS from the next sequence, desense must be disabled and enabled again.

The desense status register DPLLC Desense Status Register (DPLLC_DESTAT) shows the status of the toggle_enable and the MFN value sent to the DPLL.

19.2.1.3 DVFS Support: HFS Mode

DPLL supports DVFS settings through an alternate set of registers which can be used to store high frequency settings corresponding to high voltage. This alternate set of HFS registers is used to restart the PLL with high frequency settings stored in HFS registers whenever system detects a voltage change from low to high level. Following diagram describes this configuration.

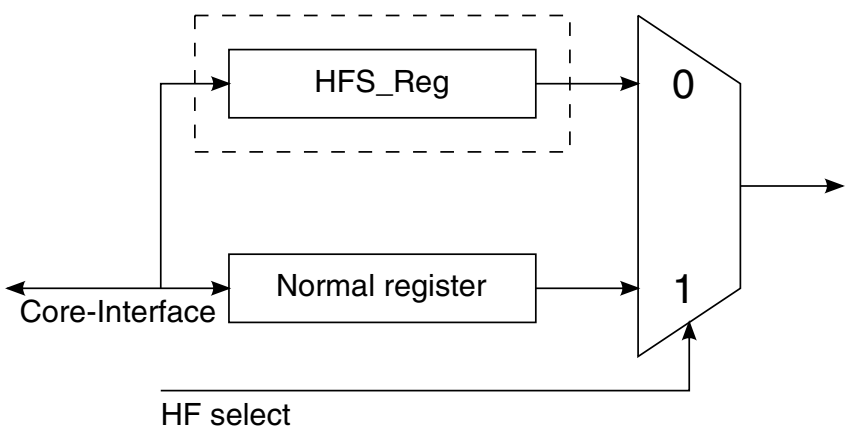

Figure 19-4. DVFS Support for High Frequency Settings

19.2.2 Operations

19.2.2.1 DPLLC_DP_CTL, DPLLC_DP_OP, DPLLC_DP_MFD Register Update

The DPLLs require special timing considerations when updating their ports. Whenever one of the DPLL control register DPLLC_DP_CTL, DPLLC_DP_OP, or DPLLC_DP_MFD, or the shadow registers DPLLC_DP_HFS_OP or DPLLC_DP_HFS_MFD is written (even if the bits don't change), a restart is issued to the DPLL before the actual control bits are sent to the DPLL. The restart assertion and port update will be synchronous to the reference input clock of the DPLL. Writing to any of these registers will cause following procedure to come into effect.

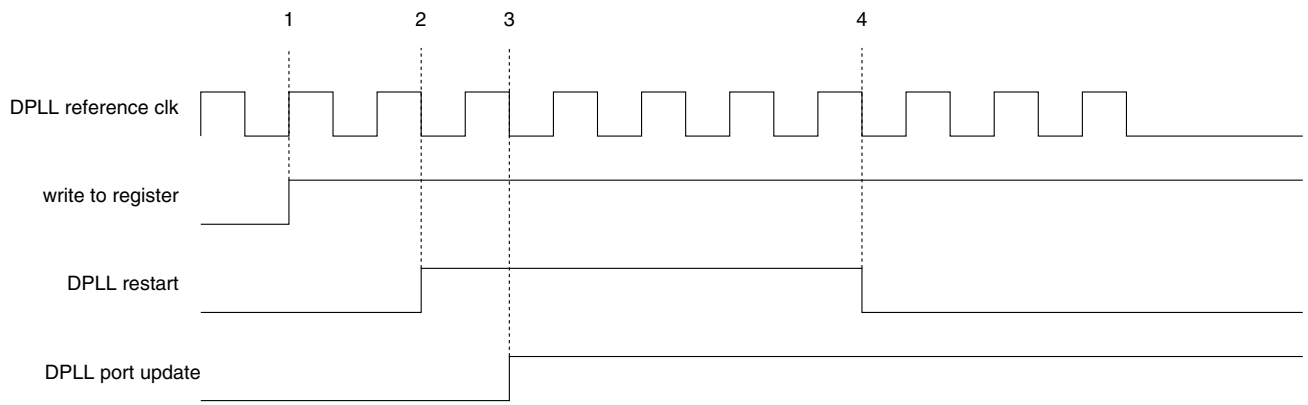

Figure 19-5. DPLL Port Timings

1. Register is written.
2. One clock cycle later restart is asserted.
3. One clock cycle later the appropriate port is updated.
4. Four clock cycles later restart is released.

NOTE

Setting the RST bit of DPLL Control Register will cause the restart (crstrt) signal to assert immediately. In case AREN bit of DPLL Config Register is LOW, the programmer will have to take care of restart of DPLL by setting the RST bit of DPLL Control Register appropriately.

19.2.2.2 DP_MFN Register Update

The MFN bits of DP_MFN register are the only bits in the DPLL that can be changed after the DPLL has been locked without a restart. As shown in diagram below, after writing a new value to MFN, the procedure to update the DPLL is as follows:

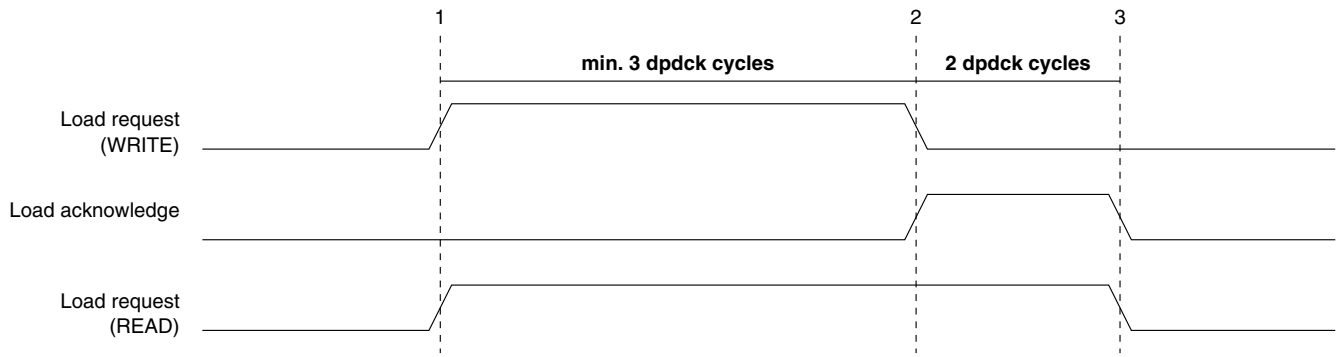

Figure 19-6. MFN Load Request Timings

1. The control bit LDREQ in DP_CONFIG is set. This sends a load request signal to the DPLL.
2. When the DPLL loads the new MFN, it sends a load acknowledge signal back to the DPLL-IP module and clears the write value of load request. At this point load request becomes a status bit, reflecting the state of the acknowledge signal.

NOTE

This write value of load request is a "sticky" bit. When set, it will remain at '1' until a load acknowledgement pulse is received.

3. The read value of load request is automatically cleared when the DPLL has completed updating MFN and has removed the load acknowledge signal, allowing the next load request to take place.

19.2.2.3 Multiple Options for DPLL Control

The DPLLC module provides multiple options for controlling the ON/OFF logic of the DPLLs from the Core and the DSM, making it possible to switch off the PLL by software and still be able to switch it on by DSM. Mul_ctrl (Bit [13]) of DPLLC_DP_CTL register provides this flexibility as shown in the following table.

Table 19-1. Options for DPLL Control

DPLLC Enable	UPEN Bit	mul_ctrl bit (Self Clearing)	DPLL Enable
X	X	1	0
X	0	X	0
posedge	1	0	1
0	X	X	0

As shown in the table above, once the DPLL is switched off by Software using the Mul_ctrl bit, the software cannot turn the PLL on thereafter, unless there is a posedge on the DPLLC enable signal, during DSM entry sequence.

19.2.2.4 Calculating the Output Frequency

The output frequency is given by the formula:

$$f_{dck=2} = 4 \bullet f_{ref} \bullet \left[\frac{\text{MultiplicationFactor}}{\text{PreDividerFactor}} \right]$$

Where:

$$\text{MultiplicationFactor} = MF_I + \frac{MF_N}{MF_D + 1}$$

$$\text{PreDividerFactor} = PDF + 1$$

For normal mode, registers DPLLC_DP_OP, DPLLC_DP_MFN, and DPLLC_DP_MFD are used.

For HFS mode, the shadow registers DPLLC_DP_HFS_OP, DPLLC_DP_HFS_MFN, and DPLLC_DP_HFS_MFD are used.

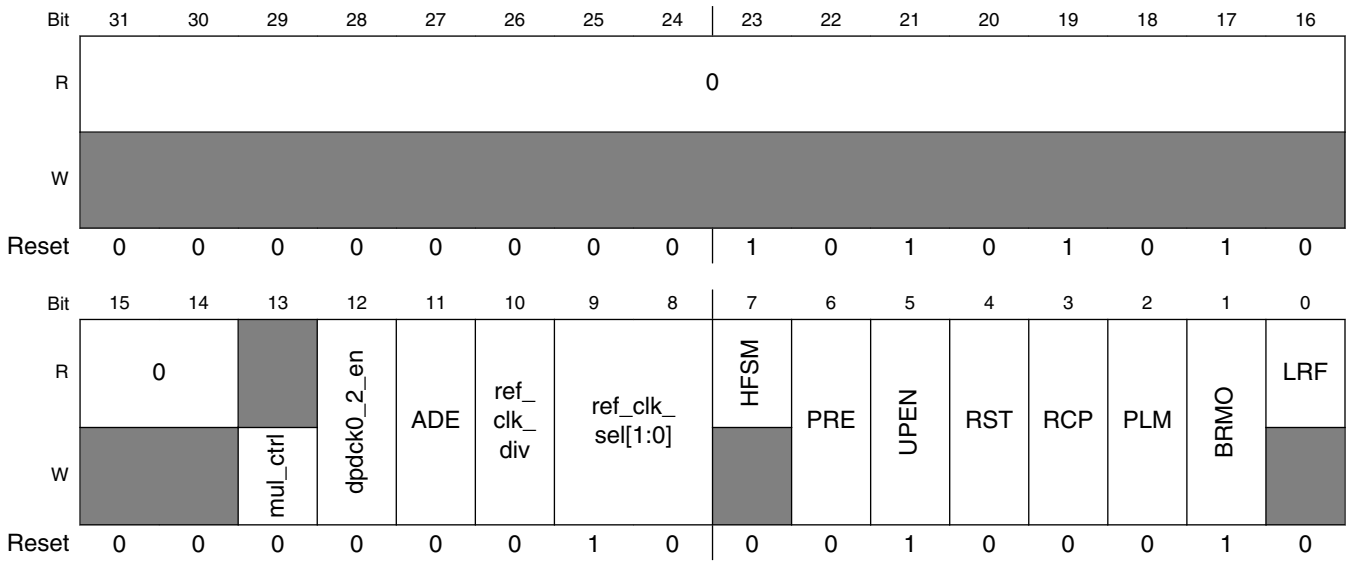
19.31.1 DPLLC Control Register (DPLLC*x*_CTL)

Addresses: DPLLC-1_CTL is 63F8_0000h base + 0h offset = 63F8_0000h
DPLLC-2_CTL is 63F8_4000h base + 0h offset = 63F8_4000h
DPLLC-3_CTL is 63F8_8000h base + 0h offset = 63F8_8000h



DPLLC*x*_CTL field descriptions

Field	Description
31–14 Reserved	This read-only field is reserved and always has the value zero. Reserved
13 mul_ctrl	Multiple Control. This is a self clearing bit cleared on the next posedge of PLL reference clock. Setting this bit deasserts the enable signal to the DPLL. Using this bit instead of UPEN to disable the DPLL gives DSM the control to independently switch on the DPLL. See Multiple Options for DPLL Control for more details. 0 No Effect 1 DPLL disabled
12 dpdck0_2_en	dpdck0_2 Enable. To enable PLL output before divide by 2 flip-flop. It will enable clock dpdck0_2 which will have double the frequency of dpdck/dpgdck clock. 0 Disable dpdck0_2. 1 Enable dpdck0_2.
11 ADE	The output corresponding to this bit is left unconnected for future use.
10 ref_clk_div	Ref Clk Division factor. Decides whether selected reference clock input needs to be divided by two or one. 0 Divide by 1 1 Divide by 2

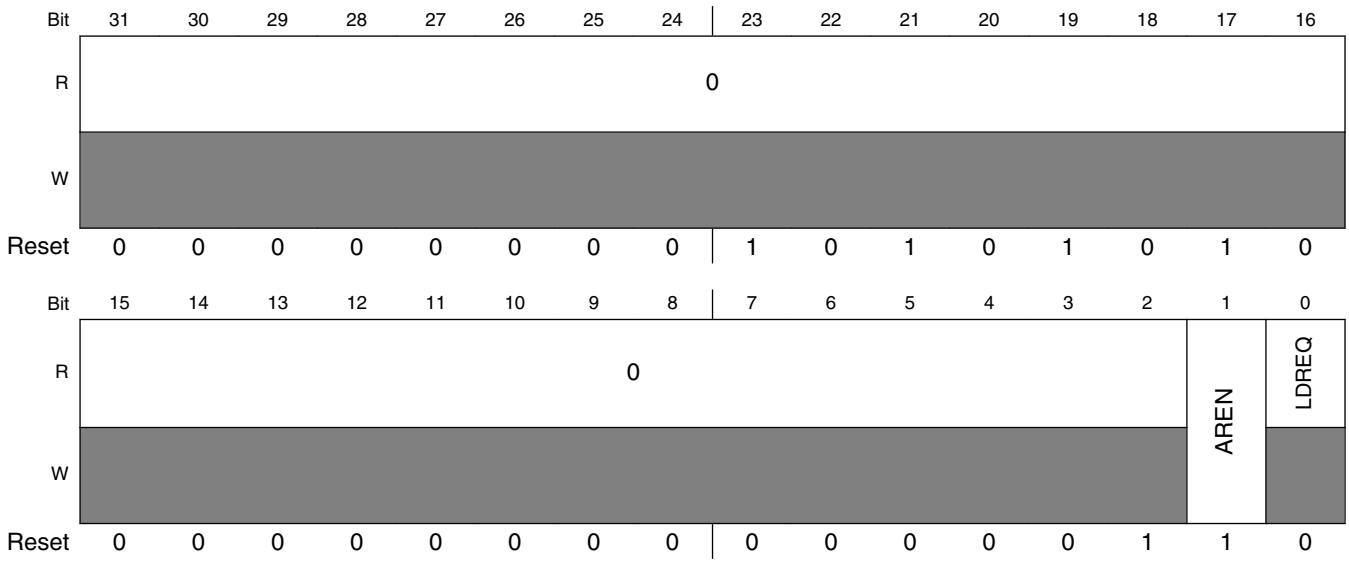
DPLLCx_CTL field descriptions (continued)

Field	Description
9–8 ref_clk_sel[1:0]	ref_clock_select. Used to select the reference clock for DPLL. 00 clock0 is selected. 01 clock1 is selected. 10 clock2 is selected. 11 clock3 is selected.
7 HFSM	HFS-Mode Status bit. Indicates which frequency mode of operation is active. In HFS mode all the shadow registers (DPLLC_DP_HSF_OP, DPLLC_DP_HSF_MFD, DPLLC_DP_HSF_MFN) are used whereas in LFS mode normal registers are used. Reset value of this bit is '0'. 0 LFS mode, normal registers are read. 1 HFS mode is active.
6 PRE	Power Up Reset. Asserts a hard reset to DPLL. 0 Reset cleared. 1 Reset asserted
5 UPEN	PLL Enable. Enables DPLL operation. 0 DPLL disabled. 1 DPLL enabled.
4 RST	Restart. Restarts DPLL. It should not be used as a status bit. 0 DPLL not in restart. 1 DPLL restarted.
3 RCP	Reference Clock Polarity. Selects which edge the chip clock is adjusted to. 0 Positive edge of reference clock. 1 negative edge of reference clock.
2 PLM	Phase Lock Mode. Selects if phase is to be considered (in addition to frequency) during lock-in. 0 DPLL in frequency only lock mode. 1 DPLL in frequency and phase lock mode.
1 BRMO	BRM Order Bit. Binary Rate Modulator order 0 BRM in first order. 1 BRM in second order.
0 LRF	Lock Ready Flag. Shows if the DPLL is in lock. This is a sticky bit. Following events will break the already established lock: (1) DPLLC_DP_CTL, DPLLC_DP_OP, DPLLC_DP_MFD, DPLLC_DP_HSF_OP or DPLLC_DP_HSF_MFD is written (2) Hard reset (3) pll_lvs toggle (4) DPLL enable Reset value of this bit is '0' 0 DPLL not locked. 1 DPLL locked.

19.31.2 DPLLC Configuration Register (DPLLCx_CONFIG)

Writing to this register does not generate an automatic 'restart.'

Addresses: DPLLC-1_CONFIG is 63F8_0000h base + 4h offset = 63F8_0004h
DPLLC-2_CONFIG is 63F8_4000h base + 4h offset = 63F8_4004h
DPLLC-3_CONFIG is 63F8_8000h base + 4h offset = 63F8_8004h



DPLLCx_CONFIG field descriptions

Field	Description
31–2 Reserved	This read-only field is reserved and always has the value zero. Reserved
1 AREN	Auto Restart Enable. If auto restart is enabled, then a restart sequence will be issued automatically whenever a write is performed to one of the DPLL registers (DPLLC_DP_CTL, DPLLC_DP_OP, DPLLC_DP_MFD) in normal mode. In HFS mode, same is true if a write is performed to one of the HFS mode registers (DPLLC_DP_CTL, DPLLC_DP_HFS_OP or DPLLC_DP_HFS_MFD). Otherwise, software will need to set the restart bit manually. Bit 4 of DPLL Control Register. Default Value of this bit is '1'. 0 Auto-restart is disabled 1 Auto-restart is enabled
0 LDREQ	Load Request. Notifies the DPLL that the numerator factor of the fractional part (MFN) has changed. This bit is cleared by an acknowledge from the DPLL. Writing a '0' to it has no effect. Default Value of this bit is '0' 0 DPLL has finished updating MFN. 1 Request that the DPLL updates MFN.

19.31.3 DPLLC Operation Register (DPLLCx_OP)

Addresses: DPLLC-1_OP is 63F8_0000h base + 8h offset = 63F8_0008h
DPLLC-2_OP is 63F8_4000h base + 8h offset = 63F8_4008h
DPLLC-3_OP is 63F8_8000h base + 8h offset = 63F8_8008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

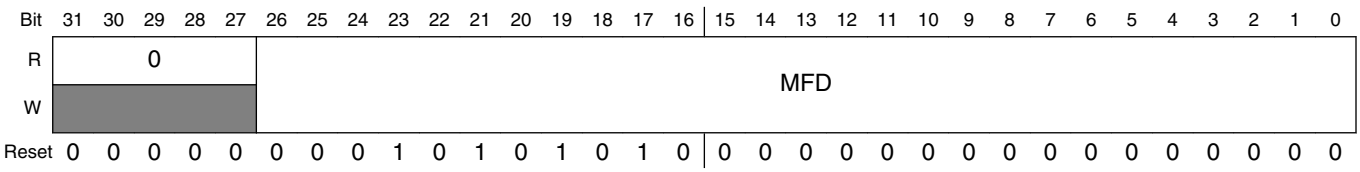
DPLLCx_OP field descriptions

Field	Description
31–8 Reserved	This read-only field is reserved and always has the value zero. Reserved
7–4 MFI	Multiplication Factor, Integer part (MFI). If MFI[3:0] is written with a value of less than 5, MFI will default to 5. See Calculating the Output Frequency Example settings: 0000 Integer part equals 5 0001 Integer part equals 5 0101 Integer part equals 5 0110 Integer part equals 6 1111 Integer part equals 15
3–0 PDF	Pre-division Factor (PDF). PDF determines the value of the PreDividerFactor used in the output frequency formula. See Calculating the Output Frequency Example settings: 0000 PreDividerFactor equals 1 0001 PreDividerFactor equals 2 0010 PreDividerFactor equals 3 1110 PreDividerFactor equals 15 1111 PreDividerFactor equals 16

19.31.4 DPLLC Multiplication Factor Denominator Register (DPLLCx_MFD)

Addresses: DPLLC-1_MFD is 63F8_0000h base + Ch offset = 63F8_000Ch
DPLLC-2_MFD is 63F8_4000h base + Ch offset = 63F8_400Ch
DPLLC-3_MFD is 63F8_8000h base + Ch offset = 63F8_800Ch



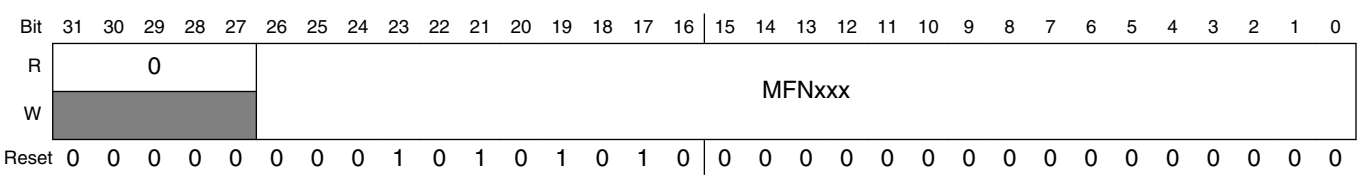
DPLLCx_MFD field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved.
26–0 MFD	Multiplication Factor Denominator Bits. The MFD[26:0] bits, in a 2's complement format, give the denominator of the fractional part. See Calculating the Output Frequency **NOTE:** Bit 26 is always 0. MFD should be in a range from 0 to 67108863; otherwise, the output clock frequency will differ from the desired frequency. Example settings: 0x000000 MFD equals 0 0x000001 MFD equals 1 0x000002 MFD equals 2 0x3FFFFFE MFD equals 67108862 0x3FFFFFF MFD equals 67108863

19.31.5 DPLLC Multiplication Factor Numerator Register (DPLLCx_MFN)

MFNxxx denotes the registers DPLLC_DP_MFN, DPLLC_DP_MFNMINUS and DPLLC_DP_MFNPLUS.

Addresses: DPLLC-1_MFN is 63F8_0000h base + 10h offset = 63F8_0010h
DPLLC-2_MFN is 63F8_4000h base + 10h offset = 63F8_4010h
DPLLC-3_MFN is 63F8_8000h base + 10h offset = 63F8_8010h



DPLLCx_MFN field descriptions

Field	Description
31–27 Reserved	This read-only field is reserved and always has the value zero. Reserved.
26–0 MFNxxx	Multiplication Factor Numerator Bits (nominal, "MINUS", or "PLUS"). The MFNxxx[26:0] bits, in a 2's complement format, give the numerator of the fractional part. See Calculating the Output Frequency **NOTE:** MFN should be in a range from -67108864 to 67108863. If the absolute value of the MFN is larger than MFD, the output clock frequency will differ from the desired frequency. Example settings: 0x4000000 MFN equals -67108864 0x4000001 MFN equals -67108863 0x4000002 MFN equals -67108862 0xFFFFFFF MFN equals -1 0x0000000 MFN equals 0 (default) 0x0000001 MFN equals 1 0x3FFFFFE MFN equals 67108862 0x3FFFFFF MFN equals 67108863

19.31.6 DPLLC Multiplication Factor Numerator PLUS/MINUS Registers (DPLLCx_MFNn)

MFNxxx denotes the registers DPLLC_DP_MFN, DPLLC_DP_MFNMINUS and DPLLC_DP_MFNPLUS.

Addresses: DPLLC-1_MFNMINUS is 63F8_0000h base + 14h offset = 63F8_0014h
DPLLC-1_MFNPLUS is 63F8_0000h base + 18h offset = 63F8_0018h
DPLLC-2_MFNMINUS is 63F8_4000h base + 14h offset = 63F8_4014h
DPLLC-2_MFNPLUS is 63F8_4000h base + 18h offset = 63F8_4018h
DPLLC-3_MFNMINUS is 63F8_8000h base + 14h offset = 63F8_8014h
DPLLC-3_MFNPLUS is 63F8_8000h base + 18h offset = 63F8_8018h

Chapter 20
DRAM Memory Controller (DRAM MC)

20.1 Overview

This chapter describes the DRAM MC implemented on the i.MX50. See the Programmable Registers section for all registers.

The i.MX50 supports off-chip DRAM storage using the DRAM MC, which is connected to the internal AXI bus. The DRAM MC supports multiple external memory types, including:

- Standard 1.8 V DDR2
- 1.8 V Mobile DDR1 (LP-DDR1)
- 1.2 V Mobile DDR2 (LP-DDR2)

The DRAM MC consists of 3 major components:

- AXI bus interface
- DRAM Controller
- DRAM PHY

The DRAM MC uses 3 primary clocks: the AHB bus clock HCLK, the AXI bus clock SYS_CLK, and, the ddr interface clock DDR_CLK.

- Supports up to 266 MHz clock frequency at the ddr interface. (532 MHz data rate)
- Supports up to 266 MHz clock frequency at the AXI interface.
- Supports up to 133 MHz clock frequency at the AHB interface.
- The SYS_CLK & DDR_CLK could be either Synchronous or Asynchronous, configurable.
- The HCLK & SYS_CLK are always treated asynchronously by the DRAM MC.

20.1.1 Block Diagram

A high level block diagram of the DRAM MC is shown in Figure 20-1.

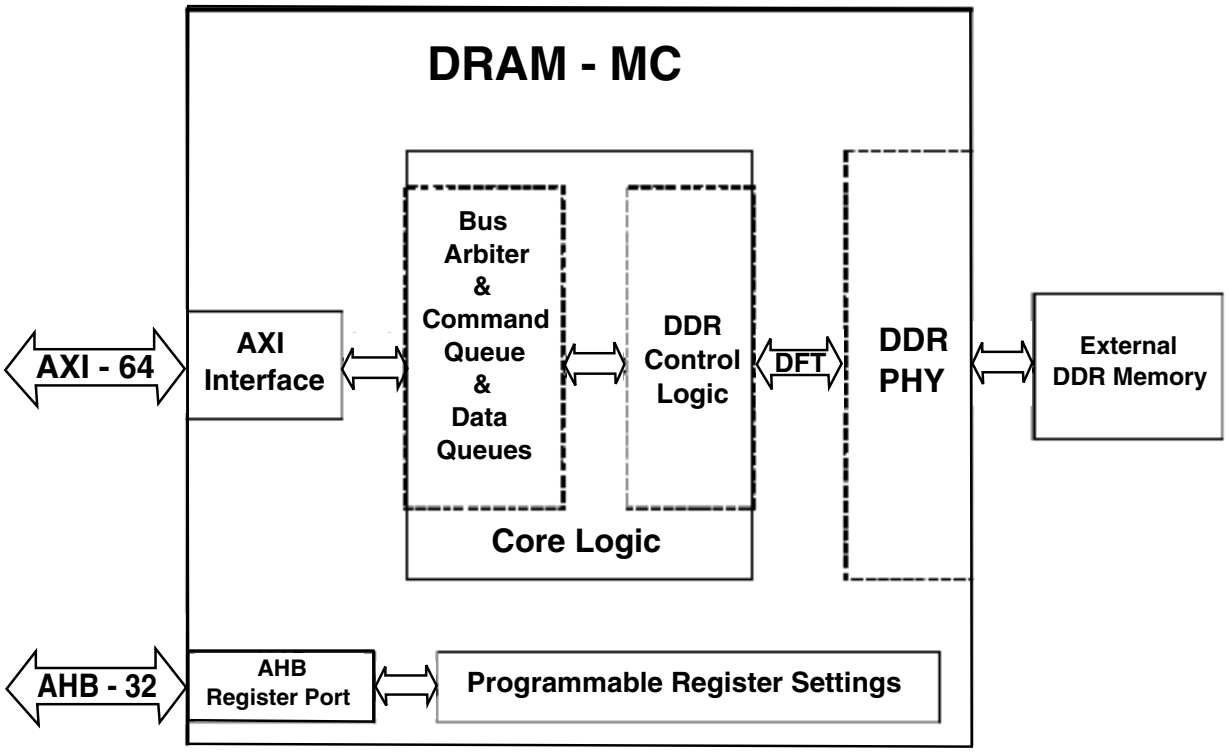

Figure 20-1. DRAM MC Top-Level Block Diagram

DRAM MC implements 2 bus interface. The 64-bit AXI bus interface to read/write data from/to external DDR memory. The AHB interface is dedicated to read/write PIO registers.

20.1.2 DRAM MC Special Signal Considerations

This section list some special signal considerations for the i.MX50 DRAM MC:

- **DRAM_OPEN,DRAM_OPENFB**-These are the echo gating output and feedback pins used by the DRAM PHY to put a window around the DQS transition. They should be routed so that the sum of the trace lengths of DRAM_OPEN + DRAM_OPENFB is equal to the sum of the trace lengths of DRAM_SDCLK0 + DRAM_SDQS0. This connection is required for mDDR, LPDDR2, and DDR2. For the i.MX50 PoP package, these signals are connected on the substrate.
- **DRAM_SDODT0, DRAM_SDODT1**-These are the On-die termination outputs from the i.MX50. For DDR2, these pins should be connected to the DDR2 DRAM ODT pins. For LPDDR2 and mDDR, these pins should be left floating.
- **DRAM_CALIBRATION**-This pin is the ZQ calibration used to calibrate DRAM Ron and ODT. For LPDDR2, this pin should be connected to ground through a 240 ohm 1% resistor. For LPDDR1, this pin should be connected to ground through a 300

ohm 1% resistor. For DDR2, this pin should be connected to ground through a 180 ohm 1% resistor.

- **VREF**-This pin is the VREF input. For LPDDR2 and DDR2, this pin should be connect to ½ of NVCC_EMI_DRAM. For mDDR, this pin should be left floating.

20.2 DRAM MC Address Mapping

The DRAM MC automatically maps AXI bus addresses to the DRAM memory in a contiguous block. Addressing starts at user address 0 and ends at the highest available address according to the size and number of DRAM devices present. This mapping is dependent on how the memory controller was configured and how the parameters in the internal DRAM MC registers are programmed. The exact number and values of these parameters depends on the configuration and the type of memory for which the memory controller was designed.

The mapping of the address space to the internal data storage structure of the DRAM devices is based on the actual size of the DRAM devices available. The size is stored in user-programmable parameters that must be initialized at power up. Certain DRAM devices allow for different mapping options to be chosen, while other DRAM devices depend on the burst length chosen.

20.2.1 DDR SDRAM Address Mapping Options

The address structure of DDR SDRAM devices contains five fields. Each of these fields can be individually addressed when accessing the DRAM. The address map for this DRAM MC is ordered as follows:

Chip Select => Row => Bank => Column => Datapath

The maximum widths of the fields are based on the configuration settings. The actual widths of the fields may be smaller if the device address width parameters (addr_pins, eight_bank_mode and column_size) are programmed differently.

- Chip Select-DRAM MC supports 2 chip-select; "Chip Select" field occupy 1-bit.
- Datapath-DRAM MC supports 16 or 32-bit data width for external DDR memory; "Datapath" field occupy 1 or 2-bit.
- Bank-The DDR memory device defines the bank number. The DRAM MC supports 4 or 8 banks DDR memory, occupy 2 or 3-bits.
- Row, Column-The DDR memory device defines the width of these fields;

20.2.2 Maximum Address Space

The maximum user address range is determined by the width of the memory datapath, the number of chip select pins, and the address space of the DRAM device. The maximum amount of memory can be calculated by the following formula:

chip-selects x bank x $2^{(row+column)}$ x datapath (unit: byte)

For this DRAM controller, the maximum values for these fields are as follows:

- Chip Selects = 2
- Bank-4 or 8, max 8
- Row-max 15-bits
- Column-max 10-bits
- Datapath width = 2 bytes (16-bits) or 4 bytes (32-bits)

As a result, the maximum accessible memory area could reach 2 Gbyte for DRAM MC module.

20.2.3 Memory Mapping to Address Space

An example of address space mapping from 32-bit bus address to DRAM address fields is shown in Figure 20-2 to Figure 20-5.

Example 1: This example corresponds to a memory device with 8 banks, 13 row bits, and 10 column bits; 16-bit datapath mode;

don't care [31:28]	chip-select [27]	row [26:14]	bank [13:11]	column [10:1]	datapath [0]

Figure 20-2. memory address mapping example 1

Example 2: 8 banks, 14 row bits and 10 column bits; 16-bit datapath mode;

don't care [31:29]	chip-select [28]	row [27:14]	bank [13:11]	column [10:1]	datapath [0]

Figure 20-3. memory address mapping example 2

Example 3: 8 banks, 14 row bits and 9 column bits; 32-bit datapath mode;

don't care [31:28]	chip-select [28]	row [27:14]	bank [13:11]	column [10:2]	datapath [1:0]

Figure 20-4. memory address mapping example 3

Example 4: 8 banks, 15 row bits and 10 column bits; 32-bit datapath mode;

don't care [31]	chip-select [30]	row [29:15]	bank [14:12]	column [11:2]	datapath [1:0]

Figure 20-5. memory address mapping example 4

20.2.4 Out-of-Range Address Checking

It is possible that the master attempts to write to an invalid address. For this reason, all incoming addresses are always checked against the addressable physical memory space. If a transaction is addressed to an out-of-range memory location, then a bus error response would be returned by the MC. This feature help debugging. For example: this allows the use of abort exceptions which can be tracked to specific instructions when a debugger is used.

20.3 DRAM MC Clocking

20.3.1 Changing the Input Clock Frequency

The operating frequency of the DRAM MC is dependent on an ASIC-level input clock. There are situations in which the user may wish to modify the frequency of the clock without resetting the memory controller. To change the clock frequency at which the DRAM MC operates, the memory controller must stop processing requests, the clock must be adjusted, the memory controller's timing parameters must be reprogrammed and then the memory controller can be restarted. The procedure to follow for changing the clock frequency is as follows:

1. Ensure that the DRAM MC is idle, that is when the controller_busy parameter is zero. (CTL_BUSY: Bit [8] of DRAM_CTL79)
2. Put the memory devices into self-refresh mode by asserting the srefresh parameter to b1. It is imperative that the memory devices be placed into self-refresh through this parameter, and not through any other means. If the devices have been placed into self-refresh mode through one of the low power modes (programming of the

lowpower_control parameter), then the user should bring the devices out of that low power mode manually, then program the srefresh parameter with a b1.

3. Wait until the memory devices have been placed into self-refresh mode, indicated by the cke_status parameter (Bit [16] of DRAM_CTL63). This parameter is the value of the control_cke signal inside the memory controller, delayed by the number of clocks specified in the cke_delay parameter.
4. Mask the DLL lock state change bit (bit 8) in the int_status parameter, by setting bit 8 in the int_mask parameter to b1.
5. Stop the MC by writing a b0 to the start parameter.
6. Clear the DLL lock state change bit (bit 8) in the int_status parameter, by writing bit 8 in the int_ack parameter to b1. Also clear any other interrupts in the int_status parameter by writing to the int_ack parameter.
7. If the user wishes to use a controller interrupt to signal when the DLL has re-locked, then unmask the DLL lock state change bit (bit 8) in the int_status parameter by clearing bit 8 in the int_mask parameter to a b0.
8. The clock frequency may now be changed. The user should modify any parameters that may be affected by the frequency change such as caslat_lin, caslat_lin_gate, any of the timing parameters, and so on. The user should review the parameters carefully to ensure that all parameters that require modification are changed.
9. After all parameters have been updated, restart the MC by writing a b1 to the start parameter. This forces the DLL to lock to the new frequency.
10. Once the DLL has locked and the PHY has initialized, the memory controller input signal dfi_init_complete will be asserted. If the user is using a controller interrupt to monitor DLL re-lock, then wait for a controller interrupt or poll the int_status parameter for the DLL lock state change bit (bit 8) to be set.
11. At this point, the user may bring the memory devices out of self-refresh by clearing the srefresh parameter to b0. The user should poll the cke_status bit (bit 16 in the DRAM_CTL63 register) to ensure that the self-refresh has been exited before issuing any memory commands. This bit will be set high to indicate that self-refresh has been exited.
12. If any of the memory mode registers require updating at this point, the values must be set in the mode register parameters, and then written to the memory devices by setting the write_modereg parameter to b1.

20.4 DRAM MC AHB and AXI Interface

20.4.1 AHB Register Port

The register port is an independent AHB port to the DRAM MC. This port operates Asynchronously.

The register port only supports the AHB SINGLE access type. The register port only supports transfer types of NONSEQ or IDLE.

There is no support for INCR or WRAP burst types.

There is no support for SEQ or BUSY transfer types.

20.4.2 AXI Interface

The AXI interface function as AXI slave. Transfers are burst-based of variable byte counts. The transfer types INCR and WRAP are fully supported. FIXED burst types are not supported.

Each interface contains five separate channels of traffic to/from the memory: write response, read command, write command, read data, and write data.

20.4.2.1 Internal Command Handling

The DRAM MC uses placement logic to fill the command queue with a command order that maximizes the throughput and efficiency of the core logic.

If the placement logic is being used, the DRAM MC will optimize the core by reordering read and write commands as necessary based on these rules:

- Two read commands from the same thread ID on a port will not be re-ordered and will always execute in the same order as they were accepted into their port.
- Two read commands from different thread IDs on a port may be automatically re-ordered in the core logic to execute out-of-order. When commands from different thread IDs are reordered, read data returned to the AXI port interfaces will also be out-of-order and may be interleaved. To avoid reordering within a port, the AXI bus master should use one thread ID for all commands from any port.
- Two write commands from the same thread ID on a port must remain sequential and will not be reordered. These transactions occur in the order that the commands were received at the port.
- Two write commands from different thread IDs on a port must remain sequential and will not be re-ordered. These transactions will always occur in the order that the commands were received at the port.

- A read command that follows a write command from the same thread ID may be reordered to execute in an optimal order, as long as there are no collisions between the commands.
- A read command that follows a write command from a different thread ID on a port may be reordered to execute in an optimal order, as long as there are no collisions between the commands.
- A write command that follows a read command from the same thread ID may be re-ordered to execute in an optimal order, as long as there are no collisions between the commands.
- A write command that follows a read command from a different thread ID on a port may be re-ordered to execute in an optimal order, as long as there are no collisions between the commands.

Command handling is summarized in Table 20-1

Table 20-1. Re-Ordering / Interleaving Behavior

COMMANDS	THREAD ID	Can Commands be Re-Arranged and Data be Interleaved?
Two Read Commands from 1 port	Same	No
Two Read Commands from 1 port	Different	Yes
Two Write Commands from 1 port	Same	No
Two Write Commands from 1 port	Different	No
Read following a Write from 1 port	Same	Yes
Read following a Write from 1 port	Different	Yes
Write following a Read from 1 port	Same	Yes
Write following a Read from 1 port	Different	Yes

An incoming AXI transaction is mapped into a core logic level transaction, then synchronized from the AXI clock domain to the core logic clock domain and stored in the AXI port FIFOs. Each instruction consists of an address, size, length and thread ID. Since a port may utilize multiple thread IDs, the source ID that is used in the core logic is a combination of both the port and thread information. This concatenation occurs in the Arbiter and this source ID is used in the placement logic. From the AXI FIFOs, the transaction is presented to the Arbiter which arbitrates requests from all ports and forwards a single transaction to the core logic.

20.4.2.2 Configured Options

Each AXI port has been defined for the requirements of the intended system. The configured options are:

Type of interface to the DRAM MC core clock

All ports are clock domain programmable relative to the core clock. These ports initialize in Synchronous operation, but can be changed by programming the associated axi_fifo_type_reg parameter. For more information on the programming of this parameter, refer to Port Clocking. Asynchronous FIFOs handle the clock domain crossing when operating in the Asynchronous modes.

NOTE

When switching between asynchronous and synchronous mode of operation, ensure that there are no outstanding transactions on the port whose behavior is being changed. If transactions are waiting, there may be unexpected loss of data or a lockout condition on that AXI port.

Datapath Width

Each port has a data interface width of 64 bits.

Width of the ID

Each port is configured with a thread ID of 16 bits.

Priority Definition

Command priority is defined based on the port and the command type. For each port Y, there is an axiY_r_priority parameter which defines priorities for all read commands and an axiY_w_priority parameter which defines priorities for all write commands. Supported priority values range from 0 to 7, with 0 as the highest priority.

Register Port

The 32-bit AHB register port is fixed in Asynchronous mode between the AHB bus clock domain and the core clock domain.

Buffering

Each AXI interface contains a command, a read and a write FIFO, and a response storage array. In addition, each programmable port contains an asynchronous response

FIFO to synchronize the memory response to the port clock domain when operating asynchronously.

Table 20-2. AXI Port FIFOs

port number	port data width	clock domain type	command fifo depth	write fifo depth	read fifo depth	response fifo depth	response Storage array depth
Port 0	64	Program mable	8	8	8	4	8
Port 1	none	none	none	none	none	none	none

Narrow Transfer FIFO

For each command from a requestor that may send a narrow transfer (based on axiY_en_size_lt_width_instr parameter programming), an entry is created in the port narrow transfer FIFO with the address, bytes-per-beat and a narrow transfer flag. This will include transfers which may not be narrow in size, but originating from a requestor enabled to support narrow transfers. Each port has been configured with a set number of entries in this FIFO. Therefore, if multiple requestors enabled for narrow transfers issue enough commands to fill the narrow transfer FIFO, the associated port command FIFO may be stalled from accepting more commands. Therefore, the user should only program the axiY_en_size_lt_width_instr parameters carefully with only the requestors expected to use these transfers enabled. The Depth of the Narrow Transfer FIFO is 8.

Exclusive Access Buffer Depth

Exclusive access is an optional AXI feature. This type of access will only be used if exclusive access commands are issued to the memory controller by driving the axiY_ARLOCK signal to 'b10 with a read command. Each native AXI port contains 4 exclusive buffer and therefore each port may monitor the exclusivity of up to 4 transaction at any time. Refer to Exclusive Access, for more information.

Error Detection

When an illegal operational condition is detected on a new AXI transaction entering the port, the port responds through an AXI error signal and the controller interrupt signal, and the error signature is recorded in the register space. The AXI error signal flagged is dependent on the type of transaction that caused the error (read or write). The controller interrupt and the signature information is dependent on type of error (command or data). Refer to Error Responses, for more information on error detection.

20.4.3 Port Clocking

There are 2 user-selectable modes of operation for the AXI port interface: Synchronous & Asynchronous. The mode is selected by programming the axi0_fifo_type_reg parameter. A clock mux was implemented to select the clock mode.

Figure 20-6 shows the DDR clock mux.

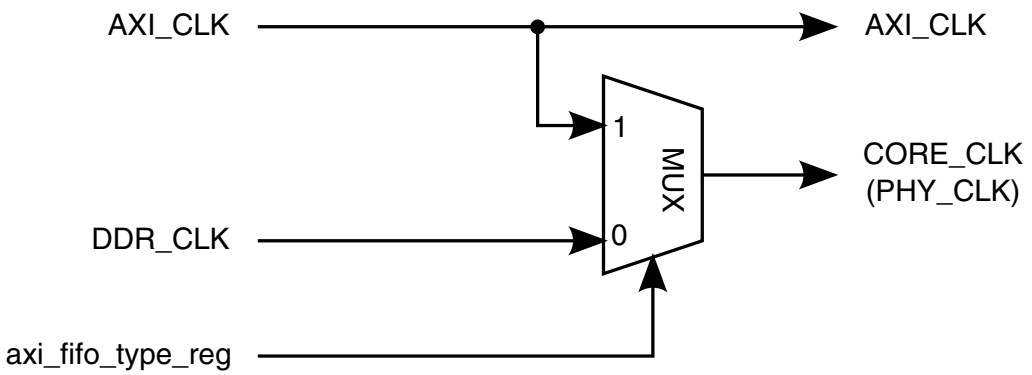

Figure 20-6. ddr clock mux

Synchronous (b11)

CORE_CLK = SYS_CLK. The DDR_CLK was unused. The AXI port interface block will not be required to perform any clock synchronization in any of the FIFOs.

Reserved (b10)

Reserved (b01)

Asynchronous (b00)

CORE_CLK = DDR_CLK. The SYS_CLK & DDR_CLK are treated as Asynchronous to each other. The AXI port FIFOs use two stages of synchronization logic to synchronize commands, write data and read data from SYS_CLK to the CORE_CLK domain.

20.4.4 AXI Interface FIFOs

Each AXI port contains four FIFOs for commands, read data, write data and response synchronization. The response synchronization FIFOs are only used when operating in asynchronous mode. In addition to the FIFOs, each port contains a storage array to hold the read and write responses. The depths and clock domain relativity of the FIFOs and the array are shown in Table 20-2.

The five channels of traffic and their relationship to the port FIFOs are shown in Figure 20-7.

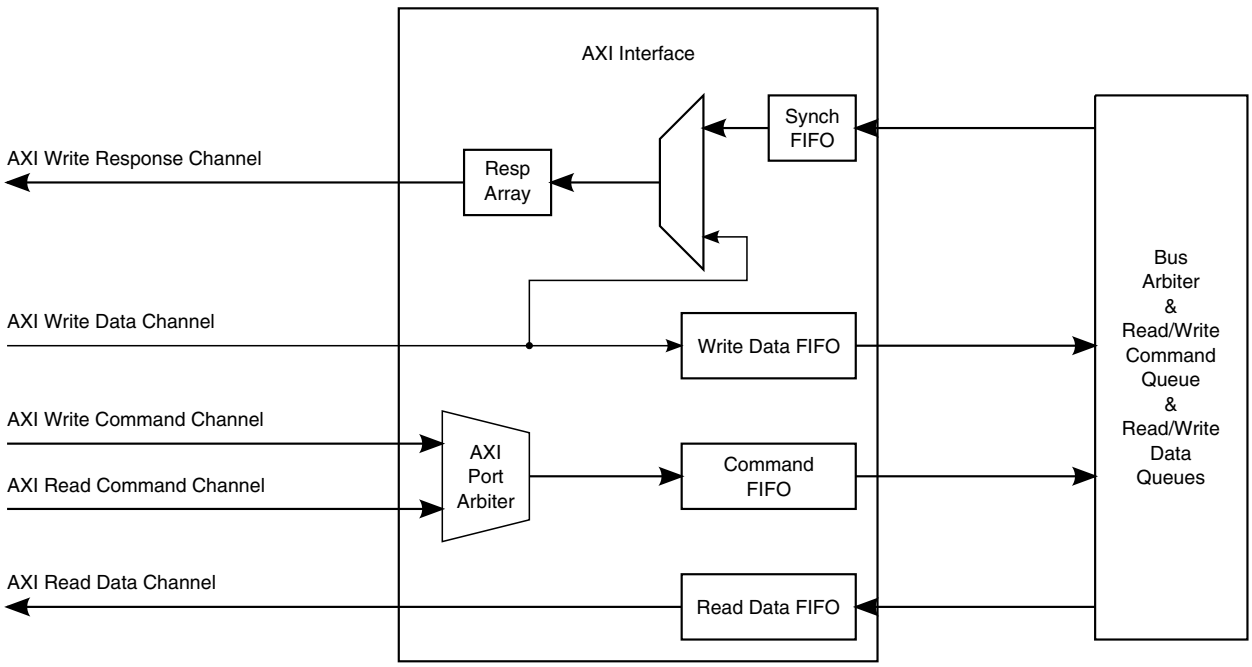

Figure 20-7. AXI Interface FIFOs

20.4.4.1 In-Port Arbitration

Within each port, it is possible that both the read and write command channel of the AXI bus are active concurrently. If this occurs, each port performs a simple arbitration to select the command to pass through. This arbitration is based on the following factors, in order of importance:

1. Order of command acceptance into the port

   The "VALID" signal is set to 'b1 when the master has sent a valid command to the port. The "READY" signal indicates that the port has registered the command. Therefore, a command is considered accepted when both the VALID and READY signals are both asserted. (axiY_AWREADY and axiY_AWVALID both asserted or axiY_ARREADY and axiY_ARVALID both asserted).

2. Priority of read command versus priority of the write command (values of the signals axiY_ARPRIORITY versus axiY_AWPRIORITY).
3. Default Read over Write preference

   If both read and write commands are accepted simultaneously, and their priorities match, then the read channel will be selected first.

Table 20-3 shows the system behavior when the port FIFO is full, allowing commands to accumulate on both channels. The commands will be arbitrated into the port command FIFO based on the order that they are accepted at the port.

Table 20-3. In-Port Arbitration Example 1

CYCLE	PORT COMMAND FIFO	READ CHANNEL		WRITE CHANNEL		ARDITRATED RESULT
		COMMAND ACCEPTED	PRIORITY	COMMAND ACCEPTED	PRIORITY	
1	FULL	1st Read	Any	-	-	None (FIFO full)
2	FULL	-	-	1st Write	Any	None (FIFO full)
3	Available	-	-	-	-	1st Read (Arrived First)
4	Available	2nd Read	Any	-	-	1st Write (Arrived First)
5	Available	-	-	-	-	2nd Read

Table 20-4 shows the system behavior when read and write commands are accepted simultaneously. The commands will be arbitrated into the port command FIFO based on their port priority. When the commands are not simultaneous, they will be arbitrated based on the order that they are accepted at the port.

Table 20-4. In-Port Arbitration Example 2

CYCLE	PORT COMMAND FIFO	READ CHANNEL		WRITE CHANNEL		ARDITRATED RESULT
		COMMAND ACCEPTED	PRIORITY	COMMAND ACCEPTED	PRIORITY	
1	Available	1st Read	Lower	1st Write	Higher	1st Write (Higher Priority)
2	Available	-	-	2nd Write	Higher	1st Read (Arrived First)
3	Available	-	-	-	-	2nd Write
4	Available	2nd Read	Lower	3rd Write	Higher	3rd Write (Higher Priority)
5	Available	-	-	-	-	2nd Read

Table 20-5 shows the system behavior when read and write commands are accepted simultaneously and their priorities are the same. Read commands will automatically be arbitrated ahead of write commands when both other conditions match. When the commands are not simultaneous, they will be arbitrated based on the order that they are accepted at the port.

Table 20-5. In-Port Arbitration Example 3

CYCLE	PORT COMMAND FIFO	READ CHANNEL		WRITE CHANNEL		ARDITRATED RESULT
		COMMAND ACCEPTED	PRIORITY	COMMAND ACCEPTED	PRIORITY	
1	FULL	1st Read	Same	1st Write	Same	1st Read (Read over Write)

Table continues on the next page...

Table 20-5. In-Port Arbitration Example 3 (continued)

CYCLE	PORT COMMAND FIFO	READ CHANNEL		WRITE CHANNEL		ARDITRATED RESULT
		COMMAND ACCEPTED	PRIORITY	COMMAND ACCEPTED	PRIORITY	
2	FULL	2nd Read	Same	-	-	1st Write (Arrived First)
3	Available	-	-	2nd Write	Same	2nd Read (Arrived First)
4	Available	-	-	-	-	2nd Write
5	Available	3rd Read	Same	3rd Write	Same	3rd Read (Read over Write)

20.4.5 AXI Write Response Channel

When a write request is accepted into the AXI interface, an entry will be created in the Response Storage Array for that command. The array will maintain information on the order of received commands from each thread ID for each port. Write responses will be returned in the same order as the commands were received, regardless of the thread ID or the type of response requested (bufferable, coherent bufferable or non-bufferable).

When a write response is ready, the array will verify that this is oldest command for that port and if so, the response will be sent out. The timing of this response is dependent on the type of response requested and the contents of the command queue. Responses for bufferable commands will be available when the port has received all of the data, responses for coherent bufferable commands will be available when the core has received the command and responses for non-bufferable commands will be available when all data has been sent to the PHY. It is possible that the response for a newer command for that port will be ready and waiting until the responses for all older commands for that port are ready and sent to the user interface.

Write responses will be returned to the AXI master through the signal axiY_BRESP and its associated valid indicator, the axiY_BVALID signal.

20.4.5.1 Bufferable, Coherent Bufferable and Non-Bufferable Response Types

Each data port is configured with two signals that work together to determine when an instruction is considered complete and the write completion response (axiY_BRESP) will be returned to the master. These signals are axiY_AWCACHE [0] and axi_AWCOBUF. Table 20-6 details the relationship between these signals. "AXI_AWCOBUF" is a programmable register bit.

Table 20-6. Write Response Types

axi_awcache[0]	axi_awcobuf	Response information[1]
0	0 or 1	Non-bufferable write Command. Response will be ready when the write data has been issued to the PHY.
1	0	Standard bufferable write command. Response will be ready when the command and all associated data have been received by the AXI data port. There is no guarantee of data coherency across all AXI ports.
1	1	Coherent bufferable write command. Response will be ready when the command has been accepted by the command queue in the core logic. This guarantees data coherency across all ports but reduces the overall write response latency relative to the non-bufferable option.

1. The response will only be sent if all of the older write responses have been issued for any thread ID on that port.

20.4.6 AXI Transactions

The AXI Interface supports burst tpye of INCR and WRAP.

The AXI Interface supports burst length of 1-16 bits.

20.4.7 Exclusive Access

The exclusive access feature allows a master to monitor if a memory area has been altered since its last read. Exclusive access does not imply that the memory area is locked; other thread IDs of that port, or other ports, may access the area for reads or writes even though an exclusive access exists. If any writes occur to a memory area with a valid exclusive access request, the master will lose exclusivity and be informed of this status when it attempts to write to the area again. A loss of exclusivity does not trigger an interrupt or any error conditions; however, the AXI protocol requires that the write data is not written to memory if an exclusive write fails its exclusivity check. The master that has lost exclusivity must determine whether to restart the sequence by requesting another exclusive read or to write the data to the memory regardless via a non-exclusive write.

20.4.7.1 Initiating an Exclusive Access Request

Exclusivity is enabled by issuing a read command to memory with the axi_ARLOCK signal driven to b01.

20.4.7.2 Verifying the Request

The AXI specification dictates restrictions for exclusive access requests. After being accepted in the port, an exclusive read request will be checked against these requirements. If any of these conditions are violated, the command will be passed to the core logic as a non-exclusive read. These restrictions are as follows:

- The address must be aligned to the total byte count. (Byte Count = (axi_ARLEN + 1) x 2^{axi_ARSIZE})
- The byte count must be a power-of-two, and less than 128 bytes.

In addition, the AXI specification states that exclusive accesses can not be cacheable. However, since the DRAM MC does not support cacheable commands, this bit is ignored and any cacheable exclusive access requests will be processed as non-cacheable exclusive accesses.

20.4.7.3 Processing Exclusive Accesses

Within the MC core, an exclusive read will behave similarly to any other read data command, accessing memory and returning data to the requestor when the command is processed. The command type is distinguished by its access to the exclusive access buffer, and by the response sent to the master.

An exclusive read will trigger the MC core to store the source ID (axiY_ARID and port number), beat length (axiY_ARLEN), start address (axiY_ARADDR) and beat size (axiY_ARSIZE) for the transaction into an entry of the exclusive access buffer of that port. In addition, each buffer entry contains a single bit to track validity. This bit is set when the exclusive access is requested.

NOTE

The core logic will only maintain one exclusive access request for each source ID. If a new exclusive read request is from a source ID with an existing exclusive access buffer entry, the previous entry will be overwritten with the new transaction.

NOTE

Exclusive access buffer entries may overlap the memory space across a single port or across multiple ports.

If the exclusive access buffer is full when a new exclusive access request is received, one entry of the buffer will be overwritten by the new request. The core logic will attempt to overwrite invalidated entries first, but if all regions are still valid, it will overwrite one of the older valid regions. When the master attempts an exclusive write to the overwritten region, it will fail the exclusivity check.

All read transactions return a response on the read response channel (axiY_RRESP). Successful normal access respond with an OKAY ('b00) whereas successful exclusive accesses respond with EXOKAY (b01). The type of response issued will inform the master how the command was processed.

20.4.7.4 Validity of an Exclusive Request

The exclusive access will be considered valid from the point that the entry is created in the buffer until an activity occurs to invalidate it. These activities cause the "valid" bit of the exclusive access buffer entry to be cleared:

- The same source ID from the same port issues an exclusive write command for the same starting addressing of the same length and beat size, completing the exclusive access request.
- Any source ID from the same port issues a standard (non exclusive) write which partially or completely falls within the range of the exclusive read request.
- The same source ID from the same port issues another exclusive read request for another memory region. This will not clear the valid bit, but will actually overwrite the entire exclusive access buffer entry (and then set the valid bit). The core logic will only track one exclusive region for each source ID.
- Any other source ID from the same port, or any source ID from another port, issues a standard write or a passing exclusive write to any memory address within the range of the exclusive read request. Since the monitored region has been altered, exclusivity is lost.
- The core logic is tracking enough exclusive access commands that the exclusive access buffer for the port is full. Newer commands will be stored, overriding a previous exclusive access entry.

20.4.7.5 Read Commands to Exclusive Access Regions

A memory area is not locked while an exclusive access is valid and therefore other source IDs may issue read commands to a memory area identified as exclusive. Reads, even other exclusive reads, do not affect the exclusivity of a region. Normal read commands will be processed as usual and, if successful, respond to the master with an OKAY ('b00) on the axi_RRESP signal. Exclusive read commands will result in additional entries being created in the exclusive access buffers and, if successful, an EXOKAY ('b01) response will be sent on the axi_RRESP signal.

Note: An exclusive read request from any source ID, from the same port or another port, even to an overlapping address within an exclusive access region, will not affect the initial exclusive access. Another entry will be created in that port's buffer for this request.

20.4.7.6 Non-Exclusive Write Commands to Exclusive Access Regions

Any master in the system may issue a write command to a memory area identified as exclusive. However, a standard write to any address within an active exclusive access region will invalidate the exclusivity of that region. In this case, the "valid" bit of any exclusive access buffer entry that spans the modified locations in memory will be cleared and future exclusive write requests to this region will fail their exclusivity check.

20.4.7.7 Exclusive Writes

An exclusive write command is only distinguished from a standard write command by the axi_AWLOCK signal being driven to 'b01. When an exclusive write is received, the DRAM MC will first compare the source ID (axi_AWID and port number), transaction beat length (axi_AWLEN), transaction start address (axi_AWADDR) and transaction beat size (axi_AWSIZE) to the entries in the exclusive access buffer of that port.

20.4.7.8 Passing Exclusive Access Check

If any of the valid buffer entries exactly match the incoming command, then the following activities will occur:

- That buffer entryís "valid" bit will be cleared.
- All other buffer entries, from this port or other ports, will be checked to see if this write invalidates any other exclusive access regions. If so, the "valid" bits of these entries will be cleared.
- The transaction will be processed.
- If successful, the write response channel (axi_BRESP) will return an EXOKAY response ('b01) to the master.

20.4.7.9 Failing Exclusive Access Check

If an invalid buffer entry exactly matches the incoming command, or no buffer entries exactly match the incoming command, then the write will fail. The command will be processed internally as a flushed write command.

For a flushed write, the write data will be cleared out of the memory controller FIFOs but the data stored in external DRAM memory will NOT change.

The user will be informed of this condition through the write response channel (axi_BRESP). However, instead of an EXOKAY response, the memory controller will issue an OKAY response. This indicates to the master that the exclusive write did not occur. The master may re-issue the request as a non-exclusive write, or may restart the process by re-issuing the exclusive read.

20.4.8 Error Responses

20.4.8.1 AXI Error Response

When an illegal operational condition is detected on a new AXI transaction entering the port, the port responds with an error condition. Instructions that generate AXI errors will result in unpredictable behavior and may cause memory corruption and/or hang conditions.

20.4.8.2 AXI Error Reporting

If an AXI command error occurs, a bit will be set in the int_status parameter and the address and source ID of the command are saved in the port_cmd_error_addr and port_cmd_error_id parameters, respectively. In addition, the access type that relate to the error are stored in the port_cmd_error_type parameter.

Similarly, when a data error occurs, the source ID of the command is saved in the port_data_error_id parameter. The access type that relate to the error are stored in the port_data_error_type parameter.

The bits in the error type parameters are not exclusive. Multiple bits may be set to indicate the type of errors that occurred. Reading the int_ack parameter will allow future errors to be captured in these error parameters.

If multiple errors occur prior to an acknowledgment of the first error, the parameters will still represent the first error attributes. Other error signatures will be lost. If multiple errors occur simultaneously on different ports, the error information will represent the lowest numbered erring port.

20.4.9 Arbiter

From the port interface blocks, commands are presented to the Arbiter, which is responsible for arbitrating between the port requests and sending a single command to the core logic. Refer to DRAM MC Core-Logic for details.

20.4.10 Write Data Queue

The write data queue is a write data storage array for transactions. The queue consists of multiple buffers holding write data for the write requests of a particular port. Write data is stored in these buffers for commands in the command queue until the command is processed in the placement logic and needed by the DRAM command arbitration logic. The buffers can accept data whenever any space is available. The buffers are defined to hold 8 entries.

20.4.11 DRAM Command Processing

The DRAM command processing logic is used to process the commands in the Command Queue. The logic organizes the commands to the memory devices in such a way that data throughput is maximized. DRAM-Bank opening and closing cycles are used for data transfers.

The logic uses a variety of factors to determine when to issue bank open and close commands. The logic reviews the entire Command Queue for look-ahead of which banks are to be accessed in the future. The timing is then set to meet the trc and tras_min timing parameters of the memory devices, values which were programmed into the memory controller on initialization. This flexibility allows the memory controller to be tuned to extract the maximum performance out of memory devices. The parameters that relate to DRAM device protocol are listed in the "DRAM MC Parameter Descriptions" Chapter.

20.4.12 Latency

By using the placement logic of the command queue in the core logic, a new request through any port can be immediately placed at the top of the command queue or can interrupt an ongoing request. This scheme allows a high priority request to be serviced in the shortest possible time.

However, since there are many factors that determine the placement into the command queue, there are also many factors that affect the actual latency of the command. These factors include:

- The coherency status of the transactions already in the command queue: If there is a data coherency conflict with a transaction already in the command queue, the new transaction will be placed after the transaction that produced the conflict. The position of the conflicting transaction determines the latency of the high priority read or write command.
- The priority status of the transactions already in the command queue: If the new command has a higher priority than those already in the command queue, the new request will be serviced ahead of the lower priority command. As a result, the latency of the new command will be lower than the latency of the older command.
- The read, write, and bank information of the transactions already in the command queue: In general, reads will be placed ahead of writes when both are of the same priority level. Read commands are grouped with other read commands of similar priorities and write commands are grouped with other write commands of similar priorities. Among these groupings, transactions with similar bank and different row destinations are separated as much as possible.

If all of the placement conditions are met, then a new command would be placed at the top of the command queue. However, if the new command is of a higher priority than the transaction executing, the current command will be interrupted and the new command will execute first. The interruption will occur at a natural burst boundary of the DRAMs. The interrupted transaction will placed at the top of the placement queue and it will resume after the new request is completed. The page status of the new transaction determines when the current transaction is interrupted. If the page for the new transaction is already open, then the current transaction will be interrupted at the next natural burst boundary of the DRAM device. If the page is not currently open, then the new request will be placed at the top of the command queue while its page is prepared.

20.5 DRAM MC Core-Logic

Figure 20-8 shows the DRAM MC core-logic.

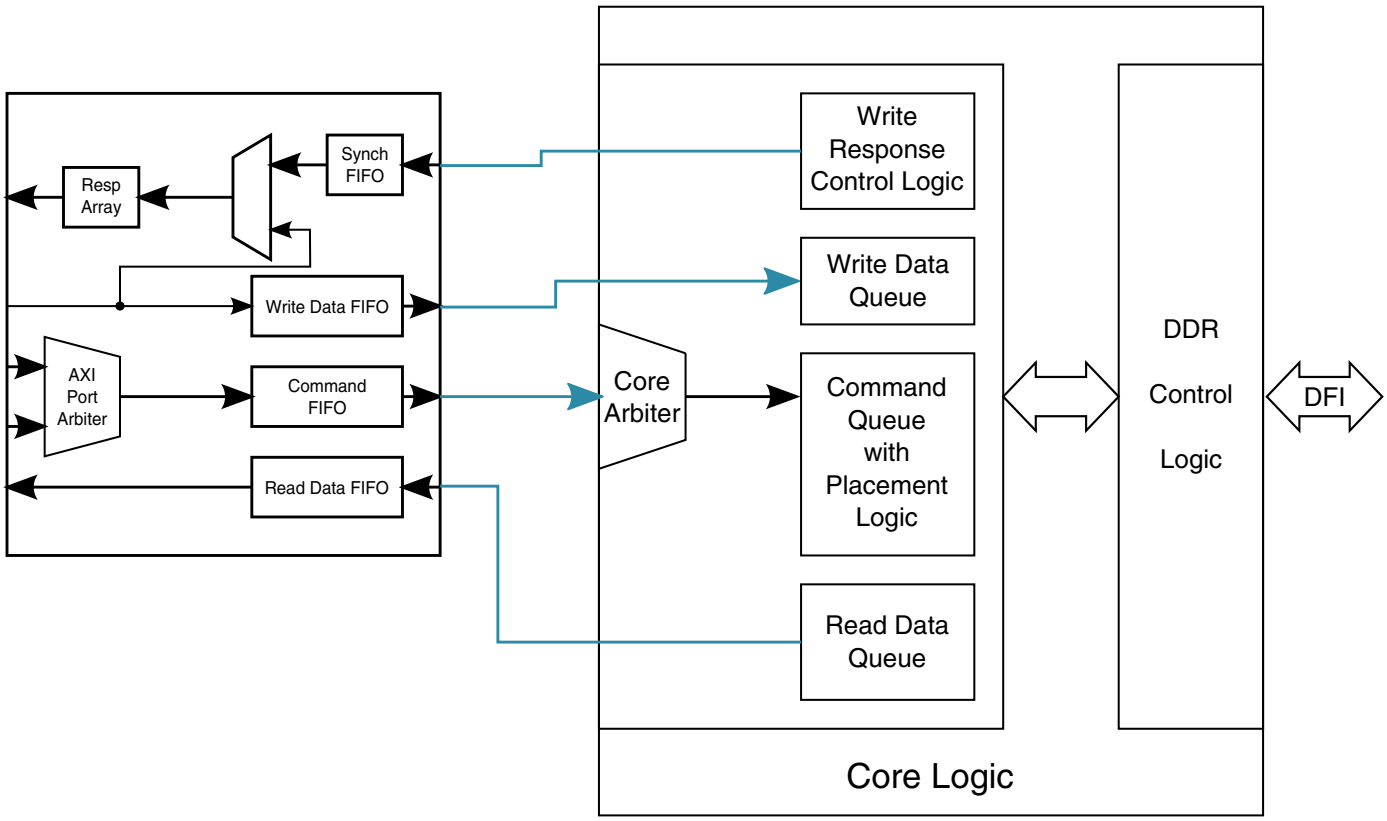

Figure 20-8. DRAM MC Core Logic

The core-logic suports either multi-ports or single-port usecases. A single-port scheme is implemented in this DRAM MC.

The Arbiter is responsible for arbitrating requests from the ports and sending requests to the core logic. Each transaction received at the Arbiter logic has an associated priority, which works with each port's arbitration logic to determine how ports issue requests to the core logic. This memory controller supports the Bandwidth Allocation/Priority Round-Robin arbitration scheme.

The Arbiter logic routes read data from the core logic to the appropriate port. The requesting port is assumed able to receive the data. Write data from each port is connected directly to its own write data interface in the core logic, allowing the ports to independently pass write data to the core buffers.

20.5.1 Command Queue with Placement Logic

From the Arbiter, commands are routed to the command queue of the core logic. The command queue is fed using a placement algorithm. For more information on this algorithm, refer to Core Command Queue with Placement Logic.

20.6 Core Command Queue with Placement Logic

The core logic contains a command queue that accepts commands from the Arbiter. This command queue uses a placement algorithm to determine the order that commands will execute in the core logic. The placement logic follows many rules to determine where new commands should be inserted into the queue, relative to the contents of the command queue at the time. Placement is determined by considering address collisions, source collisions, data collisions, command types and priorities. In addition, the placement logic attempts to maximize efficiency of the core logic through command grouping and bank splitting. Once placed into the command queue, the relative order of commands is constant.

Many of the rules used in placement may be individually enabled/disabled. In addition, the queue may be disabled by clearing the placement_en parameter, resulting in an in-line queue that services requests in the order they are received. If the placement_en parameter is cleared to 'b0, the placement algorithm will be ignored.

20.6.1 Rules of the Placement Algorithm

The factors affecting command placement all work together to identify where a new command fits into the execution order. They are listed in order of importance.

20.6.1.1 Address Collision/Data Coherency Violation

The order in which read and write commands are processed in the memory controller is critical to proper system behavior. While reads and writes to different addresses are independent and may be re-ordered without affecting system performance, reads and writes that access the same address are significantly related. If the port requests a read after a write to the same address, then repositioning the read before the write would return the original data, not the changed data. Similarly, if the read was requested ahead of the write but accidentally positioned after the write, then the read would return the new data, not the original data prior to being overwritten. These are significant data coherency mistakes.

To avoid address collisions, reads or writes that access the same chip select, bank and row as a command already in the command queue will be inserted into the command queue after the original command, even if the new command is of a higher priority.

This factor may be enabled/disabled through the addr_cmp_en parameter and should only be disabled if the system can guarantee coherency of reads and writes.

20.6.1.2 Source ID Collision

Each port is assigned a specific source ID that is a combination of the port and thread ID information, and identifies the source uniquely. This allows the memory controller to map data from/to the correct source/destination.

Note that a source ID does contain port identification information which means that the rules for placement are dependent on the requesting port. There will not be source ID collisions between ports.

In general, read commands from the same source ID will be placed in the command queue in order. Therefore, a read command with the same source ID as a read command already in the command queue will be processed after the original read command. All write commands from a port, even with different source IDs, will be executed in order.

The behavior of commands of different types from the same source ID is dependent on the user configuration. For this Memory Controller, the placement of new read/write commands that collide in terms of source ID with existing entries in the command queue will only depend on other commands of the same type, not on different types. This means that, if there are no address conflicts, a read command could be executed ahead of a write command with the same source ID, and likewise a write command could be executed ahead of a read command with the same source ID.

This feature will always be enabled.

20.6.1.3 Write Buffer Collision

Incoming write requests in the command queue are allocated to one of the 4 write buffers of the core logic automatically based on availability. New write commands will be designated to any available buffer. However, back-to-back write requests from a particular source ID will be allocated to the same write buffer as the previous command.

Since the core logic must pull data out of the buffers in the order it was stored, if a write command is linked to a buffer that is associated with another command in the queue, then the new command will be placed in the command queue after that command, regardless of priority. This feature will always be enabled.

20.6.1.4 Priority

Priorities are used to distinguish important commands from less important commands. Each command is given a priority based on the command type through the programmable parameters axiY_r_priority and axiY_w_priority (where Y represents the port number). A priority value of 0 is the highest priority, and a priority value of 7 is the lowest priority.

The placement algorithm will attempt to place higher priority commands ahead of lower priority commands, as long as they have no source ID, write buffer or address collisions. Higher priority commands will be placed lower in the command queue if they access the same address, are from the same requestor or use the same buffer as lower priority commands already in the command queue.

20.6.1.5 Bank Splitting

Before accesses can be made to two different rows within the same bank, the first active row must be closed (pre-charged) and the new row must be opened (activated). Both activities require some timing overhead; therefore, for optimization, the placement queue will attempt to insert the new command into the command queue such that commands to other banks may execute during this timing overhead. The placement of the new commands will still follow priority, source ID, write buffer and address collision rules.

The placement logic will also attempt to optimize the core logic by inserting a command to the same bank as an existing command in the command queue immediately after the original command. This reduces the overall timing overhead by potentially eliminating one pre-charging/activating cycle. This placement will only be possible if there are no priority, source ID, write buffer or address collisions or conflicts with other commands in the command queue.

All bank splitting features are enabled through the bank_split_en parameter.

20.6.1.6 Read/Write Grouping

The memory suffers a small timing overhead when switching from read to write mode. For efficiency, the placement queue will attempt to place a new read command sequentially with other read commands in the command queue, or a new write command sequentially with other write commands in the command queue. Grouping will only be possible if no priority, source ID, write buffer or address collision rules are violated.

This feature is enabled through the rw_same_en parameter.

20.6.2 Command Execution Order After Placement

Once a command has been placed in the command queue, its order relative to the other commands in the queue at that time is fixed. While this provides simplicity in the algorithm, there are drawbacks. For this reason, the Memory Controller offers two options that affect commands once they have been placed in the command queue.

20.6.2.1 Command Aging

Since commands can be inserted ahead of existing commands in the command queue, the situation could occur where a low priority command remains at the bottom of the queue indefinitely. To avoid such a lockout condition, aging counters have been included in the placement logic that measure the number of cycles that each command has been waiting. If command aging is enabled through the active_aging parameter, then if an aging counter hits its maximum, the priority of the associated command will be decremented by one (lower priority commands are executed first). This increases the likelihood that this command will move to the top of the command queue and be executed. Note that this command does not move relative positions in the command queue when it ages; the new priority will be considered when placing new commands into the command queue.

Aging is controlled through a master aging counter and command aging counters associated with each command in the command queue. The age_count and command_age_count parameters hold the initial values for each of these counters, respectively. When the master counter counts down the age_count value, a signal is sent to the command aging counters to decrement. When the command aging counters have completely decremented, then the priority of the associated command is decremented by one number and the counter is reset. Therefore, a command does not age by a priority level until the total elapsed cycles has reached the product of the age_count and command_age_count values. The maximum number of cycles that any command can wait in the command queue until reaching the top priority level is the product of the age_count value, the command_age_count value, and the number of priority levels in the system.

20.6.2.2 High-Priority Command Swapping

Commands are assigned priority values to ensure that critical commands are executed more quickly in the memory controller than less important commands. Therefore, it is desirable that high-priority commands pass into the core logic as soon as possible. The placement algorithm takes priority into account when determining the order of

commands, but still allows a scenario in which a high-priority command sits waiting at the top of the command queue while another command, perhaps of a lower priority, is in process.

The high-priority command swapping feature allows this new high-priority command to be executed more quickly. If the user has enabled the swapping function through the swap_en parameter, then the entry at the top of the command queue will be compared with the current command in progress. If the command queue's top entry is of a higher priority (not the same priority), and it does not have an address, source ID or write buffer conflict with the current command being executed, then the original command will be interrupted.

For this memory controller, an additional check is performed before a read command is interrupted. If the read command in progress and the read command at the top of the command queue are from the same port, then the executing command will only be interrupted if the swap_port_rw_same_en parameter is set to 'b1. If this parameter is cleared to 'b0, a read command from the same port as a read command in progress, even with a higher priority and without any conflicts, would remain at the top of the command queue while the current command completes.

NOTE

All write commands from a single port, even with different source IDs, will be executed in order. Therefore, two write commands from the same port will never be swapped regardless of the settings of the swap_en and swap_port_rw_same_en parameters.

NOTE

Priorities are assigned to read commands based on the settings in the axiY_r_priority parameters. While all read commands from a port are assigned the same priority when placed in the command queue, their priorities may change over time through command aging. While uncommon, it is possible that a higher-priority read command may be at the top of the command queue while a lower-priority read command is executing. The behavior of the system in this scenario is based on the value of the swap_en and swap_port_rw_same_en parameters.

See Table 20-7 for details.

Table 20-7. Swapping Behavior

active command priority	new command priority	originating port for commands	conflicts ?	action
Higher	Lower	Same or Different	Yes or No	Current Command Continues
Lower	Higher	Same	Yes	Current Command Continues
Lower	Higher	Same	No	Will swap IF swap_en = 1 & swap_port_rw_same_en = 1
Lower	Higher	Different	No	Will swap IF swap_en = 1

If the command is to be interrupted, it will be halted after completing the current burst, stored and placed at the top of the queue, and the new command will be executed. As long as the command queue is not full, new commands may continue to be inserted into the command queue based on the placement rules, even at the head of the queue ahead of the interrupted command. The top entry in the command queue will be executed next. Whenever the interrupted command is resumed, it will start from the point at which it was interrupted.

Note that priority 0 commands will never be interrupted, so the user should set any commands that should not be interrupted to priority 0. If supported by the port interfaces, setting the swap_port_rw_same_en parameter will enable interleaving.

20.7 Notes for Programming of the Timing Parameters

20.7.1 Command to Command Timing

For flexibility and maximum user control, the MC provides a set of timing parameters to control the timing between commands of different types. Each of these parameters should be programmed with the actual number of clocks of turn-around required for this transaction combination on the data bus. The parameters are:

- add_odt_clk_difftype_diffcs
- add_odt_clk_w2r_samecs
- add_odt_clk_r2w_samecs
- add_odt_clk_sametype_diffcs
- r2r_diffcs_dly
- r2r_samecs_dly
- r2w_diffcs_dly
- r2w_samecs_dly
- w2r_diffcs_dly
- w2r_samecs_dly

- w2w_diffcs_dly
- w2w_samecs_dly

20.7.2 Refresh Per Chip-select

While memory refresh operations are necessary for DRAM data integrity, they unfortunately draw a significant current and temporarily disable the memory from accepting other commands. A standard practice is to issue refresh commands to all chip selects simultaneously at each tref interval. This minimizes the downtime before another data command can be processed (trfc) but does increase peak current while the refresh is in progress.

As an alternative, the MC includes the option to individually refresh each chip select in a sequential manner. When using this feature, a memory refresh may be initiated from the user interface by setting the arefresh parameter to b1 or through an internal source such as the expiration of the tref counter or an exit from Self-Refresh.

Regardless of the source, when the refresh command is received, all transactions will be inhibited and a refresh sequence will be initiated. This refresh sequence issues refresh commands to one chip select at a time, moving through all of the chip selects in succession. A programmable delay (the tref_interval parameter) sets the time period between when refresh commands are issued to different chip selects.

A related memory-specific parameter (the trfc parameter) sets the time that a DRAM device must wait between receiving a refresh command to when a data transaction can be processed. When each refresh command is issued, the trfc counter inside the MC begins a countdown from the programmed value (in the trfc parameter). With each refresh command, the counter is reset and the memory controller will only accept commands trfc cycles after when the final refresh command has been issued.

Once the trfc time expires, normal read/write traffic and behavior resumes in the memory controller. All other transactions will be inhibited during this refresh sequence until all chip selects have been issued their refresh commands and the associated timing requirements have been met.

20.7.3 Programming of the tref Parameter

The tref parameter sets the average interval between refreshes. The actual interval may vary by up to 8 cycles from refresh to refresh, depending on other activities that are occurring in the controller at the time. Over an infinite time period, the average interval

will be equal to the number of clocks set by this parameter; however, if the user sets this parameter to be exactly equal to the specification value tREF, then local variations might mean that the memory tREF value may be violated by a very small amount.

Although we never seen a failure in a real system as a result of programming the tref parameter to the exact tREF parameter, but it is recommended that the user should program the tref parameter to the value a litter smaller than (tREF/tCK), which will result in slightly lower overall bandwidth and slightly higher memory power usage.

20.7.4 Programming of the tref_interval Parameter

The interval is a critical value in achieving real current savings. The following considerations should be taken for programming the tref_interval parameter:

- A larger interval will increase the time that the MC is held off from processing data transactions.
- Peak current restrictions will guide the interval value. The interval should be defined to the minimum value that still meets peak current restrictions.
- Programming the interval to zero will disable the refresh per chip select logic and refresh commands will be issued simultaneously to all chip selects.
- The refresh per chip select logic requires at least one dead cycle between refresh commands, and therefore the minimum interval used is actually 2 cycles. Programming the tref_interval parameter to 1 will default to 2 cycles.
- Other factors in the design also affect timing, and therefore the actual delay between refresh commands may exceed the programmed value. This is particularly likely when the interval value programmed is very low, such as b002.
- When the trfc counter completes its countdown, the memory controller will accept any pending commands. Since no read or write commands may occur during the entire refresh sequence, the tref_interval parameter should always be set to a value lower than the trfc parameter.

20.8 DRAM Low Power Operation

In many applications, it is desirable to minimize the power consumption of the DRAM MC and the memory devices. The MC provides various user-configurable low power options to address power savings.

20.8.1 Low Power Modes

There are four low power modes available in the MC. The low power modes are listed from least to most power saving.

Note: It is not possible to exit one low power mode and enter another low power mode simultaneously. The user should plan for a minimum delay between exit and entry between the two low power modes of 15 cycles in which the memory controller must remain stable.

1. **Memory Power-Down**

   The MC sets the memory devices into power-down, which reduces the overall power consumption of the system, but has the least effect of all the low power modes. In this mode, the MC and memory clocks are fully operational, but the CKE input bit to the memory devices is de-asserted. The MC will continue to monitor memory refresh needs and will automatically bring the memory out of power-down to perform these refreshes. When a refresh is required, the CKE input bit to the memory devices will be reenabled. This action brings the memory devices out of power-down. Once the refresh has been completed, the memory devices will be returned to power-down by de-asserting the CKE input bit.

2. **Memory Power-Down with Memory Clock Gating**

   The memory controller sets the memory devices into power-down and gates off the clock to the memory devices. Refreshes will be handled as in the Memory Power-Down mode (Mode 1), with the exception that gating on the memory clock will be removed before asserting the CKE pin. After the refresh has been completed, the memory devices will be returned to power-down with the clock gated. Before the memory devices are removed from power-down, the clock will be gated on again. The user should not use this mode for memory devices that do not support memory clock gating. Clock gating is not supported for standard DDR1, DDR2 or DDR3 devices. When set into this mode, the memory controller will attempt to place the memory devices in power-down and gate off the memory clock. The memory will function unpredictably and may hang.

3. **Memory Self-Refresh**

   The MC sets the memory devices into self-refresh. In this mode, the MC and memory clocks are fully operational and the CKE input bit to the memory devices is de-asserted. Since the memory automatically refreshes its contents, the MC does not need to send explicit refreshes to the memory.

4. **Memory Self-Refresh with Memory Clock Gating**

The MC sets the memory devices into self-refresh and gates off the clock to the memory devices. Before the memory devices are removed from self-refresh, the clock will be gated on again.

20.8.2 Low Power Mode Control

The memory controller may enter and exit the various low power modes in the following ways:

- **Automatic Entry**

  When the MC is idle, three timing counters begin counting the cycles of inactivity. If any of the counters expires, the MC will enter the low power mode associated with that counter.

- **Manual Entry**

  The user may initiate any low power mode by setting the bit of the lowpower_control parameter associated with the desired mode. The MC will enter the selected low power mode when it is has completed its current memory burst.

Automatic and Manual entry methods are both controlled by two parameters: lowpower_control and lowpower_auto_enable. The lowpower_control parameter contains individual enable/disable bits for each low power mode, and the lowpower_auto_enable parameter controls whether each mode will be entered automatically or manually.

Note: The user should not use both automatic and manual modes for the various low power modes. All modes should be entered automatically or all entered manually.

20.8.3 Automatic Entry

Automatic Entry will occur if all of the following conditions are true:

- The mode is programmed for automatic entry by setting the relevant bit in the lowpower_auto_enable parameter to b1.
- The particular mode is enabled in the lowpower_control parameter.
- The memory controller is idle.
- The counter associated with this mode expires.

There are three counters in all to cover the low power modes. There are separate counters for each of the three memory self-refresh low power modes (Modes 3 and 4). Memory Power-Down mode (Mode 1) and Memory Power-Down with Memory Clock Gating mode (Mode 2) share the same counter.

The counters determine the number of idle cycles before entry into the associated low power mode. All of these counters are re-initialized each time there is a new read or write transaction entering or executing in the MC. This ensures that the MC will not enter any of the low power modes when active.

20.8.4 Automatic Exit

All low power modes can be entered through automatic entry, and will be exited automatically when any of the following conditions occur:

- A new read or write transaction appears at the memory controller interface.
- The MC must refresh the memory when in either of the power-down modes (Modes 1 or 2). After completing the memory refresh, the memory controller re-enters power-down.
- The counter for a deeper low power mode expires. The MC must exit the current low power mode in order to enter the deeper low power mode. A minimum of 15 cycles occur between exit from one low power mode before entering into the next low power mode, even if the counters expire within 15 cycles of each other. Note that the MC will not enter a less deep low power mode, regardless of which counters expire.

20.8.5 Manual "On-Demand" Entry

Manual Entry will occur if all of the following conditions are true:

- The mode is programmed for manual entry by clearing the relevant bit in the lowpower_auto_enable parameter to b0.
- The particular mode is set to íb1 in the lowpower_control parameter.

For manual entry, the lowpower_control parameter triggers entry into the low power modes. The MC does not need to be idle when the a low power mode bit is enabled. When a particular mode that is programmed for manual entry is enabled, the memory controller will complete the current memory burst access, and then, regardless of the activity inside the MC or at the memory interface, it will enter the selected low power mode.

If new transactions enter the MC while it is in any of the low power modes, they will accumulate inside the MC's command queue until the queue is full.

20.8.6 Manual "On-Demand" Exit

Exit from a manually-entered low power mode is also manual. Clearing the lowpower_control parameter bits to b0 will trigger the MC to pull the memory devices out of powerdown or self-refresh, and command processing will resume.

If a different lowpower_control parameter bit is set to b1 while in one of the low power modes, or on clearing of the original bit to b0, the MC will exit the current low power mode. There will be at least a 15 cycle delay before the MC is fully operational, or enters the new low power mode.

20.8.7 Register Programming

The low power modes of the MC are controlled through the lowpower_control and lowpower_auto_enable parameters. These parameters each contain one bit for controlling each low power mode. The lowpower_control parameter enables the associated low power mode, and the lowpower_auto_enable parameter sets the entry method into that mode as manual or automatic. Table 20-8 shows the relationship between the lowpower_control and lowpower_auto_enable parameters and the various low power modes.

Table 20-8. Low Power Mode Parameters

Low Power Mode	Enable	Entry
Memory Power-Down (Mode 1)	lowpower_control [4] = 1	lowpower_auto_enable [4] 0 = Manual 1 = Automatic
Memory Power-Down with Memory Clock Gating (Mode 2)	lowpower_control [3] = 1	lowpower_auto_enable [3] 0 = Manual 1 = Automatic
Memory Self-Refresh (Mode 3)	lowpower_control [2] = 1	lowpower_auto_enable [2] 0 = Manual 1 = Automatic
Memory Self-Refresh with Memory Clock Gating (Mode 4)	lowpower_control [1] = 1	lowpower_auto_enable [1] 0 = Manual 1 = Automatic
Reserved	lowpower_control [0] Please keep this bit to zero.	lowpower_auto_enable [0] Please keep this bit to zero.

When a lowpower_control parameter bit is set to íb1 by the user, the MC checks the lowpower_auto_enable parameter.

- If the associated bit in the lowpower_auto_enable parameter is set to b1, then the MC will watch the associated counter for expiration, and then enter that low power mode. Table 20-9 shows the correlation between the low power modes and the counters that control each modeís automatic entry.
- If the associated bit in the lowpower_auto_enable parameter is cleared to b0, then the MC will complete its current memory burst access and then enter the specified low power mode.

Table 20-9. Low Power Mode Counters

Low Power Mode	Entry
Memory Power-Down (Mode 1)	lowpower_power_down_cnt
Memory Power-Down with Memory Clock Gating (Mode 2)	lowpower_power_down_cnt
Memory Self-Refresh (Mode 3)	lowpower_self_refresh_cnt
Memory Self-Refresh with Memory Clock Gating (Mode 4)	lowpower_external_cnt

NOTE

The counter parameters must be programmed to non-zero values for proper operation.

NOTE

The values in the lowpower_auto_enable parameter are only relevant when the associated lowpower_control bit is set to b1.

Multiple bits of the lowpower_control and lowpower_auto_enable parameters can be set to b1 at the same time. When this happens, the MC always enters the deepest low power mode of all the modes that are enabled. If the MC is already in one low power mode when a deeper low power mode is requested automatically or manually, it must first exit the current low power mode, and then enter the deeper low power mode. A minimum 15 cycle delay occurs before the second entry.

The timing for automatic entry into any of the low power modes is based on the number of idle cycles that have elapsed in the MC.

20.9 Interface for LPDDR2 Devices

This MC is designed to interface with LPDDR2 memory devices. While other memory devices may also be supported, the MC will only interface with a single type of memory at a time. The user must set the mode through the dram_class mode parameters. Certain features of LPDDR2 memories require special logic in the MC.

20.9.1 Restrictions

The MC does not support interleaving (MR1 [3]), wrapping (MR1 [4]) and only supports memory burst lengths of 4 or 8. The burst terminate command and data not valid commands are not used.

20.9.2 ZQ Calibration for off-chip LPDDR2 Devices

ZQ calibration is a feature of LPDDR2 memories used to calibrate DRAM Ron and ODT values. There are four types of ZQ commands defined by the JEDEC LPDDR2 specification:

- ZQCS, or ZQ short calibration, is used for a periodic update to the DRAM values.
- ZQCL, or ZQ long calibration, is used for longer updates to the DRAM values.
- ZQINIT, or ZQ initialization, is used during initialization of memory.
- ZQRESET, or ZQ reset, is used to reset the ZQ calibration values to their default state.

All commands are supported by the MC. Before a ZQ command is initiated, regardless of how the command was requested, pending refreshes and power down commands are all handled, any commands in process are completed, and all active memory banks are closed. While the ZQ command is in process, the MC core command queue will be halted. During this time, no other commands are allowed, CKE must be held asserted and the DQ bus must be held in high impedence state. Mode register MR10 in the LPDDR2 memory devices control ZQ calibration.

NOTE

If the refresh cycle time is long, PHY update times are extensive, and there are many chip selects in the system, it is possible that a large number of cycles may elapse without allowing any user activity.

NOTE

Although ZQ calibration is only required for LPDDR2, Freescale recommends the use of ZQ calibration for mDDR and DDR2 as well.

20.9.3 Programmable Control

- refresh_per_zq

  Defines the number of refresh cycles that will occur between automatic ZQ calibration sequences. The refresh timer will only trigger a short ZQ calibration sequence. Setting this parameter to 0x0 will disable automatic ZQCS commands. When using the rotate option, this parameter should be programmed to the total number of cycles desired between ZQCS commands divided by the number of chip selects in the system.

- zq_in_progress

  Status parameter to indicate if a ZQ calibration of any type is in progress.

- zq_on_sref_exit

  May be enabled to issue a short ZQ, long ZQ, ZQ reset or ZQ initialization calibration automatically when exiting self-refresh mode. A short calibration sequence may calibrate all chip selects in the system (if the parameter zqcs_rotate is cleared to b0) or just one chip select on each self-refresh exit, in rotating fashion. A long, initialization or reset calibration will affect all chip selects in the system. It is recommended to set this parameter to execute a ZQCL on self-refresh exit. By setting this parameter this way, a ZQCL will be issued before any other commands are permitted to execute. If this parameter is set to any other setting, the system must manage self-refresh exit and ZQ calibration. If using the ZQCS option, it is recommanded that the rotate function should be disabled (the parameter zqcs_rotate should be cleared to b0) to calibrate all chip selects.

NOTE

If a ZQ command is issued prior to a self-refresh command, once the self-refresh command is accepted, it will cause the ZQ command to be aborted. Therefore, the user should utilized the zq_on_sref_exit parameter to ensure that a ZQ calibration is executed.

NOTE

If a ZQ command is issued while the memory is in self-refresh, and the zq_on_sref_exit parameter has been

programmed to a non-zero value, then the new ZQ command will be issued only AFTER self-refresh exit and the ZQ command specified in zq_on_sref_exit has completed. Therefore, if the zq_on_sref_exit function is being used, then issuing any ZQ commands during self-refresh will only result in added latency and is not recommended.

- zq_req

  Triggers a short, long, initialization or reset ZQ calibration. A short calibration sequence may calibrate all chip selects in the system (if the parameter zqcs_rotate is cleared to b0) or just one chip select on each self-refresh exit, in rotating fashion. A long, initialization or reset calibration will affect all chip selects in the system.

- zqcl

  Specifies the number of cycles required for the memory devices to complete a long (noninitialization) ZQ calibration.

- zqcs

  Specifies the number of cycles required for the memory devices to complete a short ZQ calibration. This parameter can be programmed as needed for the user system, either to the number of cycles required to complete a ZQCS to all chip selects in the system (if the zqcs_rotate parameter will be cleared to b0) or the number of cycles to complete a ZQCS to a single chip select (if the zqcs_rotate parameter will be set to b1).

- zqcs_rotate

  Defines if all chip selects or just one (on a fixed rotational basis) will be calibrated on any tuype of ZQCS request. Setting this parameter to b1 enables the single chip select calibration and minimizes the overhead of periodic ZQ calibrations.

- zqinit

  Specifies the number of cycles required for the memory devices to complete a ZQ initialization command.

- zqreset

  Specifies the number of cycles required for the memory devices to complete a ZQ reset operation.

20.9.4 ZQ Short Calibration

A ZQ short calibration may calibrate each chip select enabled in the cs_map parameter on each request, or just one chip select on each ZQ short calibration request. The value of the zqcs_rotate parameter determines whether all chip selects or just one chip select are calibrated on each request. The MC will issue the appropriate ZQCS commands.

A ZQCS will be issued in the following cases:

- The user requests a short ZQ calibration by setting the zq_req parameter to b01.
- If the zq_on_sref_exit parameter is set to b01, then a ZQ short calibration will be issued whenever the memory devices exit self-refresh mode.
- The number of refreshes that have occurred since the last ZQCS exceeds the value specified in the refresh_per_zq parameter.

20.9.5 ZQ Long Calibration

A ZQ long calibration will calibrate each chip select in the system, one chip select at a time. The MC will issue the appropriate ZQCL commands to each chip select.

A ZQCL will be issued in the following cases:

- The user requests a long ZQ calibration by setting the zq_req [1] parameter bit to b1.
- If the zq_on_sref_exit [1] parameter bit is set to b1, then a ZQ long calibration will be issued whenever the memory devices exit self-refresh mode.

20.9.6 ZQ Initialization

A ZQ initialization calibration will calibrate each chip select in the system, one chip select at a time. The MC will issue the appropriate ZQINIT commands to each chip select.

A ZQINIT will be issued in the following cases:

- The user requests a ZQ initialization by setting the zq_req [2] parameter bit to b1.
- If the zq_on_sref_exit [2] parameter bit is set to b1, then a ZQ initialization will be issued whenever the memory devices exit self-refresh mode.

20.9.7 ZQ Reset

A ZQ reset calibration will calibrate each chip select in the system, one chip select at a time. The MC will issue the appropriate ZQRESET commands to each chip select.

A ZQRESET will be issued in the following cases:

- The user requests a ZQ reset by setting the zq_req [3] parameter bit to b1.
- If the zq_on_sref_exit [3] parameter bit is set to b1, then a ZQ reset will be issued whenever the memory devices exit self-refresh mode.

20.10 DDR PHY

The DDR PHY encapsulates all functionality required to interface to external DDR DRAM devices into a single module. This module is used to control the off-chip data capture and synchronization logic for the read data. This module performs the following functions:

- Contains all data registers used to launch data, address, and control signals to the DDR memory and the memory controller.
- Controls the off-chip data capture and synchronization logic for the read data.
- Includes DLL for timing.

20.10.1 High Level Block Diagram

DRAM MC uses a slice-based approach for the DDR PHY. Each slice manages a byte (8 bits) of data and its corresponding DQS and DM signals.

A high level block diagram of the PHY is provided in Figure 20-9.

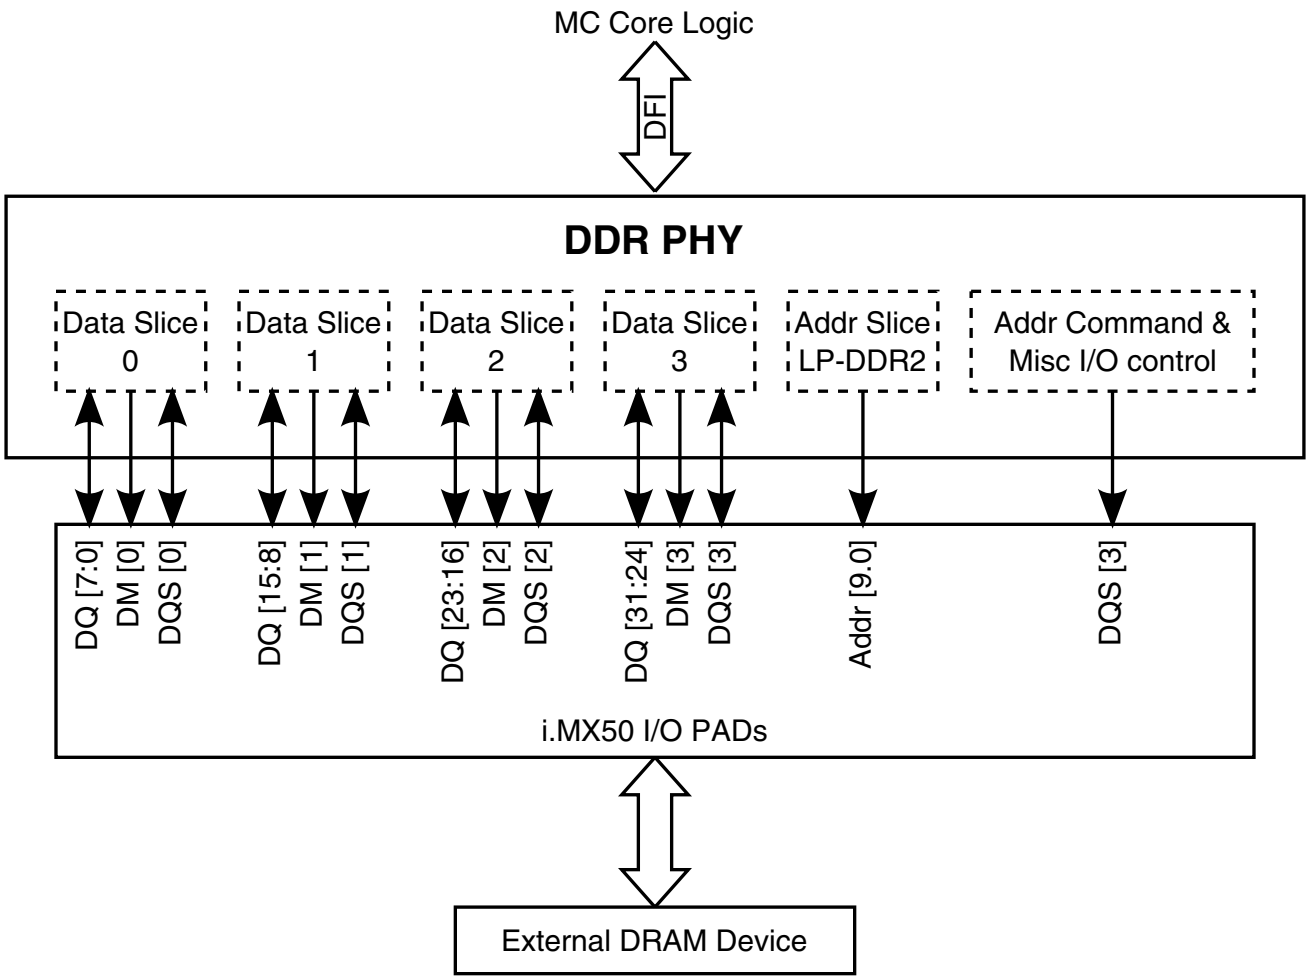

Figure 20-9. DDR PHY High Level Block Diagram

20.10.2 DFI

The interface between the DRAM MC core logic and the DDR_PHY is called "DFI". The "D" stands for "DRAM Controller" while "FI" is a reference to "PHY".

20.10.3 The I/O Timing of Address & Command

Figure 20-10 illustrates the I/O timing of Address and Command.

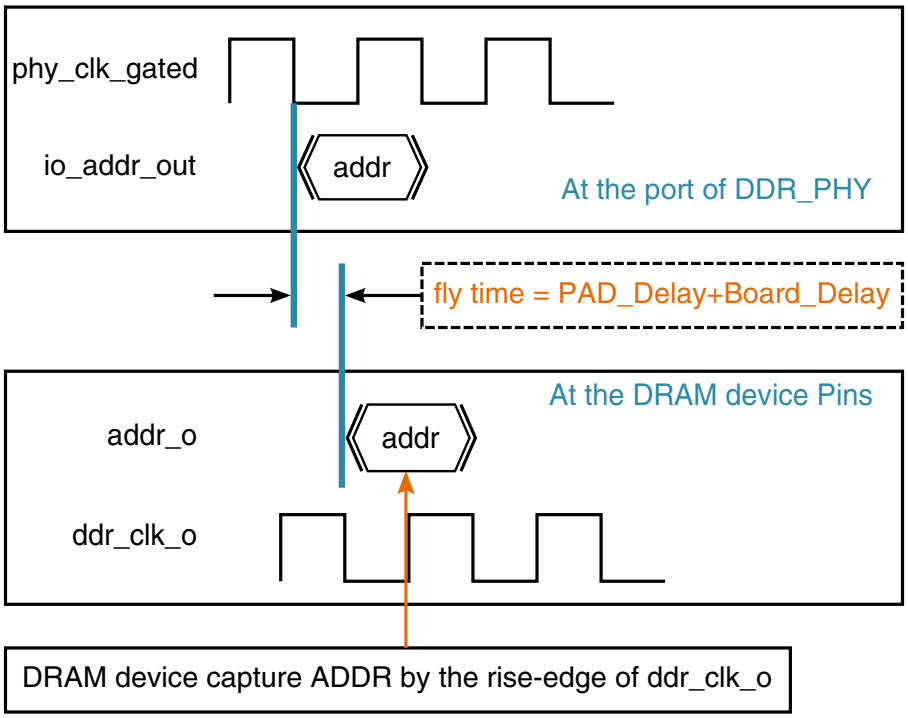

Figure 20-10. The I/O Timing of Address

The address & command signals including all DRAM interface signals except the DQ & DQS: clock-enable (CKE), chip-select, bank-address, row/cloumn_address, CASn, RASn, WEn, etc.

1. The Address & command signals is latched out by the fall-edge of PHY_CLK; In another word, the rise-edge of PHY_CLK is center-aligned with the output Address & Command signals.
2. The "fly-time" means the signals propagation time start from the DDR_PHY logic, go accross the output I/O (PAD), go through the signal trace on the board, then arrive the PIN of the DRAM device.
3. The DRAM device would capture the Address & Command signals by the rise edge of ddr_clk_o.
4. Figure 20-10 illustrates the address timing for Standard DDR2 & LP-DDR1. The timing of LP-DDR2 is quite different.

20.10.4 The Address Timing of LP-DDR2

There's a specail slice "Addr Slice" illustrated in Figure 20-9. It is designed to deal with the address[9:0] of LP-DDR2 device which require double-data-rate timing. Either the address[9:0] (in LP-DDR2 mode) or the ddr write data timing can be illustrated by Figure 20-14.

20.10.5 Data Slice Overview

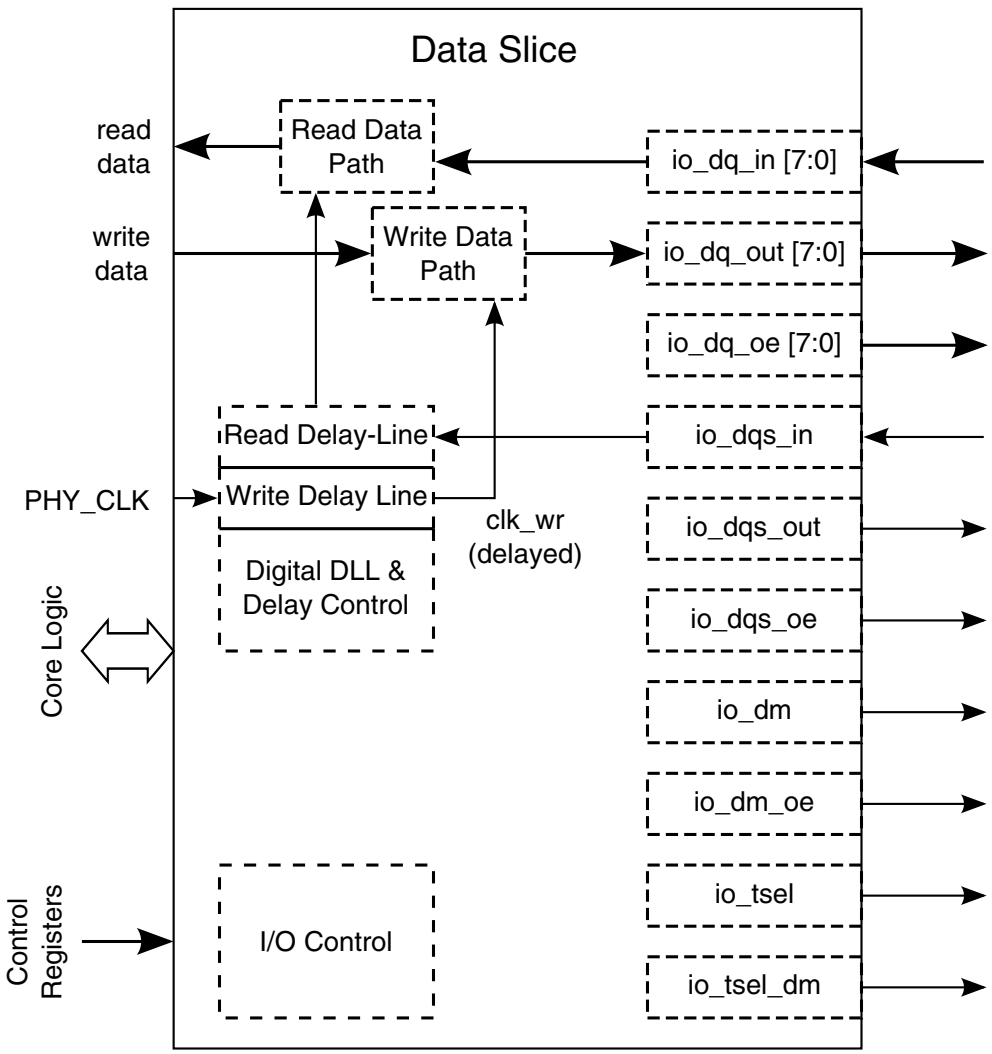

Figure 20-11. DDR PHY Data Slice

Each data-slice manages a byte (8-bit) of data and its corresponding signals.

The "Read Data Path" capture read data by latching it into read data buffers by both the posedge & negedge of "delayed_dqs". Then, the read data is synchronized from "delayed_dqs" clock domain to PHY_CLK domain.

The "Write Data Path" synchronize write data and write data mask (the "dm") from PHY_CLK domain to "dqs_out" domain.

The "Digital DLL" controls the delay values of "read delay-line" and "write delay-line". It can be bypassed and switched to manual delay control mode. In manual delay control mode, the delay values of read/write delay-line can be programmed into it's control registers separately.

20.10.6 Read Data Capture

When reading, DDR (dual data rate) devices send a data strobe (DQS) signal coincident with the read data. The edges of this DQS strobe are aligned (edge-aligned) with the data output by the DDR devices.

To latch read data into DRAM MC read data buffer, it requires that the latch clock edge is center-aligned with the data. Thus, a delayed version of the DQS strobe signal must be used to capture the data. Because the frequency of the DQS strobe signal is matched to the PHY_CLK, the delay is a relative number based on the period of the PHY_CLK. In the example shown in Figure 20-12, the delay is set to approximately 25% of the PHY_CLK cycle.

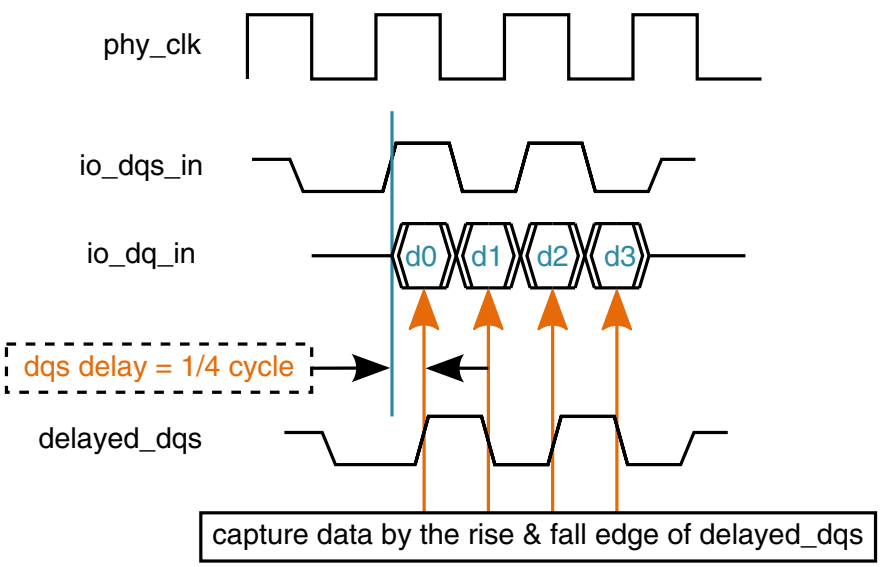

Figure 20-12. Read Data Capture

20.10.7 Synchronize Read Data From delayed_dqs To PHY_CLK domain

Read data is captured into data buffers by the "delayed_dqs". It must be synchronized into PHY_CLK domain, then returned to DRAM MC core logic.

Figure 20-13 illustrates how the read data from the external DRAM device is captured and synchronized to DRAM MC core logic.

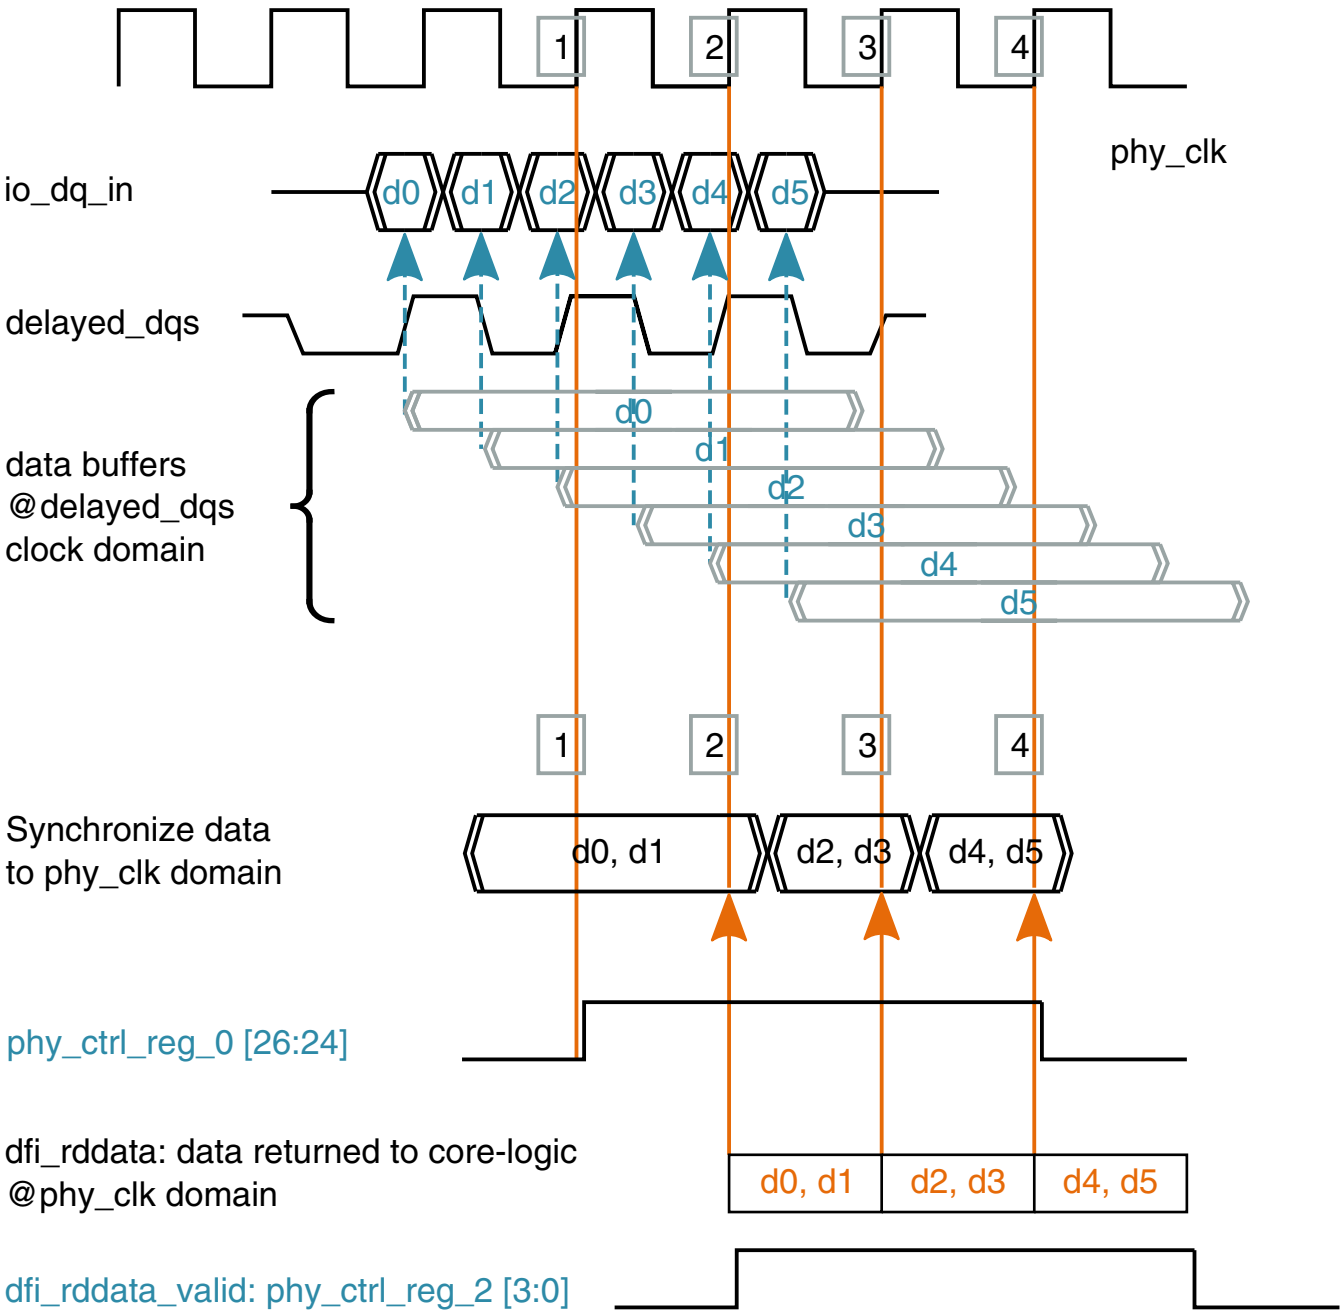

Figure 20-13. Synchronize Read Data

1. io_dq_in & io_dqs_in are not aligned with PHY_CLK in phase. Many factors affect the phase of io_dq/dqs_in, such as voltage, temperature, board layout, manufacture process, and so on.

2. Must capture the io_dq_in by delayed_dqs to meet the critical timing requirement in high frequency.
3. The data path width @PHY_CLK domain is twice of the data path width @delayed_dqs domain.
4. The DRAM MC core logic fetch read data by the rise-edge of PHY_CLK. The DRAM MC core logic fetch read data by two important signals: dfi_rddata & dfi_rddata_valid.
5. The user can program the timing position of "dfi_rddata & dfi_rddata_valid" by programmable registers "phy_ctrl_reg_0[26:24]" & "phy_ctrl_reg_2[3:0]". The unit is one cycle of PHY_CLK.
6. In this example, read data "d0,d1" getting valid before edge number "1" of PHY_CLK and is synchronized at edge "2" of PHY_CLK. Both the setup & hold time requirement are met which means read data could be fetched by core logic safely. Alternatively, read data can also be returned to core logic at edge number "1" of PHY_CLK, a cycle prior to the example. In this scenario, need to set the value of register "phy_ctrl_reg_0[26:24]" & "phy_ctrl_reg_2[3:0]" one number less. The, the "dfi_rddata" & "dfi_rddata_valid" would getting valid one cycle earlier. The benefit is that the read latency was shorten by one cycle, it help increasing the system performance. But, there's a timing risk on the "setup time", if the io_dq/dqs_in comes a little late, "setup time violation" may occur and the un-expected data would be returned to core logic, and, might lead to system crash.

20.10.8 Write Data Path

Figure 20-14 illustrates the write data path.

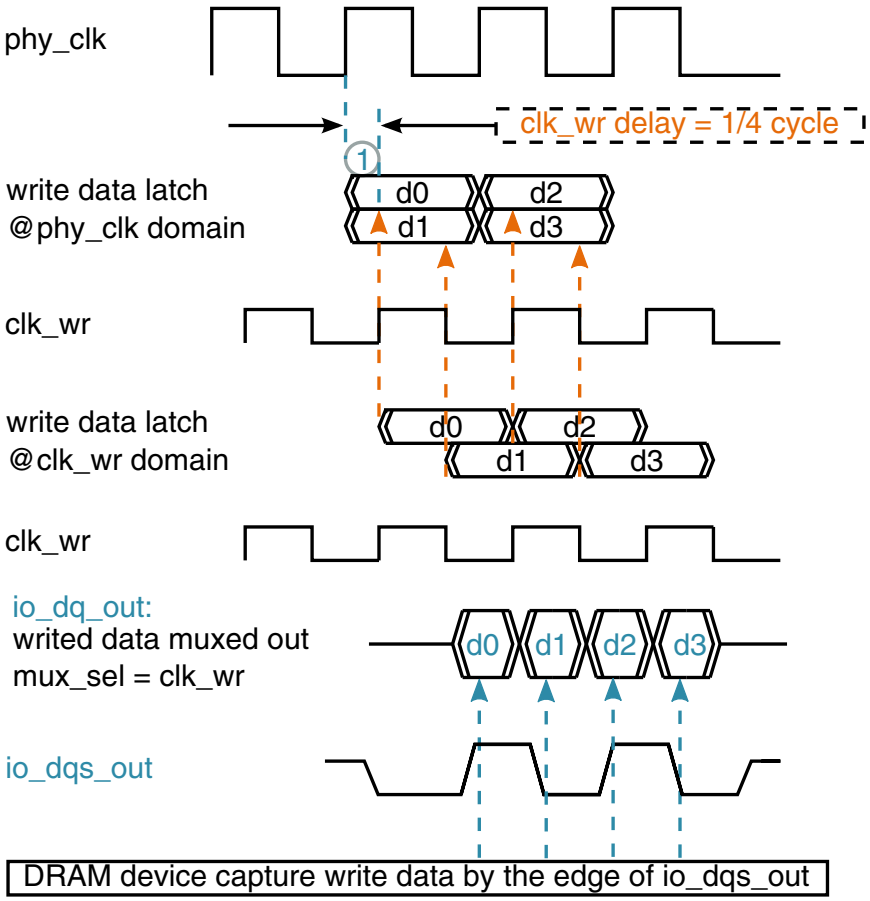

Figure 20-14. Write Data Path

NOTE

The marker "1" indicates that the "setup time" here for data "d0" is only "1/4 cycle", that would be critical in timing. The Low-Latency Option of Write Data Path , contains more detail on it.

The "io_dqs_out" and the PHY_CLK are edge-aligned in this DRAM MC design. This helps to meet the "tDQSS" timing requirement defined by the DRAM device.

The "io_dqs_out" and the "io_dq_out" are center-aligned, as required by the DRAM device.

20.10.8.1 The Low-Latency Option of Write Data Path

DDR_PHY provides 2 write data path options for the user :

1. The "Standard-Latency" option.

An extra latch at PHY_CLK domain is asserted into the write data path, right ahead of the latch at clk_wr domain (at the place of marker "1" in Figure 20-14). By this means, the asserted-latch and the latch@clk_wr are put back-to-back. The total delay in write data path is "1+1/4" cycle. It is safe in timing but decrease the performance by adding one cycle latency.

2. The "Low-Latency" option.

   The asserted latch for standard-latency is bypassed. The total delay in write data path is "1/4" cycle. There's risk in timing of write data path but it has higher performance than standard-latency case.

20.10.9 Digital DLL and the Delay-Line

Due to the asynchronous nature of the DRAM devices, the timing requirements for capturing and receiving data between the MC and the DRAM devices must be addressed. This DRAM MC contains a circuit that, in conjunction with I/O cell circuitry, can be used to meet the timing requirements for DRAM devices. The delay compensation circuit was designed with the following features:

- Programmable read strobe delay specified as a percentage of a clock cycle.
- Programmable write data delays specified as percentages of a clock cycle.
- Delay compensation circuit re-sync circuitry activated during refresh cycles to compensate for temperature and voltage drift.
- Separate delay chains for each read DQS signal from the DRAM devices.

The delay compensation circuitry relies on a master/slave approach. There is a master delay line which is used to determine how many delay elements constitute a complete cycle. This count is used, along with the programmable fractional delay settings, to determine the actual number of delay elements to program into the slave delay lines. The master and slave delay lines are identical. This approach allows the memory controller to observe a clock and then delay other signals a fixed percentage of that clock. The DLL logic does not actively generate clock signals.

The actual delay element for the delay lines is user-selectable.

Figure 20-15 shows the block diagram for a digital DLL.

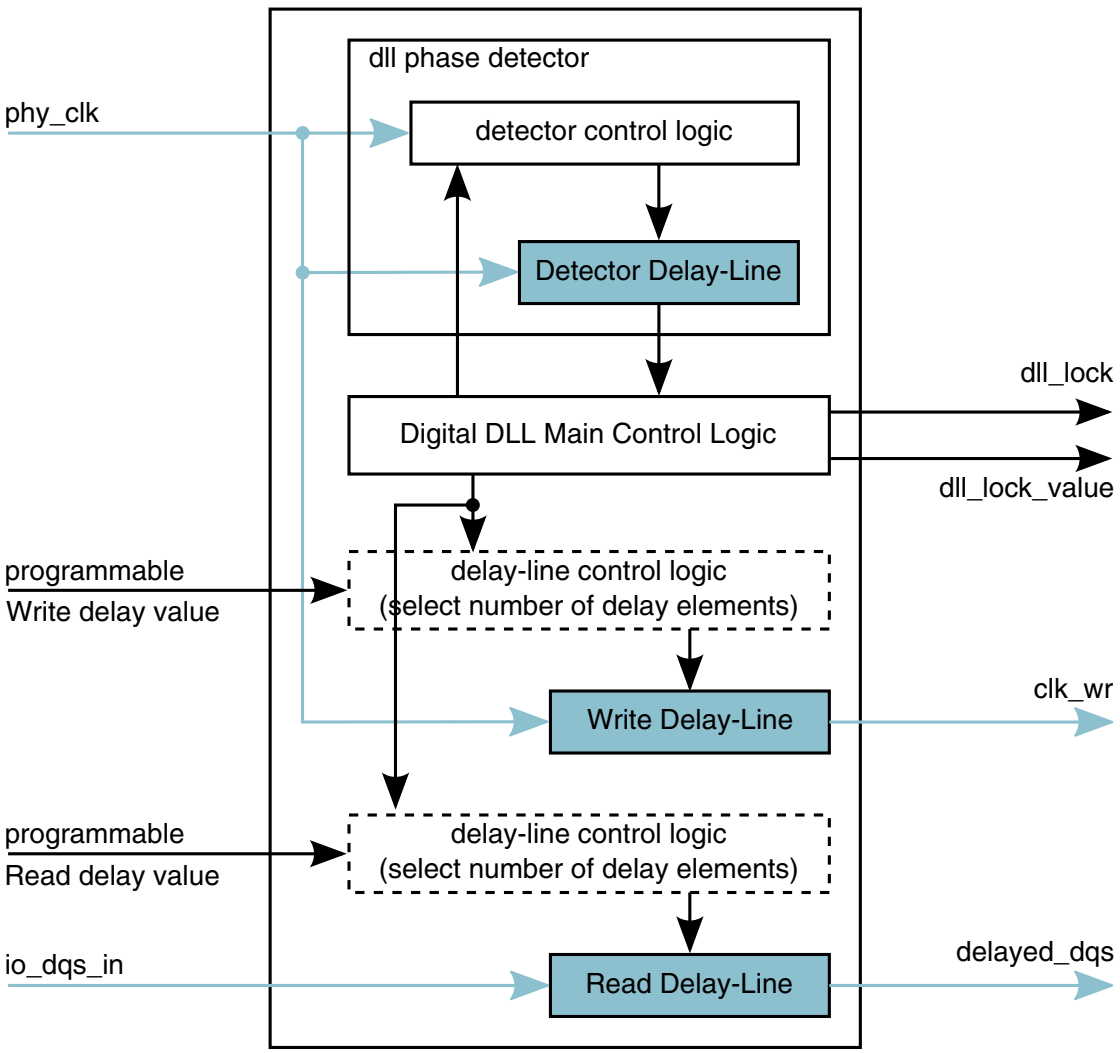

Figure 20-15. Digital DLL

The delay-line is comprised by 255 tiny delay-elements. The delay value of each delay element are almost the same. And the number of delay elements which is in use to form a delay result is configurable.

There are two modes for the delay-line control :

1. Auto-configure mode:

   This process begins by the "phase-detector". Once the phase-detector successfully complete the detection, it will raise the "dll_lock" signal and output "dll_lock_value" which indicates the delay of cone cycle. The number of elements that are needed to capture an entire clock cycle is then converted into an unsigned integer named encoder [7:0]. This integer is used as the dividend for the read and write delay parameters. The actual delay setting for the delay lines is calculated by multiplying

the encoder [7:0] integer by the parameter settings for each delay line and then dividing by 128 and rounding. These values are then encoded into a one-hot counter and updated at initialization and at every refresh interval.

2. Bypass mode, or manual configure mode:

   The phase detector can be bypassed. The number of delay elements for read & write delay line is programmed manually.

NOTE

In case the number of delay elements is fixed, the actual delay value (in nanoseconds) of a delay-line would change according to environmental conditions such as voltage, temperature, etc.

Using the auto-configure mode helps to eliminate the change of delay value because the reference delay itself also changes along with environmental conditions.

20.10.10 Configure the "output enable" of I/O Control

Some DRAM MC I/Os require a control signal named "output enable". Only when the "output enable" signal is active, the I/O can drive signals out, refer to Figure 20-16.

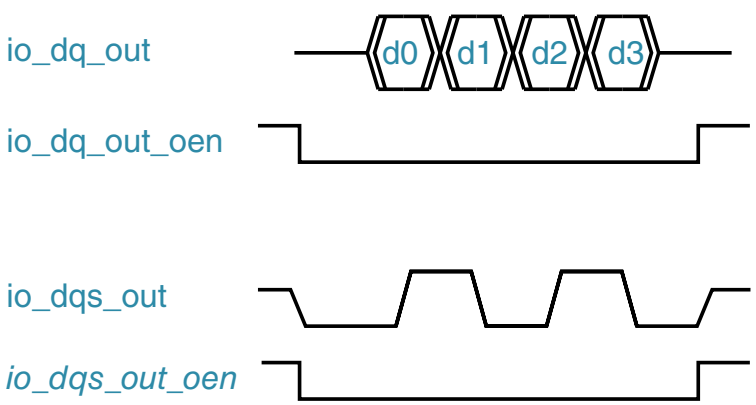

Figure 20-16. Output Enable of DRAM MC i/Os

There are 3 kinds of output enable signals in this DRAM MC design:

- io_dq_out_oen

  output enable for write data.

- io_dqm_oen

output enable for write data mask. Please configure it exactly the same as io_dq_out_oen.

- io_dqs_oen

  output enable for write data strobe.

The suffix "_oen" means the output enable signal is active low. The start time and the end time of a output enable signal can be configured separately. The start time and the end time can be adusted by 1/4 clock cycle in unit.

To meet the timing requirement of the I/O circuits, the start time of each output enable must be prior to it's corresponding output signal, and, the end time must be later than it's corresponding signal. In another word, the output enable signal must be "wider" than the output signal. The margin at start time is named "pre-amble" and the margin at end time is named "post-amble". In the example of Figure 20-16, pre-amble = 1/2 cycle while post-amble = 1/4 cycle.

20.11 Programmable Registers

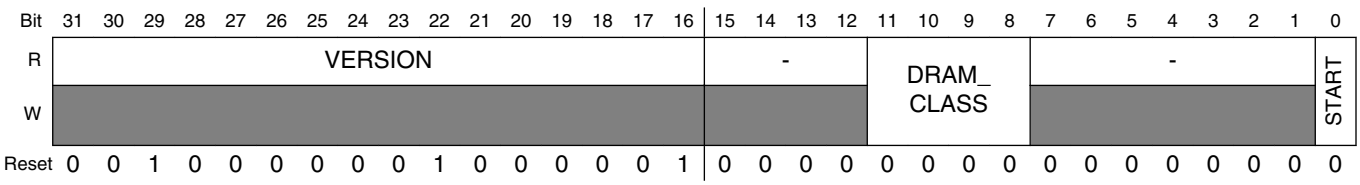
20.11.1 DRAM CTL Register 00 (DRAM_CTL00)

Address: DRAM_CTL00 is 1400_0000h base + 0h offset = 1400_0000h



DRAM_CTL00 field descriptions

Field	Description
31–16 VERSION	Controller version number. READ-ONLY
15–12 -	Reserved.
11–8 DRAM_CLASS	Defines the mode of operation of the controller. b0001 = LPDDR1 - Mobile DDR1 (supports burst lengths of 2, 4 or 8) b0100 = DDR2 (supports burst length of 4) b0101 = LPDDR2 (supports burst lengths of 4 or 8) All other settings reserved
7–1 -	Reserved.
0 START	Prior to setting this parameter to b1, the memory controller will not issue any commands to the DRAM devices or respond to any signal activity except for reading and writing PIO parameters. Once this parameter is set to b1, the memory controller will respond to inputs from the bus interface and begin to process memory access commands. Note that resetting this parameter to b0 will not shut off traffic. However, cycling this parameter to b0 and then resetting it to b1 will reset the digital DLL (if present) to a new input clock frequency if desired. This protocol is described in detail in Section 13.2, Changing the Input Clock Frequency. Note: Until the initialization complete bit (bit 4) is set in the int_status parameter and the dfi_init_complete signal is asserted from the PHY, commands will not be accepted into the controller. b0 = Controller is not in active mode. b1 = Initiate active mode for the memory controller.

20.11.2 DRAM CTL Register 01 (DRAM_CTL01)

Address: DRAM_CTL01 is 1400_0000h base + 4h offset = 1400_0004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	-														MAX_CS_REG	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	1	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	-				MAX_COL_REG				-				MAX_ROW_REG			
W																
Reset	0	0	0	0	1	0	1	0	0	0	0	0	1	1	1	1

DRAM_CTL01 field descriptions

Field	Description
31–18 -	Reserved.
17–16 MAX_CS_REG	Displays the maximum number of chip selects configured for this MC. READ-ONLY.
15–12 -	Reserved.
11–8 MAX_COL_REG	Defines the maximum width of column address in the DRAM devices. This value can be used to set the column_size parameter. READ-ONLY. column_size = max_col_reg - (number of column bits in memory device)
7–4 -	Reserved.
3–0 MAX_ROW_ REG	Defines the maximum width of the memory address bus for the MC. Note: For LPDDR2 memories, the parameter addr_pins holds the difference between the maximum number of row pins configured and the actual number of row pins being used. This value can be used to set the addr_pins parameter. READ-ONLY. addr_pins = max_row_reg - (number of row bits in memory device)

20.11.3 DRAM CTL Register 02 (DRAM_CTL02)

Address: DRAM_CTL02 is 1400_0000h base + 8h offset = 1400_0008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	-																TINIT															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DRAM_CTL02 field descriptions

Field	Description
31–24 -	Reserved.
23–0 TINIT	Defines the DRAM initialization time, in cycles. This refers to the time required for clocks to be started and stabilized before clock enable becomes active. The user may set this value to CK stabilization time of 10 ns or 5 clocks before CKE active. Note: Since the counter is initially loaded with the value tinit-1, if this parameter is cleared to b0, the counter will underflow on load. This will result in setting the counter to its maximum value. Therefore, the user should set this parameter to b1 as a minimum. For LPDDR2 memories, this correlates to tinit1.

20.11.4 DRAM CTL Register 03 (DRAM_CTL03)

Address: DRAM_CTL03 is 1400_0000h base + Ch offset = 1400_000Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	-								TINIT3																							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DRAM_CTL03 field descriptions

Field	Description
31–24 -	Reserved.
23–0 TINIT3	Defines the number of cycles required from CKE assertion to memory reset. This parameter should be programmed to the tinit3 value from the memory specification. Note: Since the counter is initially loaded with the value tinit3-1, if this parameter is cleared to b0, the counter will underflow on load. This will result in setting the counter to its maximum value. Therefore, the user should set this parameter to b1 as a minimum. This parameter is only applicable when the MC is programmed for the following memory system: LPDDR2 (dram_class = b0101)

20.11.5 DRAM CTL Register 04 (DRAM_CTL04)

Address: DRAM_CTL04 is 1400_0000h base + 10h offset = 1400_0010h

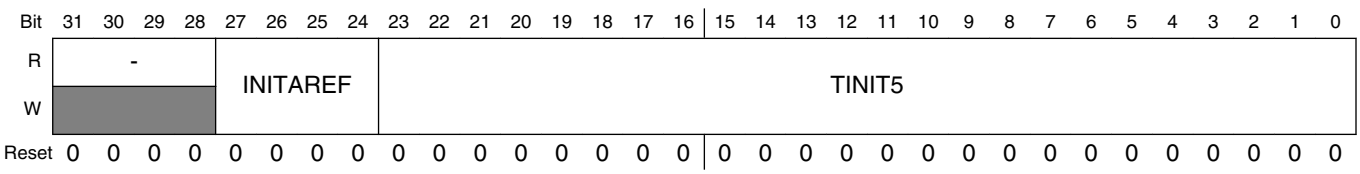
Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	-								TINIT4																							
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DRAM_CTL04 field descriptions

Field	Description
31–24 -	Reserved.
23–0 TINIT4	Defines the number of cycles required from memory reset to an MRR command. This parameter should be programmed to the tinit4 value from the memory specification. Note: Since the counter is initially loaded with the value tinit4-1, if this parameter is cleared to b0, the counter will underflow on load. This will result in setting the counter to its maximum value. Therefore, the user should set this parameter to b1 as a minimum. This parameter is only applicable when the MC is programmed for the following memory system: LPDDR2 (dram_class = b0101)

20.11.6 DRAM CTL Register 05 (DRAM_CTL05)

Address: DRAM_CTL05 is 1400_0000h base + 14h offset = 1400_0014h



DRAM_CTL05 field descriptions

Field	Description
31–28 -	Reserved.
27–24 INITAREF	Defines the number of auto-refresh commands needed by the DRAM devices to satisfy the initialization sequence. This parameter is only applicable when the MC is programmed for the following memory systems: DDR2 (dram_class = b0100) LPDDR1 (dram_class = b0001)
23–0 TINIT5	Defines the maximum number of cycles required from memory reset to initialization complete. This parameter should be programmed to the tinit5 value from the memory specification. Note: Since the counter is initially loaded with the value tinit5-1, if this parameter is cleared to b0, the counter will underflow on load. This will result in setting the counter to its maximum value. Therefore, the user should set this parameter to b1 as a minimum. This parameter is only applicable when the MC is programmed for the following memory system: LPDDR2 (dram_class = b0101)

20.11.7 DRAM CTL Register 06 (DRAM_CTL06)

Address: DRAM_CTL06 is 1400_0000h base + 18h offset = 1400_0018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	-			TCCD					-				WRLAT				-			CASLAT_LIN_ GATE					-			CASLAT_LIN				
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DRAM_CTL06 field descriptions

Field	Description
31–29 -	Reserved.
28–24 TCCD	Defines the minimum delay between CAS commands, in cycles. This value is loaded into a counter when a memory burst is issued and a new command may be issued when the counter reaches 0. Note: Since the counter is initially loaded with the value tccd-1, if this parameter is cleared to b0, the counter will underflow on load. This will result in setting the counter to its maximum value. Therefore, the user should set this parameter to b1 as a minimum.
23–20 -	Reserved.
19–16 WRLAT	Defines the write latency from when the write command is issued to the time the write data is presented to the DRAM devices, in cycles.
15–13 -	Reserved.
12–8 CASLAT_LIN_ GATE	This parameter has no meaning to this MC
7–5 -	Reserved.
4–0 CASLAT_LIN	Sets the CAS latency linear value. Note: The memory CAS latency is programmed via the mode registers. This parameter is used by the MC and should be programmed to match the memory CAS latency. Not all linear values will be supported for the memory devices being used. Refer to the specification for the memory devices being used. [Bit 0] = 1/2 cycle increment. This bit should be cleared to b0 if the memory system is LPDDR1. This bit is only applicable when the MC is programmed for the following memory systems: LPDDR1 (dram_class = b0001) b0 = No 1/2 cycle increment b1 = Additional 1/2 cycle increment on the CAS latency. [Bits 4:1] = CAS latency linear value. b0000 = Reserved b0001 = 1 cycle b0010 = 2 cycles

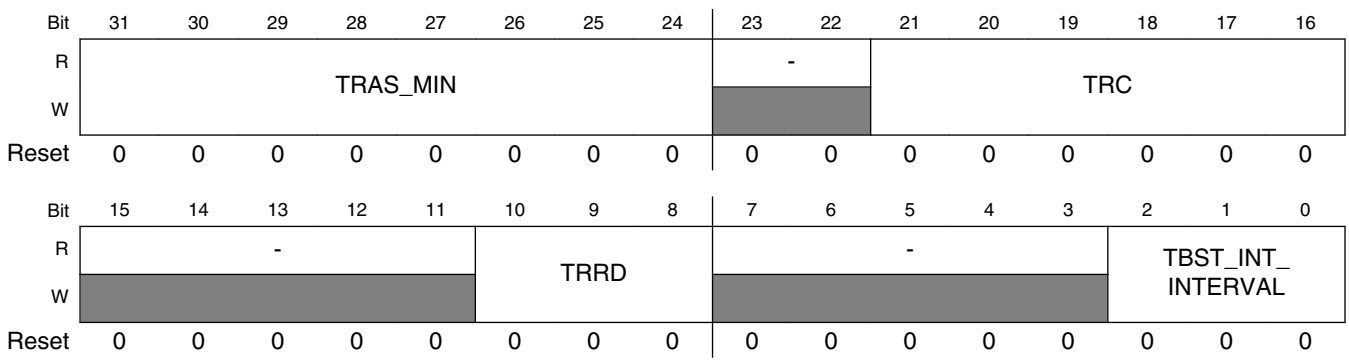
Table continues on the next page...

DRAM_CTL06 field descriptions (continued)

Field	Description
	b0011 = 3 cycles b0100 = 4 cycles b0101 = 5 cycles b0110 = 6 cycles b0111 = 7 cycles Additional values of caslat_lin are supported, in full-cycle increments up to 15 cycles. All other settings Reserved.

20.11.8 DRAM CTL Register 07 (DRAM_CTL07)

Address: DRAM_CTL07 is 1400_0000h base + 1Ch offset = 1400_001Ch



DRAM_CTL07 field descriptions

Field	Description
31–24 TRAS_MIN	Defines the DRAM minimum row activate time, in cycles. Since the counter is initially loaded with the value tras_min-1, if this parameter is cleared to b0, the counter will underflow on load. This will result in setting the counter to its maximum value. In general, it is suggested that this parameter be programmed with a value of at least 0x3.
23–22 -	Reserved.
21–16 TRC	Defines the DRAM period between active commands for the same bank, in cycles. Note: Since the counter is initially loaded with the value trc-1, if this parameter is cleared to b0, the counter will underflow on load. This will result in setting the counter to its maximum value. Therefore, the user should set this parameter to b1 as a minimum.
15–11 -	Reserved.
10–8 TRRD	Defines the DRAM activate to activate delay for different banks, in cycles. Note: Since the counter is initially loaded with the value trrd-1, if this parameter is cleared to b0, the counter will underflow on load. This will result in setting the counter to its maximum value. Therefore, the user should set this parameter to b1 as a minimum.

Table continues on the next page...

DRAM_CTL07 field descriptions (continued)

Field	Description
7–3 -	Reserved.
2–0 TBST_INT_ INTERVAL	Defines the memory burst interrupt interval. This parameter is only relevant if the burst has not completed. This value is loaded into a counter when a memory burst is issued and another command may only interrupt the current memory burst when this counter value hits 0. If the counter value hits 0 and the memory burst has not completed, the counter will be reset with the tbst_int_interval value. If a command is in progress and the memory burst has not completed, another command may only be issued on cycles after the parameter tccd value cycles have elapsed since the last CAS command and this counter value hits 0. For example with a DDR memory, if the memory burst length (the bstlen parameter) is 8, tccd is 2, tbst_int_interval is 2 and a CAS command was issued on cycle 0, another CAS command could interrupt the current memory burst on cycle 2. After cycle 3, the current memory burst will complete and this parameter would not be relevant. If instead the tbst_int_interval was 1 for the same system, then the command could interrupt on cycles 2 or 3. Note: Since the counter is initially loaded with the value tbst_int_interval-1, if this parameter is cleared to b0, the counter will underflow on load. This will result in setting the counter to its maximum value. Therefore, the user should set this parameter to b1 as a minimum.

20.11.9 DRAM CTL Register 08 (DRAM_CTL08)

Address: DRAM_CTL08 is 1400_0000h base + 20h offset = 1400_0020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	-			TMRD					-					TRTP			-			TRP					-				TWTR			
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DRAM_CTL08 field descriptions

Field	Description
31–29 -	Reserved.
28–24 TMRD	Defines the minimum number of cycles required between two mode register write commands. This is the time required to complete the write operation to the mode register. There are two parameters that control the timing after a mode register write: tmod and tmrd. This parameter (tmrd) is typically the shorter of the two timing delays. The MC will wait this delay after a mode register command before sending the next mode register command. The MC does not need to wait for the longer tmod timer to expire since termination is not used for mode register commands. Note1: Since the counter is initially loaded with the value tmrd-1, if this parameter is cleared to b0, the counter will underflow on load. This will result in setting the counter to its maximum value. Therefore, the user should set this parameter to b1 as a minimum. Note2: For LPDDR2 memories, this parameter should be set to the tmrw value from the memory specification.
23–19 -	Reserved.

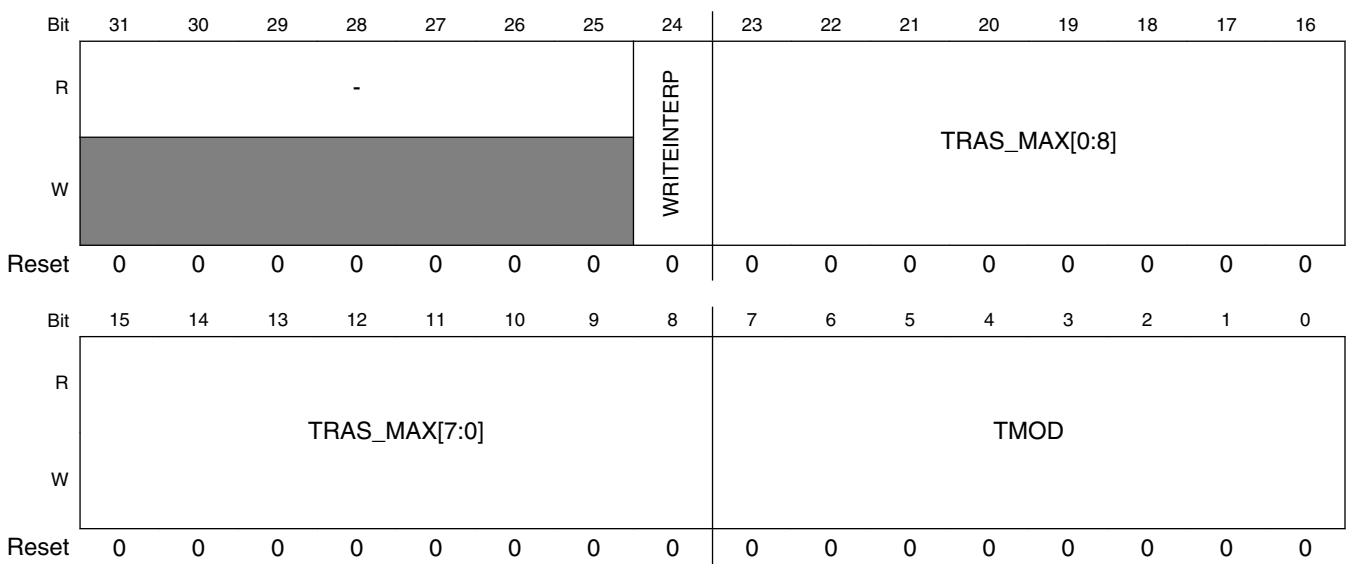
Table continues on the next page...

DRAM_CTL08 field descriptions (continued)

Field	Description
18–16 TRTP	Defines the DRAM tRTP (read to precharge time) parameter, in cycles. Note: Since the counter is initially loaded with the value trtp-1, if this parameter is cleared to b0, the counter will underflow on load. This will result in setting the counter to its maximum value. Therefore, the user should set this parameter to b1 as a minimum.
15–13 -	Reserved.
12–8 TRP	Defines the DRAM pre-charge command time, in cycles. Note: Since the counter is initially loaded with the value trp-1, if this parameter is cleared to b0, the counter will underflow on load. This will result in setting the counter to its maximum value. Therefore, the user should set this parameter to b1 as a minimum.
7–4 -	Reserved.
3–0 TWTR	Sets the number of cycles needed to switch from a write to a read operation. Note: Since the counter is initially loaded with the value twtr-1, if this parameter is cleared to b0, the counter will underflow on load. This will result in setting the counter to its maximum value. Therefore, the user should set this parameter to b1 as a minimum.

20.11.10 DRAM CTL Register 09 (DRAM_CTL09)

Address: DRAM_CTL09 is 1400_0000h base + 24h offset = 1400_0024h



DRAM_CTL09 field descriptions

Field	Description
31–25 -	Reserved.

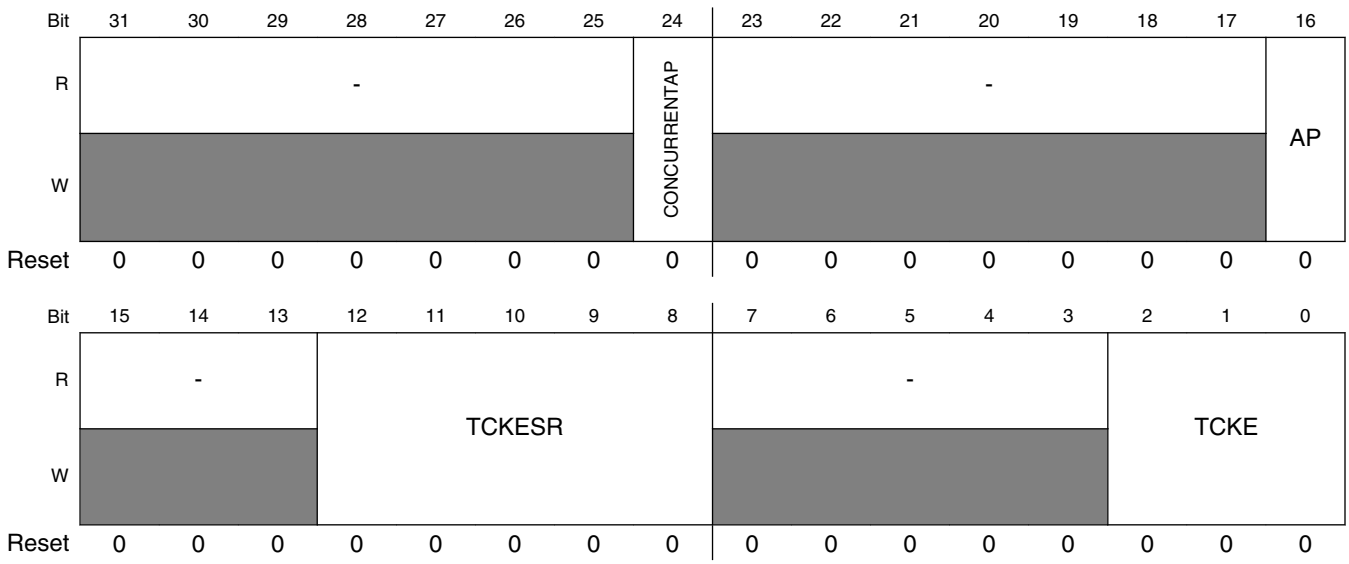
Table continues on the next page...

DRAM_CTL09 field descriptions (continued)

Field	Description
24 WRITEINTERP	Defines whether the memory controller can interrupt a write burst with a read command. Some memory devices do not allow this functionality. For DDR2 memories: This parameter must be cleared to b0. For LPDDR1 memories: Consult the memory specification for the setting for this parameter. For LPDDR2 memories: This parameter must be cleared to b0. For all memory types: b0 = The device does not support read commands interrupting write commands. b1 = The device does support read commands interrupting write commands.
23–8 TRAS_MAX	Defines the DRAM maximum row active time, in cycles.The user should set this value to the timing parameter in the memory specification. In practical use, the MC will use the value in this parameter with adjustments made for write recovery time, memory burst length and any internal delays if required. Note: Since the counter is initially loaded with the value tras_max-1, if this parameter is cleared to b0, the counter will underflow on load. This will result in setting the counter to its maximum value. Therefore, the user should set this parameter to b1 as a minimum.
7–0 TMOD	Defines the number of cycles of wait time after a mode register write to any nonmode register write command.There are two parameters that control the timing after a mode register write: tmod and tmrd. This parameter (tmod) is typically the longer timing delay (defined by the memory specification) and controls the spacing of a mode register command to any other memory command. The MC will wait this delay after a mode register command before sending any other command to memory since the controller has no way of knowing whether or not termination (ODT) will be used. Note1: Since the counter is initially loaded with the value tmod-1, if this parameter is cleared to b0, the counter will underflow on load. This will result in setting the counter to its maximum value. Therefore, the user should set this parameter to b1 as a minimum. Note2: For LPDDR2 memories, this parameter should be set to the tmrw value from the memory specification.

20.11.11 DRAM CTL Register 10 (DRAM_CTL10)

Address: DRAM_CTL10 is 1400_0000h base + 28h offset = 1400_0028h



DRAM_CTL10 field descriptions

Field	Description
31–25 -	Reserved.
24 CONCURRENTAP	Enables concurrent auto pre-charge. Some DRAM devices do not allow one bank to be auto pre-charged while another bank is reading or writing. The JEDEC standard allows concurrent auto precharge. The user should set this parameter if the DRAM device supports this feature. Note: This parameter can only be set if the device supports concurrent AP for all transactions. Some memories only support concurrent AP for writes. In this case, these memories require that reads to the same CS cannot be issued before the tWR delay has expired. If the memory devices being used do not support concurrent AP for all transactions, concurrentap must be set to b0, disabling concurrentap for all transfers. Note: It is highly recommended that user set CONCURRENTAP = 0 for this MC. b0 = Concurrent auto pre-charge disabled. b1 = Concurrent auto pre-charge enabled.
23–17 -	Reserved.
16 AP	Enables auto pre-charge mode for DRAM devices. Note: User must set AP = 0 for this MC.
15–13 -	Reserved.
12–8 TCKESR	Minimum CKE low pulse width during a self-refresh.

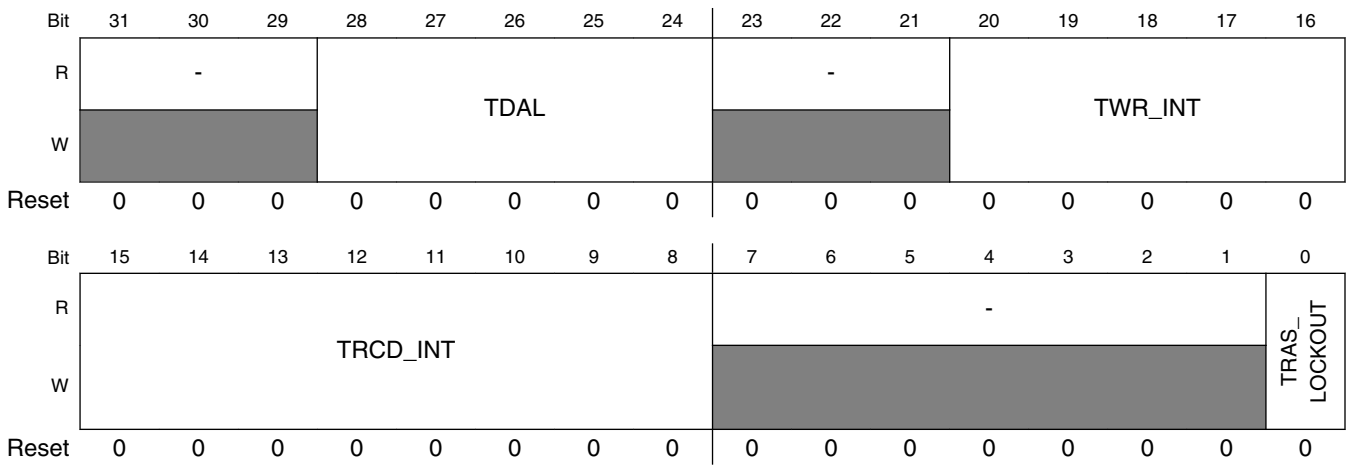
Table continues on the next page...

DRAM_CTL10 field descriptions (continued)

Field	Description
7–3 -	Reserved.
2–0 TCKE	Minimum CKE pulse width.

20.11.12 DRAM CTL Register 11 (DRAM_CTL11)

Address: DRAM_CTL11 is 1400_0000h base + 2Ch offset = 1400_002Ch



DRAM_CTL11 field descriptions

Field	Description
31–29 -	Reserved.
28–24 TDAL	DRAM TDAL parameter in cycles.
23–21 -	Reserved.
20–16 TWR_INT	Defines the DRAM write recovery time, in cycles. Note: Since the counter is initially loaded with the value twr_int-1, if this parameter is cleared to b0, the counter will underflow on load. This will result in setting the counter to its maximum value. Therefore, the user should set this parameter to b1 as a minimum.
15–8 TRCD_INT	Defines the DRAM RAS to CAS delay, in cycles. Note: Since the counter is initially loaded with the value trcd_int-1, if this parameter is cleared to b0, the counter will underflow on load. This will result in setting the counter to its maximum value. Therefore, the user should set this parameter to b1 as a minimum.
7–1 -	Reserved.

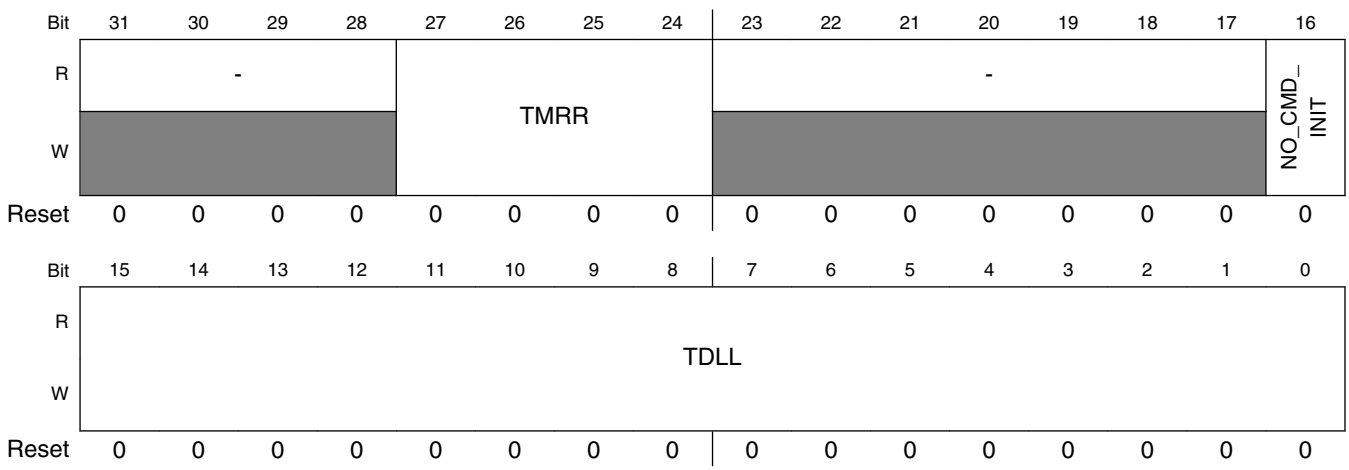
Table continues on the next page...

DRAM_CTL11 field descriptions (continued)

Field	Description
0 TRAS_ LOCKOUT	Defines the tRAS lockout setting for the DRAM device. tRAS lockout allows the memory controller to execute auto precharge commands before the tras_min parameter has expired. Note: This parameter may only be applicable to DDR1 memories. Please refer to the memory specification. 'b0 = tRAS lockout not supported by memory device. b1 = tRAS lockout supported by memory device.

20.11.13 DRAM CTL Register 12 (DRAM_CTL12)

Address: DRAM_CTL12 is 1400_0000h base + 30h offset = 1400_0030h



DRAM_CTL12 field descriptions

Field	Description
31–28 -	Reserved.
27–24 TMRR	Defines the DRAM tMRR term, in cycles. Note: Since the counter is initially loaded with the value tmrr-1, if this parameter is cleared to b0, the counter will underflow on load. This will result in setting the counter to its maximum value. Therefore, the user should set this parameter to b1 as a minimum.
23–17 -	Reserved.
16 NO_CMD_INIT	Disables DRAM commands until DLL initialization is complete and tdll has expired. This parameter is only applicable when the MC is programmed for the following memory systems: DDR2 (dram_class = b0100) LPDDR1 (dram_class = b0001)

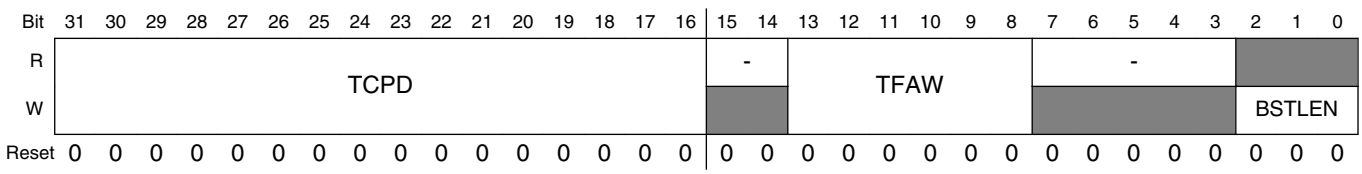
Table continues on the next page...

DRAM_CTL12 field descriptions (continued)

Field	Description
	b0 = Issue only REF and PRE commands during DLL initialization of the DRAM devices. If PRE commands are issued before DLL initialization is complete, the command will be executed immediately, and then the DLL initialization will continue. b1 = Do not issue any type of command during DLL initialization of the DRAM devices. If any other commands are issued during the initialization time, they will be held off until DLL initialization is complete.
15–0 TDLL	DRAM TDLL parameter in cycles.

20.11.14 DRAM CTL Register 13 (DRAM_CTL13)

Address: DRAM_CTL13 is 1400_0000h base + 34h offset = 1400_0034h

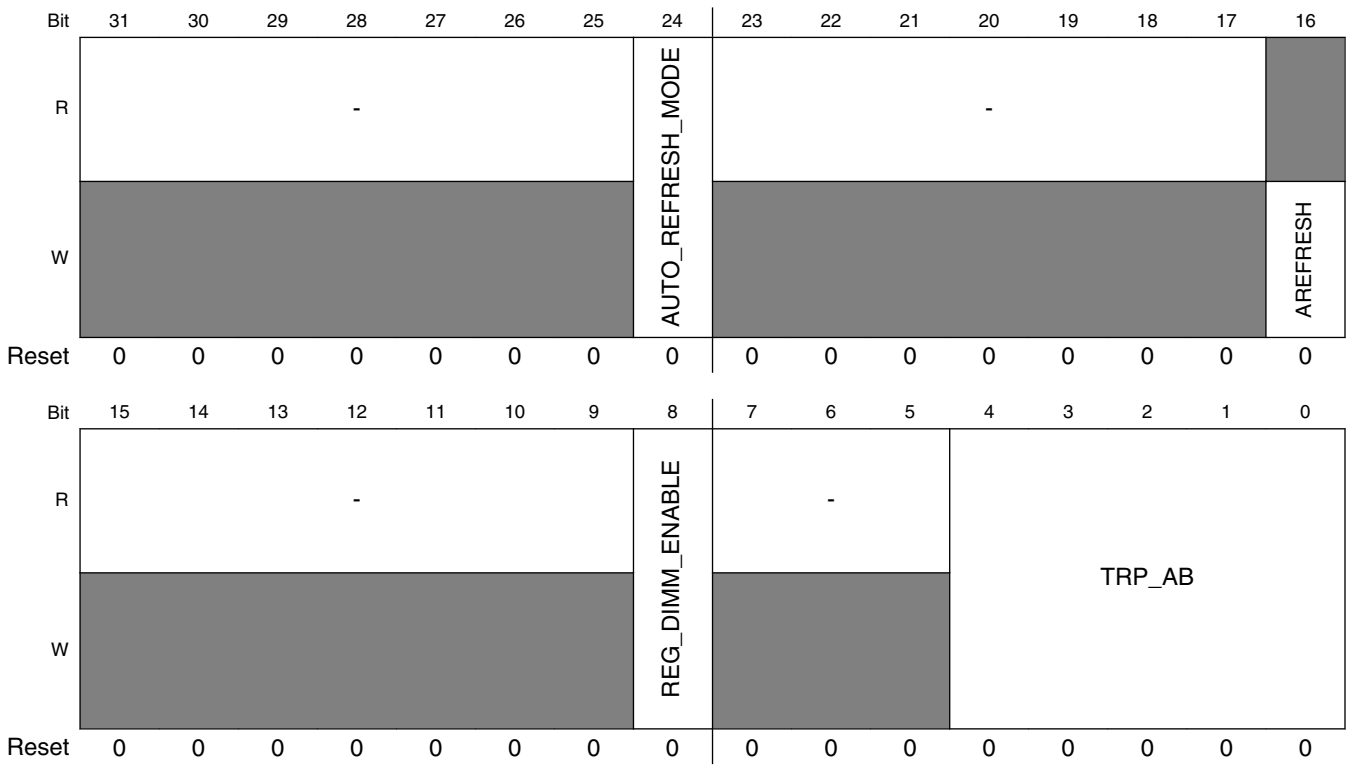


DRAM_CTL13 field descriptions

Field	Description
31–16 TCPD	DRAM TCPD parameter in cycles.
15–14 -	Reserved.
13–8 TFAW	DRAM TFAW parameter in cycles.
7–3 -	Reserved.
2–0 BSTLEN	Defines the memory burst length encoding for the MC. The mode is programmed in the dram_class parameter. b001 = 2 memory words - only applicable if the reduc parameter is set to b0 for operation in full datapath mode. Applicable for these memory systems: LPDDR1 (dram_class = b0001) b010 = 4 memory words. Applicable for these memory systems: LPDDR1 (dram_class = b0001) DDR2 (dram_class = b0100) LPDDR2 (dram_class = b0101) b011 = 8 memory words. Applicable for these memory systems: LPDDR1 (dram_class = b0001) LPDDR2 (dram_class = b0101) All other settings are Reserved

20.11.15 DRAM CTL Register 14 (DRAM_CTL14)

Address: DRAM_CTL14 is 1400_0000h base + 38h offset = 1400_0038h



DRAM_CTL14 field descriptions

Field	Description
31–25 -	Reserved.
24 AUTO_ REFRESH_ MODE	Sets the mode for when the automatic refresh will occur. If the auto_refresh_mode parameter is set and a refresh is required to memory, the memory controller will delay this refresh until the end of the current transaction (if the transaction is fully contained inside a single page), or until the current transaction hits the end of the current page. b0 = Issue refresh on the next memory burst boundary, even if the current command is not complete. b1 = Issue refresh on the next command boundary.
23–17 -	Reserved.
16 AREFRESH	Initiates an automatic refresh to the DRAM devices based on the setting of the auto_refresh_mode parameter. If there are any open banks when this parameter is set, the MC will automatically close these banks before issuing the auto-refresh command. This parameter will always read back as 0x0. For more information on the refresh per chip select feature, refer to the Other Databahn Features Chapter. b0 = No action b1 = Issue refresh to the DRAM devices

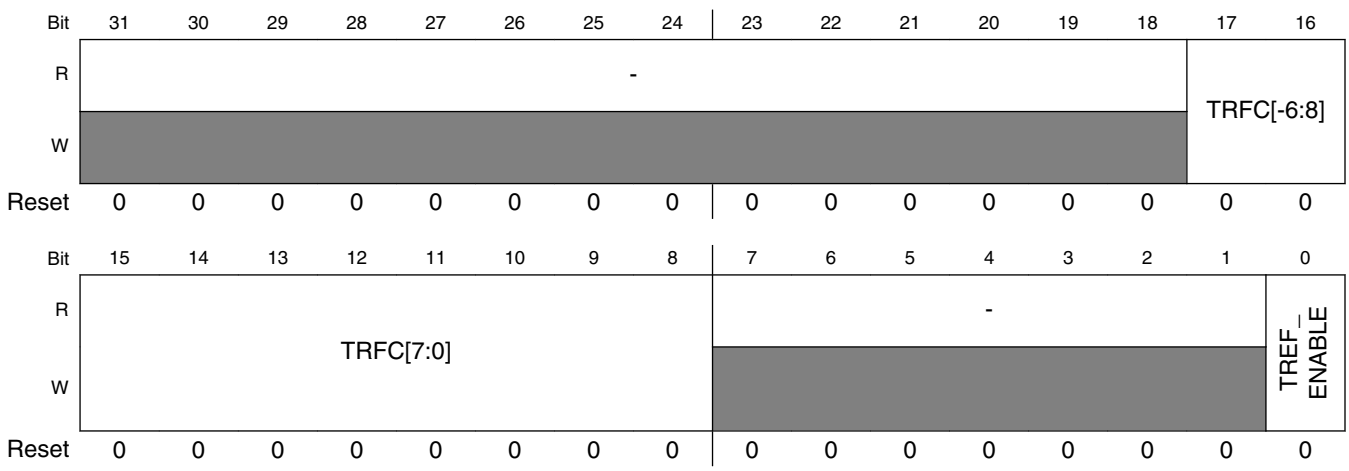
Table continues on the next page...

DRAM_CTL14 field descriptions (continued)

Field	Description
15–9 -	Reserved.
8 REG_DIMM_ENABLE	Enables registered DIMM operations to control the address and command pipeline of the memory controller. b0 = Normal operation b1 = Enable registered DIMM operation
7–5 -	Reserved.
4–0 TRP_AB	Defines the DRAM TRP time for all banks, in cycles. Note: Since the counter is initially loaded with the value trp_ab-1, if this parameter is cleared to b0, the counter will underflow on load. This will result in setting the counter to its maximum value. Therefore, the user should set this parameter to b1 as a minimum.

20.11.16 DRAM CTL Register 15 (DRAM_CTL15)

Address: DRAM_CTL15 is 1400_0000h base + 3Ch offset = 1400_003Ch



DRAM_CTL15 field descriptions

Field	Description
31–18 -	Reserved.
17–8 TRFC	Defines the DRAM refresh command time, in cycles. Note: Since the counter is initially loaded with the value trfc-1, if this parameter is cleared to b0, the counter will underflow on load. This will result in setting the counter to its maximum value. Therefore, the user should set this parameter to b1 as a minimum. For more information on the refresh per chip select feature, refer to the Other Databahn Features Chapter.

Table continues on the next page...

DRAM_CTL15 field descriptions (continued)

Field	Description
7–1 -	Reserved.
0 TREF_ENABLE	Enables refresh commands. If command refresh mode is configured, then refresh commands will be automatically issued based on the tref parameter value and any refresh commands sent through the command interface or the register interface. Refreshes will still occur even if the DRAM devices have been placed in power-down state by the assertion of the power_down parameter. Note: Even with this parameter cleared to b0, some refresh commands may still be issued to memory. This only controls the automatic refreshes issued every tref cycles. b0 = Refresh commands disabled. b1 = Refresh commands enabled.

20.11.17 DRAM CTL Register 16 (DRAM_CTL16)

Address: DRAM_CTL16 is 1400_0000h base + 40h offset = 1400_0040h

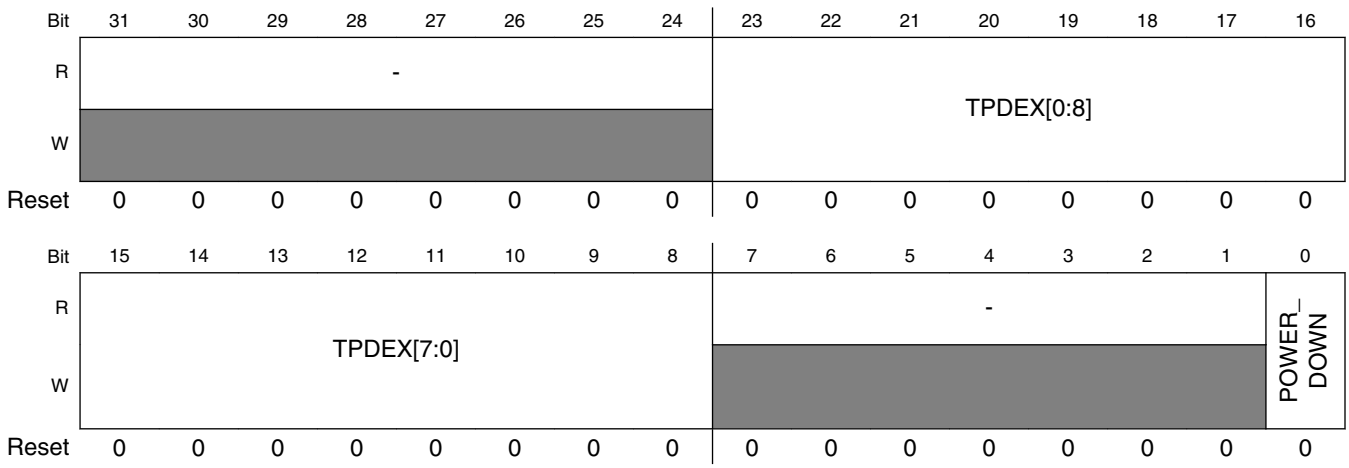
Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	-		TREF_INTERVAL														TREF															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DRAM_CTL16 field descriptions

Field	Description
31–30 -	Reserved.
29–16 TREF_ INTERVAL	Sets the time delay, in clock cycles, between when refresh commands are issued to different chip selects. If tref_interval is cleared to b000, then the refresh per chip select logic will be disabled and all chip selects will be refreshed simultaneously. The tref_interval parameter value must be less than the trfc parameter value. For more information on the refresh per chip select feature, refer to the Other Databahn Features Chapter.
15–0 TREF	Defines the DRAM cycles between refresh commands. This parameter sets the average interval between refreshes. For more information on this parameter, refer to Section 13.3, Refresh Per Command Timing. For more information on the refresh per chip select feature, refer to the Section 13.5, Refresh Per Chip Select. Note: Since the counter is initially loaded with the value tref-1, if this parameter is cleared to b0, the counter will underflow on load. This will result in setting the counter to its maximum value. Therefore, the user should set this parameter to b1 as a minimum.

20.11.18 DRAM CTL Register 17 (DRAM_CTL17)

Address: DRAM_CTL17 is 1400_0000h base + 44h offset = 1400_0044h



DRAM_CTL17 field descriptions

Field	Description
31–24 -	Reserved.
23–8 TPDEX	Defines the DRAM power-down exit command period, in cycles. Note: Since the counter is initially loaded with the value tpdex-1, if this parameter is cleared to b0, the counter will underflow on load. This will result in setting the counter to its maximum value. Therefore, the user should set this parameter to b1 as a minimum.
7–1 -	Reserved.
0 POWER_DOWN	When this parameter is set to b1, the memory controller will complete processing of the current memory burst for the current transaction (if any), issue a pre-charge all command and then disable the clock enable signal to the DRAM devices. Any subsequent commands in the command queue will be suspended until this parameter is cleared to b0. Note: This parameter should only be used when the low power logic is NOT enabled (lowpower_control = 0x00). Note: If the tref_enable parameter is set to b1, the memory controller will continue to issue refresh commands to the memory devices even when this parameter is set to b1. b0 = Enable full power state b1 = Disable the clock enable and power down the memory controller.

20.11.19 DRAM CTL Register 18 (DRAM_CTL18)

Address: DRAM_CTL18 is 1400_0000h base + 48h offset = 1400_0048h

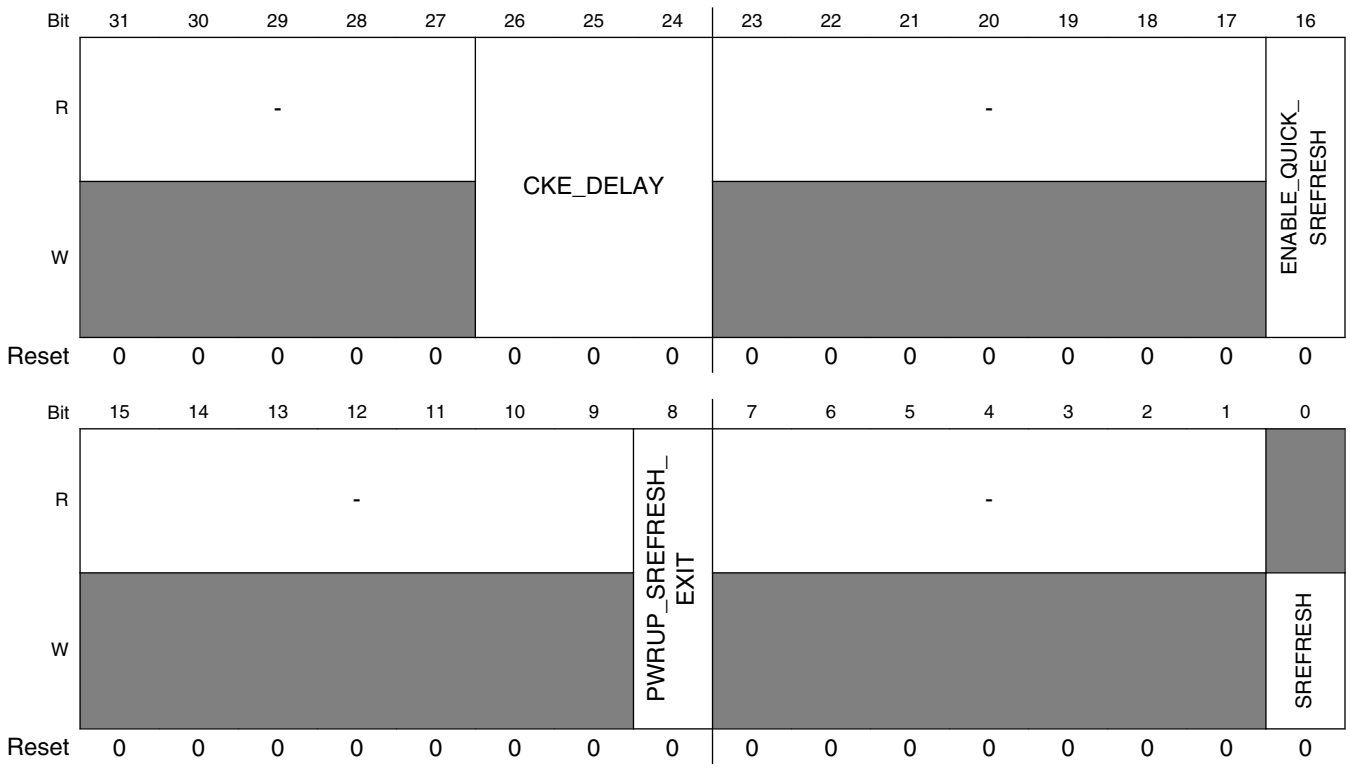
Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	TXSNR																TXSR															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DRAM_CTL18 field descriptions

Field	Description
31–16 TXSNR	Defines the DRAM time from a selfrefresh exit to a command that does not require the memory DLL to be locked. Note: Since the counter is initially loaded with the value txsnr-1, if this parameter is cleared to b0, the counter will underflow on load. This will result in setting the counter to its maximum value. Therefore, the user should set this parameter to b1 as a minimum.
15–0 TXSR	Defines the DRAM time from a selfrefresh exit to an active command that requires the memory DLL to be locked. For DDR2 memories: Set this parameter to the difference between the txsrd and trcd values in the memory specification. Note: Since the counter is initially loaded with the value txsr-1, if this parameter is cleared to b0, the counter will underflow on load. This will result in setting the counter to its maximum value. Therefore, the user should set this parameter to b1 as a minimum.

20.11.20 DRAM CTL Register 19 (DRAM_CTL19)

Address: DRAM_CTL19 is 1400_0000h base + 4Ch offset = 1400_004Ch



DRAM_CTL19 field descriptions

Field	Description
31–27 -	Reserved.
26–24 CKE_DELAY	Sets the number of additional cycles of delay to include in the CKE signal cke_status for status reporting. The default delay is 0 cycles.
23–17 -	Reserved.
16 ENABLE_ QUICK_ SREFRESH	When this bit is set to b1, the memory initialization sequence may be interrupted and the memory may enter self-refresh mode. This is used to place the memory devices into self-refresh mode when a power loss is detected during the initialization process. Setting this parameter does not initiate a self-refresh entry during initialization. Rather, if the srefresh parameter is set to b1 during initialization, the self-refresh entry will only occur if this parameter is also set to b1. b0 = Continue memory initialization. b1 = Interrupt memory initialization and enter self-refresh mode.
15–9 -	Reserved.

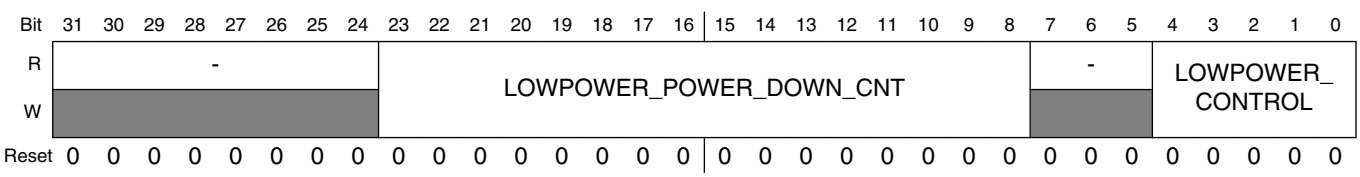
Table continues on the next page...

DRAM_CTL19 field descriptions (continued)

Field	Description
8 PWRUP_ SREFRESH_ EXIT	Allows controller to exit power-down mode by executing a self-refresh exit instead of the full memory initialization. This parameter provides a means to skip full initialization when the DRAM devices are in a known self-refresh state. b0 = Disabled b1 = Enabled
7–1 -	Reserved.
0 SREFRESH	When this parameter is set to b1, the DRAM device(s) will be placed in selfrefresh mode. To do so, the current memory burst for the current transaction (if any) will complete, all banks will be closed, the self-refresh command will be issued to the DRAM, and the clock enable signal will be de-asserted. The system will remain in self-refresh mode until this parameter is cleared to b0. The DRAM devices will return to normal operating mode after the self-refresh exit time (the txsr parameter) of the device and any DLL initialization time for the DRAM is reached. The memory controller will resume processing of the commands from the interruption point. Note1: This parameter should only be used when the low power logic is NOT enabled (lowpower_control = 0x00). Note2: If this parameter is asserted during the initialization sequence, the memory controller will only issue the self-refresh if such behavior is enabled in the enable_quick_srefresh parameter. This parameter will be updated with an assertion of the srefresh_enter signal, regardless of the behavior on the register interface. To disable self-refresh again after a srefresh_enter signal assertion, the user will need to clear the parameter to b0. b0 = Disable self-refresh mode b1 = Initiate self-refresh of the DRAM devices.

20.11.21 DRAM CTL Register 20 (DRAM_CTL20)

Address: DRAM_CTL20 is 1400_0000h base + 50h offset = 1400_0050h



DRAM_CTL20 field descriptions

Field	Description
31–24 -	Reserved.
23–8 LOWPOWER_ POWER_ DOWN_CNT	Counts the number of idle cycles before memory power-down or power-down with memory clock gating low power mode. This parameter must be programmed to a non-zero value for proper operation.

Table continues on the next page...

DRAM_CTL20 field descriptions (continued)

Field	Description
7–5 -	Reserved.
4–0 LOWPOWER_ CONTROL	Enables the individual low power modes of the device. Bit [4] = Controls memory power-down mode (Mode 1). Bit [3] = Controls memory power-down with memory clock gating mode (Mode 2). Bit [2] = Controls memory self-refresh mode (Mode 3). Bit [1] = Controls memory self-refresh with memory clock gating mode (Mode 4). Bit [0] = Controls memory self-refresh with memory and controller clock gating mode (Mode 5). Note: Unless this parameter is cleared to 0x00, the srefresh and power_down parameters should NOT be used. For all bits: b0 = Disabled b1 = Enabled

20.11.22 DRAM CTL Register 21 (DRAM_CTL21)

Address: DRAM_CTL21 is 1400_0000h base + 54h offset = 1400_0054h

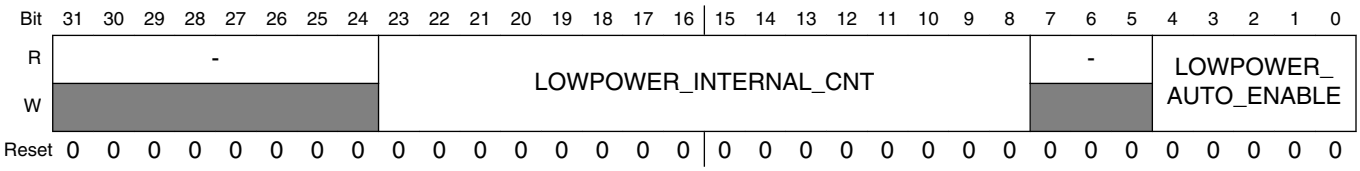
Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	LOWPOWER_EXTERNAL_CNT																LOWPOWER_SELF_REFRESH_CNT															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DRAM_CTL21 field descriptions

Field	Description
31–16 LOWPOWER_ EXTERNAL_ CNT	Counts the number of idle cycles before memory self-refresh with memory clock gating low power mode. This parameter must be programmed to a non-zero value for proper operation.
15–0 LOWPOWER_ SELF_ REFRESH_CNT	Counts the number of cycles to the next memory self-refresh low power mode. This parameter must be programmed to a non-zero value for proper operation.

20.11.23 DRAM CTL Register 22 (DRAM_CTL22)

Address: DRAM_CTL22 is 1400_0000h base + 58h offset = 1400_0058h



DRAM_CTL22 field descriptions

Field	Description
31–24 -	Reserved.
23–8 LOWPOWER_ INTERNAL_CNT	Counts the number of idle cycles before memory self-refresh with memory and controller clock gating low power mode. This parameter must be programmed to a non-zero value for proper operation.
7–5 -	Reserved.
4–0 LOWPOWER_ AUTO_ENABLE	Enables automatic entry into the low power modes of the memory controller. Bit [4] = Controls memory power-down mode (Mode 1). Bit [3] = Controls memory power-down with memory clock gating mode (Mode 2). Bit [2] = Controls memory self-refresh mode (Mode 3). Bit [1] = Controls memory self-refresh with memory clock gating mode (Mode 4). Bit [0] = Controls memory self-refresh with memory and controller clock gating mode (Mode 5). Note1: It is not possible to enter Mode 5 manually. Setting bit [0] of lowpower_control with bit [0] of this parameter cleared will not result in any change. Note2: The user should not use both automatic and manual modes for the various low power modes. All modes should be entered automatically or all entered manually. For all bits: b0 = Automatic entry into this mode is disabled. The user may enter this mode manually by setting the associated lowpower_control bit. b1 = Automatic entry into this mode is enabled. The mode will be entered automatically when the proper counters expire, and only if the associated lowpower_control bit is set.

20.11.24 DRAM CTL Register 23 (DRAM_CTL23)

Address: DRAM_CTL23 is 1400_0000h base + 5Ch offset = 1400_005Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	-				CKSRE				-						LOWPOWER_REFRESH_ENABLE	
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

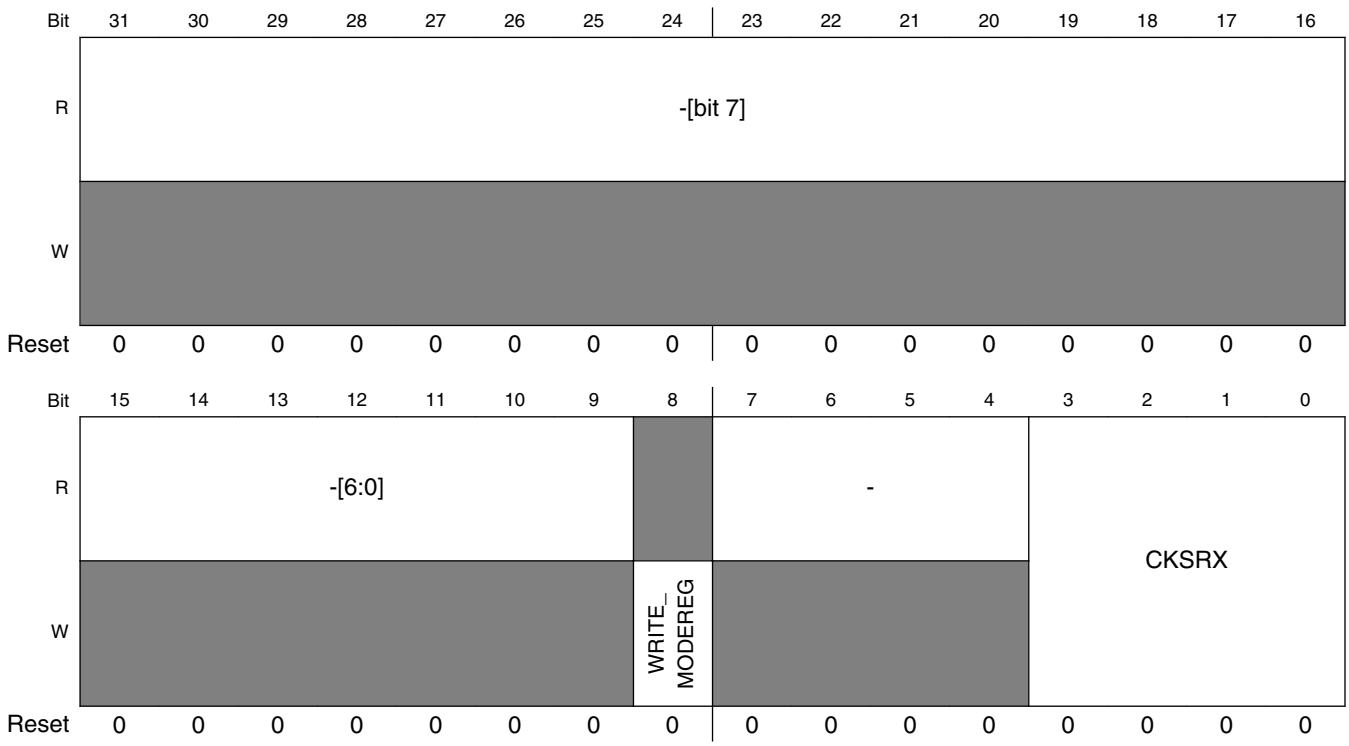
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	LOWPOWER_REFRESH_HOLD															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DRAM_CTL23 field descriptions

Field	Description
31–28 -	Reserved.
27–24 CKSRE	Sets the number of cycles to hold the clock stable after entering self-refresh mode. The clock will run for a minimum of cksre cycles after CKE falls.
23–18 -	Reserved.
17–16 LOWPOWER_REFRESH_ENABLE	Sets whether refreshes will occur while the memory controller is in one of the power-down modes. There is one bit for each chip select. Note that refreshes will not occur while in any of the self-refresh modes. Note: This parameter is active low. b0 = Refreshes still occur b1 = Refreshes do not occur
15–0 LOWPOWER_REFRESH_HOLD	Sets the number of cycles that the MC will wait before attempting to re-lock the DLL when using the Memory Self-Refresh with Memory and Controller Clock Gating low power mode. This counter will only be used in this mode, which is the deepest low power mode. When this counter expires, the DLL will be un-gated for at least 16 cycles during which the DLL will attempt to re-lock. After 16 cycles have elapsed and the DLL has locked, then the DLL controller clock will be gated again and the counter will reset to this value. If the DLL requires more than 16 cycles to re-lock, then the un-gated time will be longer.

20.11.25 DRAM CTL Register 24 (DRAM_CTL24)

Address: DRAM_CTL24 is 1400_0000h base + 60h offset = 1400_0060h

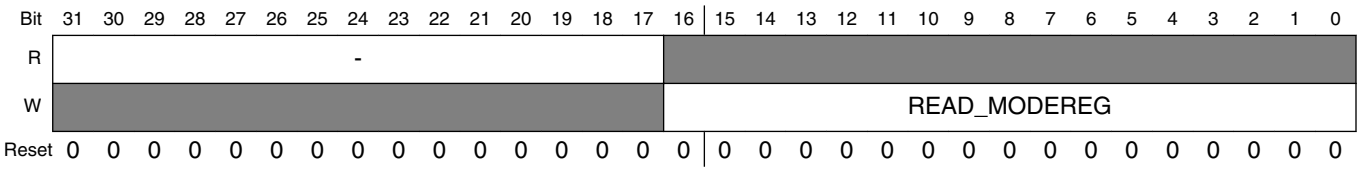


DRAM_CTL24 field descriptions

Field	Description
31–9 -	Reserved.
8 WRITE_ MODEREG	Writes mode register information into the memory devices. The user should program the appropriate mrY_data_X parameters with valid information based on the memory type being used. All of the mode registers that are relevant for the memory type specified in the dram_class parameter will be written on each write_modereg setting. This parameter will always read back as b0. The mode registers are automatically written at initialization of the memory controller. There is no need to initiate a mode register write after setting the start parameter in the memory controller unless some value in these registers needs to be changed after initialization. Note: This parameter may not be changed when the memory is in power-down mode (when the CKE input is deasserted).
7–4 -	Reserved.
3–0 CKSRX	Sets the number of cycles to hold the clock stable before exiting self-refresh mode. The clock will run for a minimum of cksrx cycles before CKE rises.

20.11.26 DRAM CTL Register 25 (DRAM_CTL25)

Address: DRAM_CTL25 is 1400_0000h base + 64h offset = 1400_0064h

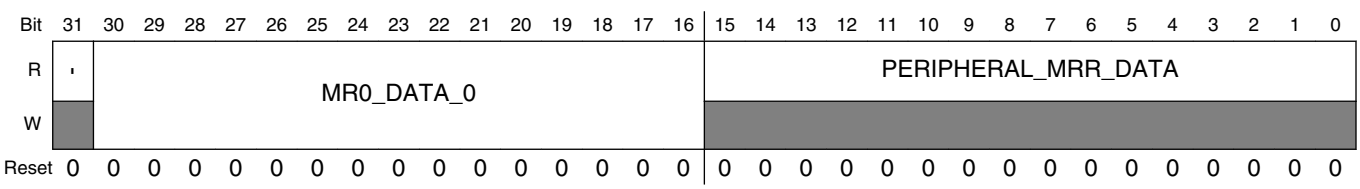


DRAM_CTL25 field descriptions

Field	Description
31–17 -	Reserved.
16–0 READ_ MODEREG	Read from the mode register MRx. Bits [7:0] = Defines the mode register number being requested (MRx). Bits [15:8] = Defines the chip select for which to read the command. Bit [16] = Trigger the mode register read. b0 = No action b1 = Read the mode register specified

20.11.27 DRAM CTL Register 26 (DRAM_CTL26)

Address: DRAM_CTL26 is 1400_0000h base + 68h offset = 1400_0068h



DRAM_CTL26 field descriptions

Field	Description
31 -	Reserved.
30–16 MR0_DATA_0	Holds the memory mode register 0 data for chip select 0 written during memory initialization or when the write_modereg parameter is asserted. Consult the memory specification for the fields of this mode register. The use of this parameter varies based on the memory type connected to this MC: For DDR2 memories: (MR) The memory controller does not support interleaving and therefore the A3 bit should be cleared to b0. In addition, the DLL Reset bit (A8) will be ignored in favor of an internal state machine that sets the DLL Reset bit during initialization. For a memory burst length of 4, the bits A2:A0 should be set to b010.

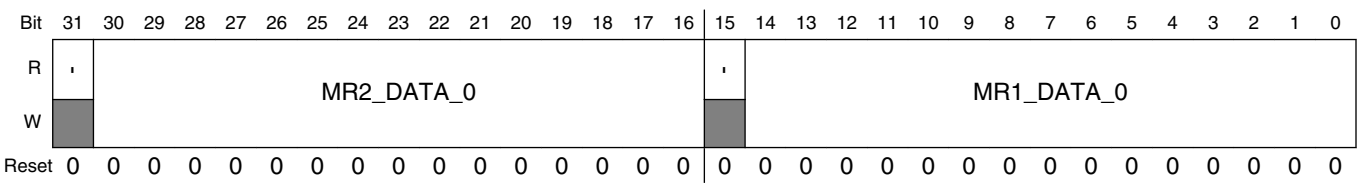
Table continues on the next page...

DRAM_CTL26 field descriptions (continued)

Field	Description
	For LPDDR1 memories: (MR) The memory controller does not support interleaving and therefore the A3 bit should be cleared to b0. For a memory burst length of 4, the bits A2:A0 should be set to b010. For LPDDR2 memories: (MR0) For this memory type, the fields of MR0 are all read-only, therefore this parameter has no meaning during initialization, or when the write_modereg parameter is set to b1. To gather the contents of this memory register, the user must set the read_modereg parameter appropriately and then read the peripheral_mrr_data parameter.
15–0 PERIPHERAL_MRR_DATA	Data and chip returned from the mode register read issued as a result of setting the parameter read_modereg to b1. The contents of this parameter are only valid when the peripheral mode read complete bit (bit 6) in the int_status parameter is asserted. Bits [15:8] = MRR chip information Bits [7:0] = Mode register data

20.11.28 DRAM CTL Register 27 (DRAM_CTL27)

Address: DRAM_CTL27 is 1400_0000h base + 6Ch offset = 1400_006Ch



DRAM_CTL27 field descriptions

Field	Description
31 -	Reserved.
30–16 MR2_DATA_0	Holds the memory mode register 2 data for chip select 0 written during memory initialization. Consult the memory specification for the fields of this mode register. The use of this parameter varies based on the memory type connected to this MC: For DDR2 memories: This parameter correlates to the extended memory mode register 2 (EMR2). For LPDDR1 memories: This parameter correlates to the extended mode register (EMR). For LPDDR2 memories: This parameter correlates to memory mode register 2 (MR2). This data will be programmed into the appropriate memory register of the DRAM at initialization or when the write_modereg parameter is asserted.
15 -	Reserved.
14–0 MR1_DATA_0	Holds the memory mode register 1 data for chip select 0 written during memory initialization. Consult the memory specification for the fields of this mode register. The use of this parameter varies based on the memory type connected to this MC: For DDR2 memories: This parameter correlates to the extended memory mode register 1 (EMR1). The memory controller does not support additive latency and therefore the A5:A3 bits should be cleared to b000.

Table continues on the next page...

DRAM_CTL27 field descriptions (continued)

Field	Description
	For LPDDR1 memories: This parameter has no meaning for this memory type. For LPDDR2 memories: This parameter correlates to memory mode register 1 (MR1). The memory controller does not support interleaving and therefore the OP3 bit should be cleared to b0. This data will be programmed into the appropriate memory register of the DRAM at initialization or when the write_modereg parameter is asserted.

20.11.29 DRAM CTL Register 28 (DRAM_CTL28)

Address: DRAM_CTL28 is 1400_0000h base + 70h offset = 1400_0070h

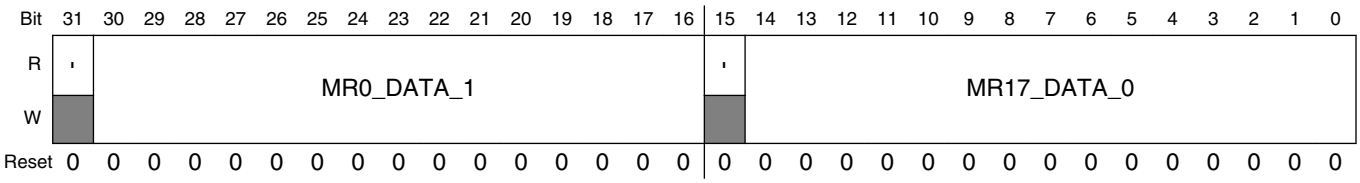
Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	'	MR16_DATA_0															'	MR3_DATA_0														
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DRAM_CTL28 field descriptions

Field	Description
31 -	Reserved.
30–16 MR16_DATA_0	Holds the memory mode register 16 data for chip select 0 written during memory initialization. Consult the memory specification for the fields of this mode register. The use of this parameter varies based on the memory type connected to this MC: For DDR2 memories: This parameter has no meaning for this memory type. For LPDDR1 memories: This parameter has no meaning for this memory type. For LPDDR2 memories: This parameter correlates to the memory mode register 16 (MR16). The fields of MR16 will be programmed into the DRAM at initialization or when the write_modereg parameter is asserted.
15 -	Reserved.
14–0 MR3_DATA_0	Holds the memory mode register 3 data for chip select 0 written during memory initialization. Consult the memory specification for the fields of this mode register. The use of this parameter varies based on the memory type connected to this MC: For DDR2 memories: This parameter correlates to the extended memory mode register 3 (EMR3). For LPDDR1 memories: This parameter has no meaning for this memory type. For LPDDR2 memories: This parameter correlates to memory mode register 3 (MR3). This data will be programmed into the appropriate memory register of the DRAM at initialization or when the write_modereg parameter is asserted.

20.11.30 DRAM CTL Register 29 (DRAM_CTL29)

Address: DRAM_CTL29 is 1400_0000h base + 74h offset = 1400_0074h

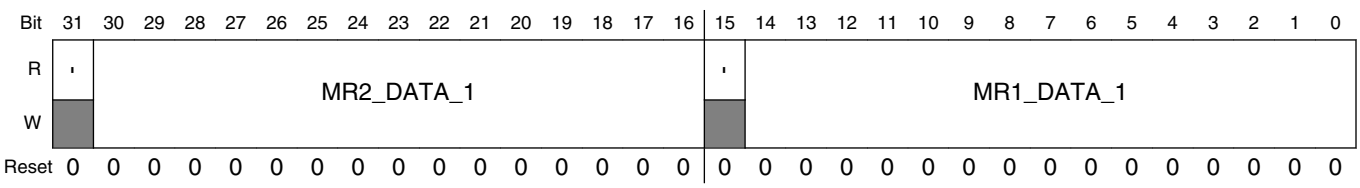


DRAM_CTL29 field descriptions

Field	Description
31 -	Reserved.
30–16 MR0_DATA_1	MRS data to program to memory mode register 0 for chip select 1. Refer to MR0_DATA_0 for detailed description.
15 -	Reserved.
14–0 MR17_DATA_0	Holds the memory mode register 17 data for chip select 0 written during memory initialization. Consult the memory specification for the fields of this mode register. The use of this parameter varies based on the memory type connected to this MC: For DDR2 memories: This parameter has no meaning for this memory type. For LPDDR1 memories: This parameter has no meaning for this memory type. For LPDDR2 memories: This parameter correlates to the memory mode register 17 (MR17) for LPDDR2-S4 memory devices. If the lpddr2_s4 parameter is set to b1, the fields of MR17 will be programmed into the DRAM at initialization or when the write_modereg parameter is asserted.

20.11.31 DRAM CTL Register 30 (DRAM_CTL30)

Address: DRAM_CTL30 is 1400_0000h base + 78h offset = 1400_0078h



DRAM_CTL30 field descriptions

Field	Description
31 -	Reserved.

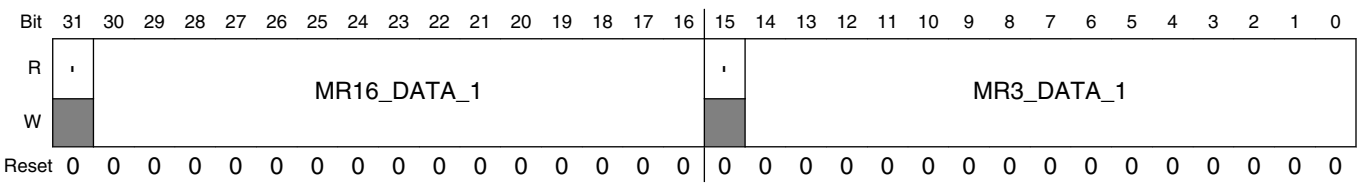
Table continues on the next page...

DRAM_CTL30 field descriptions (continued)

Field	Description
30–16 MR2_DATA_1	Data to program into memory mode register 2 for chip select 1. Refer to MR2_DATA_0 for detailed description.
15 -	Reserved.
14–0 MR1_DATA_1	Data to program into memory mode register 1 for chip select 1. Refer to MR1_DATA_0 for detailed description.

20.11.32 DRAM CTL Register 31 (DRAM_CTL31)

Address: DRAM_CTL31 is 1400_0000h base + 7Ch offset = 1400_007Ch

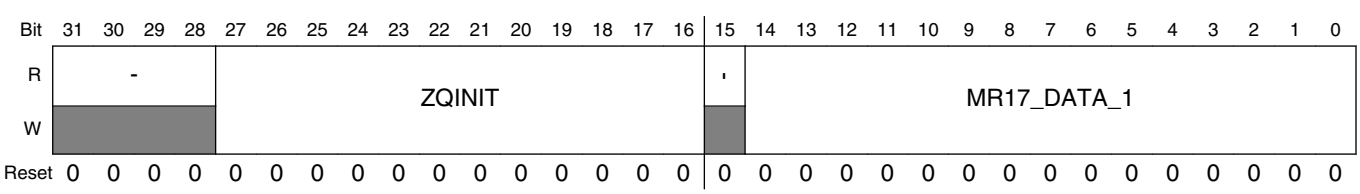


DRAM_CTL31 field descriptions

Field	Description
31 -	Reserved.
30–16 MR16_DATA_1	Data to program into memory mode register 16 for chip select 1. Refer to MR16_DATA_0 for detailed description.
15 -	Reserved.
14–0 MR3_DATA_1	Data to program into memory mode register 3 for chip select 1. Refer to MR3_DATA_0 for detailed description.

20.11.33 DRAM CTL Register 32 (DRAM_CTL32)

Address: DRAM_CTL32 is 1400_0000h base + 80h offset = 1400_0080h

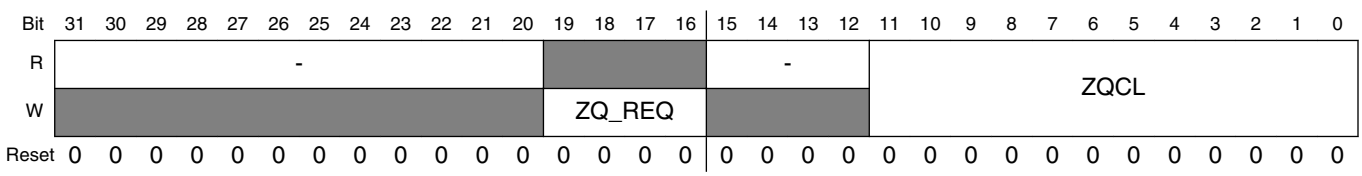


DRAM_CTL32 field descriptions

Field	Description
31–28 -	Reserved.
27–16 ZQINIT	Specifies the duration of wait time, in cycles, required for the memory devices to complete a ZQ command during initialization. Note: This parameter should be set to the ZQCL time. Internally, the MC will set the time required for a ZQCL to 1/2 of this setting. This parameter is only applicable when the MC is programmed for the following memory system: LPDDR2 (dram_class = b0101)
15 -	Reserved.
14–0 MR17_DATA_1	Data to program into memory mode register 17 for chip select 1. Refer to MR17_DATA_0 for detailed description.

20.11.34 DRAM CTL Register 33 (DRAM_CTL33)

Address: DRAM_CTL33 is 1400_0000h base + 84h offset = 1400_0084h



DRAM_CTL33 field descriptions

Field	Description
31–20 -	Reserved.
19–16 ZQ_REQ	Triggers a user-requested ZQ operation. This parameter is write-only and any writes will be cleared once the process is initiated. This parameter is only applicable when the MC is programmed for the following memory system: LPDDR2 (dram_class = b0101) Bit [3] = Triggers a ZQ reset to all chip selects in the system. Bit [2] = Triggers a ZQ initialization to all chip selects in the system. Bit [1] = Triggers a long ZQ calibration to all chip selects in the system. Bit [0] = Triggers a short ZQ calibration. If the zqcs_rotate parameter is set to b1, only one chip select will be calibrated (in round-robin fashion). If the zqcs_rotate parameter is cleared to b0, all chip selects defined in the parameter cs_map will be calibrated.
15–12 -	Reserved.

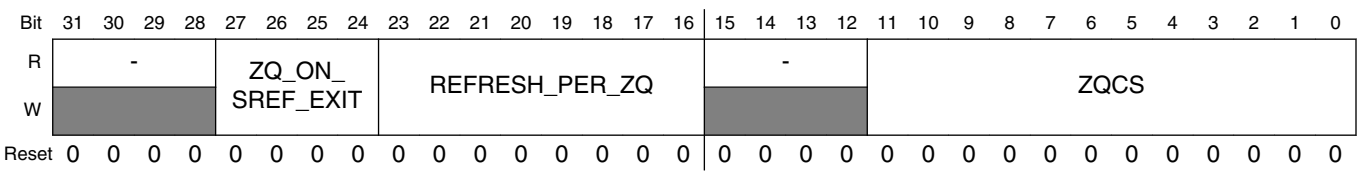
Table continues on the next page...

DRAM_CTL33 field descriptions (continued)

Field	Description
11–0 ZQCL	Specifies the duration of wait time, in cycles, required for the memory devices to complete a long ZQ calibration command (ZQCL). This parameter is only applicable when the MC is programmed for the following memory system: LPDDR2 (dram_class = b0101) Note: This parameter must be set to 1/2 of the time set in the zqinit parameter.

20.11.35 DRAM CTL Register 34 (DRAM_CTL34)

Address: DRAM_CTL34 is 1400_0000h base + 88h offset = 1400_0088h



DRAM_CTL34 field descriptions

Field	Description
31–28 -	Reserved.
27–24 ZQ_ON_SREF_ EXIT	Issues a ZQ command when exiting selfrefresh mode. This is a one-hot parameter which determines the type of operation performed on self-refresh exit. Note: It is recommended to set this parameter to execute a ZQCL on selfrefresh exit. By setting this parameter this way, a ZQCL will be issued before any other commands are permitted to execute. If this parameter is set to any other setting, the system must manage self-refresh exit and ZQ calibration. If using the ZQCS option, It advises that the rotate function should be disabled (the parameter zqcs_rotate should be cleared to b0) to calibrate all chip selects. This parameter is only applicable when the MC is programmed for the following memory system: LPDDR2 (dram_class = b0101) Bit [3] = Triggers a ZQ reset to all chip selects in the system on self-refresh exit. Bit [2] = Triggers a ZQ initialization to all chip selects in the system on selfrefresh exit. Bit [1] = Triggers a long ZQ calibration to all chip selects in the system on selfrefresh exit. Bit [0] = Triggers a short ZQ calibration. If the zqcs_rotate parameter is set to b1, only one chip select will be calibrated (in round-robin fashion). If the zqcs_rotate parameter is cleared to b0, all chip selects defined in the parameter cs_map will be calibrated.
23–16 REFRESH_ PER_ZQ	Sets the maximum number of refreshes allowed between automatic ZQCS commands. Setting this parameter to 0x0 will disable automatic ZQCS commands. When using the rotate option (the parameter zqcs_rotate is set to b1, this parameter should be programmed to the total number of cycles desired between ZQCS commands divided by the number of chip selects in the system. This parameter is only applicable when the MC is programmed for the following memory system:

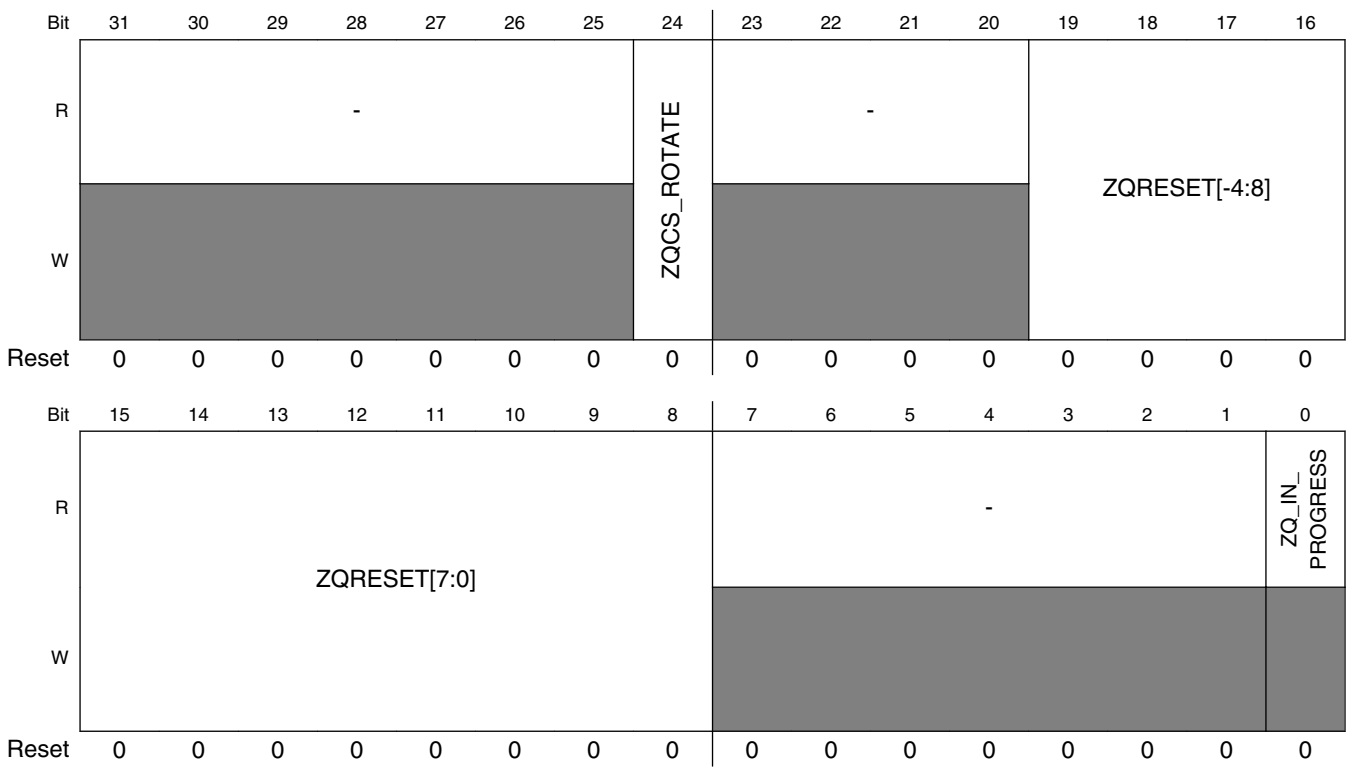
Table continues on the next page...

DRAM_CTL34 field descriptions (continued)

Field	Description
	LPDDR2 (dram_class = b0101)
15–12 -	Reserved.
11–0 ZQCS	Specifies the duration of wait time, in cycles, required for the memory devices to complete a short ZQ calibration command (ZQCS). If the zqcs_rotate parameter will be used, the user should program this parameter accordingly. If each memory device must receive a ZQCS command every Y cycles, and there are a total of X chip selects in the system, then the zqcs parameter should be programmed to Y/X. This parameter is only applicable when the MC is programmed for the following memory system: LPDDR2 (dram_class = b0101)

20.11.36 DRAM CTL Register 35 (DRAM_CTL35)

Address: DRAM_CTL35 is 1400_0000h base + 8Ch offset = 1400_008Ch



DRAM_CTL35 field descriptions

Field	Description
31–25 -	Reserved.

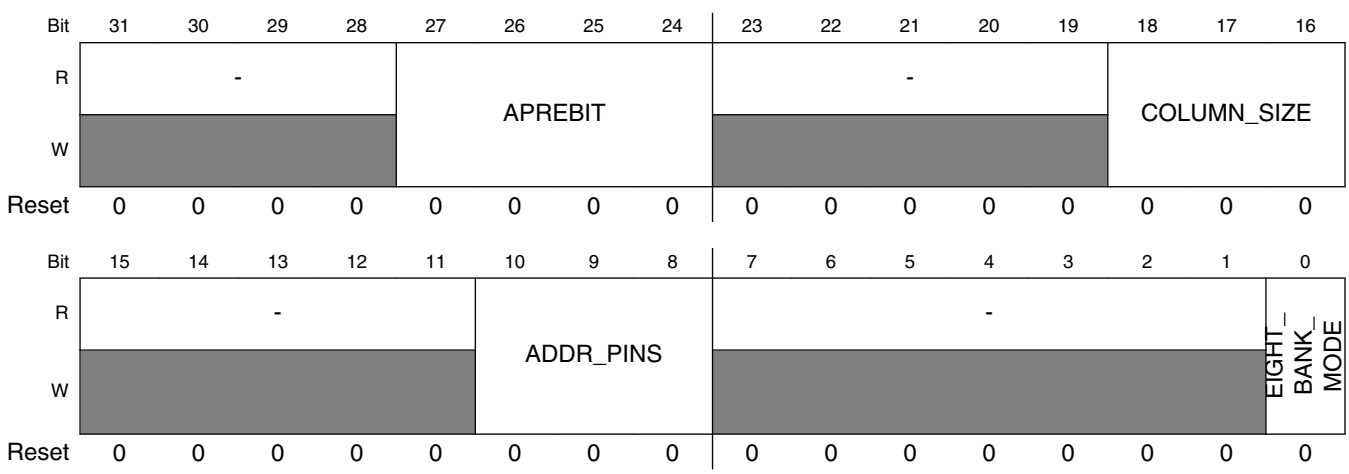
Table continues on the next page...

DRAM_CTL35 field descriptions (continued)

Field	Description
24 ZQCS_ROTATE	Defines the behavior of short ZQ calibrations. If this parameter is set to b1, a ZQCS request will only be issued to one chip select on each request, regardless of the source of the request. The MC will maintain a counter such that the chip selects are calibrated in a fixed rotating sequence. This option can be used to minimize the overhead of periodic ZQ calibrations. If the total time to calibrate all chip selects is acceptable offline time, the user may disable the zqcs_rotate parameter. Note: If this parameter is set to b1, the user should program the refresh_per_zq parameter to the total time allowed between ZQCS commands divided by the number of chip selects. If this parameter is cleared to b0, the user should program the refresh_per_zq parameter to the time between ZQCS commands for all chip selects. This parameter is only applicable when the MC is programmed for the following memory system: LPDDR2 (dram_class = b0101) b0 = Calibrate all chip selects on each ZQCS request. b1 = Calibrate only one chip select on the next ZQCS request.
23–20 -	Reserved.
19–8 ZQRESET	Specifies the duration of wait time, in cycles, required for the memory devices to complete a ZQRESET command. This parameter is only applicable when the MC is programmed for the following memory system: LPDDR2 (dram_class = b0101)
7–1 -	Reserved.
0 ZQ_IN_PROGRESS	Indicates that a ZQ command is currently in progress. If a ZQ command is requested while this parameter is set to b1, the new ZQ request will be ignored. This parameter is only applicable when the MC is programmed for the following memory system: LPDDR2 (dram_class = b0101)

20.11.37 DRAM CTL Register 36 (DRAM_CTL36)

Address: DRAM_CTL36 is 1400_0000h base + 90h offset = 1400_0090h

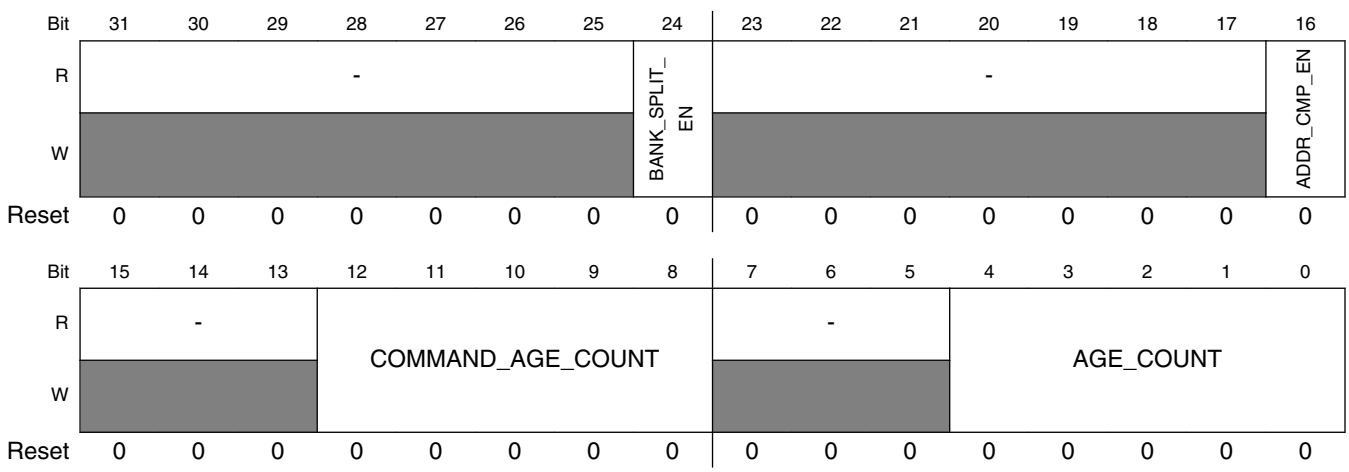


DRAM_CTL36 field descriptions

Field	Description
31–28 -	Reserved.
27–24 APREBIT	Defines the location of the auto precharge bit in the DRAM address in decimal encoding.
23–19 -	Reserved.
18–16 COLUMN_SIZE	Shows the difference between the maximum column width available (10) and the actual number of column pins being used. The user address is automatically shifted so that the user address space is mapped contiguously into the memory map based on the value of this parameter. For details, refer to the Databahn Address Mapping Chapter.
15–11 -	Reserved.
10–8 ADDR_PINS	Defines the difference between the maximum number of address pins configured (15) and the actual number of pins being used. Note: For LPDDR2 memories, this parameter holds the difference between the maximum number of row pins configured and the actual number of row pins being used for chip select X. The user address is automatically shifted so that the user address space is mapped contiguously into the memory map based on the value of this parameter. For details, refer to the Databahn Address Mapping Chapter.
7–1 -	Reserved.
0 EIGHT_BANK_MODE	Indicates that the memory devices have eight banks. b0 = Memory devices have 4 banks. b1 = Memory devices have 8 banks.

20.11.38 DRAM CTL Register 37 (DRAM_CTL37)

Address: DRAM_CTL37 is 1400_0000h base + 94h offset = 1400_0094h

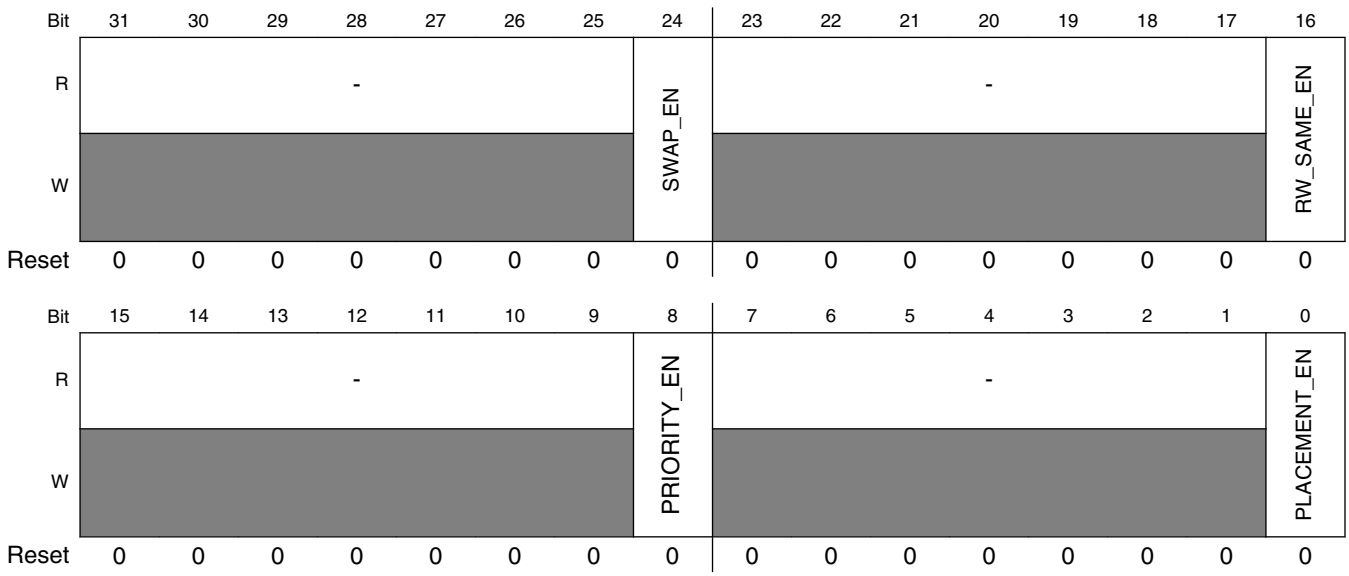


DRAM_CTL37 field descriptions

Field	Description
31–25 -	Reserved.
24 BANK_SPLIT_EN	Enables bank splitting as a condition when using the placement logic to fill the command queue. b0 = Disabled b1 = Enabled
23–17 -	Reserved.
16 ADDR_CMP_EN	Enables address collision/data coherency detection as a condition when using the placement logic to fill the command queue. b0 = Disabled b1 = Enabled
15–13 -	Reserved.
12–8 COMMAND_AGE_COUNT	Holds the initial value of the command aging counters associated with each command in the command queue. When using the placement logic to fill the command queue, the command aging counters decrement one each time the master aging-rate counter counts down the number of cycles in the age_count parameter. This parameter is only applicable when priority is enabled as a placement factor (the priority_en parameter is set to b1).
7–5 -	Reserved.
4–0 AGE_COUNT	Holds the initial value of the master aging-rate counter. When using the placement logic to fill the command queue, the command aging counters will be decremented one each time the master aging-rate counter counts down age_count cycles. This parameter is only applicable when priority is enabled as a placement factor (the priority_en parameter is set to b1).

20.11.39 DRAM CTL Register 38 (DRAM_CTL38)

Address: DRAM_CTL38 is 1400_0000h base + 98h offset = 1400_0098h



DRAM_CTL38 field descriptions

Field	Description
31–25 -	Reserved.
24 SWAP_EN	Enables swapping of the active command for a new higher-priority command when using the placement logic. b0 = Disabled b1 = Enabled
23–17 -	Reserved.
16 RW_SAME_EN	Enables read/write grouping as a condition when using the placement logic to fill the command queue. b0 = Disabled b1 = Enabled
15–9 -	Reserved.
8 PRIORITY_EN	Enables priority as a condition when using the placement logic to fill the command queue. b0 = Disabled b1 = Enabled
7–1 -	Reserved.
0 PLACEMENT_EN	Enables using the placement logic to fill the command queue. b0 = Placement logic is disabled. The command queue is a straight FIFO.

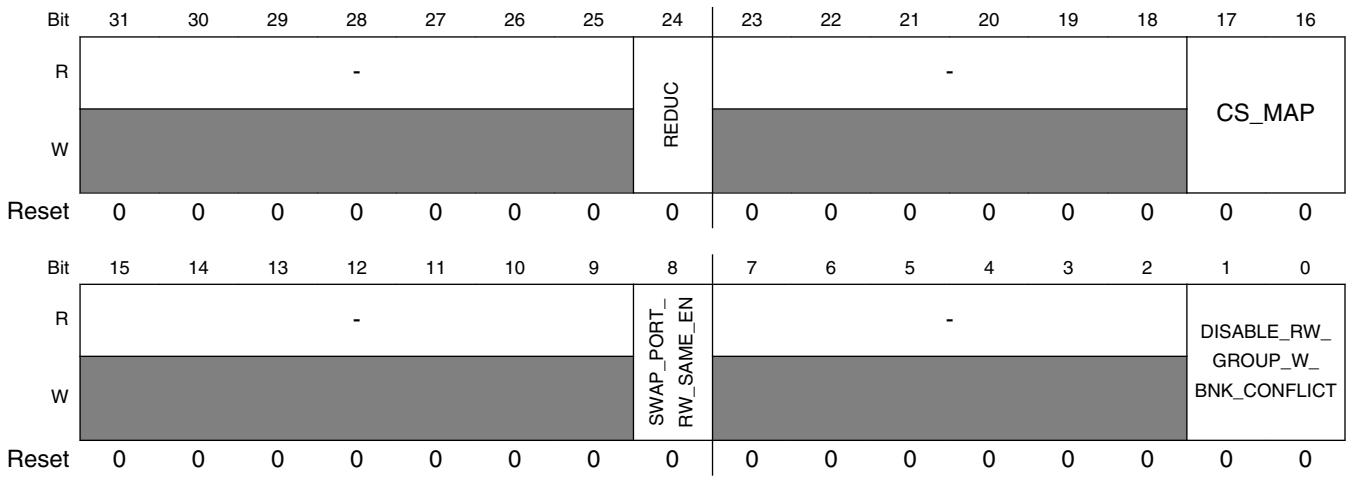
Table continues on the next page...

DRAM_CTL38 field descriptions (continued)

Field	Description
	b1 = Placement logic is enabled. The command queue will be filled according to the placement logic factors.

20.11.40 DRAM CTL Register 39 (DRAM_CTL39)

Address: DRAM_CTL39 is 1400_0000h base + 9Ch offset = 1400_009Ch



DRAM_CTL39 field descriptions

Field	Description
31–25 -	Reserved.
24 REDUC	Allows the MC to be used with memory devices with a smaller datapath (16-bit). When enabled, certain bits of the DFI data bus are unused since the memory data bus is half the width of the initial configured size. The use of bits is detailed in Section 13.7, Data Byte Disable and the Half Datapath Option in the Other Databahn Features Chapter. Note1: The entire user datapath is used regardless of this setting. Note2: It is not possible to run with a burst length of 2 when operating in half datapath mode. b0 = Standard operation using full memory bus. b1 = Memory datapath width is half of the maximum size. Irrelevant bits of the data_byte_disable bus will be driven to b1.
23–18 -	Reserved.
17–16 CS_MAP	Sets the mask that determines which chip select pins are active, with each bit representing a different chip select. The user address chip select field will be mapped into the active chip selects indicated by this parameter in ascending order from lowest to highest. This allows the memory controller to map the entire contiguous user address into any group of chip selects. Bit [0] of this parameter corresponds to chip select [0], bit [1] corresponds to chip select [1], etc. Note1: The number of chip selects, the number of bits set to b1 in this parameter, must be a power of 2 (1, 2, 4 or 8).

Table continues on the next page...

DRAM_CTL39 field descriptions (continued)

Field	Description
	Note2: The bits set must be contiguous.
15–9 -	Reserved.
8 SWAP_PORT_RW_SAME_EN	Note: User must set SWAP_PORT_RW_SAME_EN = 0 for this MC.
7–2 -	Reserved.
1–0 DISABLE_RW_GROUP_W_BNK_CONFLICT	Enables read/write grouping as a condition when using the placement logic to fill the command queue. For more information on this feature, refer to Section 8.1.6, Read/Write Grouping in the Simple Command Queue Example Chapter. Bit [0] = Prohibits placement into a command queue entry immediately before or immediately after a command with a bank conflict. b0 = Allowed b1 = Prohibited Bit [1] = Prohibits placement into a command queue entry 2 entries away (before or after) from a command with a bank conflict. b0 = Allowed b1 = Prohibited Note: It is not meaningful to set bit [1] of this parameter without setting bit [0].

20.11.41 DRAM CTL Register 40 (DRAM_CTL40)

Address: DRAM_CTL40 is 1400_0000h base + A0h offset = 1400_00A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	-							FAST_WRITE	-							LPDDR2_S4
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

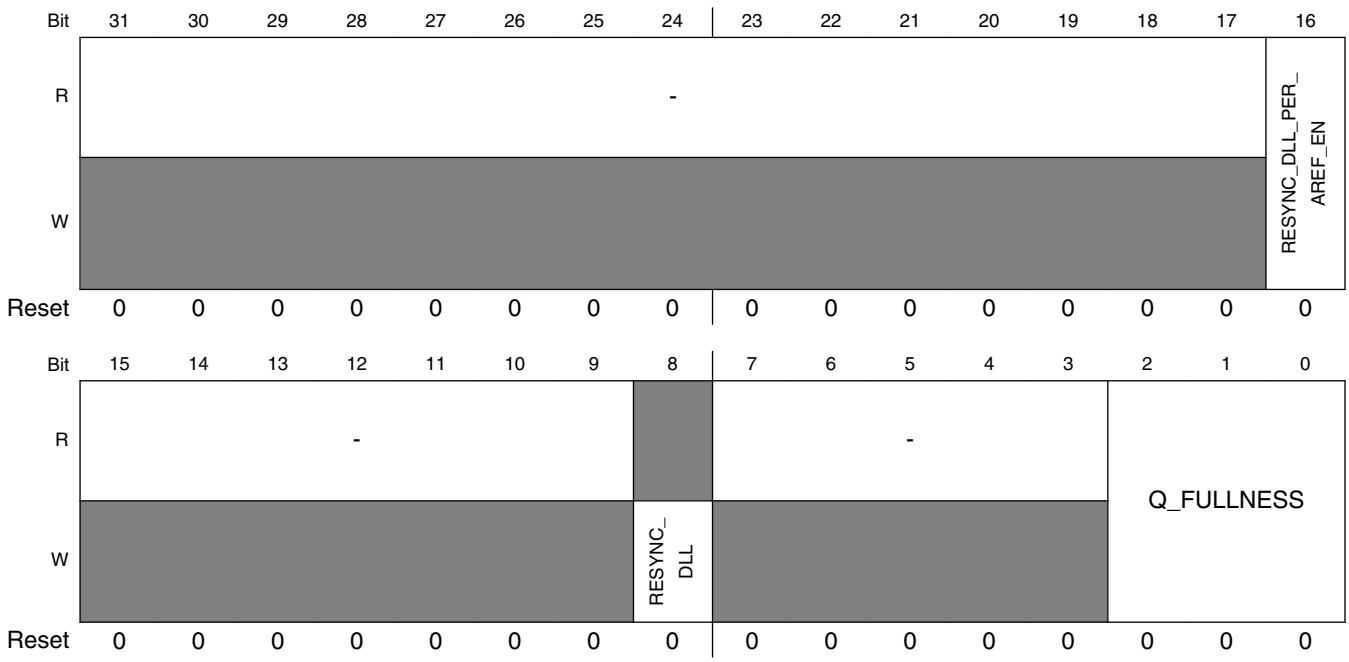
Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	-							WRDATALAT_REDUC_EN	-							CMDLAT_REDUC_EN
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DRAM_CTL40 field descriptions

Field	Description
31–25 -	Reserved.
24 FAST_WRITE	Controls when the write commands are issued to the DRAM devices. b0 = The memory controller will issue a write command to the DRAM devices when it has received enough data for one memory burst. In this mode, write data can be sent in any cycle relative to the write command. This mode also allows for multi-word write command data to arrive in non-sequential cycles. b1 = The memory controller will issue a write command to the DRAM devices after the first word of the write data is received by the memory controller. The first word can be sent at any time relative to the write command. In this mode, multi-word write command data must be available to the memory controller in sequential cycles.
23–17 -	Reserved.
16 LPDDR2_S4	Indicates the type of LPDDR2 device being used. The user must manually set this bit for LPDDR2-S4 devices. This parameter is only applicable when the MC is programmed for the LPDDR2 (dram_class = b0101). b0 = LPDDR2-S2 or LPDDR-NVM device b1 = LPDDR2-S4 device
15–9 -	Reserved.
8 WRDATALAT_ REDUC_EN	Enables data path latency reduction for the I/O cells of the PHY. b0 = Disable b1 = Enable
7–1 -	Reserved.
0 CMDLAT_ REDUC_EN	Enables reducing the latency of the command path in the MC by one clock cycle. b0 = Disabled b1 = Enabled

20.11.42 DRAM CTL Register 41 (DRAM_CTL41)

Address: DRAM_CTL41 is 1400_0000h base + A4h offset = 1400_00A4h

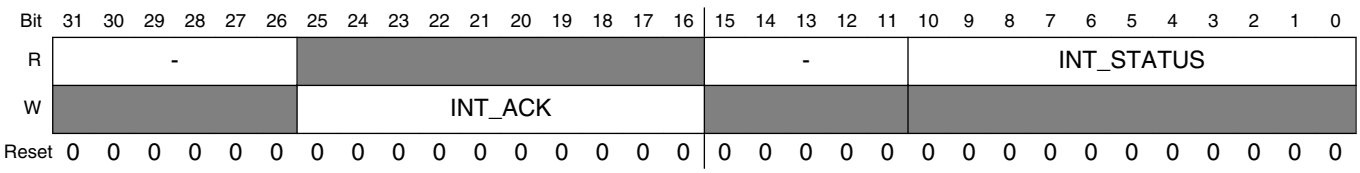


DRAM_CTL41 field descriptions

Field	Description
31–17 -	Reserved.
16 RESYNC_DLL_PER_AREF_EN	Enables an automatic re-synchronization of the DLL after every refresh.
15–9 -	Reserved.
8 RESYNC_DLL	Initiates a re-synchronization of the DLL. This parameter is write-only. Note: For proper operation, the user must issue at least one read or write command to memory after reset prior to setting this parameter.
7–3 -	Reserved.
2–0 Q_FULLNESS	Defines quantity of data that will be considered full for the command queue. When this value is reached, the q_almost_full parameter will be set.

20.11.43 DRAM CTL Register 42 (DRAM_CTL42)

Address: DRAM_CTL42 is 1400_0000h base + A8h offset = 1400_00A8h

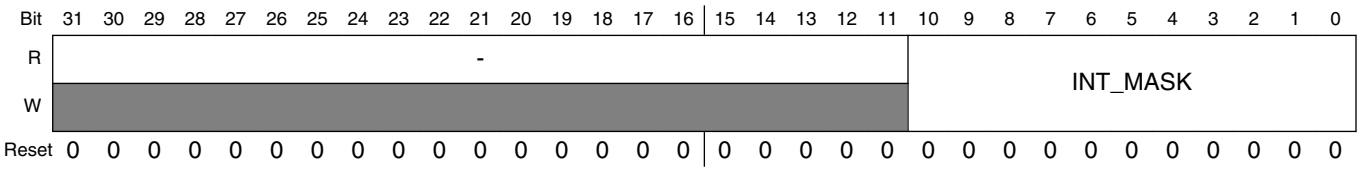


DRAM_CTL42 field descriptions

Field	Description
31–26 -	Reserved.
25–16 INT_ACK	Controls the clearing of the int_status parameter. If any of the int_ack bits are set to b1, the corresponding bit in the int_status parameter will be cleared to b0. Any int_ack bits cleared to b0 will not alter the corresponding bit in the int_status parameter. This parameter will always read back as 0x0.
15–11 -	Reserved.
10–0 INT_STATUS	Shows the status of all possible interrupts generated by the memory controller. The MSB is the result of a logical OR of all the lower bits. READ-ONLY. Note: Backwards compatibility is available for register parameters across configurations. However, even with this compatibility, the individual bits, their meaning and the size of the int_status parameter may change. The int_status bits correspond to these interrupts: Bit [10] = Logical OR of all lower bits. Bit [9] = User-initiated DLL resync is finished. Bit [8] = dfi_init_complete state change detected. Bit [7] = Indicates that a register interface mode register write has finished and that another register interface mode register write may be issued. Bit [6] = Indicates that a peripheral register interface mode register read has finished and that the mode register data and chip can be found in the param_peripheral_mrr_data register. Bit [5] = ODT enabled and CAS Latency 3 programmed error detected. This is an unsupported programming option. Bit [4] = DRAM initialization complete. Bit [3] = Error was found with command data channel in a port. Bit [2] = Error was found with command channel in a port. Bit [1] = Multiple accesses outside the defined PHYSICAL memory space detected. Bit [0] = A single access outside the defined PHYSICAL memory space detected.

20.11.44 DRAM CTL Register 43 (DRAM_CTL43)

Address: DRAM_CTL43 is 1400_0000h base + ACh offset = 1400_00ACh

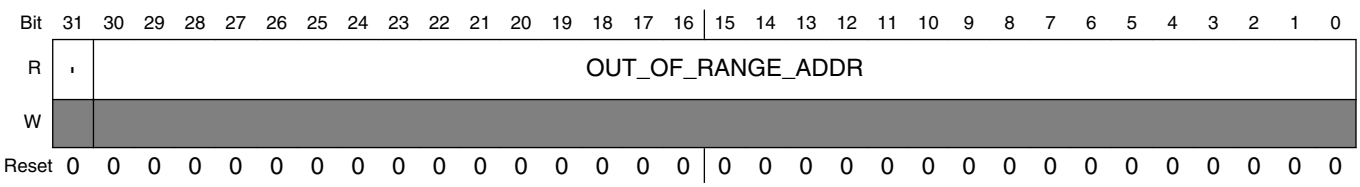


DRAM_CTL43 field descriptions

Field	Description
31–11 -	Reserved.
10–0 INT_MASK	Active-high mask bits that control the value of the memory controller_int signal on the ASIC interface. Unless the user has suppressed interrupt reporting (by setting the most significant bit of this parameter to b1), all lower bits of the int_mask parameter will be inverted and logically ANDed with the corresponding bits of the int_status parameter and the result is reported on the controller_int signal.

20.11.45 DRAM CTL Register 44 (DRAM_CTL44)

Address: DRAM_CTL44 is 1400_0000h base + B0h offset = 1400_00B0h

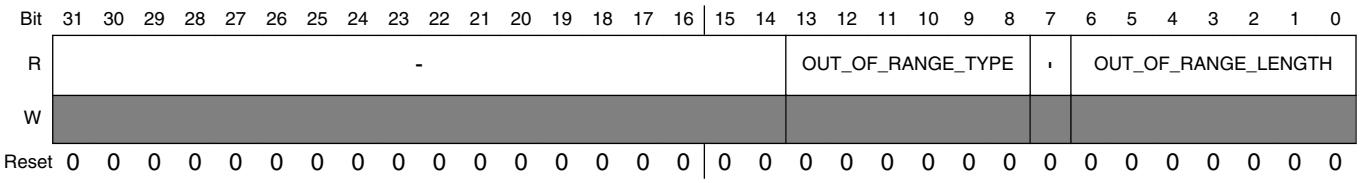


DRAM_CTL44 field descriptions

Field	Description
31 -	Reserved.
30–0 OUT_OF_ RANGE_ADDR	Holds the address of the command that caused an out-of-range interrupt request to the memory devices. READ-ONLY. For more information, refer to the Other Databahn Features Chapter.

20.11.46 DRAM CTL Register 45 (DRAM_CTL45)

Address: DRAM_CTL45 is 1400_0000h base + B4h offset = 1400_00B4h

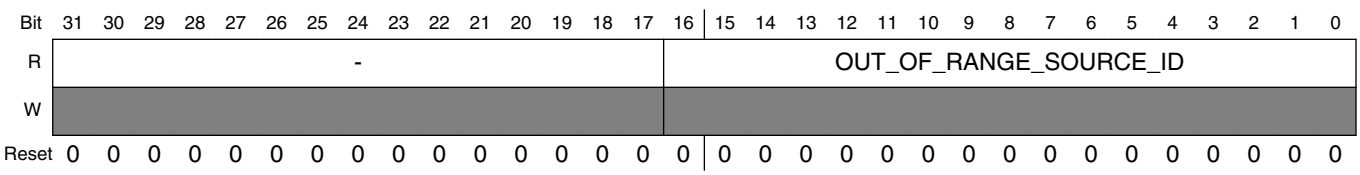


DRAM_CTL45 field descriptions

Field	Description
31–14 -	Reserved.
13–8 OUT_OF_ RANGE_TYPE	Holds the type of command that caused an out-of-range interrupt request to the memory devices. READ-ONLY. For more information, refer to the Other Databahn Features Chapter.
7 -	Reserved.
6–0 OUT_OF_ RANGE_ LENGTH	Holds the length of the command that caused an out-of-range interrupt request to the memory devices. READ-ONLY. For more information, refer to the Other Databahn Features Chapter.

20.11.47 DRAM CTL Register 46 (DRAM_CTL46)

Address: DRAM_CTL46 is 1400_0000h base + B8h offset = 1400_00B8h

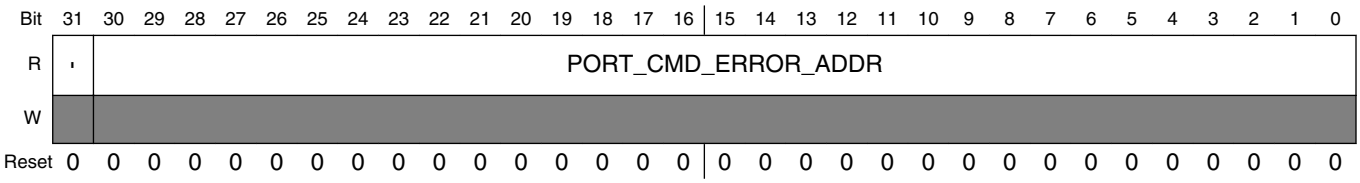


DRAM_CTL46 field descriptions

Field	Description
31–17 -	Reserved.
16–0 OUT_OF_ RANGE_ SOURCE_ID	Holds the Source ID of the command that caused an out-of-range interrupt request to the memory devices. READ-ONLY. For more information, refer to the Other Databahn Features Chapter.

20.11.48 DRAM CTL Register 47 (DRAM_CTL47)

Address: DRAM_CTL47 is 1400_0000h base + BCh offset = 1400_00BCh

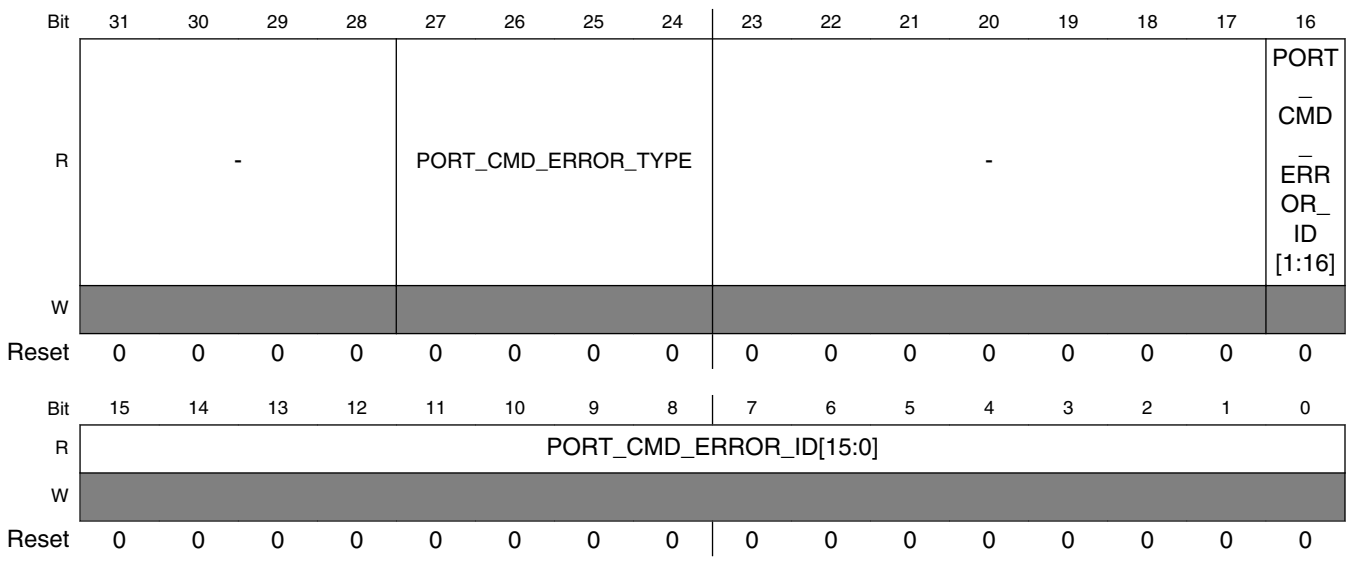


DRAM_CTL47 field descriptions

Field	Description
31 -	Reserved.
30–0 PORT_CMD_ ERROR_ADDR	Holds the address of the command that caused a port command error condition. READ-ONLY.

20.11.49 DRAM CTL Register 48 (DRAM_CTL48)

Address: DRAM_CTL48 is 1400_0000h base + C0h offset = 1400_00C0h



DRAM_CTL48 field descriptions

Field	Description
31–28 -	Reserved.

Table continues on the next page...

DRAM_CTL48 field descriptions (continued)

Field	Description
27–24 PORT_CMD_ ERROR_TYPE	Defines the type of error and the access type that caused the port command error condition. If multiple bits are set to b1, then multiple errors were found. READ-ONLY. Bit [3] = Narrow transfer requested for a requestor from port Y whose axiY_en_size_lt_width_instr parameter is clear. Bit [2] = Reserved Bit [1] = Reserved Bit [0] = Reserved
23–17 -	Reserved.
16–0 PORT_CMD_ ERROR_ID	Holds the source ID of the command that caused a port command error condition. For AXI ports, the source ID is comprised of the Port ID and the Requestor ID, where the Requestor ID is the axiY_AWID for write commands or the axiY_ARID for read commands. READ-ONLY.

20.11.50 DRAM CTL Register 49 (DRAM_CTL49)

Address: DRAM_CTL49 is 1400_0000h base + C4h offset = 1400_00C4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	-					PORT_DATA_ERROR_TYPE			-							PORT_DATA_ERROR_ID[1:16]
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	PORT_DATA_ERROR_ID[15:0]															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DRAM_CTL49 field descriptions

Field	Description
31–27 -	Reserved.
26–24 PORT_DATA_ ERROR_TYPE	Defines the type of error and the access type that caused the port data error condition. If multiple bits are set to b1, then multiple errors were found. READ-ONLY. Bit [2] = Reserved Bit [1] = Reserved

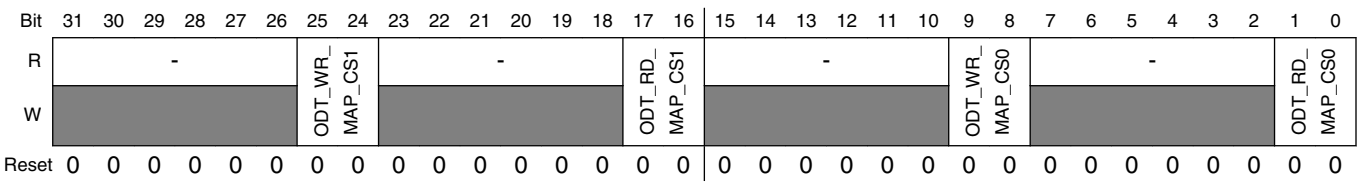
Table continues on the next page...

DRAM_CTL49 field descriptions (continued)

Field	Description
	Bit [0] = Reserved
23–17 -	Reserved.
16–0 PORT_DATA_ERROR_ID	Holds the source ID of the command that caused a port data error condition. For AXI ports, the source ID is comprised of the Port ID and the Requestor ID, where the Requestor ID is the axiY_BID for write response errors, the axiY_RID for read data errors, or the axiY_WID for write data errors. READ-ONLY.

20.11.51 DRAM CTL Register 50 (DRAM_CTL50)

Address: DRAM_CTL50 is 1400_0000h base + C8h offset = 1400_00C8h



DRAM_CTL50 field descriptions

Field	Description
31–26 -	Reserved.
25–24 ODT_WR_MAP_CS1	Sets up which (if any) chip(s) will have their ODT termination active while a write occurs on chip select 1. Refer to ODT_WR_MAP_CS0 for detailed description.
23–18 -	Reserved.
17–16 ODT_RD_MAP_CS1	Sets up which chip(s) will have their ODT termination active while a read occurs on chip select 1. Refer to ODT_RD_MAP_CS0 for detailed description.
15–10 -	Reserved.
9–8 ODT_WR_MAP_CS0	Sets up which (if any) chip(s) will have their ODT termination active while a write occurs on chip select 0. Example: If the system consists of 2 chip selects and odt_wr_map_cs0 is set to b10, then when CS0 is performing a write, CS1 will have active ODT termination. And if odt_wr_map_cs0 was set to b01, then instead CS0 would be active. Bit [1] = CS1 will have active ODT termination during a write. Bit [0] = CS0 will have active ODT termination during a write.
7–2 -	Reserved.

Table continues on the next page...

DRAM_CTL50 field descriptions (continued)

Field	Description
1–0 ODT_RD_MAP_CS0	Sets up which chip(s) will have their ODT termination active while a read occurs on chip select 0. Example: The system consists of 2 chip selects and odt_rd_map_cs0 is set to b10, then when CS0 is performing a read, CS1 will have active ODT termination. And if odt_rd_map_cs0 was set to b01, then instead CS0 would be active. Bit [1] = CS1 will have active ODT termination during a read. Bit [0] = CS0 will have active ODT termination during a read.

20.11.52 DRAM CTL Register 51 (DRAM_CTL51)

Address: DRAM_CTL51 is 1400_0000h base + CCh offset = 1400_00CCh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	-				ADD_ODT_CLK_SAMETYPE_DIFFCS				-			ADD_ODT_CLK_DIFFTYPE_DIFFCS				
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	-				ADD_ODT_CLK_W2R_SAMECS				-				ADD_ODT_CLK_R2W_SAMECS			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DRAM_CTL51 field descriptions

Field	Description
31–28 -	Reserved.
27–24 ADD_ODT_CLK_SAMETYPE_DIFFCS	Defines the number of additional clocks of delay to insert between commands of the same type (read to read, write to write) to different chip selects to meet ODT timing requirements.
23–21 -	Reserved.
20–16 ADD_ODT_CLK_DIFFTYPE_DIFFCS	Defines the number of additional clocks of delay to insert between commands of different types (read to write, write to read) to different chip selects to meet ODT timing requirements.
15–12 -	Reserved.

Table continues on the next page...

DRAM_CTL51 field descriptions (continued)

Field	Description
11–8 ADD_ODT_ CLK_W2R_ SAMECS	Defines the number of additional clocks of delay to insert after a write command before a read command to the same chip select to meet ODT timing requirements.
7–4 -	Reserved.
3–0 ADD_ODT_ CLK_R2W_ SAMECS	Defines the number of additional clocks of delay to insert after a read command before a write command to the same chip select to meet ODT timing requirements.

20.11.53 DRAM CTL Register 52 (DRAM_CTL52)

Address: DRAM_CTL52 is 1400_0000h base + D0h offset = 1400_00D0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	-					W2W_DIFFCS_DLY			-					W2R_DIFFCS_DLY			-					R2W_DIFFCS_DLY			-					R2R_DIFFCS_DLY		
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DRAM_CTL52 field descriptions

Field	Description
31–27 -	Reserved.
26–24 W2W_DIFFCS_ DLY	Defines the number of additional clocks of delay to insert from a write command to one chip select to a write command to a different chip select. The minimum allowable programming of this parameter is 1 cycle.
23–19 -	Reserved.
18–16 W2R_DIFFCS_ DLY	Defines the number of additional clocks of delay to insert from a write command to one chip select to a read command to a different chip select. The minimum allowable programming of this parameter is 1 cycle.
15–11 -	Reserved.
10–8 R2W_DIFFCS_ DLY	Defines the number of additional clocks of delay to insert from a read command to one chip select to a write command to a different chip select. The minimum allowable programming of this parameter is 1 cycle.
7–3 -	Reserved.
2–0 R2R_DIFFCS_ DLY	Defines the number of additional clocks of delay to insert from a read command to one chip select to a read command to a different chip select. The minimum allowable programming of this parameter is 1 cycle.

20.11.54 DRAM CTL Register 53 (DRAM_CTL53)

Address: DRAM_CTL53 is 1400_0000h base + D4h offset = 1400_00D4h

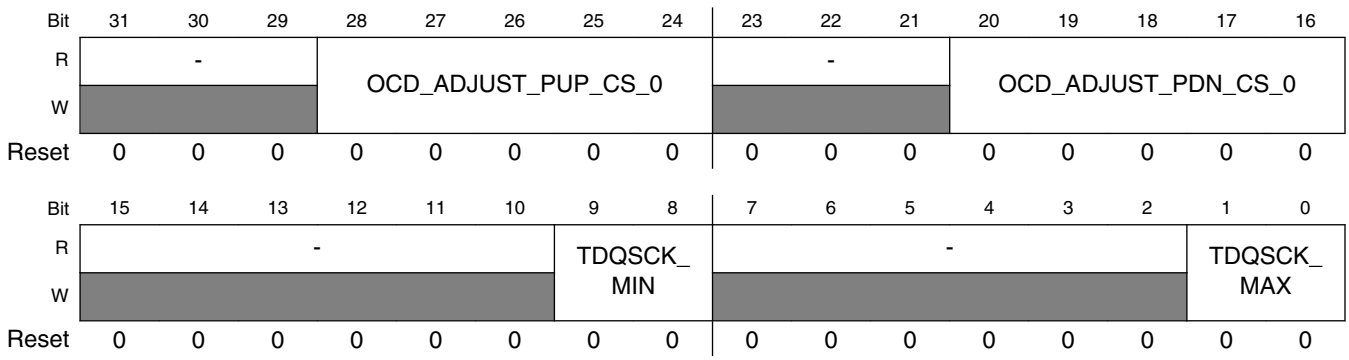
Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	-					W2W_SAMECS_DLY			-					W2R_SAMECS_DLY			-					R2W_SAMECS_DLY			-					R2R_SAMECS_DLY		
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DRAM_CTL53 field descriptions

Field	Description
31–27 -	Reserved.
26–24 W2W_SAMECS_DLY	Defines the number of additional clocks of delay to insert between two write commands to the same chip select.
23–19 -	Reserved.
18–16 W2R_SAMECS_DLY	Defines the number of additional clocks of delay to insert from a write command to a read command to the same chip select. The minimum allowable programming of this parameter is 1 cycle.
15–11 -	Reserved.
10–8 R2W_SAMECS_DLY	Defines the number of additional clocks of delay to insert from a read command to a write command to the same chip select. The minimum allowable programming of this parameter is 1 cycle.
7–3 -	Reserved.
2–0 R2R_SAMECS_DLY	Defines the number of additional clocks of delay to insert between two read commands to the same chip select.

20.11.55 DRAM CTL Register 54 (DRAM_CTL54)

Address: DRAM_CTL54 is 1400_0000h base + D8h offset = 1400_00D8h

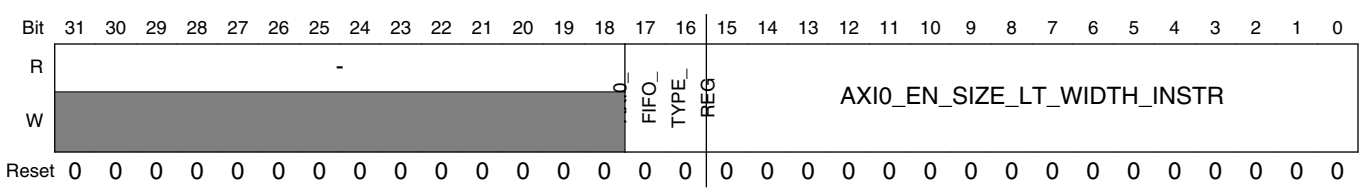


DRAM_CTL54 field descriptions

Field	Description
31–29 -	Reserved.
28–24 OCD_ADJUST_PUP_CS_0	This parameter is reserved for future use and should be programmed to 0x0.
23–21 -	Reserved.
20–16 OCD_ADJUST_PDN_CS_0	This parameter is reserved for future use and should be programmed to 0x0.
15–10 -	Reserved.
9–8 TDQSCK_MIN	Additional delay needed for tDQSCK
7–2 -	Reserved.
1–0 TDQSCK_MAX	Additional delay needed for tDQSCK

20.11.56 DRAM CTL Register 55 (DRAM_CTL55)

Address: DRAM_CTL55 is 1400_0000h base + DCh offset = 1400_00DCh

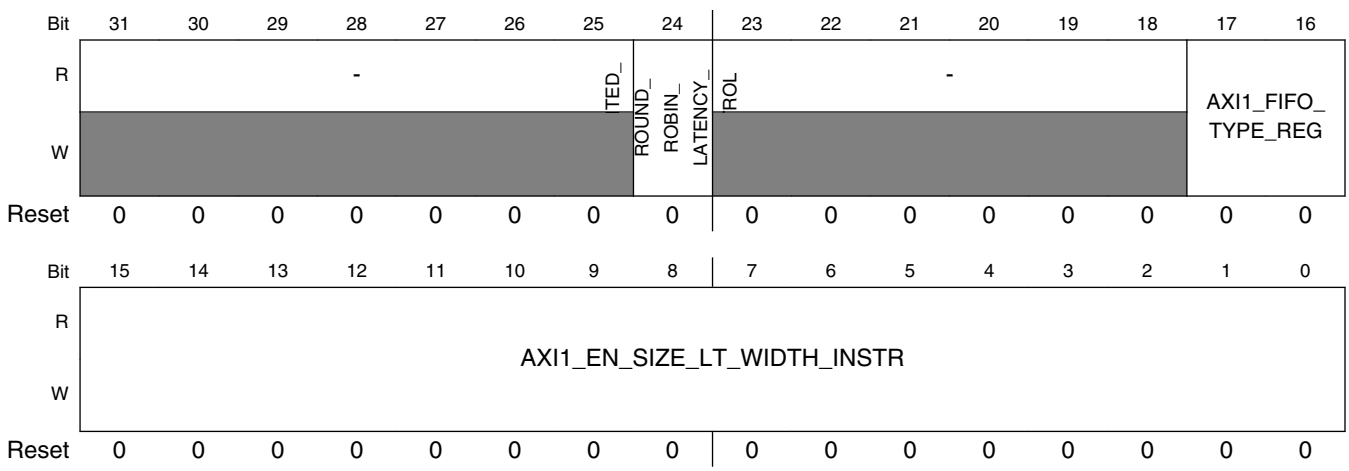


DRAM_CTL55 field descriptions

Field	Description
31–18 -	Reserved.
17–16 AXI0_FIFO_ TYPE_REG	Sets the relativity of the clock domains between AXI port Y and the MC core clock. b00 = Asynchronous b01 = Reserved b10 = Reserved b11 = Synchronous
15–0 AXI0_EN_SIZE_ LT_WIDTH_ INSTR	Allows the port to accept size less than width transactions on AXI port Y from requestors with the lowest four bits set to Z. Each bit Z corresponds to the lowest four bits of requestor Z, meaning that if bit [0] is set, then requestors with the lowest four bits of 0 for AXI port Y will be able to send size less than width transactions. Note: User must set AXI0_EN_SIZE_LT_WIDTH_INSTR = 0xFFFF for this MC. b0 = Requestor Z of port Y may only issue size equal to width instructions. b1 = Requestor Z of port Y can issue size equal to width or size less than width instructions.

20.11.57 DRAM CTL Register 56 (DRAM_CTL56)

Address: DRAM_CTL56 is 1400_0000h base + E0h offset = 1400_00E0h



DRAM_CTL56 field descriptions

Field	Description
31–25 -	Reserved.
24 WEIGHTED_ ROUND_ ROBIN_	Controls the weighted round-robin latency option. b0 = Counters only count when their port has a command waiting to be processed. b1 = Counters are always running.

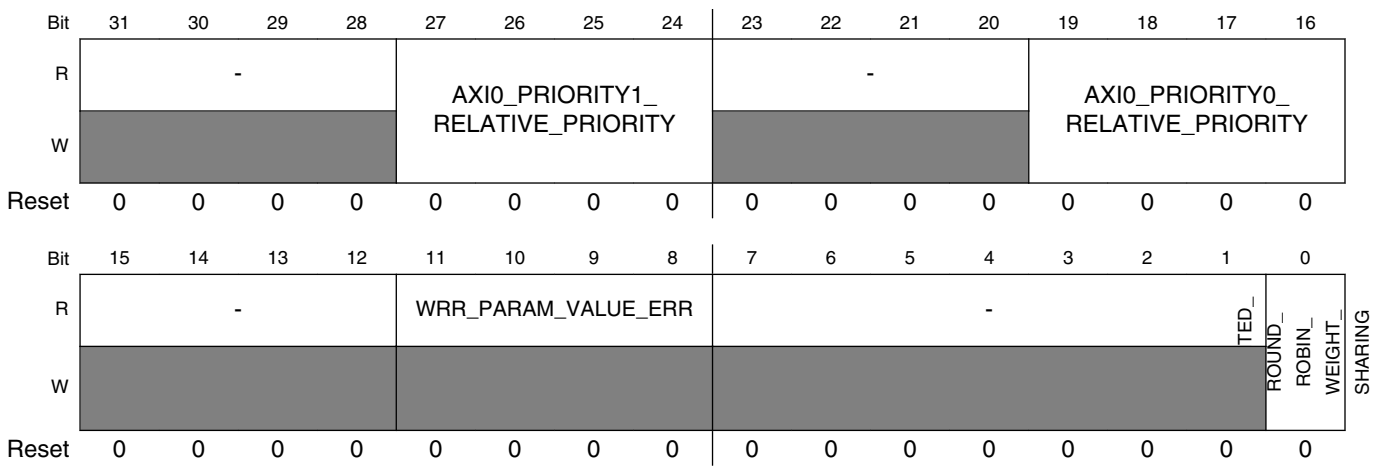
Table continues on the next page...

DRAM_CTL56 field descriptions (continued)

Field	Description
LATENCY_ CONTROL	
23–18 -	Reserved.
17–16 AXI1_FIFO_ TYPE_REG	AXI1 port is tied-off in this MC.
15–0 AXI1_EN_SIZE_ LT_WIDTH_ INSTR	AXI1 port is tied-off in this MC.

20.11.58 DRAM CTL Register 57 (DRAM_CTL57)

Address: DRAM_CTL57 is 1400_0000h base + E4h offset = 1400_00E4h



DRAM_CTL57 field descriptions

Field	Description
31–28 -	Reserved.
27–24 AXI0_ PRIORITY1_ RELATIVE_ PRIORITY	Holds the relative priority of the AXI port 0 for priority 1 commands in weighted round robin arbitration.
23–20 -	Reserved.
19–16 AXI0_ PRIORITY0_	Holds the relative priority of the AXI port 0 for priority 0 commands in weighted round robin arbitration.

Table continues on the next page...

DRAM_CTL57 field descriptions (continued)

Field	Description
RELATIVE_ PRIORITY	
15–12 -	Reserved.
11–8 WRR_PARAM_ VALUE_ERR	Shows the weighted round-robin arbitration errors/warnings. READ-ONLY. Bit [3] = The port ordering parameter values for paired ports is not sequential. Bit [2] = The relative priority values for any of the ports paired through the weighted_round_robin_weight_sharing parameter are not identical. Bit [1] = Any of the relative priority parameters have been programmed with a zero value. Bit [0] = The port ordering parameters do not all contain unique values.
7–1 -	Reserved.
0 WEIGHTED_ ROUND_ ROBIN_ WEIGHT_ SHARING	Indicates that the port pair is tied together in arbitration decisions in weighted round-robin arbitration. Bit [0] represents ports 0 and 1, bit [1] represents ports 2 and 3, etc. Each bit setting is as follows: 'b0 = The represented ports are treated independently in arbitration. b1 = The represented ports are tied together for arbitration.

20.11.59 DRAM CTL Register 58 (DRAM_CTL58)

Address: DRAM_CTL58 is 1400_0000h base + E8h offset = 1400_00E8h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	-				AXI0_PRIORITY5_ RELATIVE_PRIORITY				-				AXI0_PRIORITY4_ RELATIVE_PRIORITY

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	-				AXI0_PRIORITY3_ RELATIVE_PRIORITY				-				AXI0_PRIORITY2_ RELATIVE_PRIORITY			
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DRAM_CTL58 field descriptions

Field	Description
31–28 -	Reserved.
27–24 AXI0_ PRIORITY5_ RELATIVE_ PRIORITY	Holds the relative priority of the AXI port 0 for priority 5 commands in weighted round robin arbitration.

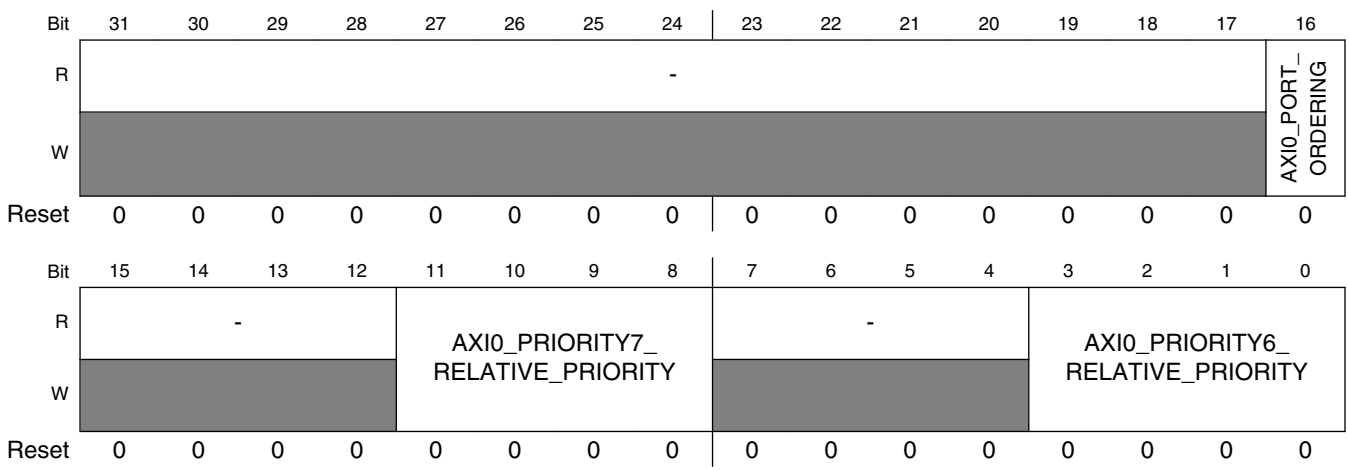
Table continues on the next page...

DRAM_CTL58 field descriptions (continued)

Field	Description
23–20 -	Reserved.
19–16 AXI0_ PRIORITY4_ RELATIVE_ PRIORITY	Holds the relative priority of the AXI port 0 for priority 4 commands in weighted round robin arbitration.
15–12 -	Reserved.
11–8 AXI0_ PRIORITY3_ RELATIVE_ PRIORITY	Holds the relative priority of the AXI port 0 for priority 3 commands in weighted round robin arbitration.
7–4 -	Reserved.
3–0 AXI0_ PRIORITY2_ RELATIVE_ PRIORITY	Holds the relative priority of the AXI port 0 for priority 2 commands in weighted round robin arbitration.

20.11.60 DRAM CTL Register 59 (DRAM_CTL59)

Address: DRAM_CTL59 is 1400_0000h base + ECh offset = 1400_00ECh



DRAM_CTL59 field descriptions

Field	Description
31–17 -	Reserved.

Table continues on the next page...

DRAM_CTL59 field descriptions (continued)

Field	Description
16 AXI0_PORT_ ORDERING	Used in weighted round-robin arbitration to modify the order than the ports are scanned when multiple commands are at the same priority level and have the same relative priorities.
15–12 -	Reserved.
11–8 AXI0_ PRIORITY7_ RELATIVE_ PRIORITY	Holds the relative priority of the AXI port 0 for priority 7 commands in weighted round robin arbitration.
7–4 -	Reserved.
3–0 AXI0_ PRIORITY6_ RELATIVE_ PRIORITY	Holds the relative priority of the AXI port 0 for priority 6 commands in weighted round robin arbitration.

20.11.61 DRAM CTL Register 60 (DRAM_CTL60)

Address: DRAM_CTL60 is 1400_0000h base + F0h offset = 1400_00F0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	-								AXI0_PRIORITY_RELAX							
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DRAM_CTL60 field descriptions

Field	Description
31–28 -	Reserved.
27–24 AXI1_ PRIORITY1_ RELATIVE_ PRIORITY	AXI1 port is tied-off in this MC.
23–20 -	Reserved.

Table continues on the next page...

DRAM_CTL60 field descriptions (continued)

Field	Description
19–16 AXI1_ PRIORITY0_ RELATIVE_ PRIORITY	AXI1 port is tied-off in this MC.
15–10 -	Reserved.
9–0 AXI0_ PRIORITY_ RELAX	Holds the counter value for AXI port Y at which the priority relax condition is triggered in weighted round robin arbitration.

20.11.62 DRAM CTL Register 61 (DRAM_CTL61)

Address: DRAM_CTL61 is 1400_0000h base + F4h offset = 1400_00F4h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DRAM_CTL61 field descriptions

Field	Description
31–28 -	Reserved.
27–24 AXI1_ PRIORITY5_ RELATIVE_ PRIORITY	AXI1 port is tied-off in this MC.
23–20 -	Reserved.
19–16 AXI1_ PRIORITY4_ RELATIVE_ PRIORITY	AXI1 port is tied-off in this MC.

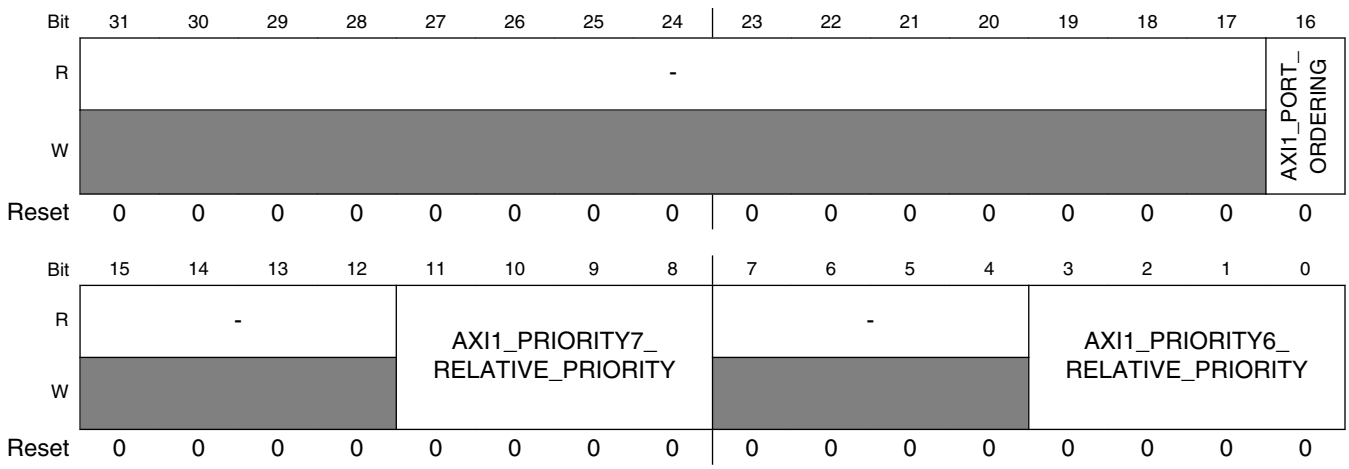
Table continues on the next page...

DRAM_CTL61 field descriptions (continued)

Field	Description
15–12 -	Reserved.
11–8 AXI1_ PRIORITY3_ RELATIVE_ PRIORITY	AXI1 port is tied-off in this MC.
7–4 -	Reserved.
3–0 AXI1_ PRIORITY2_ RELATIVE_ PRIORITY	AXI1 port is tied-off in this MC.

20.11.63 DRAM CTL Register 62 (DRAM_CTL62)

Address: DRAM_CTL62 is 1400_0000h base + F8h offset = 1400_00F8h



DRAM_CTL62 field descriptions

Field	Description
31–17 -	Reserved.
16 AXI1_PORT_ ORDERING	AXI1 port is tied-off in this MC.
15–12 -	Reserved.

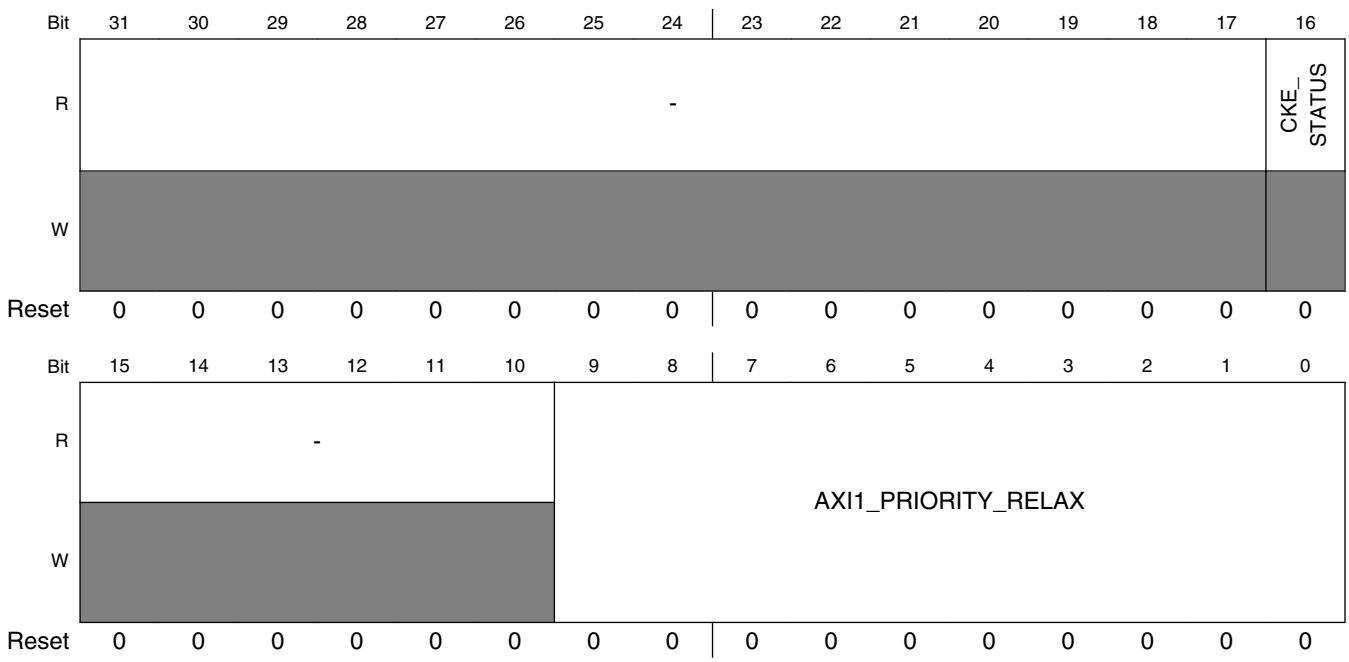
Table continues on the next page...

DRAM_CTL62 field descriptions (continued)

Field	Description
11–8 AXI1_ PRIORITY7_ RELATIVE_ PRIORITY	AXI1 port is tied-off in this MC.
7–4 -	Reserved.
3–0 AXI1_ PRIORITY6_ RELATIVE_ PRIORITY	AXI1 port is tied-off in this MC.

20.11.64 DRAM CTL Register 63 (DRAM_CTL63)

Address: DRAM_CTL63 is 1400_0000h base + FCh offset = 1400_00FCh



DRAM_CTL63 field descriptions

Field	Description
31–17 -	Reserved.
16 CKE_STATUS	Provides the value of the cke_status signal in a parameter. This signal is the value of the control_cke signal inside the MC, delayed by the number of clocks specified in the cke_delay parameter. READ-ONLY.

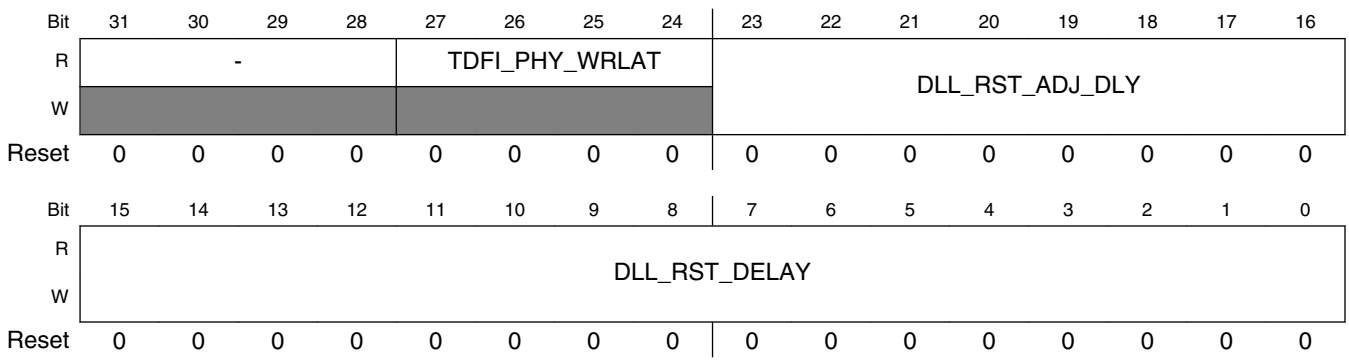
Table continues on the next page...

DRAM_CTL63 field descriptions (continued)

Field	Description
15–10 -	Reserved.
9–0 AXI1_ PRIORITY_ RELAX	AXI1 port is tied-off in this MC.

20.11.65 DRAM CTL Register 64 (DRAM_CTL64)

Address: DRAM_CTL64 is 1400_0000h base + 100h offset = 1400_0100h



DRAM_CTL64 field descriptions

Field	Description
31–28 -	Reserved.
27–24 TDFI_PHY_ WRLAT	Holds the calculated DFI tPHY_WRLAT timing parameter. READ-ONLY
23–16 DLL_RST_ADJ_ DLY	Specifies the minimum number of cycles after the master delay value is programmed before the DLL reset may be asserted.
15–0 DLL_RST_ DELAY	Sets the number of cycles that the reset must be held asserted for the DLL.

20.11.66 DRAM CTL Register 65 (DRAM_CTL65)

Address: DRAM_CTL65 is 1400_0000h base + 104h offset = 1400_0104h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	-			TDFI_RDDATA_EN_BASE					-			TDFI_RDDATA_EN					-			TDFI_PHY_RDLAT					-				TDFI_PHY_WRLAT_BASE

DRAM_CTL65 field descriptions

Field	Description
31–29 -	Reserved.
28–24 TDFI_RDDATA_EN_BASE	Sets DFI base value for the tRDDATA_EN timing parameter.
23–21 -	Reserved.
20–16 TDFI_RDDATA_EN	Holds the calculated DFI tRDDATA_EN timing parameter. READ-ONLY
15–13 -	Reserved.
12–8 TDFI_PHY_RDLAT	Holds the tPHY_RDLAT timing parameter.
7–4 -	Reserved.
3–0 TDFI_PHY_WRLAT_BASE	Sets DFI base value for the tPHY_WRLAT timing parameter.

20.11.67 DRAM CTL Register 66 (DRAM_CTL66)

Address: DRAM_CTL66 is 1400_0000h base + 108h offset = 1400_0108h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

R	-				TDFI_CTRLUPD_MIN				-						DRAM_CLK_DISABLE	
W																
Reset	0	0	0	0	0	1	0	0	0	0	0	0	0	0	0	0

DRAM_CTL66 field descriptions

Field	Description
31–16 TDFI_ CTRLUPD_MAX	Defines the maximum number of DFI clock cycles that the dfi_ctrlupd_req signal can assert.
15–12 -	Reserved.
11–8 TDFI_ CTRLUPD_MIN	Holds the minimum number of DFI clock cycles that the dfi_ctrlupd_req signal must be asserted. READ-ONLY
7–2 -	Reserved.
1–0 DRAM_CLK_ DISABLE	Sets value for the DFI output signal dfi_dram_clk_disable. Bit [0] controls CS0, Bit [1] controls CS1. For each bit: b0 = Memory clock/s should be active. b1 = Memory clock/s should be disabled.

20.11.68 DRAM CTL Register 67 (DRAM_CTL67)

Address: DRAM_CTL67 is 1400_0000h base + 10Ch offset = 1400_010Ch

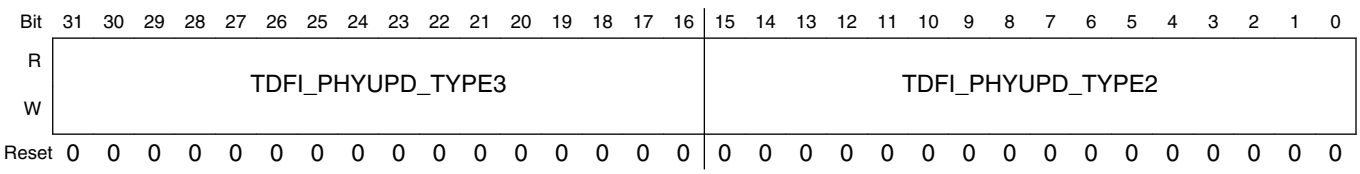
Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	TDFI_PHYUPD_TYPE1																TDFI_PHYUPD_TYPE0															
W																																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DRAM_CTL67 field descriptions

Field	Description
31–16 TDFI_PHYUPD_TYPE1	Defines the maximum number of DFI clock cycles that the dfi_phyupd_req signal may remain asserted after the assertion of the dfi_phyupd_ack signal for dfi_phyupd_type1.
15–0 TDFI_PHYUPD_TYPE0	Defines the maximum number of DFI clock cycles that the dfi_phyupd_req signal may remain asserted after the assertion of the dfi_phyupd_ack signal for dfi_phyupd_type0.

20.11.69 DRAM CTL Register 68 (DRAM_CTL68)

Address: DRAM_CTL68 is 1400_0000h base + 110h offset = 1400_0110h

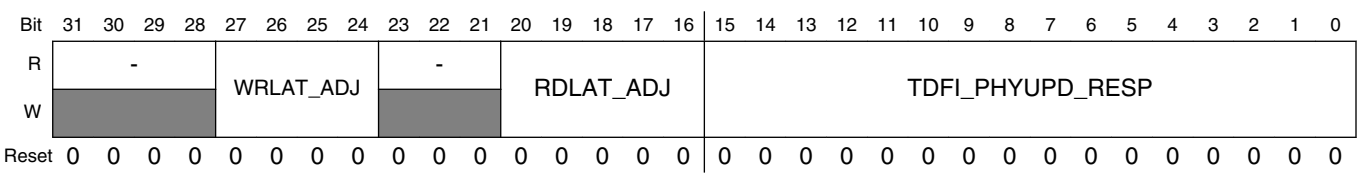


DRAM_CTL68 field descriptions

Field	Description
31–16 TDFI_PHYUPD_TYPE3	Defines the maximum number of DFI clock cycles that the dfi_phyupd_req signal may remain asserted after the assertion of the dfi_phyupd_ack signal for dfi_phyupd_type3.
15–0 TDFI_PHYUPD_TYPE2	Defines the maximum number of DFI clock cycles that the dfi_phyupd_req signal may remain asserted after the assertion of the dfi_phyupd_ack signal for dfi_phyupd_type2.

20.11.70 DRAM CTL Register 69 (DRAM_CTL69)

Address: DRAM_CTL69 is 1400_0000h base + 114h offset = 1400_0114h



DRAM_CTL69 field descriptions

Field	Description
31–28 -	Reserved.

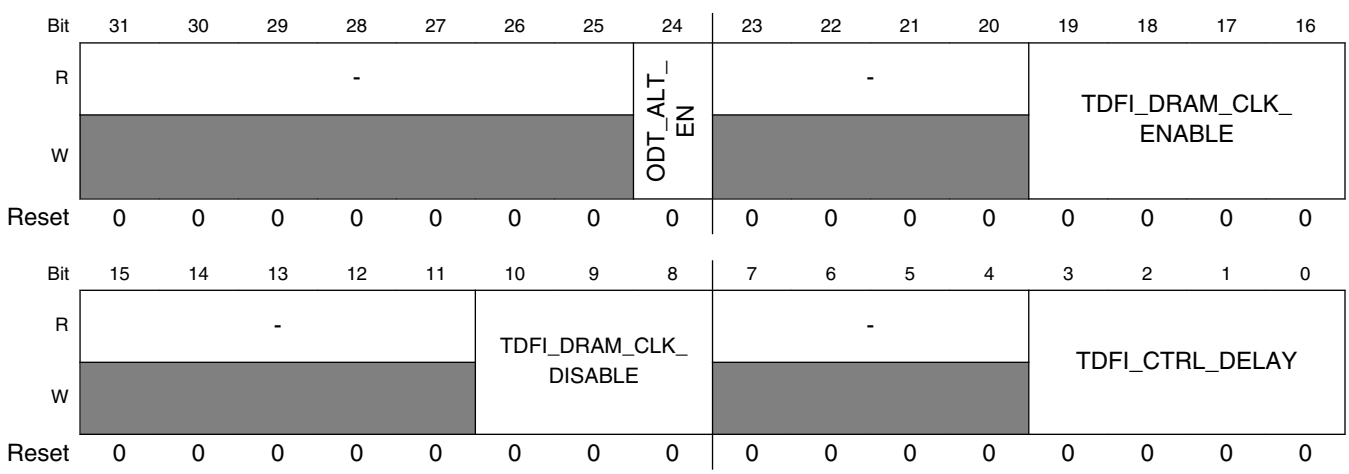
Table continues on the next page...

DRAM_CTL69 field descriptions (continued)

Field	Description
27–24 WRLAT_ADJ	Adjusts the relative timing between DFI write commands and the dfi_wrdata_en signal to conform to PHY timing requirements. Note: For LPDDR2 memory systems (dram_class = b0101), the wrlat_adj value is incremented inside the memory controller by 1 to compensate for TDSS. When this parameter is programmed to 0x0, dfi_wrdata_en will assert on the same cycle as the dfi_address. The sum of the tdfi_phy_wrlat_base parameter and this parameter must be at least 0x3. These two parameters work together to set the actual PHY write latency (tdfi_phy_wrlat). This parameter only affects the DFI.
23–21 -	Reserved.
20–16 RDLAT_ADJ	Adjusts the relative timing between DFI read commands and the dfi_rddata_en signal to conform to PHY timing requirements. When this parameter is programmed to 0x0, dfi_rddata_en will assert one cycle after the dfi_address. The sum of the tdfi_rddata_en_base parameter and this parameter must be at least 0x4. These two parameters work together to set the actual PHY read latency (tdfi_rddata_en). This parameter only affects the DFI.
15–0 TDFI_PHYUPD_RESP	Defines the maximum number of DFI clock cycles after the assertion of the dfi_phyupd_req signal to the assertion of the dfi_phyupd_ack signal.

20.11.71 DRAM CTL Register 70 (DRAM_CTL70)

Address: DRAM_CTL70 is 1400_0000h base + 118h offset = 1400_0118h



DRAM_CTL70 field descriptions

Field	Description
31–25 -	Reserved.

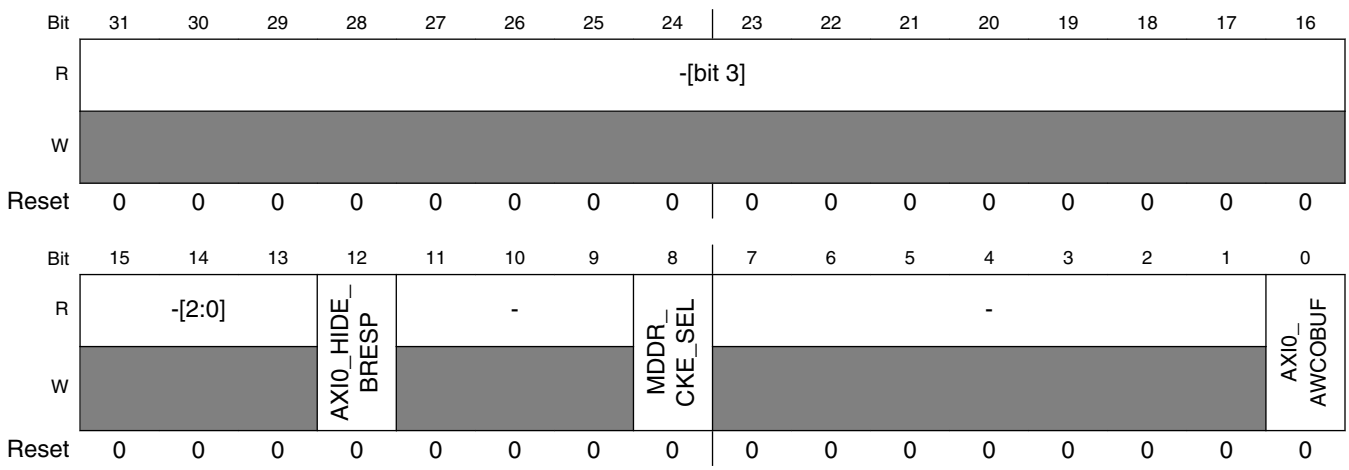
Table continues on the next page...

DRAM_CTL70 field descriptions (continued)

Field	Description
24 ODT_ALT_EN	User must set ODT_ALT_EN=0 for this MC. b0 = ODT support with CAS latency 3 is not supported. b1 = ODT support with CAS latency 3 is supported.
23–20 -	Reserved.
19–16 TDFI_DRAM_ CLK_ENABLE	Delay from DFI clock enable to memory clock enable.
15–11 -	Reserved.
10–8 TDFI_DRAM_ CLK_DISABLE	Delay from DFI clock disable to memory clock disable.
7–4 -	Reserved.
3–0 TDFI_CTRL_ DELAY	Delay from DFI command to memory command.

20.11.72 DRAM CTL Register 71 (DRAM_CTL71)

Address: DRAM_CTL71 is 1400_0000h base + 11Ch offset = 1400_011Ch



DRAM_CTL71 field descriptions

Field	Description
31–13 -	Reserved.

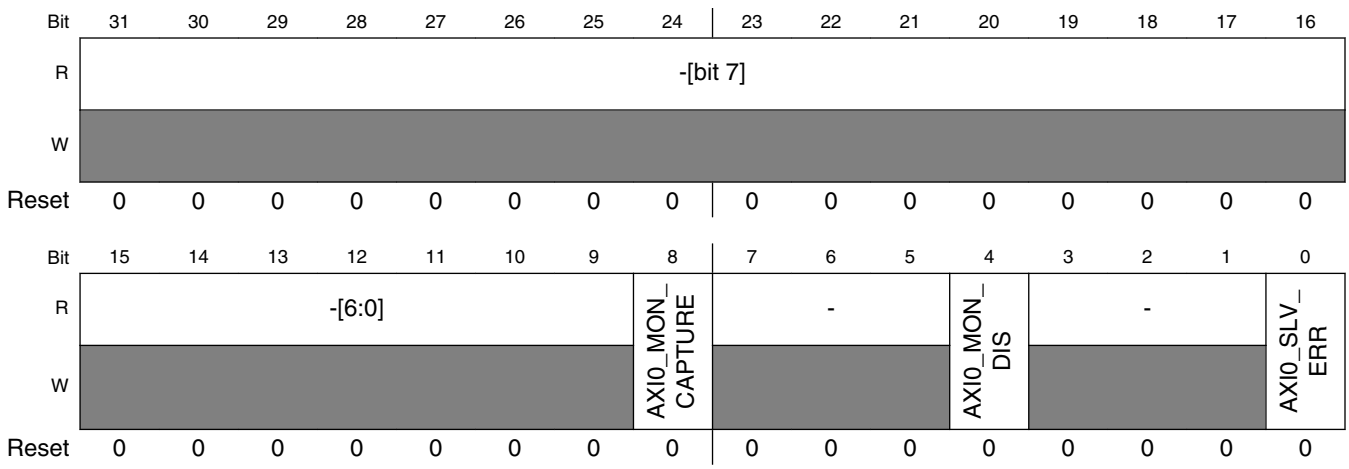
Table continues on the next page...

DRAM_CTL71 field descriptions (continued)

Field	Description
12 AXI0_HIDE_ BRESP	Hide extra latency of axi response.
11–9 -	Reserved.
8 MDDR_CKE_ SEL	Select the CKE init status for MDDR.
7–1 -	Reserved.
0 AXI0_ AWCOBUF	Coherent bufferable write command.

20.11.73 DRAM CTL Register 72 (DRAM_CTL72)

Address: DRAM_CTL72 is 1400_0000h base + 120h offset = 1400_0120h



DRAM_CTL72 field descriptions

Field	Description
31–9 -	Reserved.
8 AXI0_MON_ CAPTURE	Test purpose: capture debug data.
7–5 -	Reserved.
4 AXI0_MON_DIS	Test purpose: disable the axi0 monitor.

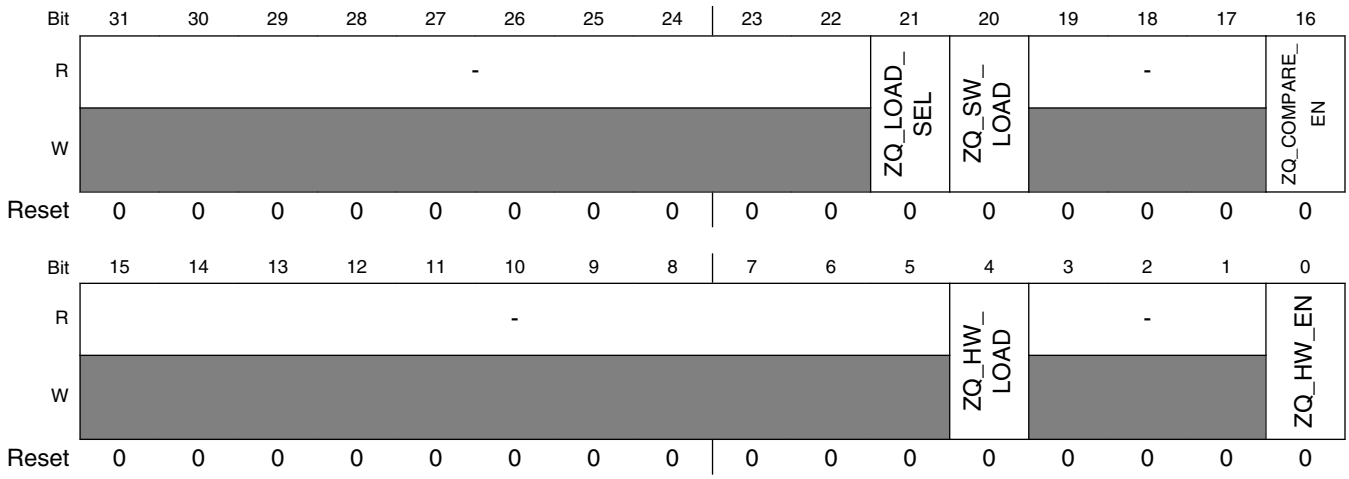
Table continues on the next page...

DRAM_CTL72 field descriptions (continued)

Field	Description
3–1 -	Reserved.
0 AXI0_SLV_ERR	Test purpose: force slave error on axi0.

20.11.74 DRAM CTL Register 73 (DRAM_CTL73)

Address: DRAM_CTL73 is 1400_0000h base + 124h offset = 1400_0124h



DRAM_CTL73 field descriptions

Field	Description
31–22 -	Reserved.
21 ZQ_LOAD_SEL	Select the mode of on-chip ZQ loading. b0 = Select hardware controlled ZQ loading mode b1 = Select software controlled ZQ loading mode
20 ZQ_SW_LOAD	When ZQ_LOAD_SEL=1, set this bit high loading ZQ values into the on-chip ZQ buffers.
19–17 -	Reserved.
16 ZQ_COMPARE_EN	Enable the on-chip ZQ comparator. It needs at least 300ns for the ZQ comparator to complete a comparsion. Please clear this bit before starting a new ZQ comparsion process. b0 = The on-chip ZQ comparator disabled b1 = The on-chip ZQ comparator enabled
15–5 -	Reserved.

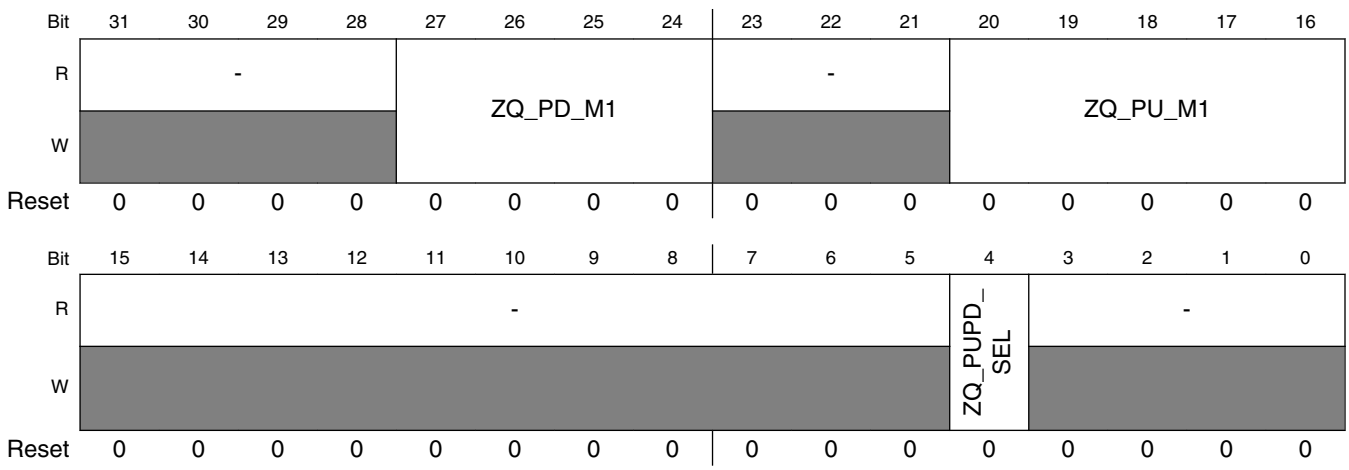
Table continues on the next page...

DRAM_CTL73 field descriptions (continued)

Field	Description
4 ZQ_HW_LOAD	When ZQ_LOAD_SEL=0 and ZQ_HW_EN=1, hardware start the ZQ loading routine on the posedge of ZQ_HW_LOAD.
3–1 -	Reserved.
0 ZQ_HW_EN	Enable the on-chip ZQ hardware controlled loading. The ZQ_PU/PD value would be loaded into the on-chip ZQ buffer on the next auto-refresh event.

20.11.75 DRAM CTL Register 74 (DRAM_CTL74)

Address: DRAM_CTL74 is 1400_0000h base + 128h offset = 1400_0128h



DRAM_CTL74 field descriptions

Field	Description
31–28 -	Reserved.
27–24 ZQ_PD_M1	The PD minus 1 value for on-chip ZQ. ZQ_PD_M1 = (ZQ_PD==0) ? 0 : (ZQ_PD - 1)
23–21 -	Reserved.
20–16 ZQ_PU_M1	The PU minus 1 value for on-chip ZQ. ZQ_PU_M1 = (ZQ_PU==0) ? 0 : (ZQ_PU - 1)
15–5 -	Reserved.
4 ZQ_PUPD_SEL	Select the PU or PD to be calibrated or loading buffer. b0 = Select PU calibration/loading mode b1 = Select PD calibration/loading mode

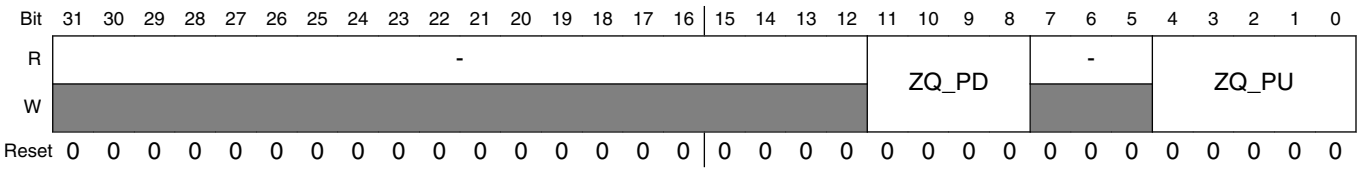
Table continues on the next page...

DRAM_CTL74 field descriptions (continued)

Field	Description
3–0 -	Reserved.

20.11.76 DRAM CTL Register 75 (DRAM_CTL75)

Address: DRAM_CTL75 is 1400_0000h base + 12Ch offset = 1400_012Ch

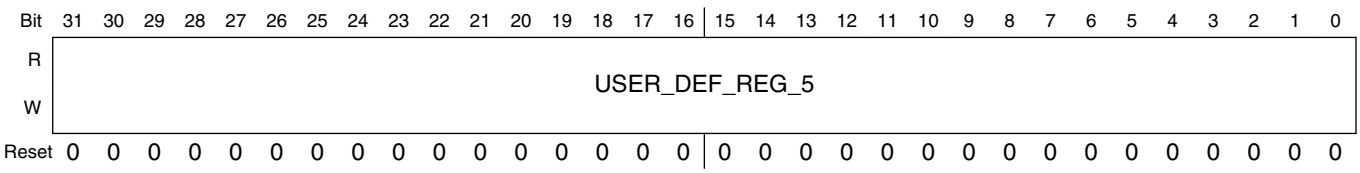


DRAM_CTL75 field descriptions

Field	Description
31–12 -	Reserved.
11–8 ZQ_PD	The PD value for on-chip ZQ.
7–5 -	Reserved.
4–0 ZQ_PU	The PU value for on-chip ZQ.

20.11.77 DRAM CTL Register 76 (DRAM_CTL76)

Address: DRAM_CTL76 is 1400_0000h base + 130h offset = 1400_0130h



DRAM_CTL76 field descriptions

Field	Description
31–0 USER_DEF_ REG_5	User-defined output register 5.

20.11.78 DRAM CTL Register 77 (DRAM_CTL77)

Address: DRAM_CTL77 is 1400_0000h base + 134h offset = 1400_0134h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

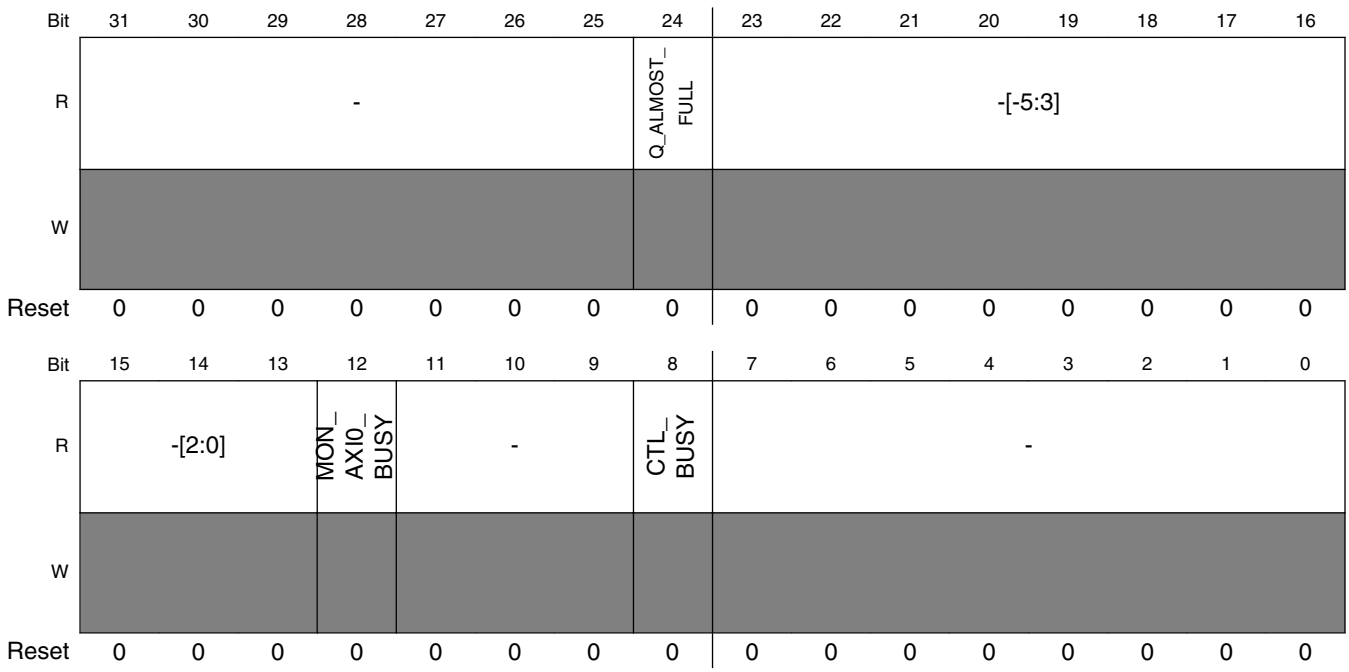
DRAM_CTL78 field descriptions

Field	Description
31–0 USER_DEF_ REG_7	User-defined output register 7.

20.11.80 DRAM CTL Register 79 (DRAM_CTL79)

Address: DRAM_CTL79 is 1400_0000h base + 13Ch offset = 1400_013Ch



DRAM_CTL79 field descriptions

Field	Description
31–25 -	Reserved.
24 Q_ALMOST_FULL	Indicate the command queue is almost full. READ-ONLY Refer to parameter Q_FULLNESS
23–13 -	Reserved.
12 MON_AXI0_BUSY	AXI0 port monitor busy. READ-ONLY
11–9 -	Reserved.
8 CTL_BUSY	Controller busy. READ-ONLY
7–0 -	Reserved.

20.11.81 DRAM CTL Register 80 (DRAM_CTL80)

Address: DRAM_CTL80 is 1400_0000h base + 140h offset = 1400_0140h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

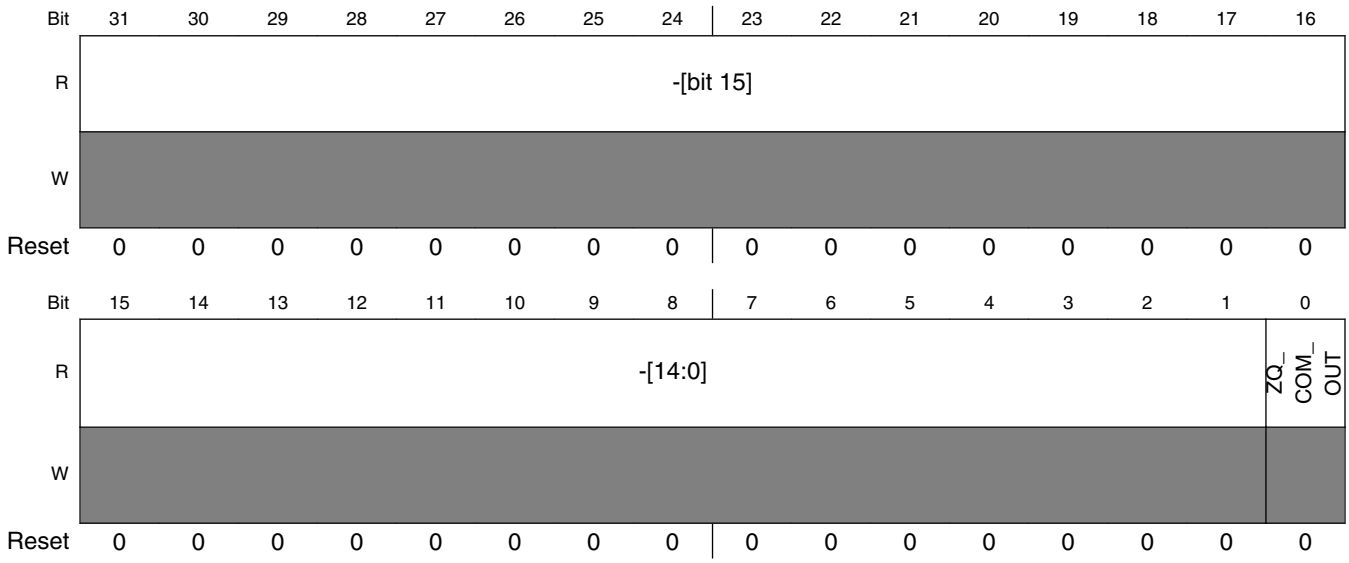
DRAM_CTL82 field descriptions

Field	Description
31–0 AXI0_MON_ DBG1	Test purpose: debug data 1.

20.11.84 DRAM CTL Register 83 (DRAM_CTL83)

Address: DRAM_CTL83 is 1400_0000h base + 14Ch offset = 1400_014Ch

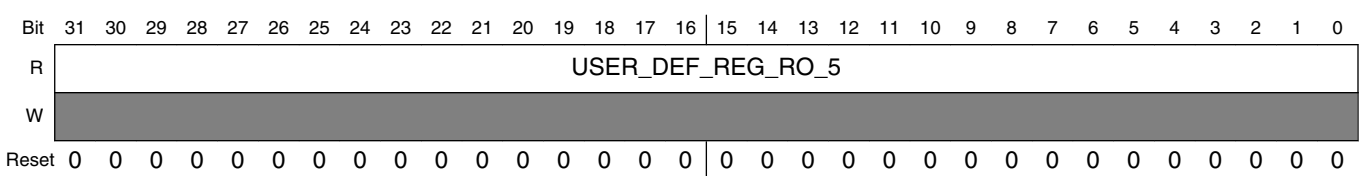


DRAM_CTL83 field descriptions

Field	Description
31–1 -	Reserved.
0 ZQ_COM_OUT	ZQ comparator output. READ-ONLY

20.11.85 DRAM CTL Register 84 (DRAM_CTL84)

Address: DRAM_CTL84 is 1400_0000h base + 150h offset = 1400_0150h

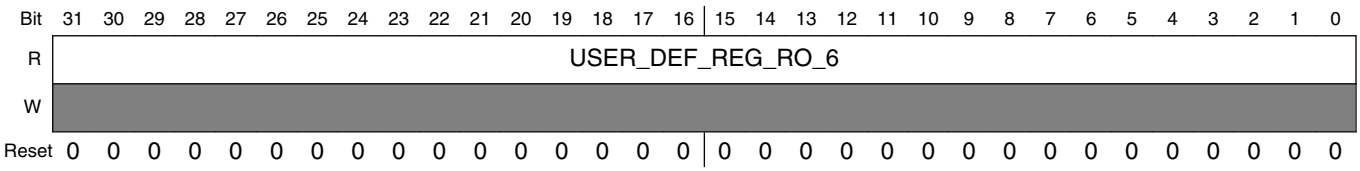


DRAM_CTL84 field descriptions

Field	Description
31–0 USER_DEF_ REG_RO_5	User-defined input register 5. READ-ONLY

20.11.86 DRAM CTL Register 85 (DRAM_CTL85)

Address: DRAM_CTL85 is 1400_0000h base + 154h offset = 1400_0154h

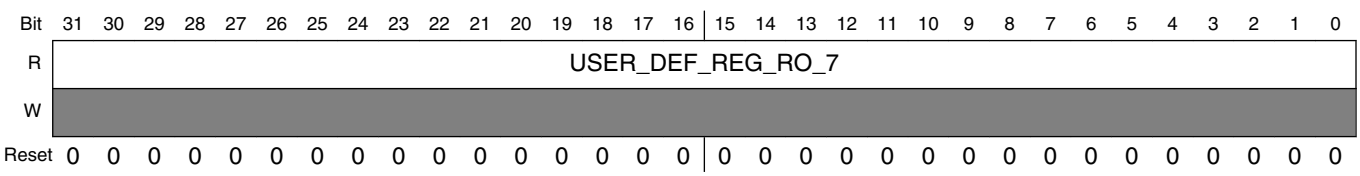


DRAM_CTL85 field descriptions

Field	Description
31–0 USER_DEF_ REG_RO_6	User-defined input register 6. READ-ONLY

20.11.87 DRAM CTL Register 86 (DRAM_CTL86)

Address: DRAM_CTL86 is 1400_0000h base + 158h offset = 1400_0158h

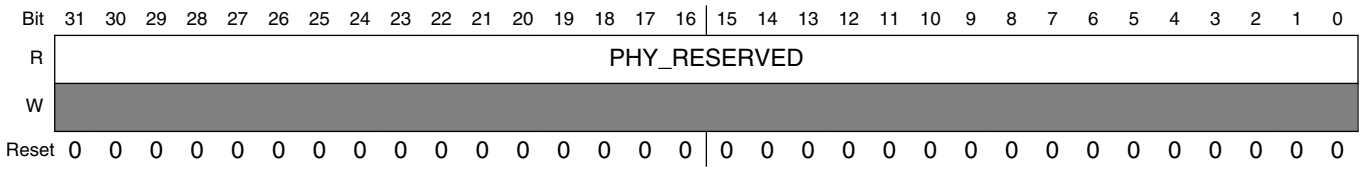


DRAM_CTL86 field descriptions

Field	Description
31–0 USER_DEF_ REG_RO_7	User-defined input register 7. READ-ONLY

20.11.88 DRAM PHY Register 00 (DRAM_PHY00)

Address: DRAM_PHY00 is 1400_0000h base + 200h offset = 1400_0200h

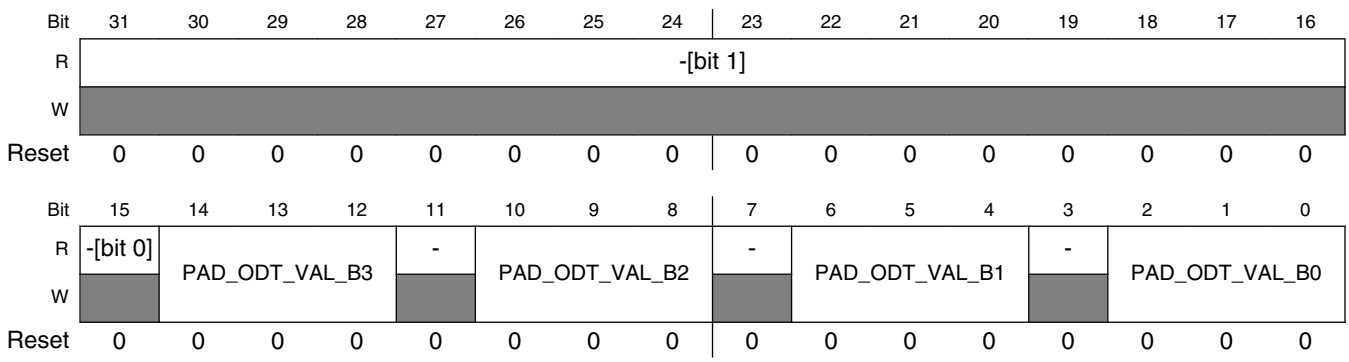


DRAM_PHY00 field descriptions

Field	Description
31–0 Reserved	This field is reserved. This parameter has no meaning for this PHY.

20.11.89 DRAM PHY Register 01 (DRAM_PHY01)

Address: DRAM_PHY01 is 1400_0000h base + 204h offset = 1400_0204h



DRAM_PHY01 field descriptions

Field	Description
31–15 -	Reserved.
14–12 PAD_ODT_ VAL_B3	DDR IO ODT settings for ddr data byte 3. Refer to PAD_ODT_VAL_B0 for detailed description.
11 -	Reserved.
10–8 PAD_ODT_ VAL_B2	DDR IO ODT settings for ddr data byte 2. Refer to PAD_ODT_VAL_B0 for detailed description.
7 -	Reserved.

Table continues on the next page...

DRAM_PHY01 field descriptions (continued)

Field	Description
6–4 PAD_ODT_ VAL_B1	DDR IO ODT settings for ddr data byte 1. Refer to PAD_ODT_VAL_B0 for detailed description.
3 -	Reserved.
2–0 PAD_ODT_ VAL_B0	DDR IO ODT settings for ddr data byte 0. Configure on-chip DDR IO in DDR2 ODT mode (ddr_sel=b00, refer to the IOMUXC chapter for ddr_sel definition): b000 = ODT disabled b001 = 150 Ohm ODT b010 = 75 Ohm ODT b011 = 50 Ohm ODT Note: It defines the ODT function of on-chip ddr IO, not the ODT function of external ddr devices. The ODT function of external ddr devices is controlled by the ODT pin.

20.11.90 DRAM PHY Register 02 (DRAM_PHY02)

Controls the PHY parameters for data slice 0 Alias - PHY_CTRL_REG_0_B0

Address: DRAM_PHY02 is 1400_0000h base + 208h offset = 1400_0208h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

DRAM_PHY02 field descriptions

Field	Description
31 DM_TSEL_EN	Enables on-chip pad ODT for the DM pads. b0 = Disabled b1 = Enabled

Table continues on the next page...

DRAM_PHY02 field descriptions (continued)

Field	Description
30 DQ_TSEL_EN	Enables on-chip pad ODT for the DQ pads. b0 = Disabled b1 = Enabled
29 DQS_RATIO	Controls on-chip pad ODT for the DM pads. b0 = Enabled b1 = Disabled
28 ECHO_GATE_EN	Echo gate control for data slice X. Default 0x0. b0 = Uses the dfi_rddata_en signal to create a gate. b1 = Creates an echo_gate signal.
27 -	Reserved.
26–24 RD_DLY_SEL	Defines the read data delay. Holds the number of cycles to delay the dfi_rddata_en signal prior to enabling the read FIFO. After this delay, the read pointers begin incrementing the read FIFO. Default 0x3. Changes to this field affect phy_ctrl_reg_2 [3:0]. If this field is increased, the value in phy_ctrl_reg_2 [3:0] must be increased by at least the same amount.
23–21 -	Reserved.
20 PAD_OE_POLARITY	Sets the pad output enable polarity. Default 0x0. Note: User must set PAD_OE_POLARITY = 0 for this MC. b0 = OEN pad b1 = OE pad
19–17 -	Reserved.
16 ENABLE_HALF_CAS	Subtracts 1/2 cycle from the DQS gate value programmed into phy_ctrl_reg_1_X [2:0] by 1/2 cycle. Default 0x0. This is used when the gate is being aligned to the first DQS, and then is removed to move the gate back into the center of the preamble. b0 = Do not adjust b1 = Adjust the DQS gate by 1/2 clock forward
15–12 DQS_OE_START	Adjusts the starting point of the DQS pad output enable window. Lower numbers pull the rising edge earlier in time, and larger numbers cause the rising edge to be delayed. Each bit changes the output enable time by a 1/4 cycle resolution. Default 0x2.
11–8 DQS_OE_END	Adjusts the ending point of the DQS pad output enable window. Lower numbers pull the falling edge earlier in time, and larger numbers cause the falling edge to be delayed. Each bit changes the output enable time by a 1/4 cycle resolution. This field must be set to at least the value of bits [14:12]+2 to prevent disabling the pad before the data is completely written. Default 0x7.
7 -	Reserved.
6–4 DATA_OE_START	Adjusts the starting point of the DQ pad output enable window. Lower numbers pull the rising edge earlier in time, and larger numbers cause the rising edge to be delayed. Each bit changes the output enable time by a 1/4 cycle resolution. Default 0x2.
3 -	Reserved.

Table continues on the next page...

DRAM_PHY02 field descriptions (continued)

Field	Description
2–0 DATA_OE_END	Adjusts the ending point of the DQ pad output enable window. Lower numbers pull the falling edge earlier in time, and larger numbers cause the falling edge to be delayed. Each bit changes the output enable time by a 1/4 cycle resolution. This field must be set to at least the value of bits [14:12]+2 to prevent disabling the pad before the data is completely written. Default 0x7.

20.11.91 DRAM PHY Register 03 (DRAM_PHY03)

Controls the PHY parameters for data slice 0 Alias - PHY_CTRL_REG_1_B0

Address: DRAM_PHY03 is 1400_0000h base + 20Ch offset = 1400_020Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	TSEL_START				TSEL_END				DQS_TSEL_EN	TSEL_POLARITY	LPBK_ERR_CHECK	LPBK_FAIL_SEL	LPBK_CTRL		LPBK_INTERNAL	LPBK_EN
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	-	LPBK_ERR_DELAY			-			GATE_ERR_DELAY			GATE_CLOSE_CFG		-	GATE_CFG		
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

DRAM_PHY03 field descriptions

Field	Description
31–28 TSEL_START	Defines the on-chip pad ODT enable time. Larger values add greater delay to when tsel turns on. Each bit changes the output enable time by a 1/2 cycle resolution.
27–24 TSEL_END	Defines the on-chip pad ODT disable time. Larger values increase the delay to when tsel turns off. Each bit changes the output enable time by a 1/2 cycle resolution.
23 DQS_TSEL_EN	Enables on-chip pad ODT for the DQS pads. b0 = Disabled b1 = Enabled
22 TSEL_ POLARITY	Controls the polarity of the tsel signal for the DQS and DM pads. b0 = Negative Polarity b1 = Positive Polarity
21 LPBK_ERR_ CHECK	Triggers a data return to the memory controller. b0 = No action b1 = Sends loopback data on the dfi_rddata signal.

Table continues on the next page...

DRAM_PHY03 field descriptions (continued)

Field	Description
20 LPBK_FAIL_SEL	Selects data output type for den_phy_obs_reg_0_X [23:8]. b0 = Return the expected data. b1 = Return the actual data.
19–18 LPBK_CTRL	Loopback control b00 = Normal operational mode b01 = lpbk_start; Enables loopback write mode b10 = lpbk_stop; Stop loopback to check the error register b11 = clear; Clear loopback registers
17 LPBK_ INTERNAL	Controls the loopback read multiplexer. b0 = External loopback b1 = Internal loopback
16 LPBK_EN	Controls the internal write multiplexer. b0 = Normal operation b1 = Enable loopback
15 -	Reserved.
14–12 LPBK_ERR_ DELAY	Sets the cycle delay between the LFSR and loopback error check logic. Note that h7 is not a valid selection and will result in a false passing result.
11–9 -	Reserved.
8–6 GATE_ERR_ DELAY	Defines the number of cycles of margin allowed for the final DQS falling edge of a read burst. An error will occur if the final DQS is not found after DQS_FALLING_EDGE_EXP_DLY and before (DQS_FALLING_EDGE_EXP_DLY+ gate_error_delay) cycles. If this field is set to a non-zero value and an error occurs, the PHY will automatically deassert (close) the read DQS gate and log the error in den_phy_obs_reg_0_X [24]. In the event of an error, the user should check the connections between the SOC and DRAM devices. This field can be useful for debugging the I/O during RTL integration. The default value is based on the delay information provided at configuration. A delayed version of the falling edge of dfi_rddata_en is used to determine when the final DQS falling edge is expected. The delay of the falling edge of dfi_rddata_en, in clock cycles is: DQS_FALLING_EDGE_EXP_DLY = (den_phy_ctrl_reg_1_X [2:0] + N*TCK), where N is 1/2 when enable_half_cas is off (den_phy_ctrl_reg_0_X [16] = b0), or 1 when enable_half_cas is on (den_phy_ctrl_reg_0_X [16] = b1) This field is only relevant when mobile support is disabled (den_phy_ctrl_reg_2 [6] = b0). Clearing this field to 0x0 disables error detection.
5–4 GATE_CLOSE_ CFG	Program either or both of these bits to b1 to extend the closing of the DQS gate by 1 cycle. This should be done when the round trip flight time of the DQS (IO_Pad_Delay + (Flight Time * 2) + IO_Input_Pad_Delay) + tDQSCK(max) is greater than 2 times the cycle time. Otherwise use b00.
3 -	Reserved.
2–0 GATE_CFG	Coarse adjust of gate open time. This value is the number of cycles to delay the dfi_rddata_en signal prior to opening the gate in full cycle increments. Decreasing this value pulls the gate earlier in time. This field, along with the den_phy_ctrl_reg_0_X [16] bit should be programmed such that the gate signal lands in the valid DQS gate window.

20.11.92 DRAM PHY Register 04 (DRAM_PHY04)

Address: DRAM_PHY04 is 1400_0000h base + 210h offset = 1400_0210h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

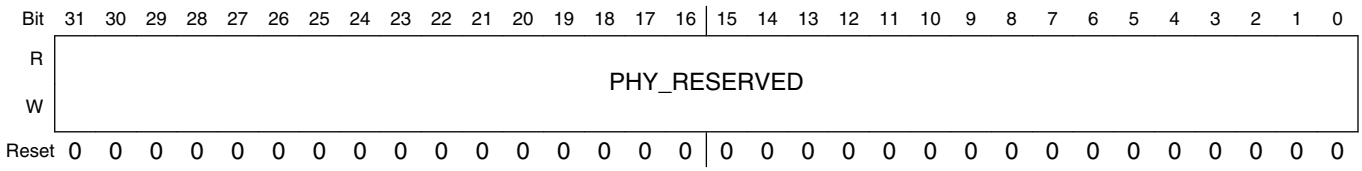
DRAM_PHY11 field descriptions

Field	Description
31–0 PHY_CTRL_ REG_1_CA	Controls the PHY parameters for data slice CA. Refer to PHY_CTRL_REG_1_B0

20.11.100 DRAM PHY Register 12 (DRAM_PHY12)

Address: DRAM_PHY12 is 1400_0000h base + 230h offset = 1400_0230h

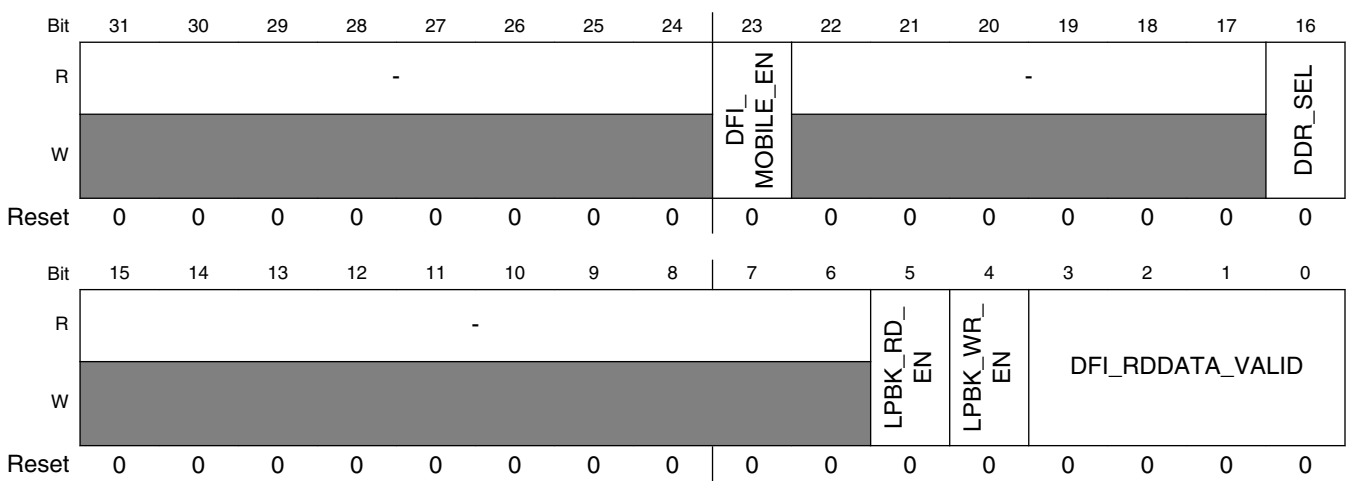


DRAM_PHY12 field descriptions

Field	Description
31–0 Reserved	This field is reserved. This parameter has no meaning for this PHY.

20.11.101 DRAM PHY Register 13 (DRAM_PHY13)

Address: DRAM_PHY13 is 1400_0000h base + 234h offset = 1400_0234h



DRAM_PHY13 field descriptions

Field	Description
31–24 -	Reserved.

Table continues on the next page...

DRAM_PHY13 field descriptions (continued)

Field	Description
23 DFI_MOBILE_EN	DFI control for Mobile ddr devices
22–17 -	Reserved.
16 DDR_SEL	Controls the PHY memory system mode. b0 = non-LPDDR2 mode b1 = LPDDR2 mode
15–6 -	Reserved.
5 LPBK_RD_EN	Enables the pad inputs specifically for external loopback. This bit is tied to the internal signal lpbk_rddata_en. b0 = Normal Operation b1 = Loopback Mode
4 LPBK_WR_EN	Enables the pad outputs specifically for external loopback. This bit is tied to the internal signal lpbk_wrdata_en. b0 = Normal Operation b1 = Loopback Mode
3–0 DFI_RDDATA_VALID	Sets the dfi_rddata_valid delay relative to dfi_rddata_en. At default, all den_phy_ctrl_reg_0_X [26:24] parameter fields have the same default values, and this field is set to den_phy_ctrl_reg_0_X [26:24] + 1. The valid ranges of this field are (phy_ctrl_reg_0_X[26:24] + 1) to MAX_VAL, using the largest value across all the slices.

20.11.102 DRAM PHY Register 14 (DRAM_PHY14)

Address: DRAM_PHY14 is 1400_0000h base + 238h offset = 1400_0238h

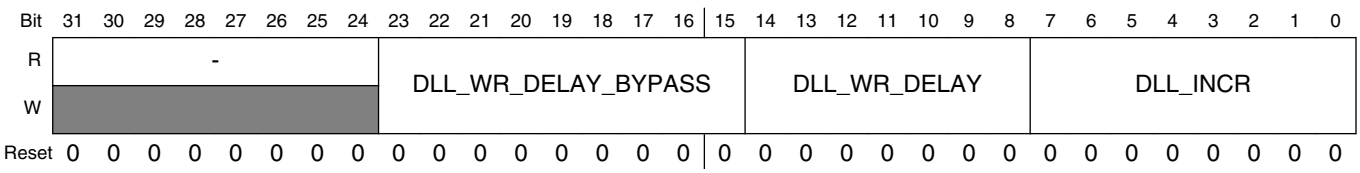
DRAM_PHY14 field descriptions

Field	Description
31–29 PHASE_ DETECT_SEL	DLL Phase Detect Selector for the master delay line. Selects the number of delay elements to be inserted between the phase detect flip-flops. Default programming is 2 elements but if a lock condition is not detected, the user should increase the number of delay elements. b000 = 1 delay element b001 = 2 delay elements b010 = 3 delay elements b011 = 4 delay elements b100 = 5 delay elements b101 = 6 delay elements b110 = 7 delay elements b111 = 8 delay elements
28 DLL_BYPASS_ MODE	DLL bypass mode control b0 = Normal operational mode. Read DQS delay is phy_dll_ctrl_reg_0_X [14:8] and clk_wr delay is phy_dll_ctrl_reg_1_X [14:8]. b1 = Bypass Mode is on. Read DQS delay is phy_dll_ctrl_reg_0_X [23:15] and clk_wr delay is phy_dll_ctrl_reg_1_X [23:15].
27–24 -	Reserved.
23–15 DLL_RD_ DELAY_ BYPASS	Holds the read DQS delay for bypass mode. (phy_dll_ctrl_reg_0_X[28] = b1)This value directly controls the number delay elements that are active.
14–8 DLL_RD_DELAY	Holds the read DQS delay for normal mode. (phy_dll_ctrl_reg_0_X[28] = b0) Typically, this value is 1/4 of a clock cycle. Each increment of this field represents 1/128th of a clock cycle.
7–0 DLL_START_ POINT	This value is loaded into the DLL at initialization and is the value at which the DLL will begin searching for a lock. This field must be set to a value greater than or equal to 4.

20.11.103 DRAM PHY Register 15 (DRAM_PHY15)

Address: DRAM_PHY15 is 1400_0000h base + 23Ch offset = 1400_023Ch



DRAM_PHY15 field descriptions

Field	Description
31–24 -	Reserved.
23–15 DLL_WR_ DELAY_ BYPASS	Holds the clk_wr delay setting when the DLL is operating in bypass mode. (phy_dll_ctrl_reg_0_X[28] = b1)
14–8 DLL_WR_ DELAY	Holds the clk_wr delay setting in normal mode. (phy_dll_ctrl_reg_0_X[28] = b0) Typically, this value is 3/4 of a clock cycle. Each increment of this field represents 1/128th of a clock cycle.
7–0 DLL_INCR	DLL Increment Value. This sets the increment used by the DLL when searching for a lock. Denali recommends keeping this field small (around 0x4) to keep the steps gradual.

20.11.104 DRAM PHY Register 16 (DRAM_PHY16)

Address: DRAM_PHY16 is 1400_0000h base + 240h offset = 1400_0240h

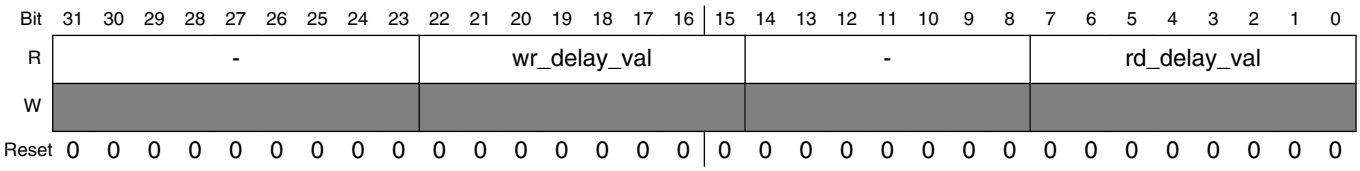
DRAM_PHY25 field descriptions

Field	Description
31–1 dll_lock_val	Reports the DLL encoder value from the master DLL to the slave DLLs. The slaves use this value to set up their delays for the clk_wr and read DQS signals.
0 dll_lock	Indicates status of the DLL.

20.11.114 DRAM PHY Register 26 (DRAM_PHY26)

Address: DRAM_PHY26 is 1400_0000h base + 268h offset = 1400_0268h

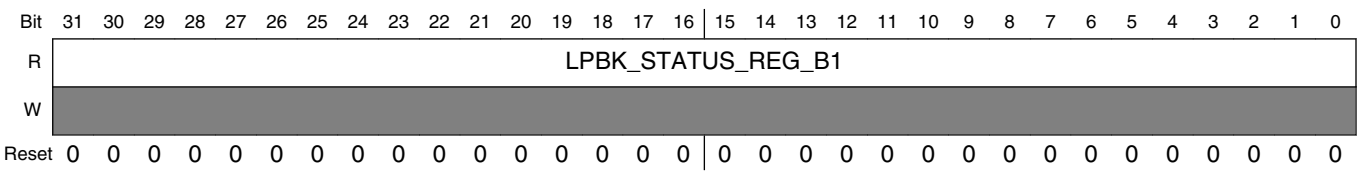


DRAM_PHY26 field descriptions

Field	Description
31–23 -	Reserved.
22–15 wr_delay_val	Holds the encoded value for the clk_wr delay line for this slice.
14–8 -	Reserved.
7–0 rd_delay_val	Holds the encoded value for the read delay line for this slice.

20.11.115 DRAM PHY Register 27 (DRAM_PHY27)

Address: DRAM_PHY27 is 1400_0000h base + 26Ch offset = 1400_026Ch

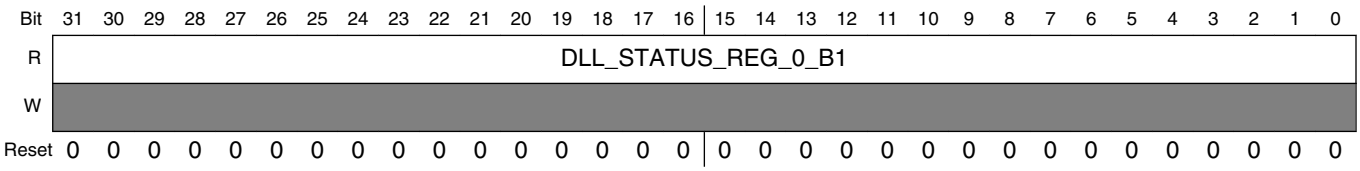


DRAM_PHY27 field descriptions

Field	Description
31–0 LPBK_STATUS_ REG_B1	Reports the Loopback status for data slice 1. Refer to LPBK_STATUS_REG_B0.

20.11.116 DRAM PHY Register 28 (DRAM_PHY28)

Address: DRAM_PHY28 is 1400_0000h base + 270h offset = 1400_0270h

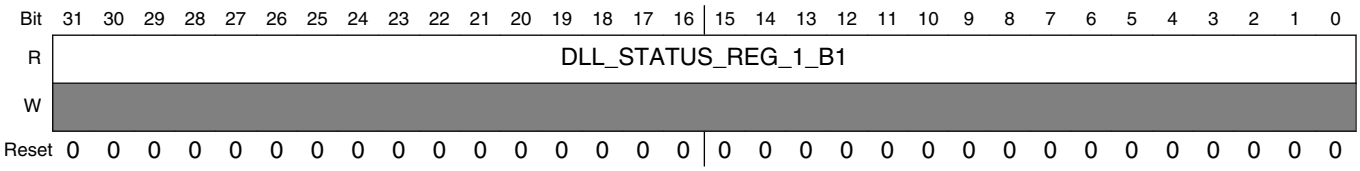


DRAM_PHY28 field descriptions

Field	Description
31–0 DLL_STATUS_ REG_0_B1	Reports the DLL status for data slice 1. Refer to DLL_STATUS_REG_0_B0.

20.11.117 DRAM PHY Register 29 (DRAM_PHY29)

Address: DRAM_PHY29 is 1400_0000h base + 274h offset = 1400_0274h

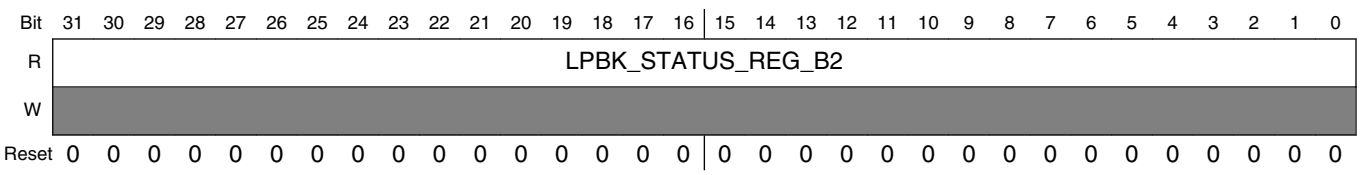


DRAM_PHY29 field descriptions

Field	Description
31–0 DLL_STATUS_ REG_1_B1	Reports the DLL status for data slice 1. Refer to DLL_STATUS_REG_1_B0.

20.11.118 DRAM PHY Register 30 (DRAM_PHY30)

Address: DRAM_PHY30 is 1400_0000h base + 278h offset = 1400_0278h

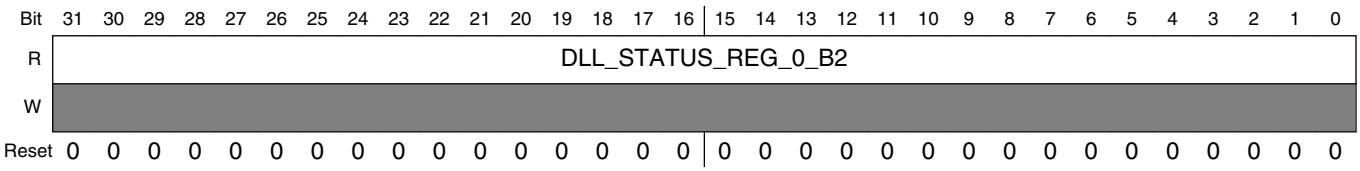


DRAM_PHY30 field descriptions

Field	Description
31–0 LPBK_STATUS_ REG_B2	Reports the Loopback status for data slice 2. Refer to LPBK_STATUS_REG_B0.

20.11.119 DRAM PHY Register 31 (DRAM_PHY31)

Address: DRAM_PHY31 is 1400_0000h base + 27Ch offset = 1400_027Ch

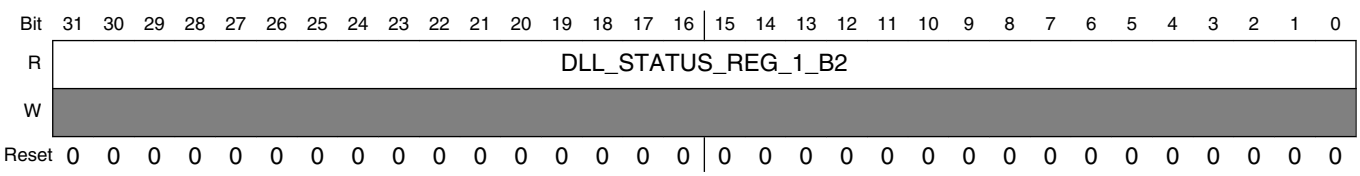


DRAM_PHY31 field descriptions

Field	Description
31–0 DLL_STATUS_ REG_0_B2	Reports the DLL status for data slice 2. Refer to DLL_STATUS_REG_0_B0.

20.11.120 DRAM PHY Register 32 (DRAM_PHY32)

Address: DRAM_PHY32 is 1400_0000h base + 280h offset = 1400_0280h



DRAM_PHY32 field descriptions

Field	Description
31–0 DLL_STATUS_ REG_1_B2	Reports the DLL status for data slice 2. Refer to DLL_STATUS_REG_1_B0.

20.11.121 DRAM PHY Register 33 (DRAM_PHY33)

Field	Description
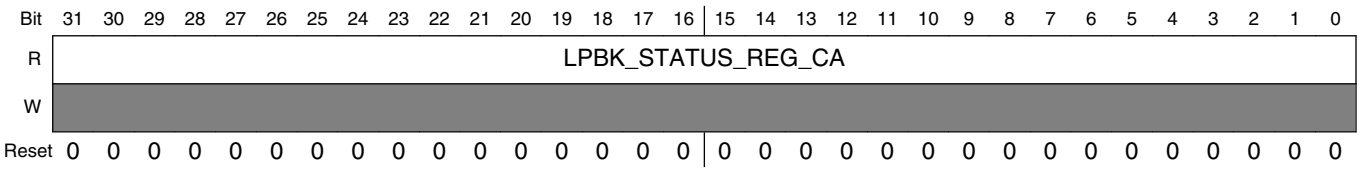
31–0 DLL_STATUS_ REG_1_B3	Reports the DLL status for data slice 3. Refer to DLL_STATUS_REG_1_B0.

20.11.124 DRAM PHY Register 36 (DRAM_PHY36)

Address: DRAM_PHY36 is 1400_0000h base + 290h offset = 1400_0290h

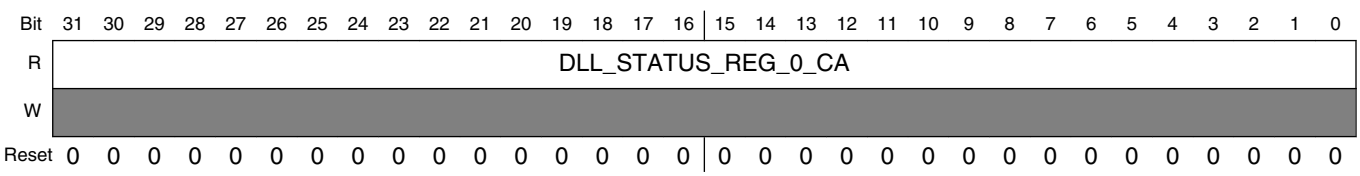


DRAM_PHY36 field descriptions

Field	Description
31–0 LPBK_STATUS_ REG_CA	Reports the Loopback status for data slice CA. Refer to LPBK_STATUS_REG_B0.

20.11.125 DRAM PHY Register 37 (DRAM_PHY37)

Address: DRAM_PHY37 is 1400_0000h base + 294h offset = 1400_0294h

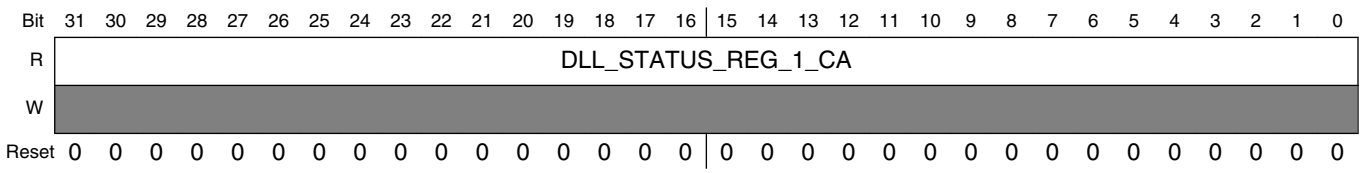


DRAM_PHY37 field descriptions

Field	Description
31–0 DLL_STATUS_ REG_0_CA	Reports the DLL status for data slice CA. Refer to DLL_STATUS_REG_0_B0.

20.11.126 DRAM PHY Register 38 (DRAM_PHY38)

Address: DRAM_PHY38 is 1400_0000h base + 298h offset = 1400_0298h



DRAM_PHY38 field descriptions

Field	Description
31–0 DLL_STATUS_ REG_1_CA	Reports the DLL status for data slice CA. Refer to DLL_STATUS_REG_1_B0.

Chapter 21
Dynamic Voltage and Frequency Scaling Core (DVFSC)

21.1 Introduction

The DVFSC allows simple dynamic voltage frequency scaling. The frequency of the core clock domain and the voltage of the core power domain can be changed on the fly while all blocks (including the ARM platform) continue their normal operation. The frequency of the core clock domain can be changed by switching temporally to an alternate PLL clock, and then get back to the updated PLL, already locked at a specific frequency, or by merely changing the post dividers division factors.

The DVFSC load tracking block allows hardware tracking on the core load and a generation of an interrupt when a frequency change is requested.

DVFSC is a sub-block of the General Power Controller (GPC). See GPC chapter for more details.

NOTE

DVFSC is a monitor that only provides an interrupt when counting exceeds the predefined value and doesn't actually send request to make a change a change of voltage and frequency. This can be done by the user in the interrupt routine or smart direct memory access (SDMA) code by using GPC or clock control module (CCM) (relocking the PLL or changing the post dividers at the CCM).

21.1.1 Overview

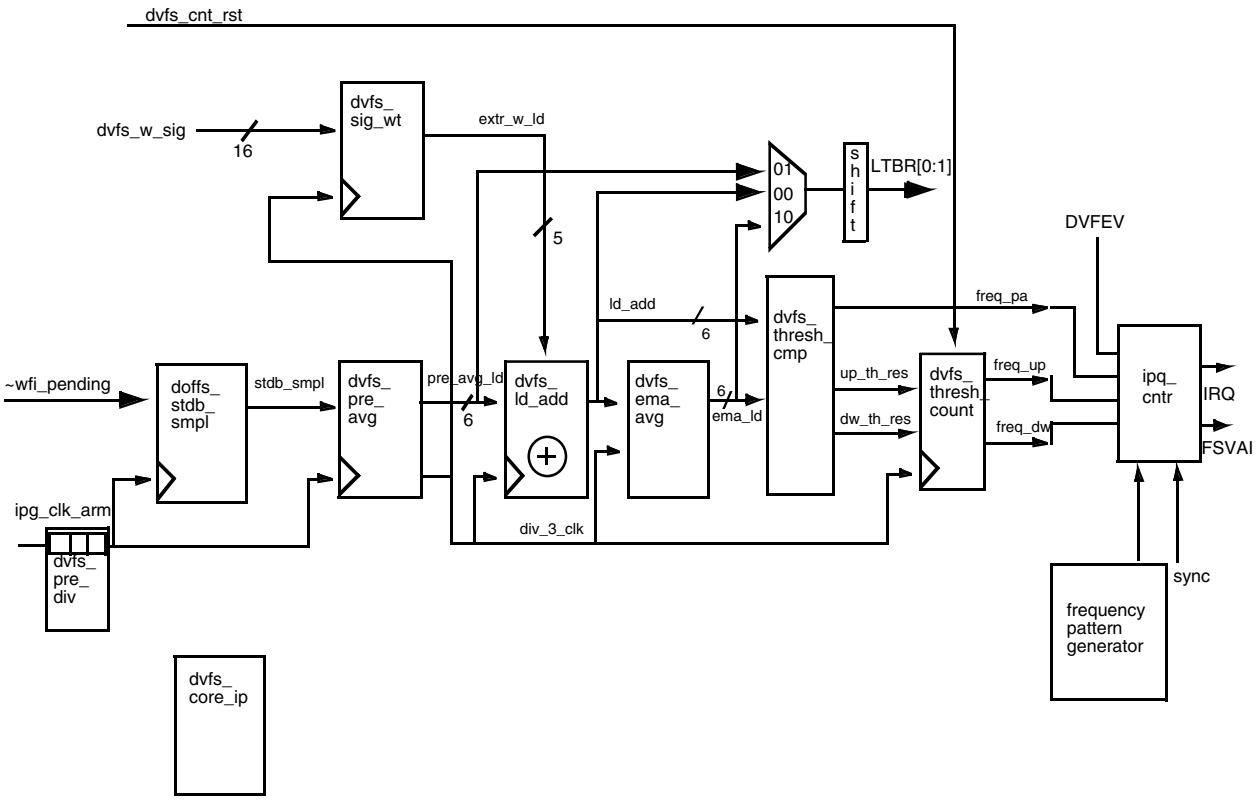


Figure 21-1. Block Diagram

21.1.2 Features

The DVFSC load tracking sub-block includes the following features:

- Configurable include/exclude of input signals:
  - ARM standby signal (idle / non-idle)
  - 16 general purpose bits
    - Configurable weight of each bit.
- Configurable generated clocks and averaging time slicing (respond time).
- Configurable panic mode respond logic (for frequency up).
- Programmable buffer for last 4,8,12, or 16 load tracking samples. Based on value in LBCF in DVFSC_CNTR. There is also a buffer full signal - LBFL.

21.2 Functional Description of DVFS Load Tracking

The DVFS load tracking sub-block includes the following features:

Configurable include/exclude of input signals:

- ARM standby signal (idle / non-idle)
- 16 general purpose load tracking signals
- Configurable weight and (level-sensitive) of GeP signals.
- Configurable generated clocks and averaging time slicing (respond time).
- Configurable panic mode respond logic (for frequency up).
- Programmable buffer for last 4,8,12, or 16 load tracking samples. Two Load Tracking Buffers are working in ping-pong mode with two buffer full signals - LBFL1, LBFL0.

21.3 Component Blocks Description

21.3.1 dvfs_stdb_smpl Block

This block samples the ccm_arm_stdb signal (ARM11 STANDBYWFI signal - idle state indicating) according to the edge of the ipg_clk_arm (ARM11 system clock) signal.

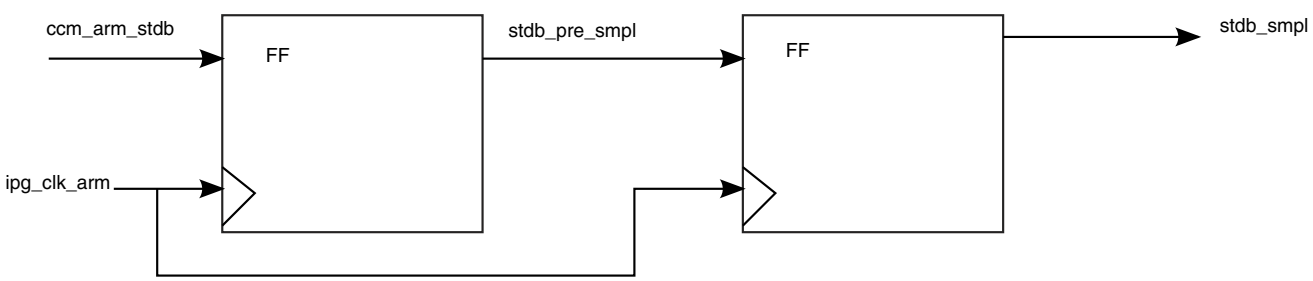

Figure 21-2. dvfs_stdb_smpl block diagram

This block synchronizes the ccm_arm_stdb signal with the ipg_clk_arm clock. The two signals enter the Flip-Flops (twice), and by doing so, are synchronized. The resulting synchronized signal is stdb_smpl.

21.3.2 dvfs_sig_wt Block

The purpose of this block is to sample the 16 GeP (general purpose) load signals, multiply each one of them by appropriate weight and sum products. The sampling is done by the slow clock div_3_clk. These signals have the only options of detection: level sampling.

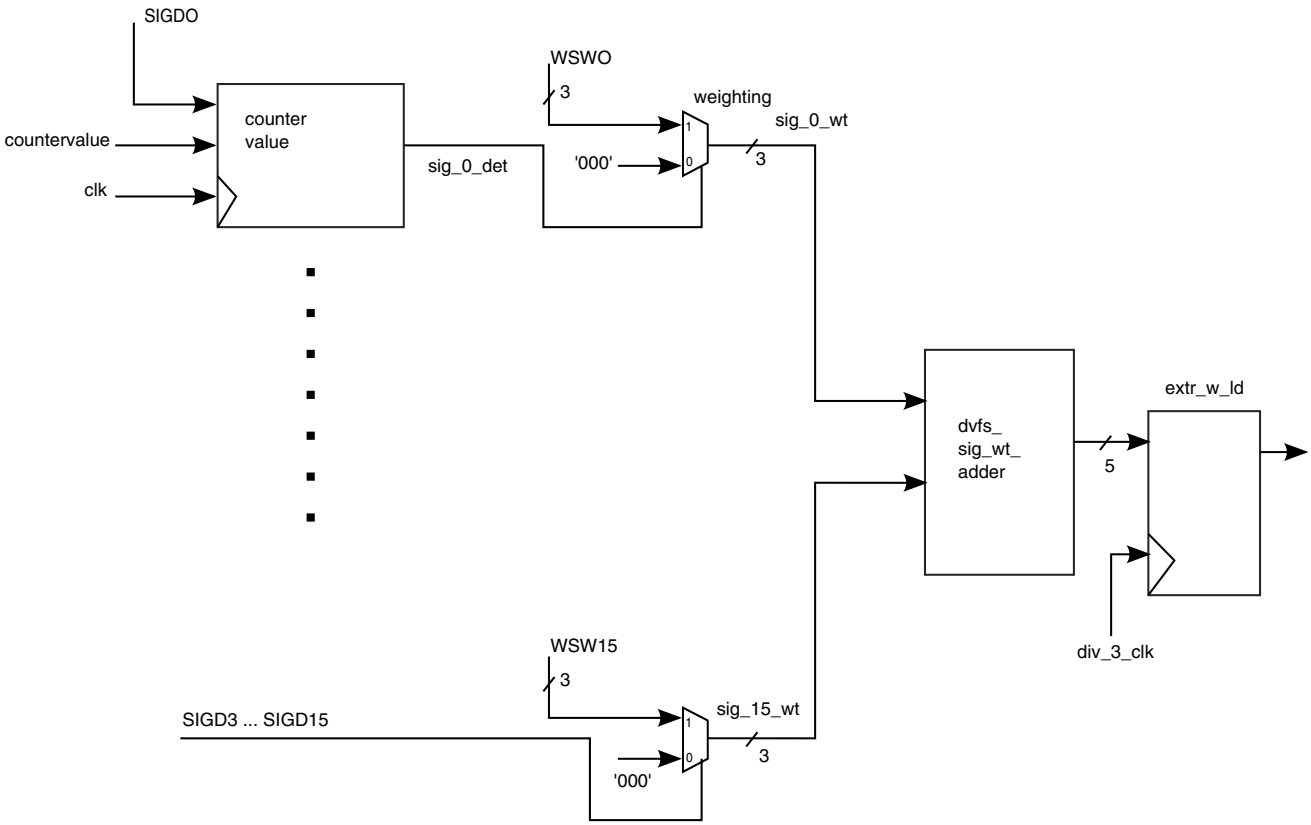

Figure 21-3. dvfs_sig_wt block diagram

There are two paths for weighted general purpose load signals to be calculated.

21.3.3 dvfs_pre_avg Block

The purpose of the dvfs_pre_avg block is to perform simple, non-overlapping averaging, reducing the sampling clock frequency and providing a level-based average index of the tracked ARM Platform load.

External signals:

- stdb_sampl - (input) sampled ARM11 standby signal
- ipg_clk_arm - (input) ARM11 system clk
- pre_avg_ld[4..0] - (output) averaged load

- div_3_clk - (output) clock, generated (reduced) from div_2_clk
- div_2_clk - (output) clock, generated (reduced) from div_1_clk
- div_1_clk - (output) clock, generated (reduced) from ipg_clk_arm

In the current implementation, the averaging is performed in three stages:

1. The first stage IDLE is sampled by divided sys_clock.
2. The second stage (counter2) performs an averaging operation with constant parameters. The counter is an nine (9) bit adder whose output is sampled by the div_2_clk clock. Five (5) highest bits of the sum_2 signal are passed to counter3 (equal to shift right operation).
3. The third (last) stage (counter3) performs an averaging operation with configurable parameters, set by the DIV3CK. The counter3 cell is a fifteen(15) bit adder with output sampled by div_3_clk. The Pre_avg_shifter_5 cell passes configurable bits from the sum_3 signal (see table1_3).

The output 5 bits avg_load signal provides a result with a tolerance of ~3%. (supported values range is 0-0.97)

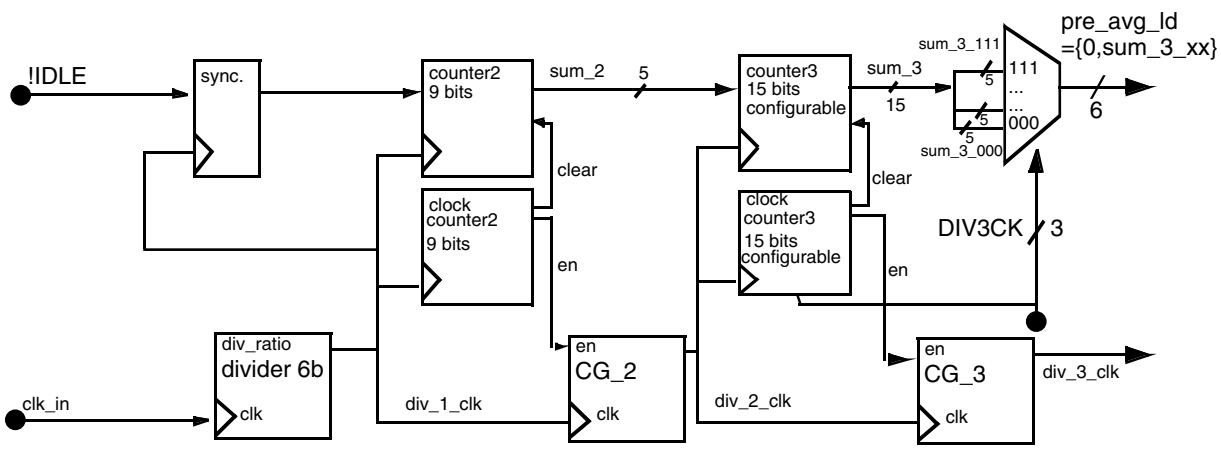

Figure 21-4. dvfs_pre_avg block diagram

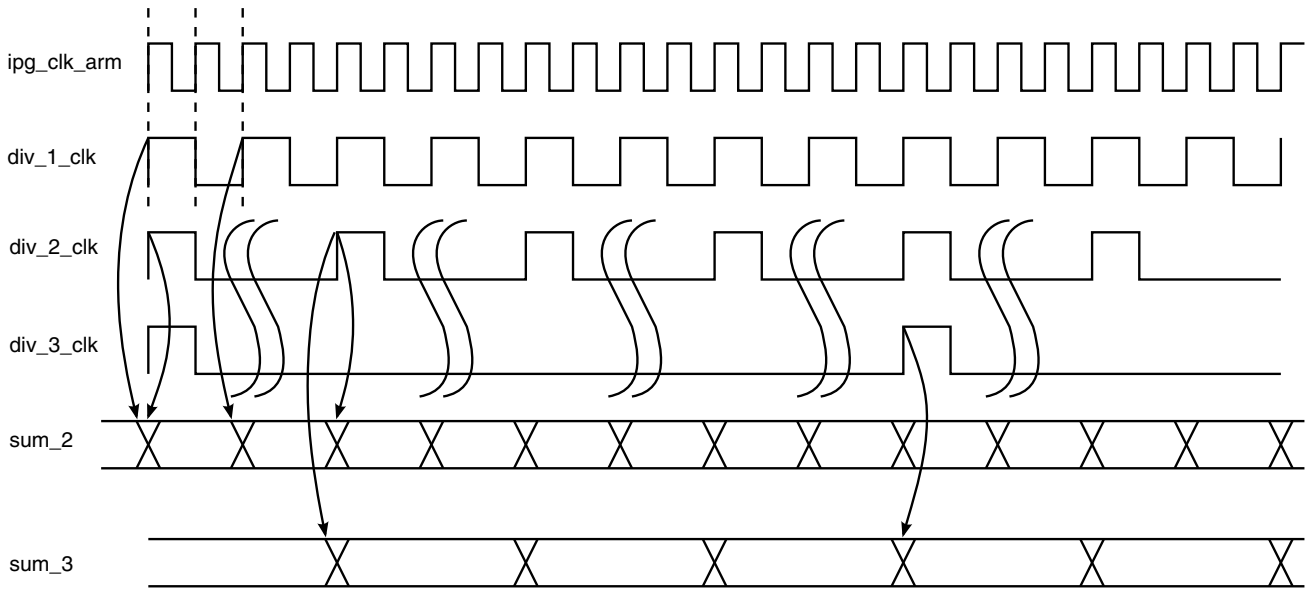

Figure 21-5. dvfs_pre_avg Clocks

The internal clocks in dvfs_avg_pre block are generated from ipg_clk_arm. The details are in the tables below:

Table 21-1. dvfs_pre_avg Signals and its Values

signal	binary max value	binary min value	decimal max value	decimal min value
sum_2	11111	0000	31	0
sum_3	111'1100'0000'0000	000'0000'0000'0000	31744	0
pre_avg_load	11111	0000	31	0

Table 21-2. dvfs_pre_avg generated clocks

clock name	generated from	ratio to source	ratio to ipg_clk_arm	max clk freq.	note
ipg_clk_arm	N/A	N/A	1	66MHz	source clock
div_1_clk	ipg_clk_arm	configurable	configurable	66MHz	configurable
div_2_clk (gated)	div_1_clk	512	configurable	128KHz	none
div_3_clk (gated)	div_2_clk	configurable	configurable	128KHz	configurable

Table 21-3. iv_3_clk Configurable Averaging

DIV3CK setting	dividing ratio	sum_3 passing bits	div_1_clk cumulative divider
00	1	4-0	1*512=512

Table continues on the next page...

Table 21-3. iv_3_clk Configurable Averaging (continued)

DIV3CK setting	dividing ratio	sum_3 passing bits	div_1_clk cumulative divider
001	4	6-2	4*512=2048
010	16	8-4	16*512=8192
011	64	10-6	64*512=32768
100	256	12-8	256*512=131072
101	1024	16-10	1024*512=524288

21.3.4 dvfs_ld_add Block

The dvfs_ld_add block sums the ARM Platform load, tracked by idle/non-idle signal and the load, detected from the additional load signals, weighted by signal_weighting block. The adder should perform the following operation:

extr_w_ld[4..0] + {0,pre_avg_ld[4..0]}

The input signals of five (5) bits produce output signal of six (6) bits, providing 3% resolution in the range of 0-1.97 of load indication. (1 is equal to 100% load tracking with no additional signals include). The output ld_add[5..0] is sampled by div_3_clk signal.

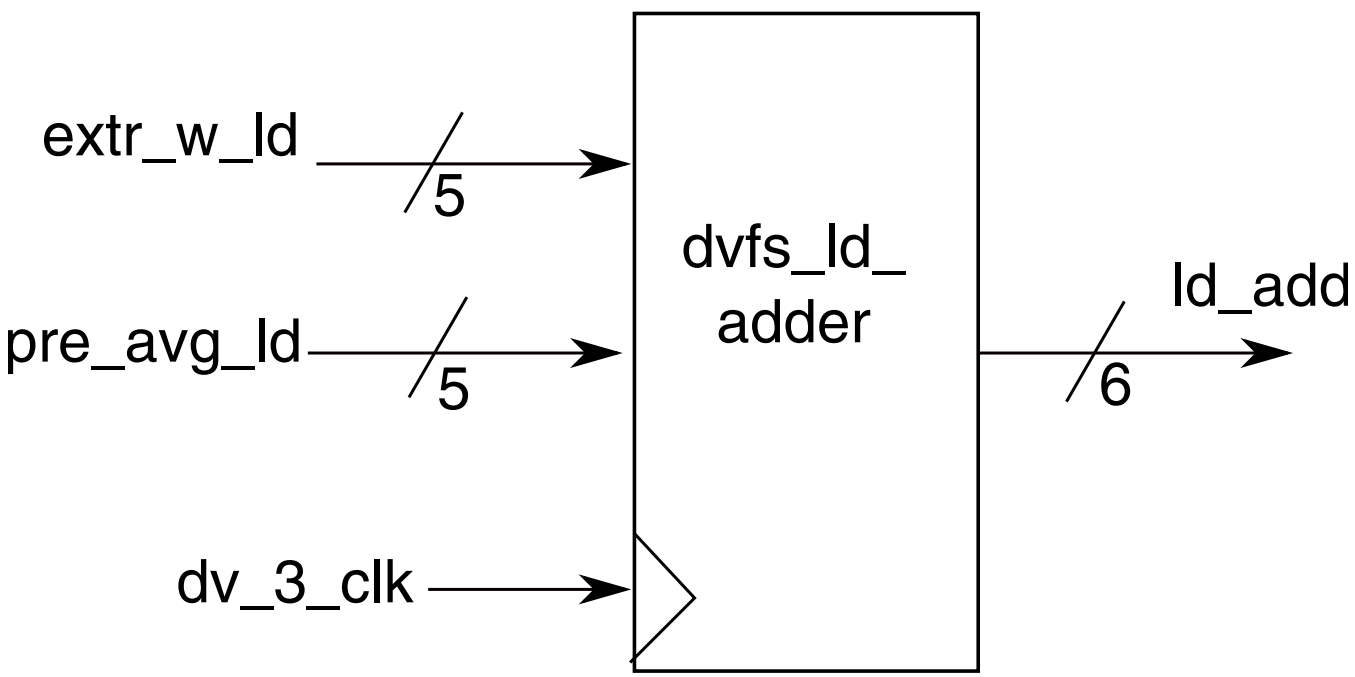

Figure 21-6. dvfs_ld_add block diagram

21.3.5 dvfs_ema_avg Block

The purpose of dvfs_ema_avg (EMA - Exponential Moving Average) block is to calculate an exponential moving average of the tracked ARM Platform load. The parameters of EMA are defined by EMAC field of the DVFSC_EMAC register. These parameters set how many samples of simple average will be taken into account.

The EMA formula is: EMA(i) = a*X(i) + (1-a)*EMA(i-1)

where:

a = 2 / (N+1);

N is the number of samples taken into account.

X(i) = current input sample;

EMA(i-1) = previous value of EMA.

By setting the value of 'a', the behavior of EMA is defined.

In the following table, the parameter 'a' is listed relative to the amount of the X(i) samples taken into account (('N')) in the equation above. (The resolution of the digital multiplier is limited, hence the lowest values of the 'a' can be linked to a range of included samples in EMA instead of single number.)

Also included in the following table is the amount of cycles in which the lower frequency will be masked from the moment the DVFS is enabled (and not between frequency switches), so that enough information about the history can be gained before the frequency is lowered.

EMA settings

samples included in EMA calculation (N)	Number of cycles while lower frequency interrupt is masked	'a' value (decimal)	'a' value, adjusted by binary resolution	'a' value (binary)								
----------		----------	----------	bit 0	bit 1	bit 2	bit 3	bit 4	bit 5	bit 6	bit 7	bit 8

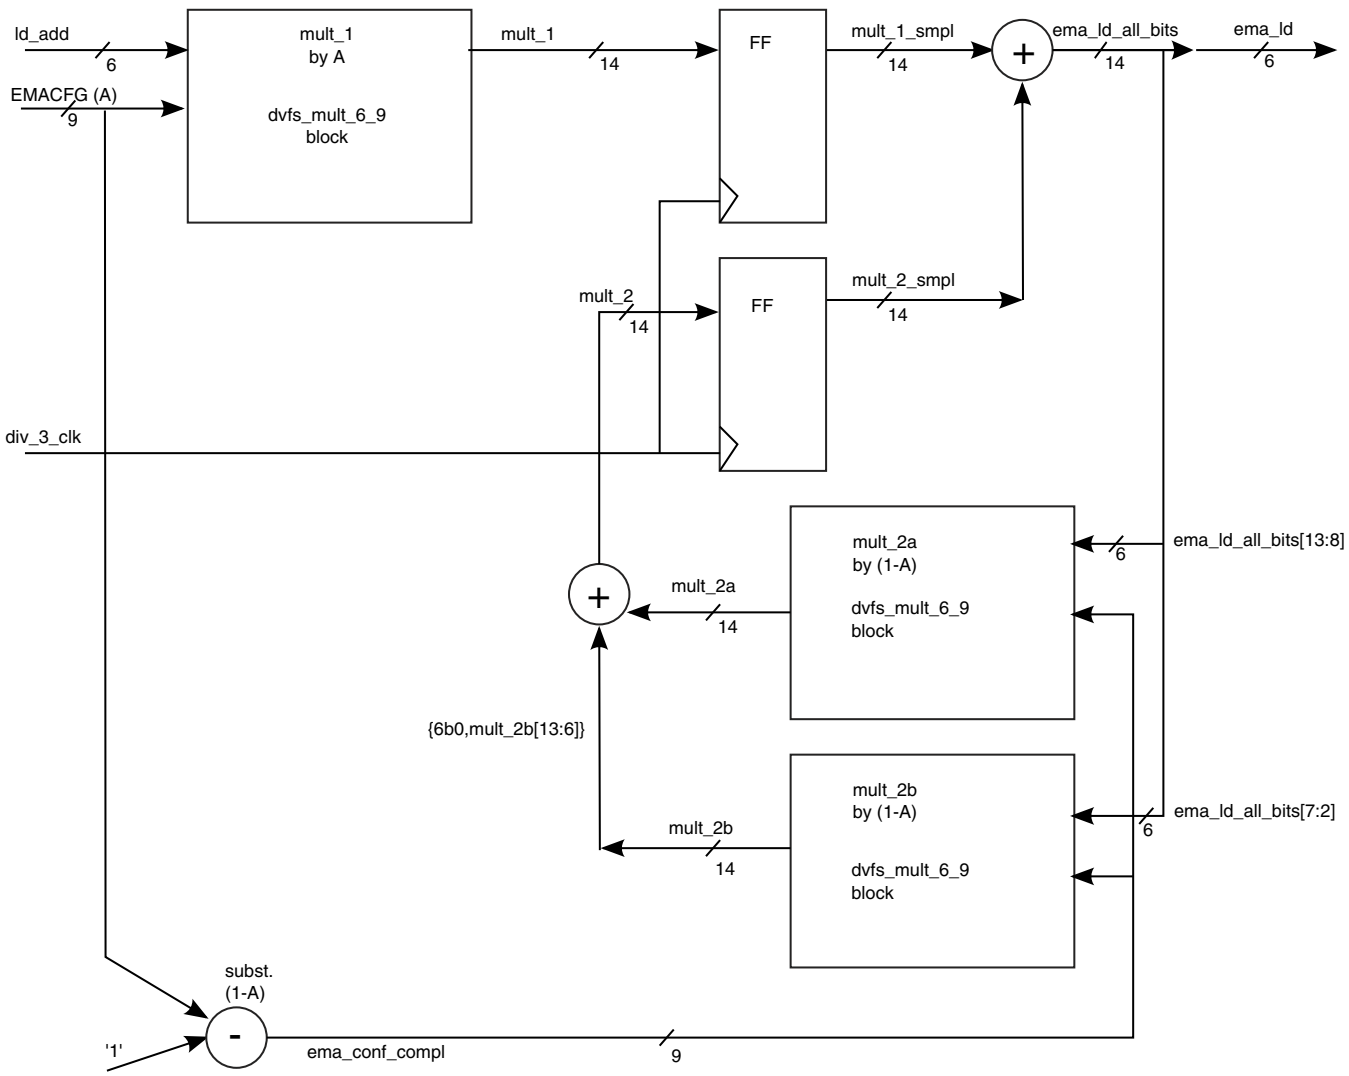

Figure 21-7. dvfs_ema_avg block diagram

The EMA block inputs are as follows:

- ld_add[5..0] - load level
- EMACFG[8..0] - 'a' parameter of EMA algorithm

- div_2_clk - fast clock don't see this in the diagram
- div_3_clk - slow clock

The EMA block outputs the following:

- ema_ld[5..0] - result of EMA algorithm (by div_3_clk)

The mult_a block provides multiplying between comp_load (6 bits) and EMACFG (9 bits). For the multiply operation, a faster clock (for internal sum) is required- this is provided by div_2_clk. Div_2_clk is faster than the div_3_clk by a factor of at least 16, which is enough for 6*9 or 9*6 operations. Only the highest 6 bits are taken from the result of mult_a.

The mult_b block operates in a similar manner.

The adder block's output is sampled with div_3_clk clock.

21.3.6 dvfs_thres_cmp Block

The dvfs_thres_cmp block compares the ARM Platform load value to programmable threshold levels. The comparators as shown in the drawing below are used:

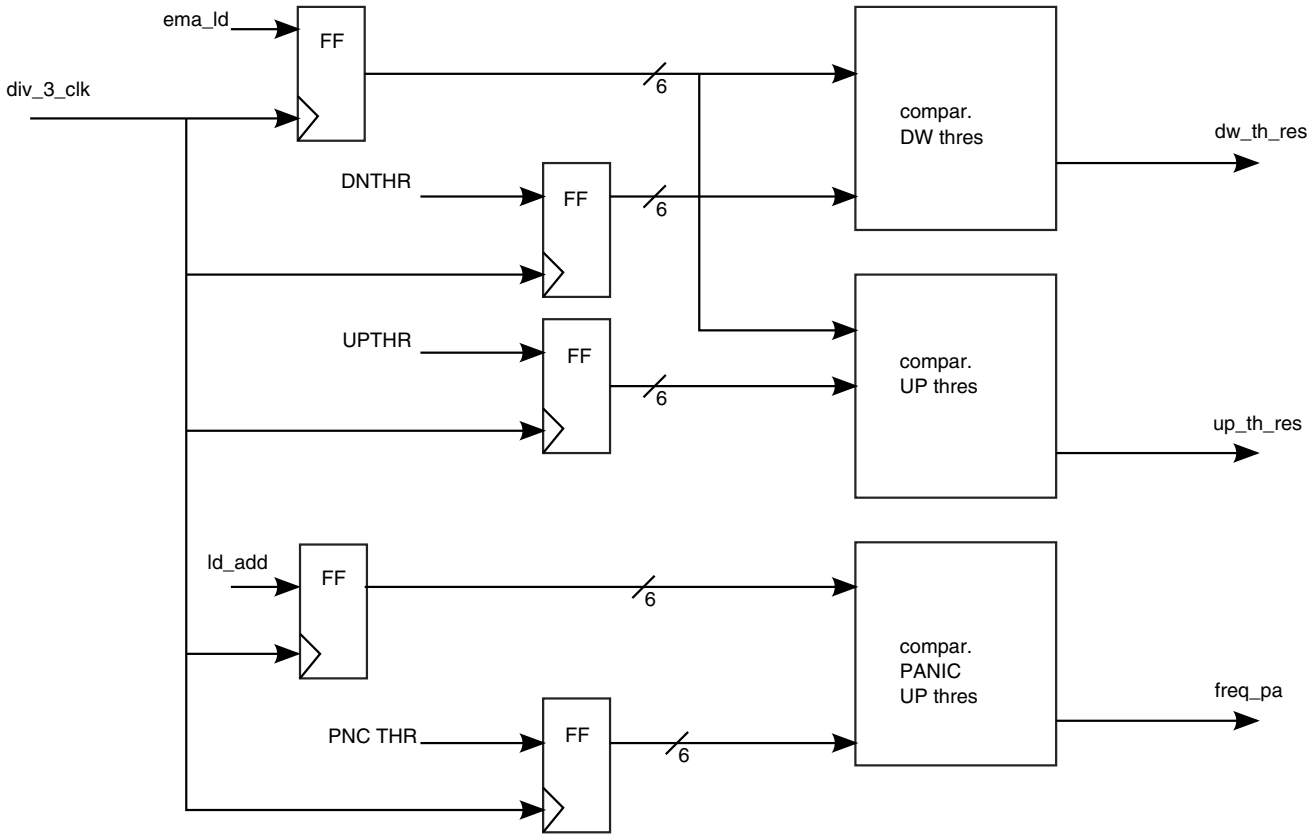

Figure 21-8. dvfs_tresh_cmp Diagram

The block is composed of three (3) comparators:

1. compar_dw_thres comparator, which compares between ema_ld signal (output of EMA block) and DNTHR signal (taken from config register, bits DNTHR).
2. compar_up_thres comparator, which compares between ema_ld signal (output of EMA block) and UPTHR signal (taken from config register, bits UPTHR).
3. compar_panic_up_thres comparator, which compares between ld_add signal (output of load_adder block) and PNCTHR signal (taken from config register, bits PNCTHR).

NOTE

The current implementation of this block enables step-by-step down frequency change. For more advanced option, the number of the DW threshold comparators should be increased (up to three for four-level DVFS).

21.3.7 dvfs_thresh_count Block

The purpose of the dvfs_thres_count block is to count consecutive threshold overcomes of dw_th_res and up_th_res (outputs of threshold_comp block). If any of the counters (see Figure 21-9 below) receives a null (zero) input synchronous with the clk3 signal, the counter is reset.

If the counter reaches a user defined value, its output is set to an active level. These counters are reset each time frequency scaling occurs or if the threshold overcomes are consecutive.

This block's output signals are saved in configuration register 0, bits [3,2].

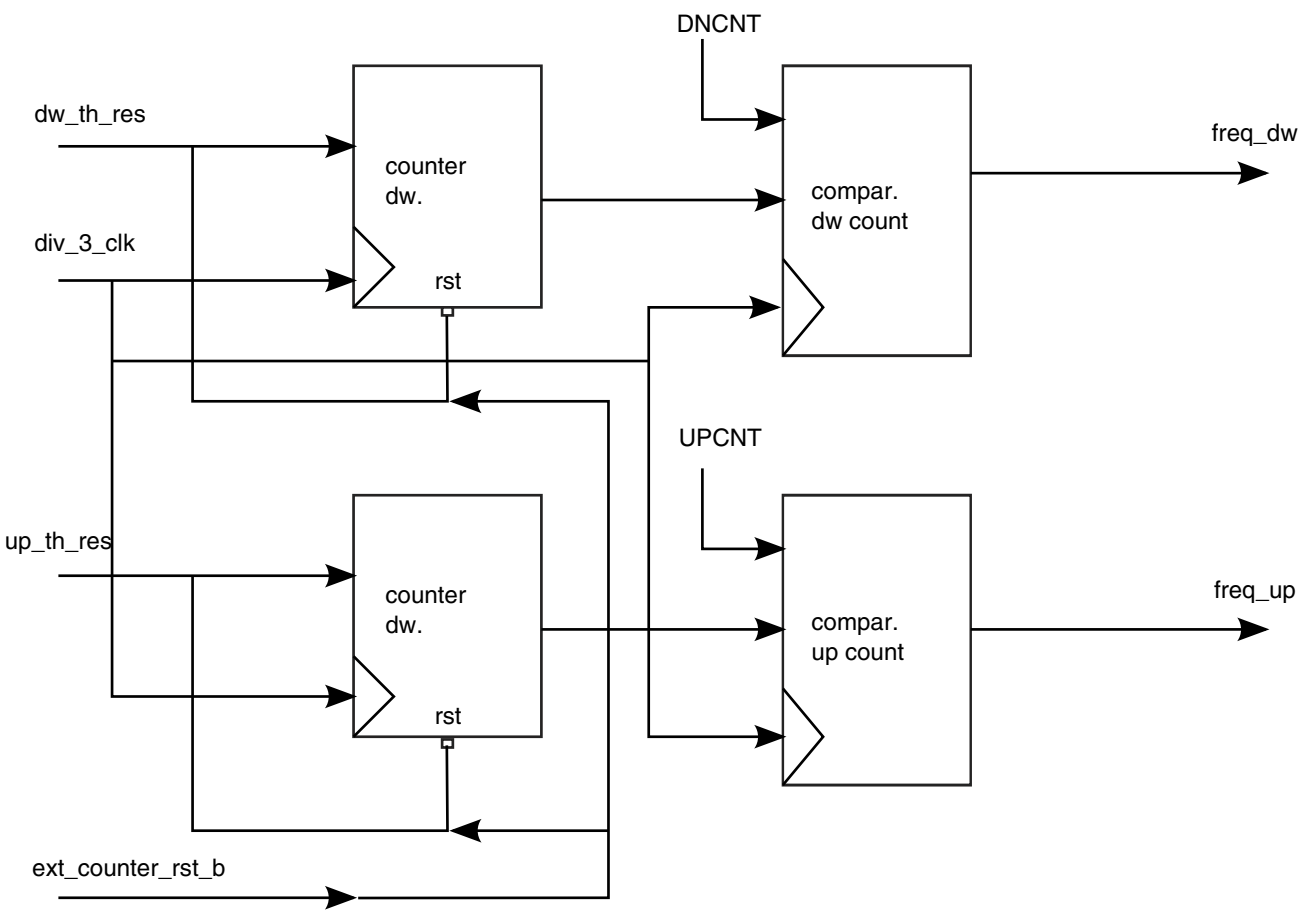

Figure 21-9. Thresh_counters block diagram

21.3.8 Load Tracking Buffer Register

The purpose of the load tracking buffer register is to save last 16 samples of the tracked load (before EMA operation). Hence, the 4 bits of ld_add signal (depending on the LTBRSH) are saved continuously, overwriting each time the latest sample. Each save is carried upon detecting an edge of the div_3_clk signal.

21.3.9 Frequency Pattern Generator

Frequency pattern generator is able to manage the frequency update requests periodically, additionally to main frequency update requests (if bit FPUE is set).

The periodic requests are created following the DVFSPT0, DVFSPT1, DVFSPT2 and DVFSPT3 register values, as described in Figure 21-10.

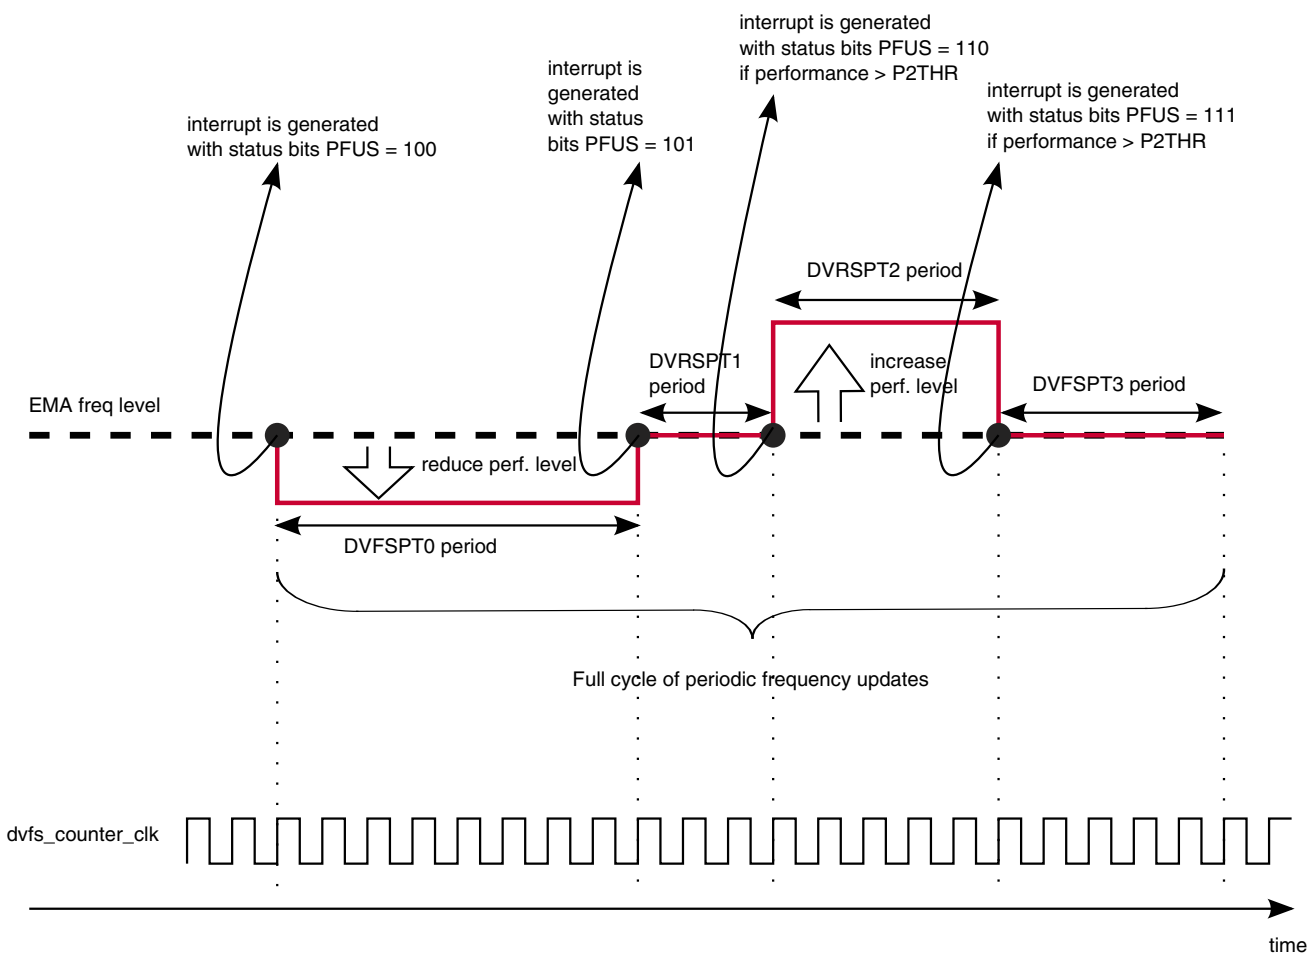

Figure 21-10. DVFS periodic frequency update requests

In case that one of the DVSPT0-DVFSPT3 period is set to "0", such frequency update will be skipped.

The periodic frequency update status is reflected in PFUS bits (reduce/increase performance request is an example - the actual steps taken upon period expiration are defined by s/w routine).

dvfs_counter_clk is ckih divided 64: 26MHz/64=0.40625MHz. The DVFSPT0, DVFSPT1, DVFSPT2 and DVFSPT3 counter are selected for 17 bits each to provide delay of 2^{18}-1=262143 counts, that are equal to 645ms. On the other hand, clk cycle of 0.40625MHz is ~2.46us, that is fast enough to provide high resolution for frequency management for tasks.

The DVFSPT2 and DVFSPT3 begin indication (interrupt) are conditional - only if the current performance is greater than P2THR bits at DVFSPT2 start, the interrupts will be created. Otherwise, the pattern delay will be counted, but without interrupt generation.

21.4 DVFS Output Event/interrupt Configuration

Event/Interrupt will be always high as long as LBFL is'1' and was not cleared by SW. Unless DVFEV (always event) is asserted. Then the event/interrupted will be toggled up and down every toggle of div_3_clk.

21.4.1 Interrupts

DVFS generates an interrupt that indicates that frequency and voltage update is needed. The user has to read the FSVAIM bits in order to know which change needs to be done.

21.5 Initialization Information

The user has to configure threshold values for load tracking and for counters and then enable the DVFS. When an interrupt is received, the user will change the frequency and the voltage in the interrupt handler.

NOTE

DVFS is a monitor that only provides an interrupt when counting exceeds the predefined value and doesn't actually send request to make a change a change of voltage and frequency. This can be done by the user in the interrupt routine or SDMA code by using GPC or CCM (re locking the PLL or changing the post dividers at the CCM).

Chapter 22
Enhanced Configurable SPI (ECSPI)

22.1 Overview

This chapter describes a block integrated into an SoC. The chapter is intended for a block driver software developer. It describes block-level operation and programming. To understand how the block is integrated at the SoC level, a system software developer should see discussions of the block in the appropriate SoC-level chapter(s).

The Enhanced Configurable Serial Peripheral Interface (ECSPI) is a full-duplex, synchronous, four-wire serial communication block. The ECSPI contains a 64 x 32 receive buffer (RXFIFO) and a 64 x 32 transmit buffer (TXFIFO). With data FIFOs, the ECSPI allows rapid data communication with fewer software interrupts. The following figure shows a block diagram of the ECSPI.

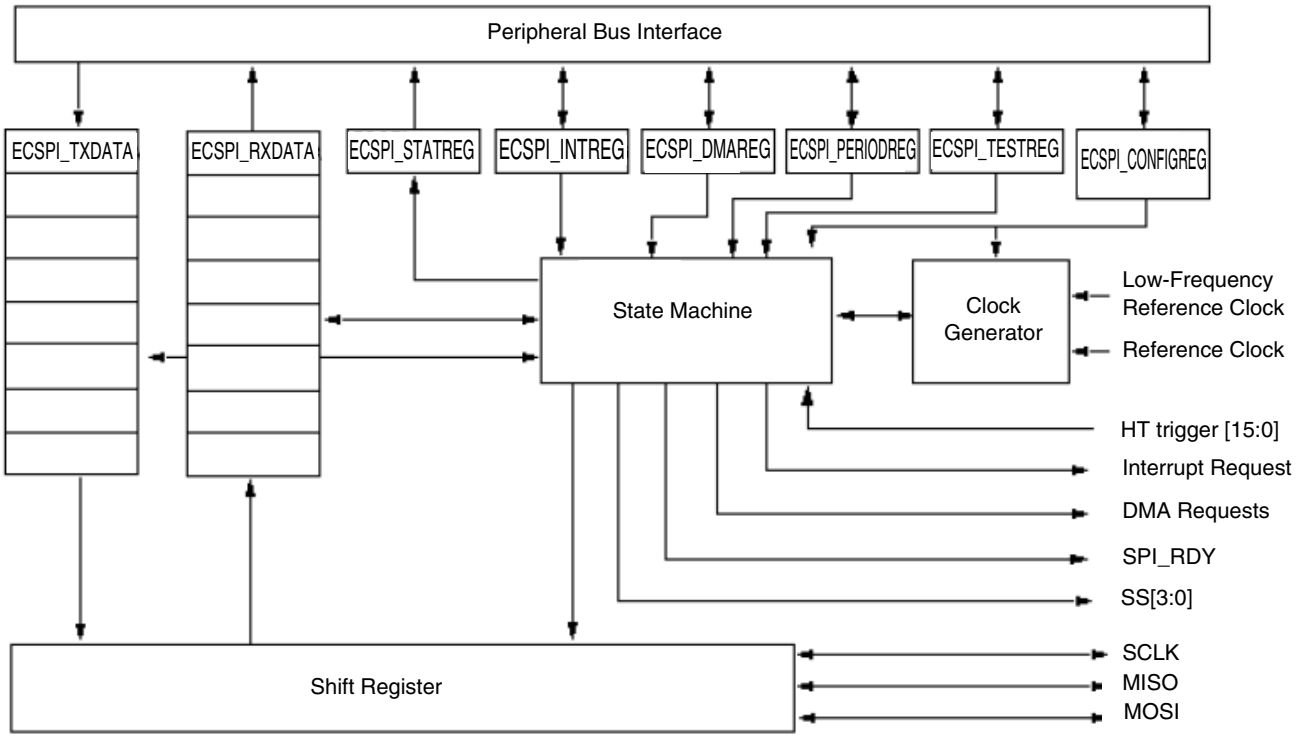

Figure 22-1. ECSPI Block Diagram

22.1.1 Features

Key features of the ECSPI include:

- Full-duplex synchronous serial interface
- Master/Slave configurable
- Four Chip Select (SS) signals to support multiple peripherals
- Transfer continuation function allows unlimited length data transfers
- 32-bit wide by 64-entry FIFO for both transmit and receive data
- 32-bit wide by 16-entry FIFO for HT message data
- Polarity and phase of the Chip Select (SS) and SPI Clock (SCLK) are configurable
- Direct Memory Access (DMA) support
- Max operation frequency up to the reference clock frequency.

22.1.2 Modes and Operations

The ECSPI supports the modes described in the indicated sections:

- Master Mode

- Slave Mode
- Low Power Modes

As described in Operations, the ECSPI supports the operations described in the indicated sections:

- Typical Master Mode
  - Master Mode with SPI_RDY
  - Master Mode with Wait States
  - Master Mode with SS_CTL[3:0] Control
  - Master Mode with Phase Control
- Typical Slave Mode

22.2 External Signals

The table below describes all ECSPI Block I/Os.

Table 22-1. Block I/O Signals

Signal	I/O	Description	Reset State[1]	Pull-Up/ Down[1]
$\overline{SS}$[3:0]	I/O	Chip selects	1	-
SCLK	I/O	SPI clock	0	Active
MISO	I/O	Master data in; slave data out	0	Passive
MOSI	I/O	Master data out; slave data in	0	-
SPI_RDY	I	Master data out; slave data in	0	Active

1. The reset state values and pull-up/down requirements provided in this table are from the block-level perspective. To understand how the block is integrated at the SoC level, the system software developer must see discussions of the block in the appropriate SoC-level chapter(s). For example, a block signal that requires a pull-up could be integrated with a pull-up option built into the SoC. In this case, the system software developer must ensure the proper programming at the SoC level.

The figure below shows the ECSPI in master mode connected to four external devices in a one-way communication link.

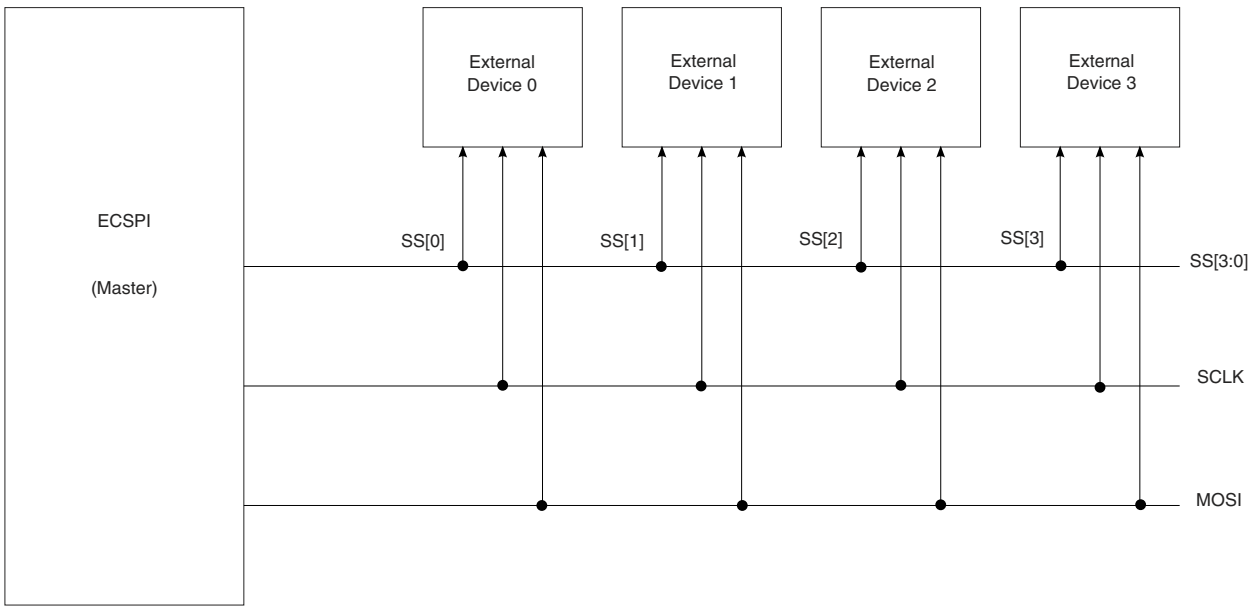

Figure 22-2. Example Connection Diagram

22.3 Functional Description

This section provides a complete functional description of the ECSPI. The figure below shows the relationship of SCLK and data lines while ECSPI has been configured with different POL and PHA settings.

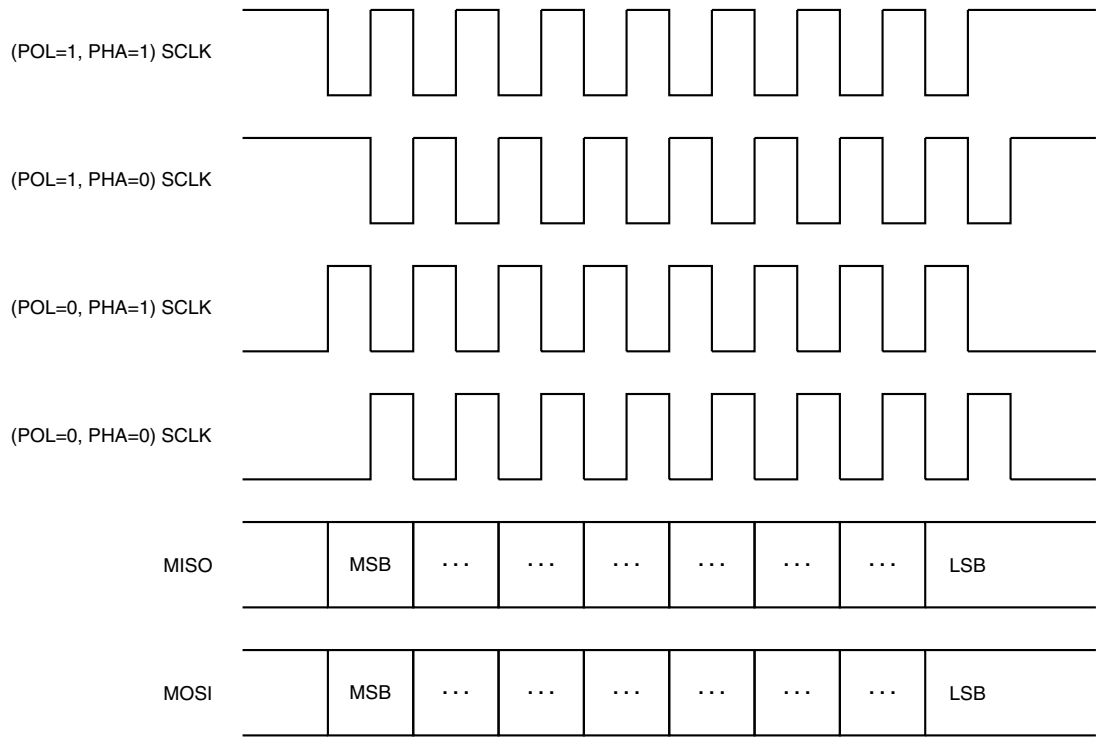

Figure 22-3. ECSPI SCLK, MISO, and MOSI Relationship

22.3.1 Master Mode

When the ECSPI is configured as a master, it uses a serial link to transfer data between the ECSPI and an external slave device. One of the Chip Select (SS) signals and the clock signal (SCLK) are used to transfer data between two devices.

If the external device is a transmit-only device, the ECSPI master's output port can be ignored and used for other purposes. In order to use the internal TXFIFO and RXFIFO, two auxiliary output signals, Chip Select (SS) and SPI_RDY, are used for data transfer rate control. Software can also configure the sample period control register to a fixed data transfer rate.

22.3.2 Slave Mode

When the ECSPI is configured as a slave, software can configure the ECSPI Control register to match the external SPI master's timing. In this configuration, Chip Select ($\overline{SS}$) becomes an input signal, and is used to control data transfers through the Shift register, as well as to load/store the data FIFO.

22.3.3 Hardware Trigger (HT) Mode

In hardware trigger (HT) mode, the behavior of the ECSPI is similar to master mode. The differences are in the trigger mechanism and the burst length.

When the block is in HT mode, the SPI burst is no longer triggered by software, setting the XCH bit or writing to the TXFIFO. Instead, there are 16 input signals HT trigger[15:0] associated with each slot of the 16-entry ECSPI_MSGDATA FIFO, and a positive pulse will trigger the ECSPI to transmit a SPI burst with data in ECSPI_MSGDATA FIFO. And in this case, the burst length is limited in 32-bit, but also configurable. Only SPI channel 0 can be used in HT mode.

22.3.4 Low Power Modes

The ECSPI does not operate under low power mode. It holds its operation when its clock is gated off in master mode. In slave mode, the ECSPI does not respond when its clock is gated off.

22.3.5 Operations

This section describes the ECSPI's operations.

22.3.5.1 Typical Master Mode

The ECSPI master uses the Chip Select (SS) signal to enable an external SPI device, and uses the SCLK signal to transfer data in and out of the Shift register. The SPI_RDY enables fast data communication with fewer software interrupts. By programming the ECSPI_PERIODREG register accordingly, the ECSPI can be used for a fixed data transfer rate.

When the ECSPI is in Master mode the SS, SCLK, and MOSI are output signals, and the MISO signal is an input.

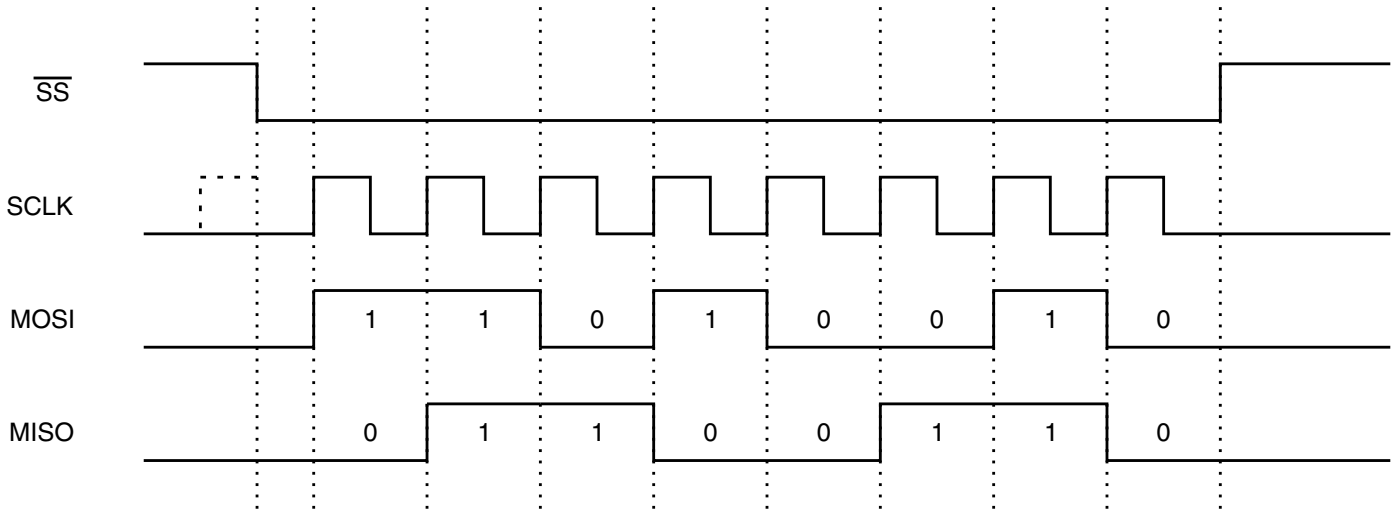

Figure 22-4. Typical SPI Burst (8-bit Transfer)

In the above figure, the Chip Select (SS) signal enables the selected external SPI device, and the SCLK synchronizes the data transfer. The MOSI and MISO signals change on rising edge of SCLK and the MISO signal is latched on the falling edge of the SCLK. The figure above shows a data of 0xD2 is shifted out, and a data of 0x66 is shifted in.

22.3.5.1.1 Master Mode with SPI_RDY

By default, the ECSPI does not use the SPI_RDY signal in master mode (MODE =1).

A SPI burst begins when the following events happen:

- The ECSPI is enabled, TXFIFO has data in it, and ECSPI_CONREG[XCH] bit or the ECSPI_CONREG[SMC] bit is set.
- When the SPI Data Ready Control (ECSPI_CONREG[DRCTL]) bits contains either 01 or 10, the SPI_RDY signal controls when a SPI burst starts.

A SPI burst is defined as a bus transaction that starts when the slave select is asserted and ends when the slave select is negated. The Chip Select (SS) signal will remain asserted until all the bits in a SPI burst are shifted out.

If ECSPI_CONREG[DRCTL] is set to 01, the SPI burst can be triggered only if a falling edge of the SPI_RDY signal has been detected.

The following figure shows the relationship between a SPI burst and the falling edge of SPI_RDY signal.

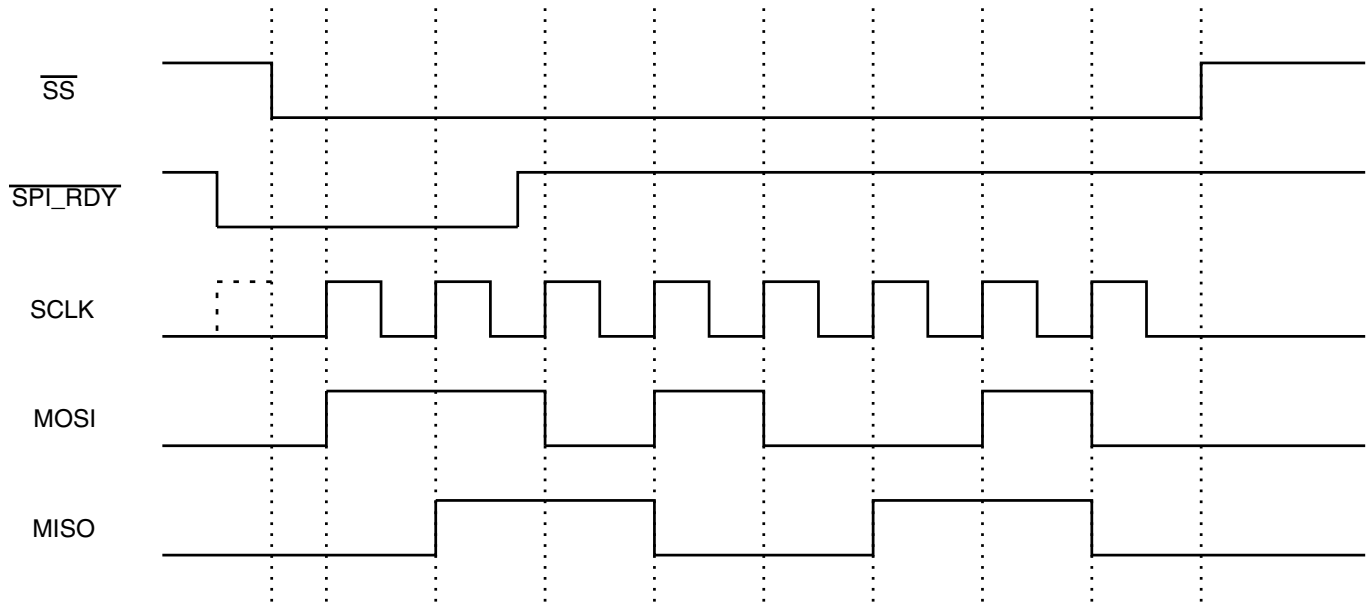

Figure 22-5. Relationship Between a SPI Burst and SPI_RDY: Falling-Edge Triggered

A SPI burst does not start until the falling edge of the SPI_RDY signal is detected. The next SPI burst starts when the next SPI_RDY falling edge is detected, after the last burst has finished.

If SPI Data Ready Control (ECSPI_CONREG[DRCTL]) is set to 10, the SPI burst can be triggered only if the SPI_RDY signal is low.

The following figure shows the relationship between a SPI burst and the SPI_RDY signal. The SPI burst does not begin until the SPI_RDY signal goes low. The ECSPI will keep transmitting SPI burst if the SPI_RDY signal remains low.

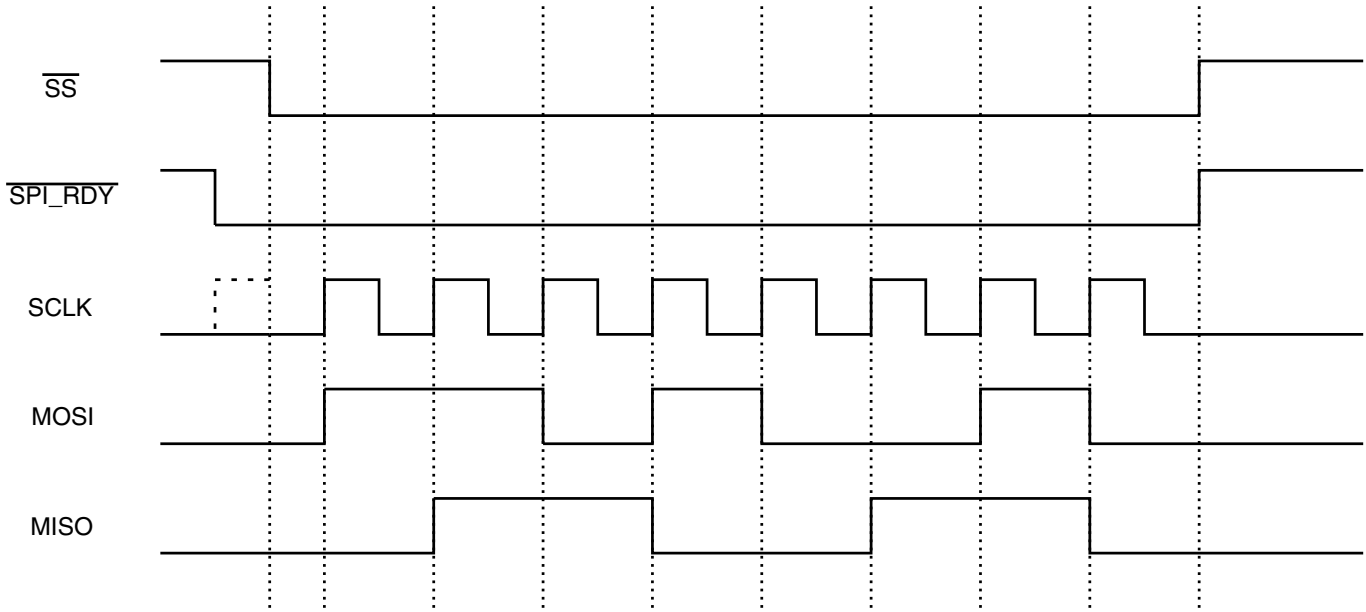

Figure 22-6. Relationship Between a SPI Burst and SPI_RDY: Low-Level Triggered

22.3.5.1.2 Master Mode with Wait States

Wait states can be inserted between SPI bursts. This provides a way for software to slow down the SPI burst to meet the timing requirements of a slower SPI device.

The following figure shows wait states inserted between SPI bursts.

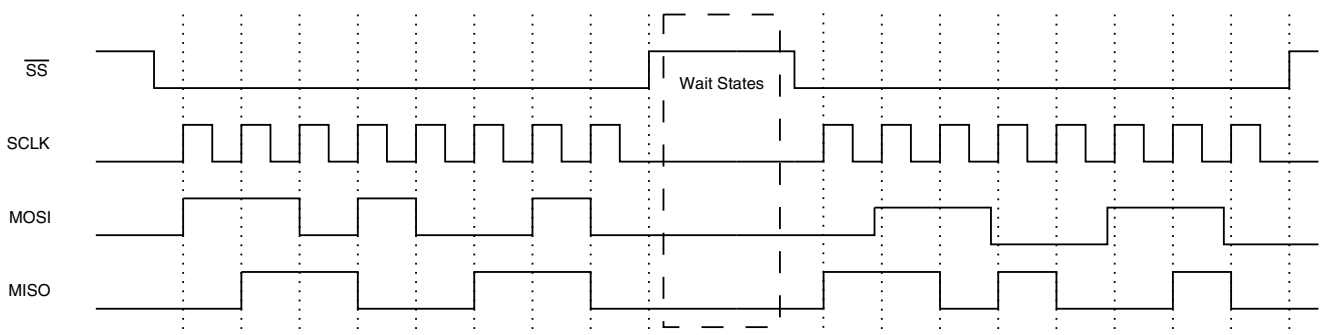

Figure 22-7. SPI Bursts with Wait States

In this case, the number of wait states is controlled by ECSPI_PERIODREG[SAMPLE PERIOD] and the wait states' clock source is selected by ECSPI_PERIODREG[CSRC].

22.3.5.1.3 Master Mode with SS_CTL[3:0] Control

The SPI SS Control (SS_CTL[3:0]) controls whether the current operation is single burst or multiple bursts. When the SPI SS Wave Form Select (SS_CTL[3:0]) is set, the current operation is multiple bursts transfer. When the SPI SS Wave Form Select (SS_CTL[3:0]) bit is cleared, the current operation is single burst transfer. A SPI burst can contains multiple words as defined in the BURST LENGTH field of the ECSPI_CONREG register.

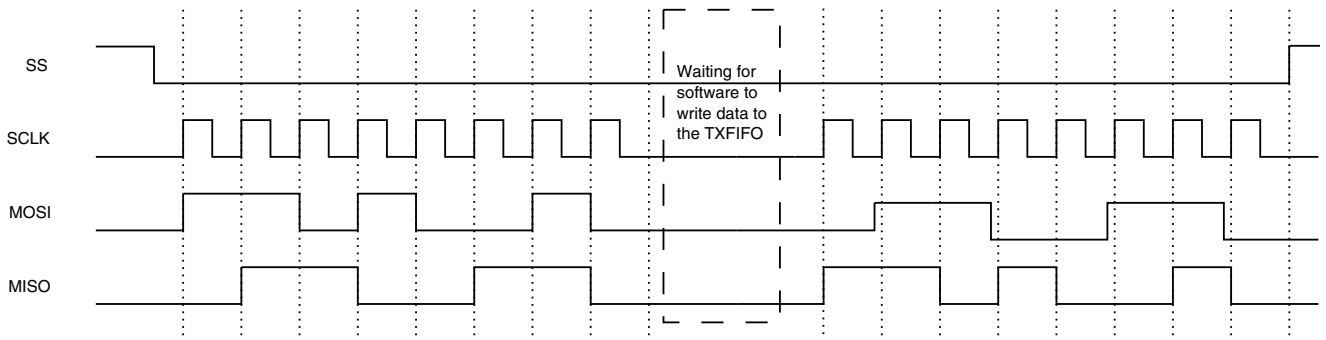

Figure 22-8. SPI Burst While SS_CTL[3:0] is Clear

In Figure 22-8, two 8-bit bursts in the TXFIFO have been combined and transmitted in one SPI burst. The maximum length of a single SPI burst is defined in the BURST LENGTH field of the ECSPI_CONREG control register. (Figure 22-8 corresponds to a BURST LENGTH of 8.) This provides a way for transferring a longer SPI burst by writing data into TXFIFO while the ECSPI is transmitting.

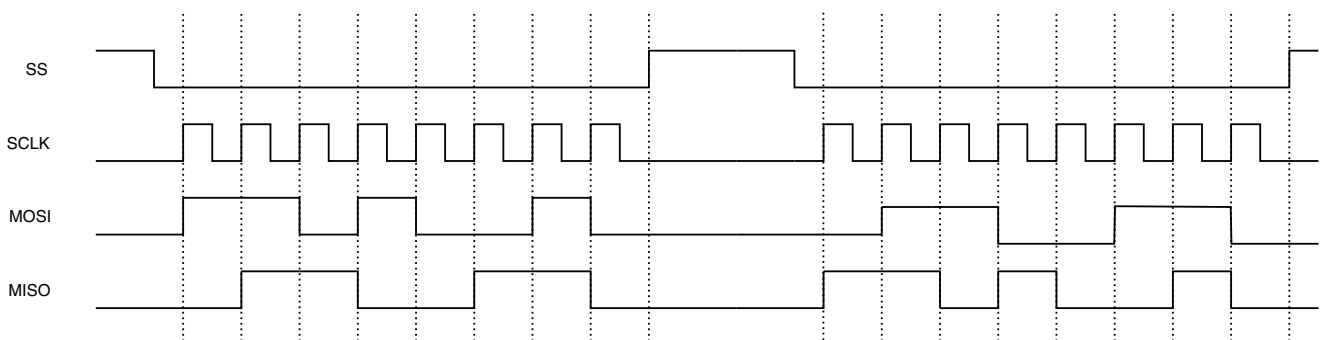

Figure 22-9. SPI Bursts While SS_CTL[3:0] is Set

In Figure 22-9, two FIFO entries are transmitted, one entry with each SPI burst. The ECSPI will continue to transmit SPI bursts until the TXFIFO is empty. When wait states can be inserted between SPI bursts, the SS will negate between SPI bursts until the wait states finish.

22.3.5.1.4 Master Mode with Phase Control

The Phase Control (ECSPI_CONREG[PHA]) bit controls how the transmit data shifts out and the receive data shifts in.

When the Phase control (ECSPI_CONREG[PHA]) bit is set, the transmit data will shift out on the rising edge of SCLK, and the receive data is latched on the falling edge of SCLK. The most-significant bit is output on the first rising SCLK edge.

When ECSPI_CONREG[PHA] is cleared, the transmit data is shifted out on the falling edge of SCLK and the receive data is latched on the rising edge of SCLK. The MSB is output when the host processor loads the transmitted data.

Inverting the SCLK polarity does not impact the edge-triggered operations because they are internal to the serial peripheral interface master.

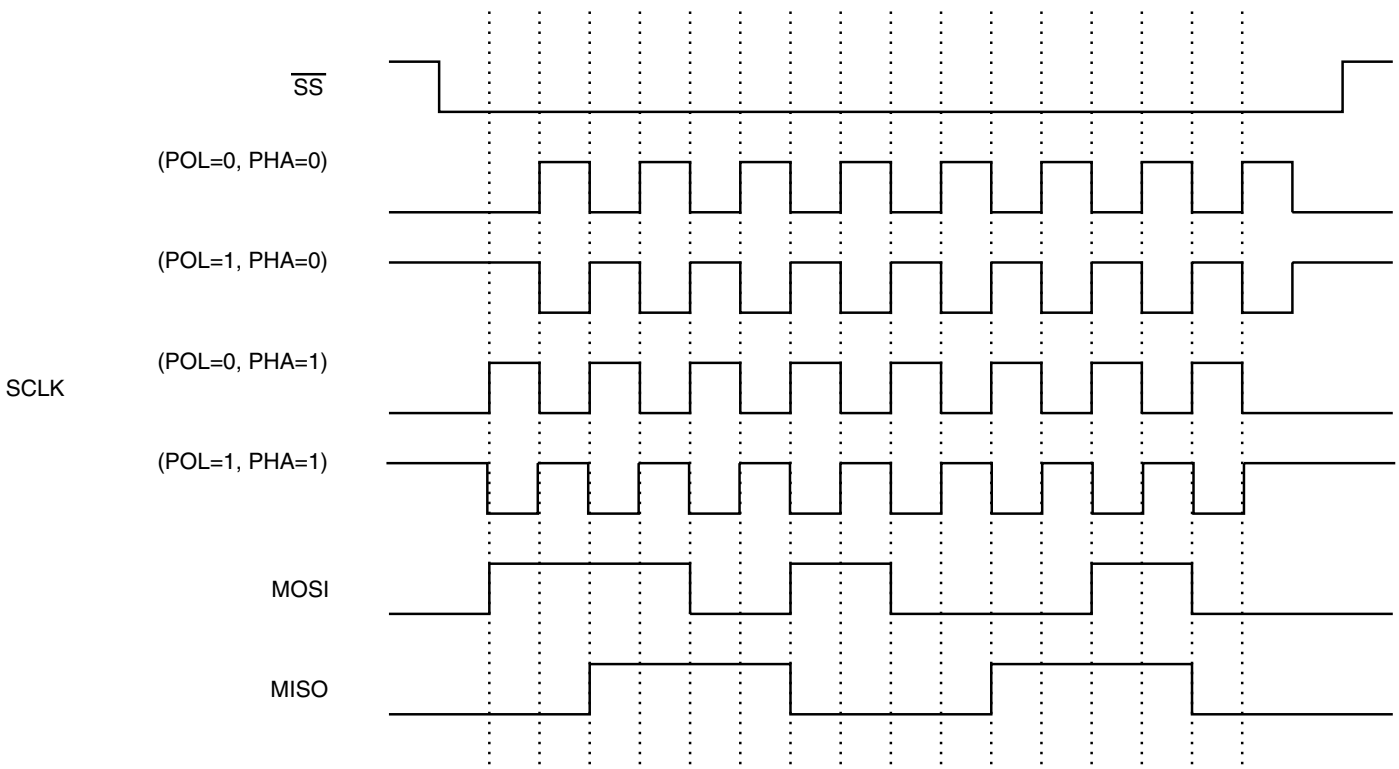

Figure 22-10. SPI Burst with Different POL and PHA Configurations

22.3.5.2 Typical Slave Mode

When the ECSPI is configured as a slave (Mode = 0), software can configure the ECSPI Control register to match the external SPI master's timing. In this configuration, SS becomes an input signal, and is used to latch data in and out of the internal data Shift registers, as well as to advance the data FIFO.

The SS, SCLK, and MOSI are inputs and MISO is output. Most of the timing diagrams are similar to the diagrams shown previously for the SPI in Master mode (Mode = 1), because the inputs come from a SPI master device.

However, the timing is different when SS is used to advance the data FIFO. When the SS_CTL[3:0] is set while the ECSPI is configured in Slave mode, the data FIFO will advance on the rising edge of the SS signal. When the polarity is reversed (SSPOL = 1), the data FIFO will advance on the falling edge of the SS signal.

The figure below shows a SPI burst in which the data FIFO is advanced by the rising edge of the SS signal.

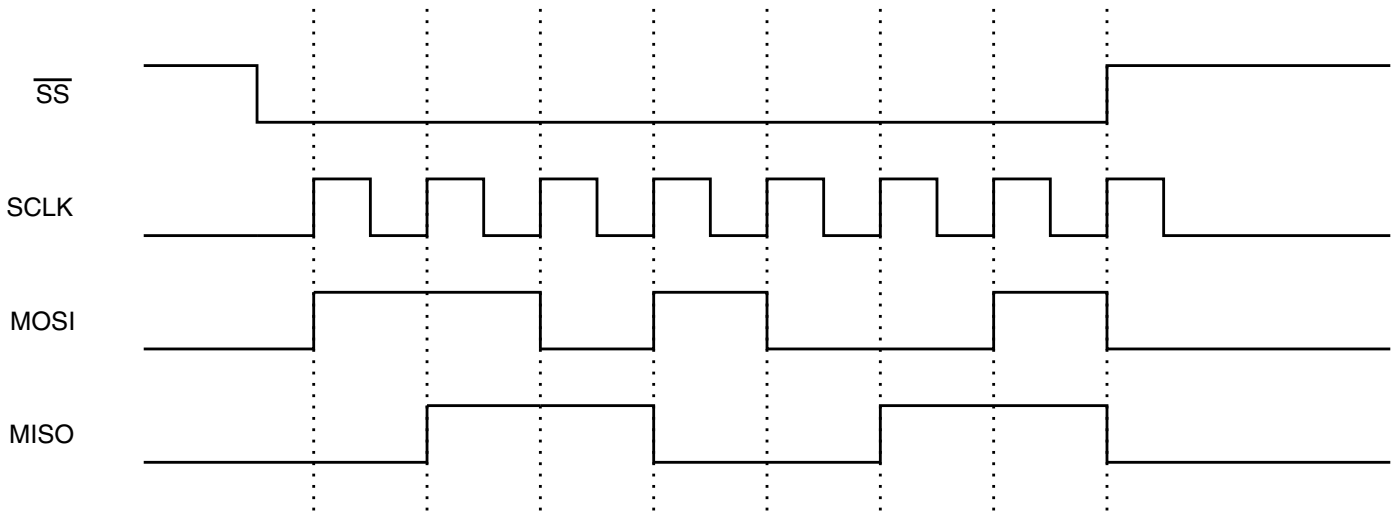

Figure 22-11. Advancing the Data FIFO on the Rising Edge of $\overline{SS}$

In the above case, only the most significant 7 bits are loaded to the RXFIFO.

22.3.6 Clocks

This section describes clocks and special clocking requirements of the block.

ECSPI has the following clock inputs:

- Reference Clock is the reference clock.
- Low-Frequency Reference Clock is a 32KHz input clock optionally used for counting wait states.

22.3.7 Reset

Whenever a device reset occurs, a reset is performed on the ECSPI, resetting all registers to their default values.

Software can reset the block using the CONREG[EN] bit; see Control Register (ECSPI_CONREG).

22.3.8 Interrupts

Interrupt control provides a way to manage the ECSPI FIFOs:

- For transmitting data, software can enable the TXFIFO empty, TXFIFO data request, and TXFIFO full interrupts to maintain the TXFIFO using an interrupt service routine.
- For receiving data, software can enable the RXFIFO ready, RXFIFO data request, and RXFIFO full interrupts to retrieve data from the RXFIFO using an interrupt service routine.

Other interrupt sources can be used to control or debug the SPI bursts:

- The transfer-completed interrupt means that there is no data left in the TXFIFO and that the data in the Shift register has been shifted out.
- The RXFIFO overflow interrupt means that the RXFIFO received more than 64 words and will not accept any other words.

.

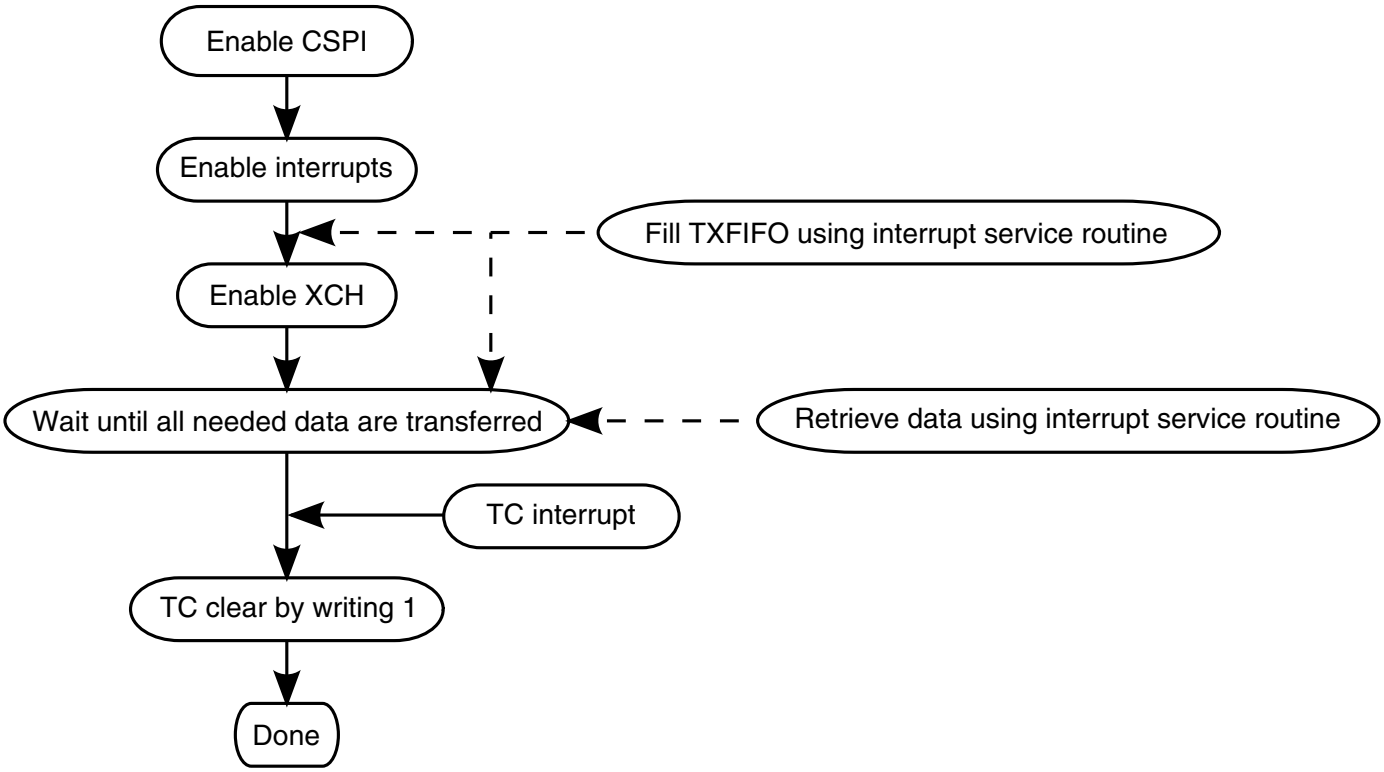

Figure 22-12. Program Sequence of SPI Burst Using Interrupt Control

22.3.9 DMA

DMA control provides another method to utilize the FIFOs in the ECSPI. By using DMA request and acknowledge signals, larger amounts of data can be transferred, and will reduce interrupts and host processor loading. When the appropriate conditions are matched, the block will send out a DMA request.

The DMA can deal with the following conditions:

- TXFIFO empty
- TXFIFO data request
- RXFIFO data request
- RXFIFO full

The figure below shows a program sequence of SPI bursts using DMA control.

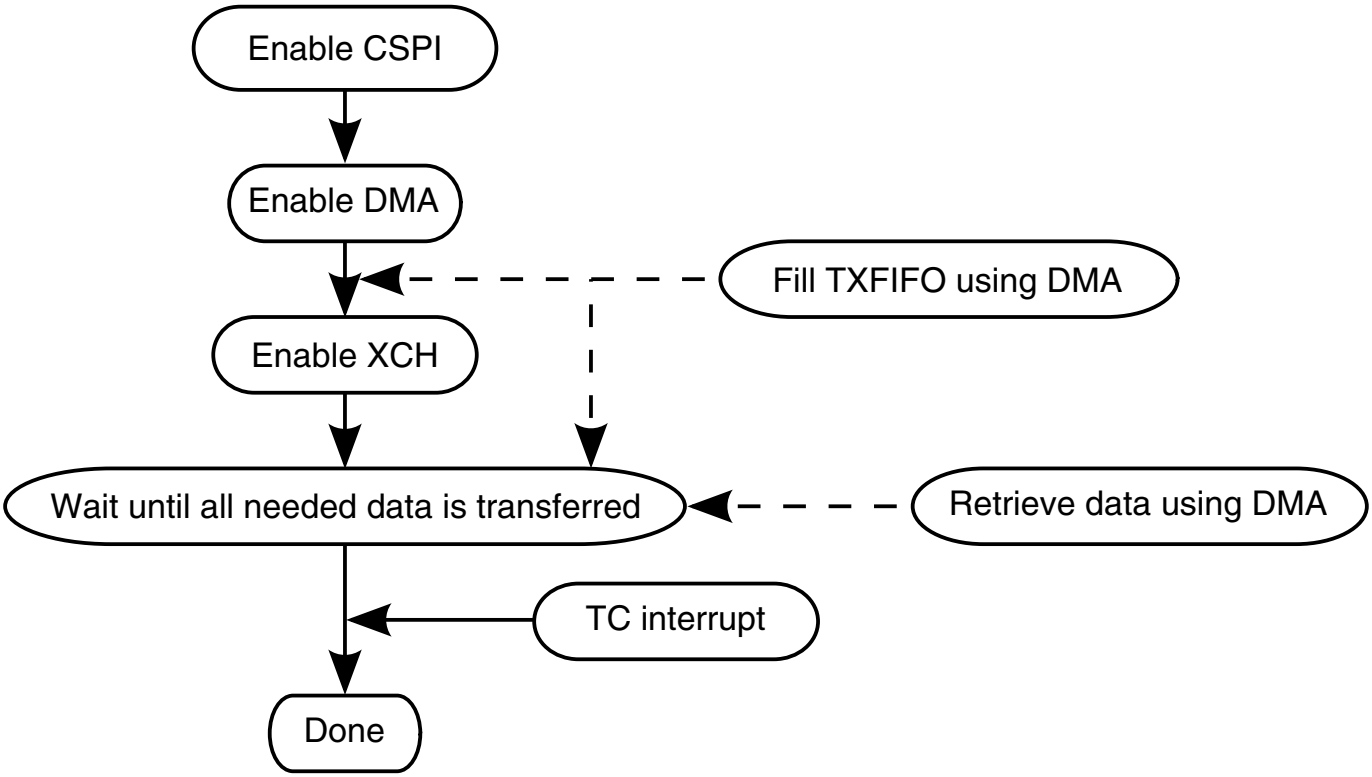

Figure 22-13. Program Sequence of SPI Burst Using DMA

22.3.10 Byte Order

The ECSPI does not support byte re-ordering in hardware.

22.4 Initialization

This section provides initialization information for ECSPI.

To initialize the block:

1. Clear the EN bit in ECSPI_CONREG to reset the block.
2. Enable the clocks for ECSPI.
3. Set the EN bit in ECSPI_CONREG to put ECSPI out of reset.
4. Configure corresponding IOMUX for ECSPI external signals.
5. Configure registers of ECSPI properly according to the specifications of the external SPI device.

22.5 Applications

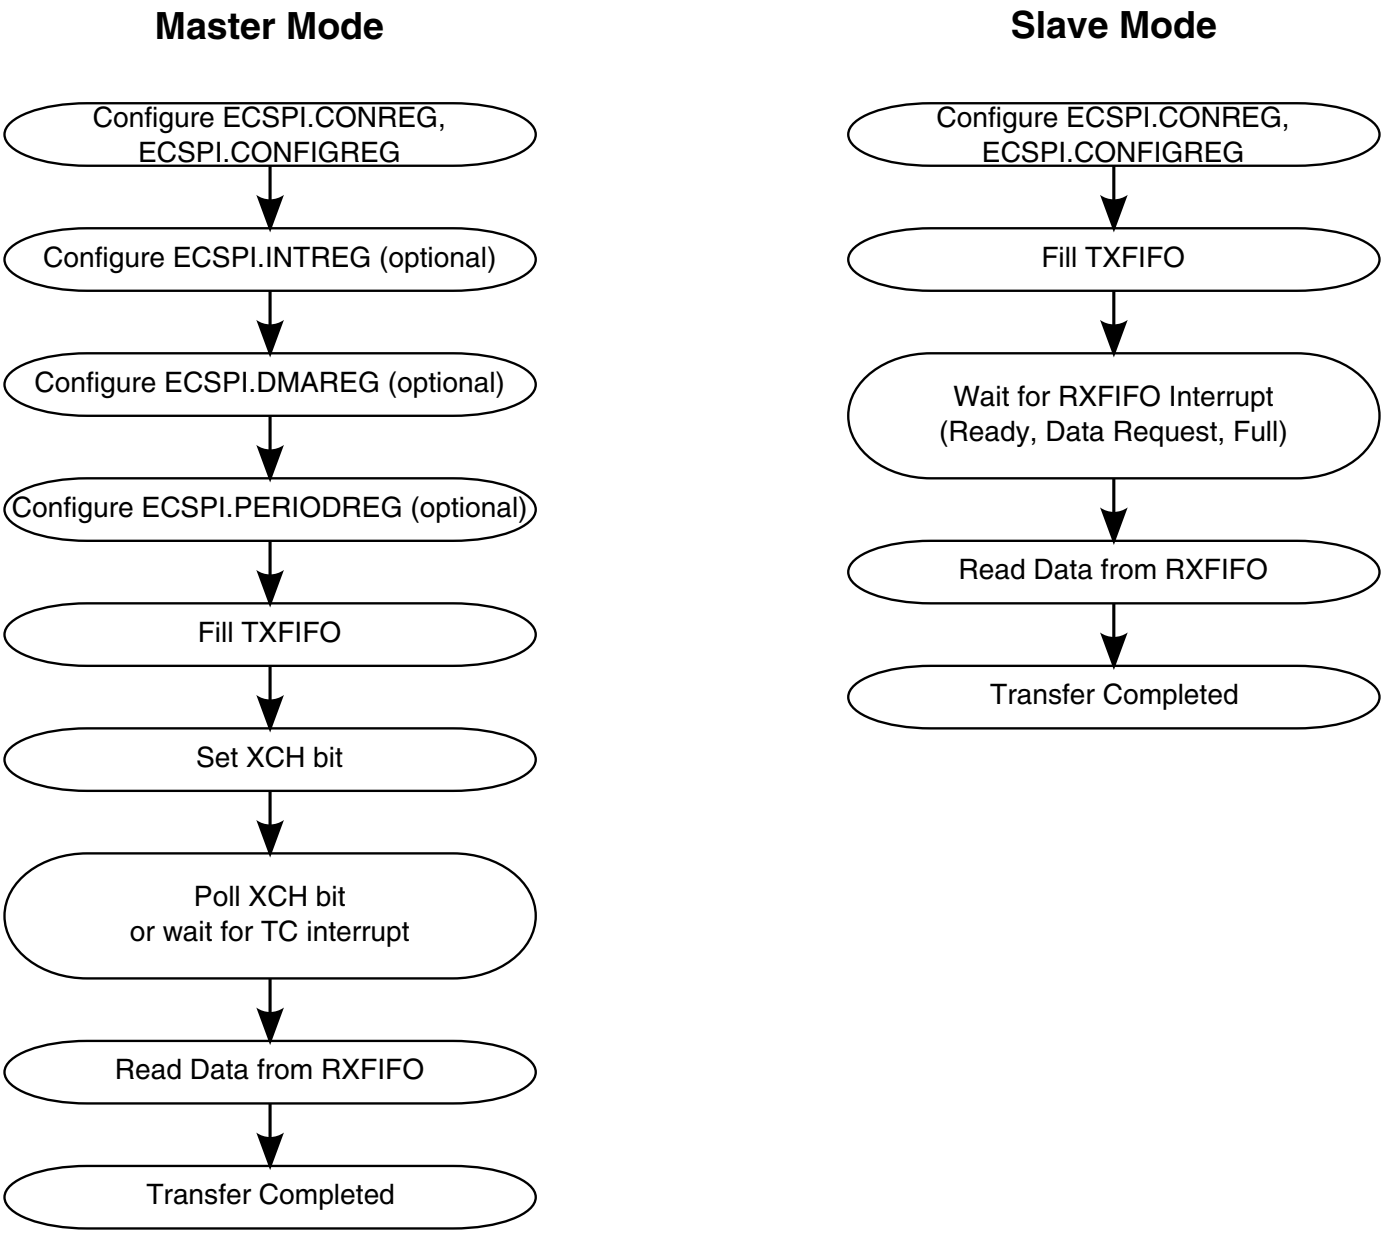

Figure 22-14. Flowchart of the ECSPI Operation

22.6 Programmable Registers

This section includes the block memory map and detailed descriptions of all registers. For the base address of a particular block instantiation, see the system memory map.

22.6.1 Receive Data Register (ECSPIx_RXDATA)

The Receive Data register (ECSPI_RXDATA) is a read-only register that forms the top word of the 64 x 32 receive FIFO. This register holds the data received from an external SPI device during a data transaction. Only word-sized read operations are allowed.

Addresses: ECSPI-1_RXDATA is 5001_0000h base + 0h offset = 5001_0000h

ECSPI-2_RXDATA is 63FA_C000h base + 0h offset = 63FA_C000h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ECSPIx_RXDATA field descriptions

Field	Description
31–0 ECSPI_RXDATA	Receive Data. This register holds the top word of the receive data FIFO. The FIFO is advanced for each read of this register. The data read is undefined when the Receive Data Ready (RR) bit in the Interrupt Control/Status register is cleared. Zeros are read when ECSPI is disabled.

22.6.2 Transmit Data Register (ECSPIx_TXDATA)

The Transmit Data (ECSPI_TXDATA) register is a write-only data register that forms the bottom word of the 64 x 32 TXFIFO. The TXFIFO can be written to as long as it is not full, even when the SPI Exchange bit (XCH) in ECSPI_CONREG is set. This allows software to write to the TXFIFO during a SPI data exchange process. Writes to this register are ignored when the ECSPI is disabled (ECSPI_CONREG[EN] bit is cleared).

Addresses: ECSPI-1_TXDATA is 5001_0000h base + 4h offset = 5001_0004h

ECSPI-2_TXDATA is 63FA_C000h base + 4h offset = 63FA_C004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ECSPIx_TXDATA field descriptions

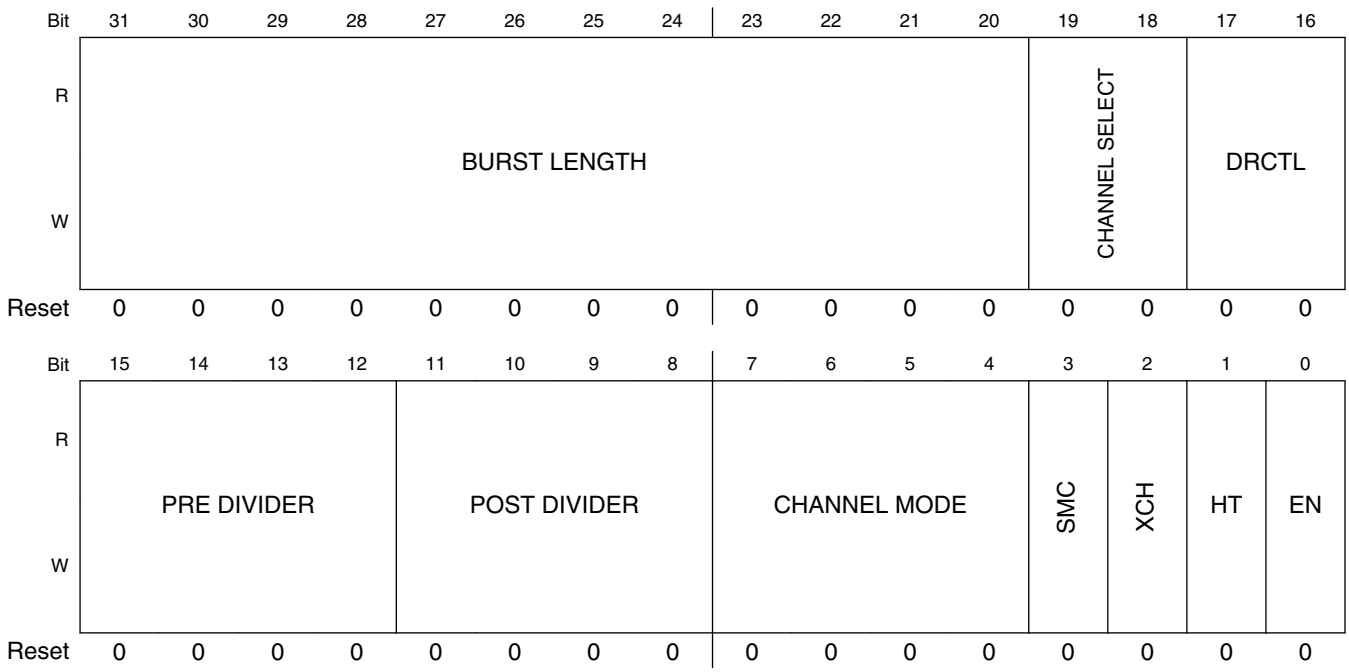
Field	Description
31–0 ECSPI_TXDATA	Transmit Data. This register holds the top word of data loaded into the FIFO. Data written to this register must be a word operation. The number of bits actually transmitted is determined by the BIT_COUNT field of the corresponding SPI Control register. If this field contains more bits than the number specified by BIT_COUNT, the extra bits are ignored. For example, to transfer 10 bits of data, a 32-bit word must be written to this register. Bits 9-0 are shifted out and bits 31-10 are ignored. When the ECSPI is operating in Slave mode, zeros are shifted out when the FIFO is empty. Zeros are read when ECSPI is disabled.

22.6.3 Control Register (ECSPIx_CONREG)

The Control Register (ECSPI_CONREG) allows software to enable the ECSPI , configure its operating modes, specify the divider value, and SPI_RDY control signal, and define the transfer length.

Addresses: ECSPI-1_CONREG is 5001_0000h base + 8h offset = 5001_0008h

ECSPI-2_CONREG is 63FA_C000h base + 8h offset = 63FA_C008h



ECSPIx_CONREG field descriptions

Field	Description
31–20 BURST LENGTH	Burst Length. This field defines the length of a SPI burst to be transferred. The Chip Select (SS) will remain asserted until all bits in a SPI burst are shifted out. A maximum of 2^12 bits can be transferred in a single SPI burst. In master mode, it controls the number of bits per SPI burst. Since the shift register always loads 32-bit data from transmit FIFO, only the n least-significant (n = BURST LENGTH + 1) will be shifted out. The remaining bits will be ignored. In slave mode, only when SS_CTL is cleared, this field will take effect in the transfer. Number of Valid Bits in a SPI burst. 0x000 A SPI burst contains the 1 LSB in a word. 0x001 A SPI burst contains the 2 LSB in a word. 0x002 A SPI burst contains the 3 LSB in a word. 0x01F A SPI burst contains all 32 bits in a word. 0x020 A SPI burst contains the 1 LSB in first word and all 32 bits in second word. 0x021 A SPI burst contains the 2 LSB in first word and all 32 bits in second word.

Table continues on the next page...

ECSPIx_CONREG field descriptions (continued)

Field	Description
	0xFFE A SPI burst contains the 31 LSB in first word and 2^7 -1 words. 0xFFF A SPI burst contains 2^7 words.
19–18 CHANNEL SELECT	SPI CHANNEL SELECT bits. Select one of four external SPI Master/Slave Devices. In master mode, these two bits select the external slave devices by asserting the Chip Select (SSn) outputs. Only the selected Chip Select (SSn) signal can be active at a given time; the remaining three signals will be negated. 00 Channel 0 is selected. Chip Select 0 (SS0) will be asserted. 01 Channel 1 is selected. Chip Select 1 (SS1) will be asserted. 10 Channel 2 is selected. Chip Select 2 (SS2) will be asserted. 11 Channel 3 is selected. Chip Select 3 (SS3) will be asserted.
17–16 DRCTL	SPI Data Ready Control. This field selects the utilization of the $\overline{\text{SPI\_RDY}}$ signal in master mode. ECSPI checks this field before it starts an SPI burst. 00 The $\overline{\text{SPI\_RDY}}$ signal is a don't care. 01 Burst will be triggered by the falling edge of the SPI_RDY signal (edge-triggered). 10 Burst will be triggered by a low level of the SPI_RDY signal (level-triggered). 11 Reserved.
15–12 PRE DIVIDER	SPI Pre Divider. ECSPI uses a two-stage divider to generate the SPI clock. This field defines the pre-divider of the reference clock. 0000 Divide by 1. 0001 Divide by 2. 0010 Divide by 3. 1101 Divide by 14. 1110 Divide by 15. 1111 Divide by 16.
11–8 POST DIVIDER	SPI Post Divider. ECSPI uses a two-stage divider to generate the SPI clock. This field defines the post-divider of the reference clock using the equation: 2^{n} . 0000 Divide by 1. 0001 Divide by 2. 0010 Divide by 4. 1110 Divide by 2^{14} . 1111 Divide by 2^{15} .
7–4 CHANNEL MODE	SPI CHANNEL MODE selects the mode for each SPI channel. CHANNEL MODE[3] is for SPI channel 3. CHANNEL MODE[2] is for SPI channel 2. CHANNEL MODE[1] is for SPI channel 1. CHANNEL MODE[0] is for SPI channel 0. 0 Slave mode. 1 Master mode.
3 SMC	Start Mode Control. This bit applies only to channels configured in Master mode (CHANNEL MODE = 1).

Table continues on the next page...

ECSPIx_CONREG field descriptions (continued)

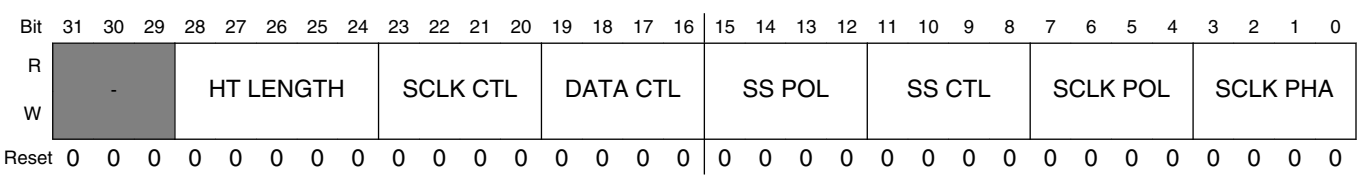
Field	Description
	It controls how the ECSPI starts a SPI burst, either through the SPI exchange bit, or immediately when the TXFIFO is written to. 0 SPI Exchange Bit (XCH) controls when a SPI burst can start. Setting the XCH bit will start a SPI burst or multiple bursts. This is controlled by the SPI SS Wave Form Select (SS_CTL). Refer to XCH and SS_CTL descriptions. 1 Immediately starts a SPI burst when data is written in TXFIFO.
2 XCH	SPI Exchange Bit. This bit applies only to channels configured in Master mode (CHANNEL MODE = 1). If the Start Mode Control (SMC) bit is cleared, writing a 1 to this bit starts one SPI burst or multiple SPI bursts according to the SPI SS Wave Form Select (SS_CTL). The XCH bit remains set while either the data exchange is in progress, or when the ECSPI is waiting for an active input if SPIRDY is enabled through DRCTL. This bit is cleared automatically when all data in the TXFIFO and the shift register has been shifted out. 0 Idle. 1 Initiates exchange (write) or busy (read).
1 HT	Hardware Trigger Enable. This bit is used in master mode only. It enables hardware trigger (HT) mode. 0 Disable HT mode. 1 Enable HT mode.
0 EN	SPI Block Enable Control. This bit enables the ECSPI. This bit must be set before writing to other registers or initiating an exchange. Writing zero to this bit disables the block and resets the internal logic with the exception of the ECSPI_CONREG. The block's internal clocks are gated off whenever the block is disabled. 0 Disable the block. 1 Enable the block.

22.6.4 Config Register (ECSPIx_CONFIGREG)

The Config Register (ECSPI_CONFIGREG) allows software to configure each SPI channel, configure its operating modes, specify the phase and polarity of the clock, configure the Chip Select (SS), and define the HT transfer length.

Addresses: ECSPI-1_CONFIGREG is 5001_0000h base + Ch offset = 5001_000Ch

ECSPI-2_CONFIGREG is 63FA_C000h base + Ch offset = 63FA_C00Ch



ECSPIx_CONFIGREG field descriptions

Field	Description
31–29 -	Reserved
28–24 HT LENGTH	HT LENGTH. This field defines the message length in HT Mode. The length in bits of one message is (HT LENGTH + 1).
23–20 SCLK CTL	SCLK CTL. This field controls the inactive state of SCLK for each SPI channel. SCLK CTL[3] is for SPI channel 3. SCLK CTL[2] is for SPI channel 2. SCLK CTL[1] is for SPI channel 1. SCLK CTL[0] is for SPI channel 0. 0 Stay high. 1 Stay low.
19–16 DATA CTL	DATA CTL. This field controls inactive state of the data line for each SPI channel. DATA CTL[3] is for SPI channel 3. DATA CTL[2] is for SPI channel 2. DATA CTL[1] is for SPI channel 1. DATA CTL[0] is for SPI channel 0. 0 Stay high. 1 Stay low.
15–12 SS POL	SPI SS Polarity Select. In both Master and Slave modes, this field selects the polarity of the Chip Select (SS) signal. SS POL[3] is for SPI channel 3. SS POL[2] is for SPI channel 2. SS POL[1] is for SPI channel 1. SS POL[0] is for SPI channel 0. 0 Active low. 1 Active high.
11–8 SS CTL	SPI SS Wave Form Select. In master mode, this field controls the output wave form of the Chip Select (SS) signal when the SMC (Start Mode Control) bit is cleared. The SS_CTL are ignored if the SMC bit is set. SS CTL[3] is for SPI channel 3. SS CTL[2] is for SPI channel 2. SS CTL[1] is for SPI channel 1. SS CTL[0] is for SPI channel 0. In slave mode, this bit controls when the SPI burst is completed. 1 An SPI burst is completed by the Chip Select (SS) signal edges. (SSPOL = 0: rising edge; SSPOL = 1: falling edge) The RXFIFO is advanced whenever a Chip Select (SS) signal edge is detected or the shift register contains 32-bits of valid data. 0 In master mode - only one SPI burst will be transmitted.

Table continues on the next page...

ECSPIx_CONFIGREG field descriptions (continued)

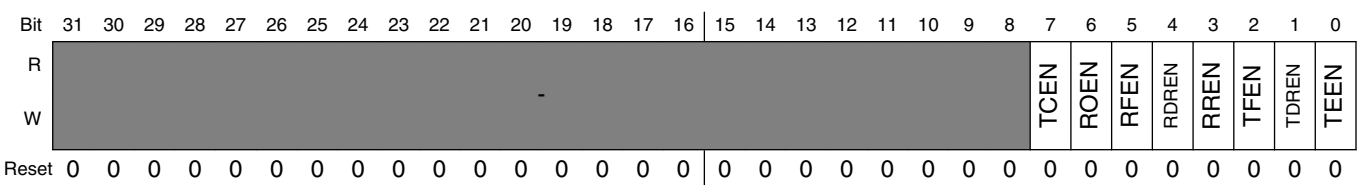
Field	Description
	1 In master mode - Negate Chip Select (SS) signal between SPI bursts. Multiple SPI bursts will be transmitted. The SPI transfer will automatically stop when the TXFIFO is empty. 0 In slave mode - an SPI burst is completed when the number of bits received in the shift register is equal to (BURST LENGTH + 1). Only the n least-significant bits (n = BURST LENGTH[4:0] + 1) of the first received word are valid. All bits subsequent to the first received word in RXFIFO are valid. 1 In slave mode - an SPI burst is completed by the Chip Select (SS) signal edges. (SSPOL = 0: rising edge; SSPOL = 1: falling edge) The RXFIFO is advanced whenever a Chip Select (SS) signal edge is detected or the shift register contains 32-bits of valid data.
7–4 SCLK POL	SPI Clock Polarity Control. This field controls the polarity of the SCLK signal. See Figure 22-10 for more information. SCLK POL[3] is for SPI channel 3. SCLK POL[2] is for SPI channel 2. SCLK POL[1] is for SPI channel 1. SCLK POL[0] is for SPI channel 0. 0 Active high polarity (0 = Idle). 1 Active low polarity (1 = Idle).
3–0 SCLK PHA	SPI Clock/Data Phase Control. This field controls the clock/data phase relationship. See Figure 22-10 for more information. SCLK PHA[3] is for SPI channel 3. SCLK PHA[2] is for SPI channel 2. SCLK PHA[1] is for SPI channel 1. SCLK PHA[0] is for SPI channel 0. 0 Phase 0 operation. 1 Phase 1 operation.

22.6.5 Interrupt Control Register (ECSPIx_INTREG)

The Interrupt Control Register (ECSPI_INTREG) enables the generation of interrupts to the host processor. If the ECSPI is disabled, this register reads zero.

Addresses: ECSPI-1_INTREG is 5001_0000h base + 10h offset = 5001_0010h

ECSPI-2_INTREG is 63FA_C000h base + 10h offset = 63FA_C010h



ECSPIx_INTREG field descriptions

Field	Description
31–8 -	Reserved
7 TCEN	Transfer Completed Interrupt enable. This bit enables the Transfer Completed Interrupt. 0 Disable 1 Enable
6 ROEN	RXFIFO Overflow Interrupt enable. This bit enables the RXFIFO Overflow Interrupt. 0 Disable 1 Enable
5 RFEN	RXFIFO Full Interrupt enable. This bit enables the RXFIFO Full Interrupt. 0 Disable 1 Enable
4 RDREN	RXFIFO Data Request Interrupt enable. This bit enables the RXFIFO Data Request Interrupt when the number of data entries in the RXFIFO is greater than RX THRESHOLD. 0 Disable 1 Enable
3 RREN	RXFIFO Ready Interrupt enable. This bit enables the RXFIFO Ready Interrupt. 0 Disable 1 Enable
2 TFEN	TXFIFO Full Interrupt enable. This bit enables the TXFIFO Full Interrupt. 0 Disable 1 Enable
1 TDREN	TXFIFO Data Request Interrupt enable. This bit enables the TXFIFO Data Request Interrupt when the number of data entries in the TXFIFO is less than or equal to TX THRESHOLD. 0 Disable 1 Enable
0 TEEN	TXFIFO Empty Interrupt enable. This bit enables the TXFIFO Empty Interrupt. 0 Disable 1 Enable

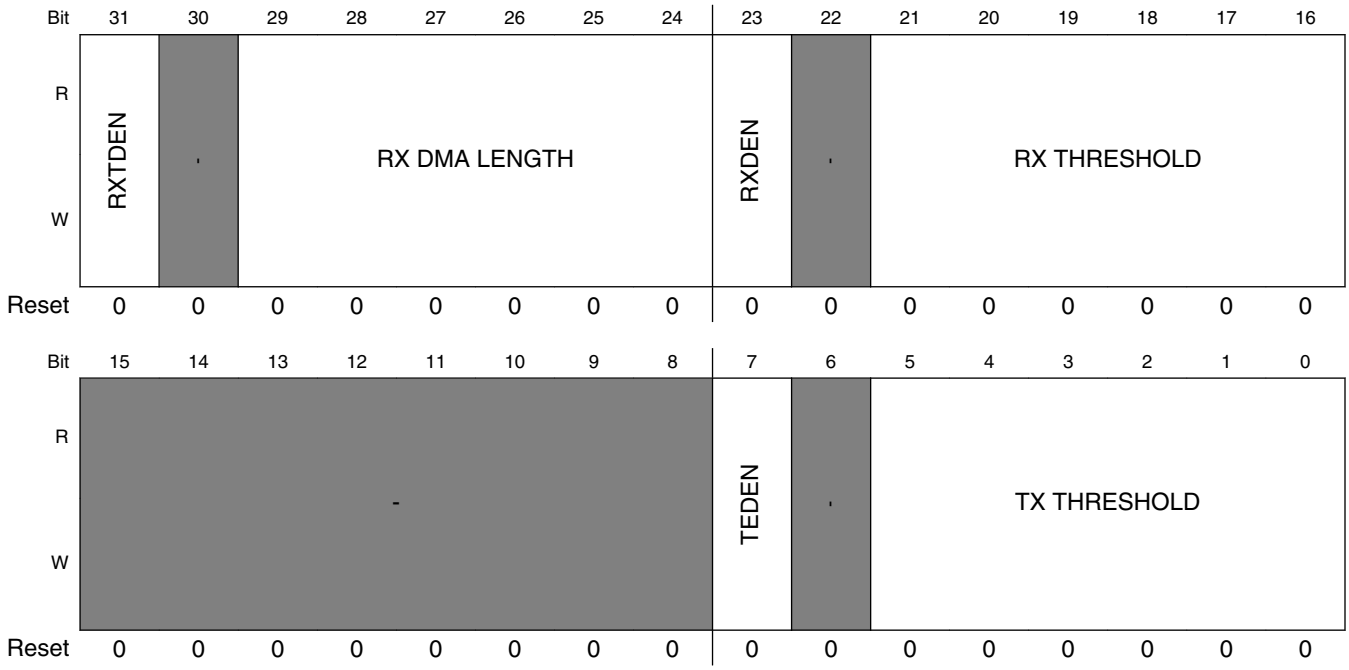
22.6.6 DMA Control Register (ECSPIx_DMAREG)

The Direct Memory Access Control Register (ECSPI_DMAREG) provides software a way to use an on-chip DMA controller for ECSPI data. Internal DMA request signals enable direct data transfers between the ECSPI FIFOs and system memory. The ECSPI sends out DMA requests when the appropriate FIFO conditions are matched.

If the ECSPI is disabled, this register is read as 0.

Addresses: ECSPI-1_DMAREG is 5001_0000h base + 14h offset = 5001_0014h

ECSPI-2_DMAREG is 63FA_C000h base + 14h offset = 63FA_C014h



ECSPIx_DMAREG field descriptions

Field	Description
31 RXTDEN	RXFIFO TAIL DMA Request Enable. This bit enables an internal counter that is increased at each read of the RXFIFO. This counter is cleared automatically when it reaches RX DMA LENGTH. If the number of words remaining in the RXFIFO is greater than or equal to RX DMA LENGTH, a DMA request is generated even if it is less than or equal to RX THRESHOLD. 0 Disable 1 Enable
30 -	Reserved
29–24 RX DMA LENGTH	RX DMA LENGTH. This field defines the burst length of a DMA operation. Applies only when RXTDEN is set.
23 RXDEN	RXFIFO DMA Request Enable. This bit enables/disables the RXFIFO DMA Request. 0 Disable 1 Enable
22 -	Reserved
21–16 RX THRESHOLD	RX THRESHOLD. This field defines the FIFO threshold that triggers a RX DMA/INT request. A RX DMA/INT request is issued when the number of data entries in the RXFIFO is greater than RX THRESHOLD.
15–8 -	Reserved
7 TEDEN	TXFIFO Empty DMA Request Enable. This bit enables/disables the TXFIFO Empty DMA Request.

Table continues on the next page...

ECSPIx_DMAREG field descriptions (continued)

Field	Description
	0 Disable 1 Enable
6 -	Reserved
5–0 TX THRESHOLD	TX THRESHOLD. This field defines the FIFO threshold that triggers a TX DMA/INT request. A TX DMA/INT request is issued when the number of data entries in the TXFIFO is greater than TX THRESHOLD.

22.6.7 Status Register (ECSPIx_STATREG)

The ECSPI Status Register (ECSPI_STATREG) reflects the status of the ECSPI's operating condition. If the ECSPI is disabled, this register reads 0x0000_0003.

Addresses: ECSPI-1_STATREG is 5001_0000h base + 18h offset = 5001_0018h

ECSPI-2_STATREG is 63FA_C000h base + 18h offset = 63FA_C018h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16

ECSPIx_STATREG field descriptions

Field	Description
31–8 -	Reserved
7 TC	Transfer Completed Status bit. Writing 1 to this bit clears it. 0 Transfer in progress. 1 Transfer completed.
6 RO	RXFIFO Overflow. When set, this bit indicates that RXFIFO has overflowed. Writing 1 to this bit clears it. 0 RXFIFO has no overflow. 1 RXFIFO has overflowed.
5 RF	RXFIFO Full. This bit is set when the RXFIFO is full. 0 Not Full. 1 Full.

Table continues on the next page...

ECSPIx_STATREG field descriptions (continued)

Field	Description
4 RDR	RXFIFO Data Request. 0 When RXTDE is set - Number of data entries in the RXFIFO is not greater than RX THRESHOLD. 1 When RXTDE is set - Number of data entries in the RXFIFO is greater than RX THRESHOLD or a DMA TAIL DMA condition exists. 0 When RXTDE is clear - Number of data entries in the RXFIFO is not greater than RX THRESHOLD. 1 When RXTDE is clear - Number of data entries in the RXFIFO is greater than RX THRESHOLD.
3 RR	RXFIFO Ready. This bit is set when one or more words are stored in the RXFIFO. 0 No valid data in RXFIFO. 1 More than 1 word in RXFIFO.
2 TF	TXFIFO Full. This bit is set when if the TXFIFO is full. 0 TXFIFO is not Full. 1 TXFIFO is Full.
1 TDR	TXFIFO Data Request. 0 Number of empty slots in TXFIFO is greater than TX THRESHOLD. 1 Number of empty slots in TXFIFO is not greater than TX THRESHOLD.
0 TE	TXFIFO Empty. This bit is set if the TXFIFO is empty. 0 TXFIFO contains one or more words. 1 TXFIFO is empty.

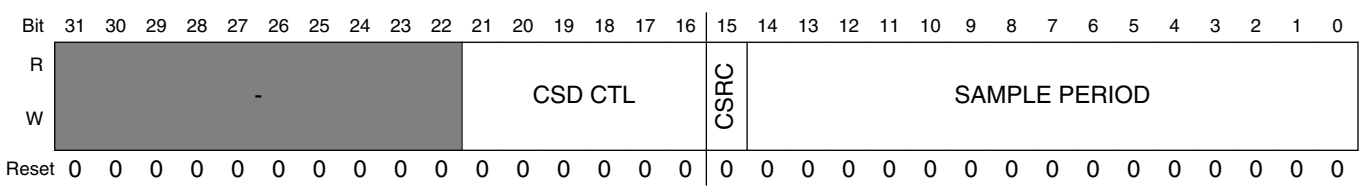
22.6.8 Sample Period Control Register (ECSPIx_PERIODREG)

The Sample Period Control Register (ECSPI_PERIODREG) provides software a way to insert delays (wait states) between consecutive SPI transfers. Control bits in this register select the clock source for the sample period counter and the delay count indicating the number of wait states to be inserted between data transfers.

The delay counts apply only when the current channel is operating in Master mode (ECSPI_CONREG[CHANNEL MODE] = 1).ECSPI_PERIODREG also contains the CSD CTRL field used to insert a delay between the Chip Select's active edge and the first SPI Clock edge.

Addresses: ECSPI-1_PERIODREG is 5001_0000h base + 1Ch offset = 5001_001Ch

ECSPI-2_PERIODREG is 63FA_C000h base + 1Ch offset = 63FA_C01Ch



ECSPIx_PERIODREG field descriptions

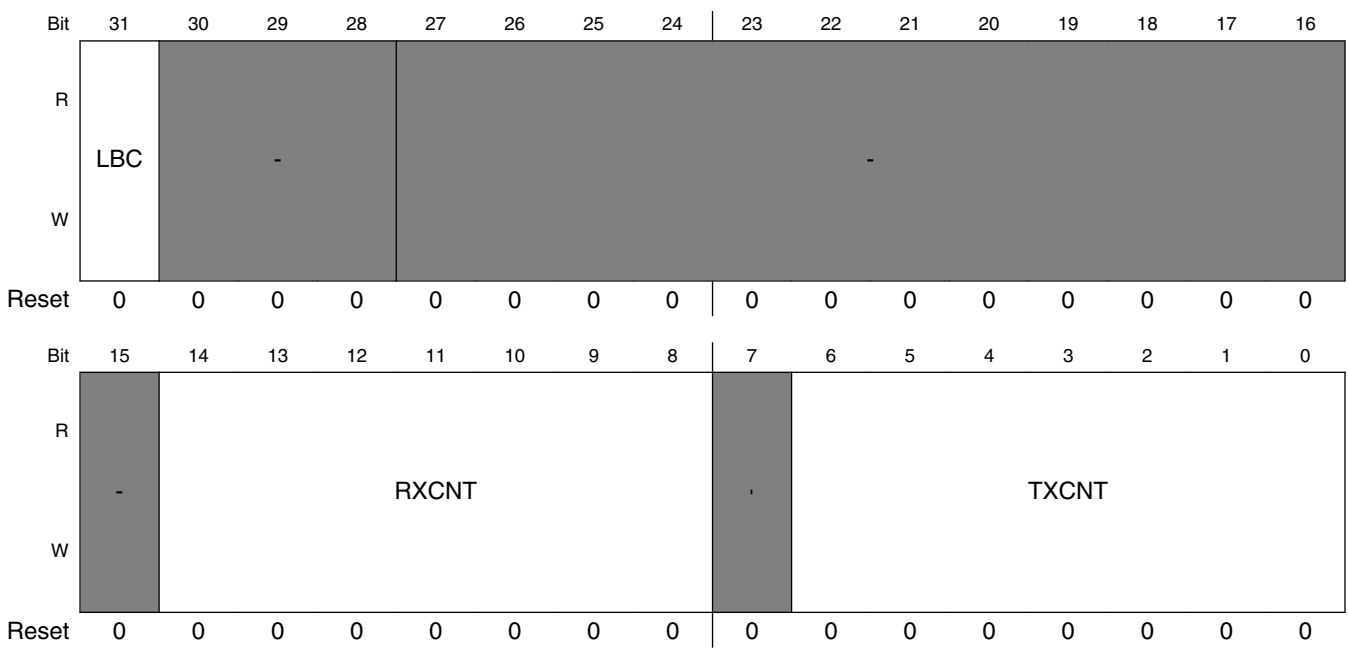
Field	Description
31–22 -	Reserved
21–16 CSD CTL	Chip Select Delay Control bits. This field defines how many SPI clocks will be inserted between the chip select's active edge and the first SPI clock edge. The range is from 0 to 63.
15 CSRC	Clock Source Control. This bit selects the clock source for the sample period counter. 0 SPI Clock (SCLK) 1 Low-Frequency Reference Clock (32.768 KHz)
14–0 SAMPLE PERIOD	Sample Period Control. These bits control the number of wait states to be inserted in data transfers. During the idle clocks, the state of the SS output will operate according to the SS_CTL control field in the ECSPI_CONREG register. 0x0000 0 wait states inserted 0x0001 1 wait state inserted ... ... 0x7FFE 32766 wait states inserted 0x7FFF 32767 wait states inserted

22.6.9 Test Control Register (ECSPIx_TESTREG)

The Test Control Register (ECSPI_TESTREG) provides software a mechanism to internally connect the receive and transmit devices of the ECSPI, and monitor the contents of the receive and transmit FIFOs.

Addresses: ECSPI-1_TESTREG is 5001_0000h base + 20h offset = 5001_0020h

ECSPI-2_TESTREG is 63FA_C000h base + 20h offset = 63FA_C020h



ECSPIx_TESTREG field descriptions

Field	Description
31 LBC	Loop Back Control. This bit is used in Master mode only. When this bit is set, the ECSPI connects the transmitter and receiver sections internally, and the data shifted out from the most-significant bit of the shift register is looped back into the least-significant bit of the Shift register. In this way, a self-test of the complete transmit/receive path can be made. The output pins are not affected, and the input pins are ignored. 0 Not connected. 1 Transmitter and receiver sections internally connected for Loopback.
30–28 -	Reserved, all bits should be ignored.
27–15 -	Reserved
14–8 RXCNT	RXFIFO Counter. This field indicates the number of words in the RXFIFO.
7 -	Reserved
6–0 TXCNT	TXFIFO Counter. This field indicates the number of words in the TXFIFO.

22.6.10 Message Data Register (ECSPIx_MSGDATA)

The Message Data Register (ECSPI_MSGDATA) forms the top word of the 16 x 32 MSG Data FIFO. Only word-size accesses are allowed for this register. Reads to this register return zero, and writes to this register store data in the MSG Data FIFO. See Hardware Trigger (HT) ModeIn hardware trigger (HT) mode, the behavior of the ECSPI is similar to master mode. The differences are in the trigger mechanism and the burst length. .

Addresses: ECSPI-1_MSGDATA is 5001_0000h base + 40h offset = 5001_0040h

ECSPI-2_MSGDATA is 63FA_C000h base + 40h offset = 63FA_C040h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

ECSPIx_MSGDATA field descriptions

Field	Description
31–0 ECSPI_ MSGDATA	ECSPI_MSGDATA holds the top word of MSG Data FIFO. The MSG Data FIFO is advanced for each write of this register. The data read is zero. The data written to this register is stored in the MSG Data FIFO.

Chapter 23
External Interface Module (EIM)

23.1 Overview

The EIM handles the interface to devices external to the chip, including generation of chip selects, clock and control for external peripherals and memory. It provides asynchronous access to devices with SRAM-like interface and synchronous access to devices with NOR-Flash-like or PSRAM-like interface.

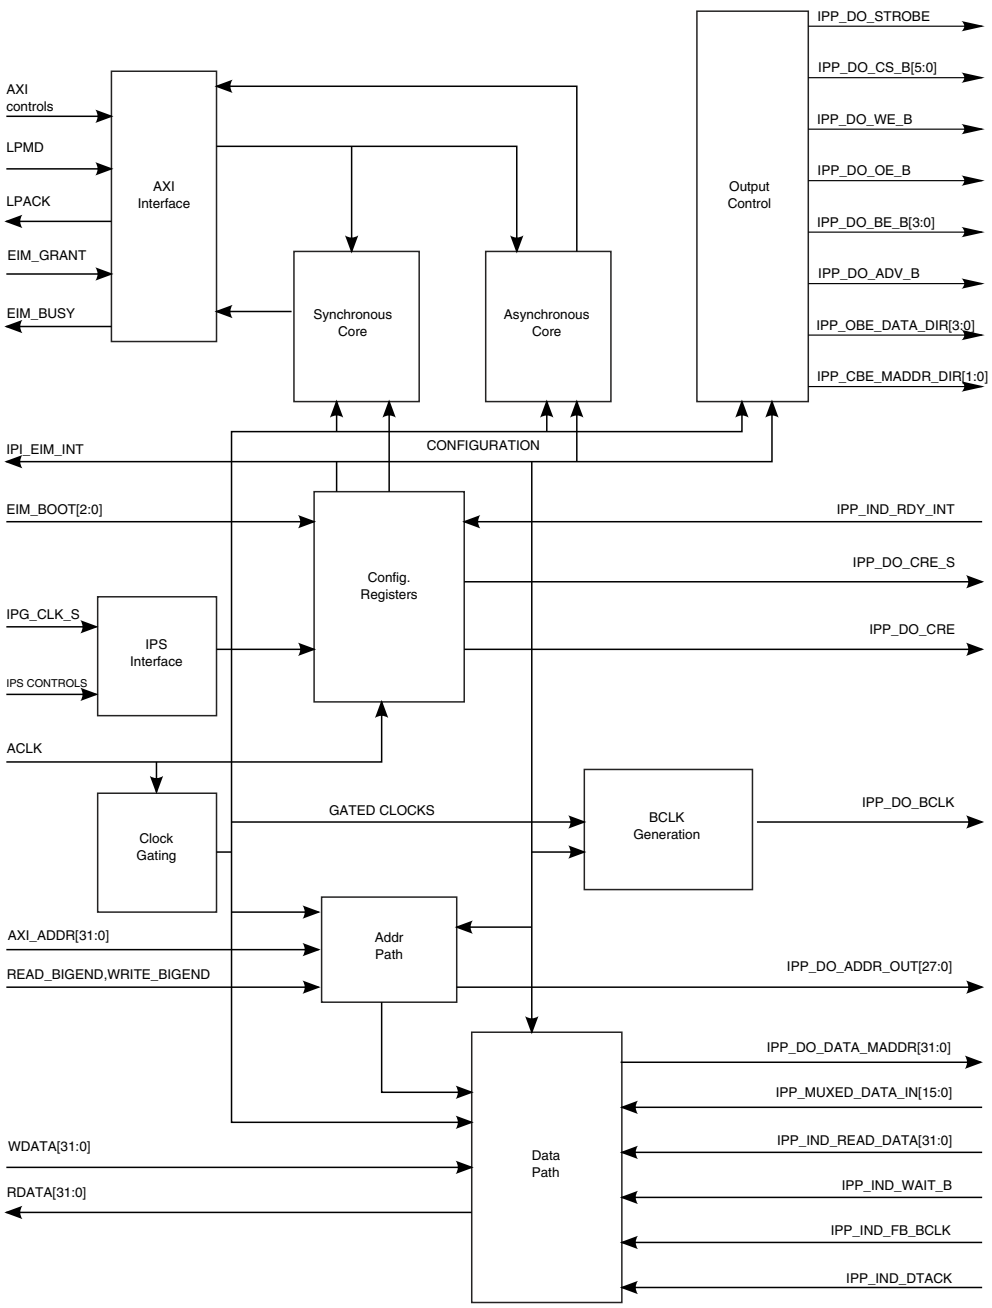

Figure 23-1. EIM Diagram

23.2 Features

- Up to four chip selects for external devices
  - Flexible address decoding. Each chip select memory space determined separately, according to VIA port configuration (see Chip Select Memory Map). Configurable Chip Select 0 base address (by VIA)
  - Individual select signal for each one of the memory space defined. Up to 6 memory spaces may be defined and programmed individually.
  - 28-bit external address bus, max memory size can be 256MByte (2 Gigabit).
- Selectable Write Protection for each Chip Select
- Support for multiplexed address / data bus operation x16 and x32 port size
- Programmable Data Port Size for each Chip Select (x8, x16 and x32)
- Programmable Wait-State generator for each Chip Select, for write and read accesses separately
- Asynchronous accesses with programmable setup and hold times for control signals
- Support for Asynchronous page mode accesses (x16 and x32 port size)
- Independent synchronous Memory Burst Read Mode support for NOR-Flash and PSRAM memories (x16 and x32 port size)
- Independent synchronous Memory Burst Write Mode support for PSRAM and NOR-Flash like memories (CellularRAM™ from Micron, Infineon, and Cypress, OneNAND™ and utRAM™ from Samsung, and COSMORAM™ from Toshiba)
- Support of NAND-Flash devices with NOR-Flash like interface - MDOC™ (M-Systems), OneNAND™ (Samsung)
- Independent programable variable/fix Latency support for read and write synchronous (burst) mode
- Support for Big Endian and Little Endian operation modes per access
- ARM AXI slave interface. One ID at a time support.
- External Interrupt support, RDY_INT signal function as external interrupt
- Boot from external device support according to boot signals, using RDY_INT signal
  - RDY signal support assertion after reset for MDOC™ (M-Systems) device
  - INT signal support assertion after reset for OneNAND™ (Samsung) device

23.3 Modes of Operation

The EIM has the following modes of operation:

- Asynchronous Mode
- Asynchronous Page Mode
- Multiplexed Address/Data mode

- Burst Clock Mode
- Low Power Modes
- Boot Mode

See details in the EIM Operational Modes.

23.3.1 Asynchronous Mode

This is a non-burst mode that is used for SRAM access. In this mode, a single data is read/written with each access (asserted address).

All controls' timings are controlled by preset values in Chip Select Configuration Registers.

23.3.2 Asynchronous Page Read Mode

Setting the APR bit causes the EIM to perform memory burst accesses by emulating page mode operation.

The external address asserts for each piece of data. The initial access timing is according to RWSC field, and the next address assertions timing is according to PAT field. When APR bit is set, RCSN OEN, RADVN and RBEN fields are ignored for burst access to the external device.

The page size can be set via the BL field to 2, 4, 8, 16, or 32 words (the word size is determined by the DSZ field).

23.3.3 Multiplexed Address/Data Mode

In this mode, multiplexing addresses and data bits on the same pins is supported for synchronous/asynchronous accesses to x8/x16/ x32 data width memory devices.

For more information about the pins that drive data/address in 8/16/32 non-muxed mode and 16/32 muxed mode, refer to the EIM Internal Module Multiplexing table in the EIM Internal Pads Allocation chapter of the datasheet.

Table 23-1. EIM multiplexing

Setup	Non Multiplexed Address/Data Mode						Multiplexed Address/ Data mode	
	8 Bit			16 Bit		32 Bit	16 Bit	32 Bit
	MUM = 0, DSZ = 100	MUM = 0, DSZ = 101	MUM = 0, DSZ = 111	MUM = 0, DSZ = 001	MUM = 0, DSZ = 010	MUM = 0, DSZ = 011	MUM = 1, DSZ = 001	MUM = 1, DSZ = 011

23.3.4 Burst Clock Mode

The controller has the ability to support a burst synchronous operations in a various frequencies, depending on the frequency of the input clock supplied by the system (EIM clock).

The EIM clock can be divided by one, two, three or four, and its frequency can be changed according to the requirements. Variable and fix latency are supported for this mode, according to the external device requirements.

- Synchronous read mode. This is a burst mode, which is used for reading from Flash/ PSRAM memory devices. In this mode, after address assertion a burst of sequential data can be read. Data exchange is carried out according to BCLK being generated by EIM. An access is delayed according to external WAIT_B signal assertion (signal from the memory device).
- Synchronous write mode. A burst mode used for accessing external devices, which support synchronous write type of access (PSRAM protocol). In this mode, after

address assertion a burst of sequential data can be written to the external device. Access may be delayed according to WAIT_B signal assertion (signal from the memory device) before first piece of data arrived to the external device.

NOTE

Maximum frequency of the EIM main clock is 133Mhz. It may be reduced by the system for special cases of external devices, which demand a different frequency then integer division of the 133MHz clock.

23.3.5 Low Power Modes

The Input Clock is gated by ACT_CS bits. When all the ACT_CS are negated (all CS disable) the internal clock is turned off; awready/wready & arready signal are de-asserted and the master can't access the EIM.

23.3.6 Boot Mode

It is possible to perform a boot operation from external device located on CS0. The configuration of the relevant bits are done with boot Mode signals according to the external device parameters (for example, port size and protocol assertion).

See System Boot for more details.

Table 23-2. EIM Boot configuration

EIM_BOOT bits	EIM affected bits	EIM Register	Boot Value
2	MUM OEA	EIM_CS0GCR1 EIM_CS0RCR1	Configurable by fuses; If SRC.SBMR[BOOT_CFG2[7:6]] = 0b00, value = 0x100 If SRC.SBMR[BOOT_CFG2[7:6]] = 0b00, value = 0x010

23.4 External Signal Description

23.4.1 Signals Overview

Table 23-3. Block I/Os

Name	Function	Input / Output	Notes
WEIM_A[27:16]	Address Bus MSB	Output	
WEIM_DA[15:0]	Address/Data Bus LSB	I/O	NFC data lines can be multiplexed on these lines as well
WEIM_BCLK	Burst Clock	Output	
WEIM_CRE	Memory Register Set	Output	
WEIM_CS[5:0]	Chip Selects	Output	
WEIM_DTACK_B	Data Acknowledge	Input	
WEIM_D[31:16]	Data MSB	I/O	
WEIM_EB[3:0]	Enable Byte Signals	Output	
WEIM_LBA	Load Burst Address	Output	
WEIM_OE	Output Enable	Output	
WEIM_RW	Read/Write	Output	
WEIM_WAIT	Memory Ready/Busy/Wait	Input	

23.4.2 Detailed Signal Descriptions

The following is a detailed description of the EIM signals mentioned in Table 23-3.

Table 23-4. Block I/O Descriptions

Name	I/O	Description
WEIM_A[27:16]	O	MSB Address Bus
WEIM_DA[15:0]	I/O	LSB multiplexed Address/Data Bus
WEIM_BCLK	O	Burst Clock (BCLK). This active-high output signal is used to clock external burst-capable devices to synchronize the loading and incrementing of addresses and delivery of burst read and write data to/from the EIM. Its behavior is affected by the BCM field in the EIM_WCR and the SWR, SRD, BCD, and BCS fields of the EIM_CSxGCR1.
WEIM_CRE	O	Used as CRE/PS for CellularRam memory. It is used for the Mode Register Set command. This signal can be configured as active low or active high. See CRE and CREP field descriptions of the EIM_CS*x*GCR1 registers.
WEIM_CS[5:0]	O	Chip Selects. These signals are active-low. Behavior is affected by the RCSA and RCSN fields of the EIM_CSxRCR1 registers and the WCSA and WCSN fields of the EIM_CSxWCR1registers.
WEIM_DTACK_B	I	Data Acknowledge, asynchronous access. This input is used as a data acknowledge signal for single asynchronous accesses.
WEIM_D[31:16]	I/O	MSB Data Bus

Table continues on the next page...

Table 23-4. Block I/O Descriptions (continued)

Name	I/O	Description
WEIM_EB[3:0]	O	Byte Enable. These active-low output signals indicate valid data bytes for the current access. They may be configured to assert for write cycles only. EIM_EB[0] corresponds to DATA_OUT[7:0] EIM_EB[1] corresponds to DATA_OUT[15:8] EIM_EB[2] corresponds to DATA_OUT[23:16] EIM_EB[3] corresponds to DATA_OUT[31:24]. For asynchronous write accesses, behavior is affected by the WBEA and WBEN fields of the EIM_CS1WCR1-EIM_CS5WCR1 Registers. On synchronous or asynchronous read accesses, these signals are always asserted at the start of the access and negated at end of the access.
WEIM_LBA	O	Address Valid. This active-low output signal is asserted during burst mode accesses to cause the external burst capable device to load a new starting burst address. Assertion of LBA indicates that a valid address is present on the address bus. Its behavior is affected by the SWR, SRD, BCD, and BCS fields of the EIM_CSxGCR1 registers, the RADVA and RADVN fields of the EIM_CSxRCR1 registers, and the WADVA and WADVN fields of the EIM_CSxWCR1 registers. In asynchronous mode, LBA length is affected by the RADVA, WADVA, RADVN, and WADVN fields. Minimum length of LBA signal in all modes is one EIM clock cycle.
WEIM_OE	O	Output Enable. This active-low output signal indicates the bus access is a read and enables external devices to drive the data bus with read data. Its behavior is affected by the OEA and OEN bit fields in the Chip Select Configuration Registers.
WEIM_RW	O	Memory Write Enable. This active-low output signal indicates the bus access is a write and enables external devices to sample the data bus. Its behavior is affected by the WEA and WEN bit fields in the Chip Select Configuration Registers.
WEIM_WAIT	I	Ready/Busy/Wait signal. This active-low input signal is asserted by external burst capable devices which support fixed or variable latency of data. It is serviced in synchronous mode only (EIM_CSxGCR1[SWR, SRD] =1). WAIT will have a pull up resistor in I/O. The signal indicates whether the External device is ready for data transaction or not. Busy cycles (or wait cycles) of the external device can occur at the start of a Burst access or at page boundary crossover. **NOTE:** For burst devices, WAIT output should be configured to change one cycle before data is ready (before delay). **NOTE:** Some External devices may not use this input signal for ready state indication (fix latency without WAIT signal monitoring). For these devices EIM should be configured accordingly (see RFL, WFL, and PSZ field descriptions). **NOTE:** This is same as what is shown in IP_IND_WAIT_B

23.4.3 Other Important Block I/O Signals Internal to the SoC

The following table provides a description of other signals which are internal to the i.MX50 that are important to understand the function of EIM.

Name	I/O	Description
WEIM_FB_BCLK	Input	Burst Clock Feedback. This block input is used to sample read data during high transfer speeds. The signal provides feedback from the I/O pad of the BCLK output pin and tends to align more closely with data from the external memory device.
EIM_BOOT[2:0]	Input	EIM Boot Configuration. These block inputs determine the reset state of DSZ[1:0] and MUM. See Table 5-4 for detailed description.
ACLK	Input	AXI clock, maximum frequency 133 Mhz
IPG_CLK_S	Input	EIM module IPG clock
RST_B	Input	Active low HW reset
EIM_WARM_RESET	Input	Warm Reset. If this signal is asserted the rst_b will reset only the internal FF and state machine while S/W registers will keep their current state.This signal is active high signal.

23.5 Chip Select Memory Map

Table 23-6. EIM Chip Select Memory Map

Address	Space Size	Use	Access
EIM_NFC_BASE/ACT_CS/ADDRS0 inputs	0MB-256MB	CS0 memory region	R/W
ACT_CS/ADDRS1 inputs	0MB-256MB	CS1 memory region	R/W
ACT_CS/ADDRS2 inputs	0MB-256MB	CS2 memory region	R/W
ACT_CS/ADDRS3 inputs	0MB-256MB	CS3 memory region	R/W

23.6 Functional Description

This section provides the functional description for the EIM.

23.6.1 Clocks

The EIM has four input clocks.

- ACLK: EIM clock (main clock, AXI clock) with a Max frequency of 133Mhz. Can be gated externally when there is no active AXI access.
- ACLK_SLOW: EIM all time running ACLK. Used for FF that must be active even when EIM is in low power down mode to provide clock for lpack/lpmd registers, IP registers and IP to AXI sync registers.
- IPG_CLK_S: IPG clock for IP accesses. IP registers are activated by ACLK_SLOW clock. BCLK is a clock created from EIM clock for External device usage. Integer division by 1, 2, 3 and 4 of the clock can be use with BCD bit field configuration,

according to external devices demands. EIM clock frequency may be reduced for lower frequency support which cannot be achieved via BCD bit field.
- FB_CLK: BCLK after pads delays.

23.6.2 Bus Sizing Configuration

The EIM supports byte, half word and word operands allowing access to x8, x16, x32 ports. It can be address/data multiplexed in x16, x32 ports. The port size is programmable via the DSZ bit field in the corresponding Chip Select Configuration Register. An 8-bit port can reside in each one of the bytes of the data bus. A 16-bit port can reside on the lower 16 bits of the data bus, DATA_IN/OUT[15:0] or on the higher 16 bits of the data bus, DATA_IN/OUT[31:16] (see Table 23-1).

In the case of a multi-cycle transfer, the lower two address bits (ADDR[1:0]) are incremented appropriately. The EIM address bus is configured according to DSZ bit field and AUS bits. There is either one bit (for x16 port size) or two bits (for x32 port size) right shift of the address bits (only when AUS=0) and no bit shift when AUS = 1 or DSZ[2] = 1.

The EIM has a data multiplexer which takes the four bytes of the AXI data bus and routes them to their required positions to properly interface to memory.

NOTE

A word access to or from a x16 port requires two external bus cycles to complete the transfer.

A word access to or from a x8 port requires four external bus cycles to complete the transfer.

23.6.2.1 8 BIT PORT SUPPORT

EIM has limited support for mot68000 & intel 386 protocols.

23.6.2.1.1 MOTOROLA 68000

EIM has limited support for mot68000 protocol. Only basic read or write asynchronous operations are supported.

The following operations are not supported:

- Read modify write
- Sync access

- All special accesses (ARM platform space, bus arbitration, bus control, bus error & reset operations)
- FC outputs

23.6.2.1.2 INTEL 386

EIM has limited support for intel 386 protocol. Only basic read or write async non-pipelined operations are supported.

The following operations are not supported:

- Other bus cycles (interrupt, halt & refresh)
- Bus lock
- M/IO, DC, LBA, NA, REFRESH & BS8 signals

23.6.3 EIM Operational Modes

EIM has the following main operational modes selected by control bit fields settings. For details, see the bit field descriptions of SWR / SRD / MUM. All modes are supported in with 8-, 16- or 32-bit port configuration, according to DSZ bit field.

Table 23-7. EIM Operation Modes Field Settings

Control bit fields			Brief mode description
MUM	SRD	SWR	
0	0	0	Asynchronous write / Asynchronous read for APR=0 / Asynchronous page read for APR=1, none multiplexed
		1	Synchronous write/ Asynchronous read or APR=0 / Asynchronous page read for APR=1,none multiplexed
	1	0	Asynchronous write/Synchronous read none multiplexed
		1	Synchronous write/read none multiplexed
1	0	0	Asynchronous write/read multiplexed
		1	Synchronous write/ Asynchronous read multiplexed
	1	0	Asynchronous write/Synchronous read multiplexed
		1	Synchronous write/read multiplexed

23.6.4 Burst Mode (Synchronous) Memory Operation

This mode is enabled for read or write access. Bit SWR sets the burst mode for write operations at the corresponding chip select and bit SRD sets it for read operation.

When this mode is set, the controller attempts to translate the Master burst accesses to memory burst accesses, being limited by the memory burst length, predefined by BL value, or memory and Master WRAP/INCR boundary crossing non-matching. Only the first address accessed is displayed by the controller on the external address bus in a memory burst sequence.

EIM may translate from some Master sequential accesses to one or few memory bursts, but not from two Master individual accesses to one memory burst.

For the first access in a memory burst sequence, the EIM asserts $\overline{\text{ADV}}$, causing the external burst device to latch the starting burst address; then toggle the burst clock (BCLK) a predefined number of cycles in order to latch the first unit of data. Subsequent accessed data units can then be burst in fewer clock cycles, realizing an overall increase in bus bandwidth.

NOTE

The BCLK signal toggles only when burst access is executed toward the external device (BCM=1'b0 for normal mode use). It runs with a 50% duty cycle until the end of access is reached. When access is terminated, BCLK stops toggling.

Memory burst accesses are terminated by the EIM whenever it detects the following:

- The specific burst length has executed completely (end of access)
- Write access - missing data in write buffer (Master is delaying the data transfer toward the EIM)
- Next sequential access crosses boundary with unequal condition (wrap/increment, burst length) on the Master and memory
- Current memory burst length reached

23.6.5 Burst Clock Divisor (BCD)

In some cases, it may be necessary to slow the external bus in relation to the internal bus to allow accesses to burst devices that have a maximum operating frequency less than the operating frequency of the internal bus.

The internal bus frequency can be divided by one, two, three or four for presentation on the external bus in burst mode operation.

To achieve frequency of BCLK other then an integer division, the cycle time of the EIM clock entering the controller must be changed accordingly.

By programming the BCD bit field to various values, two signals on the external bus are affected; $\overline{ADV}$ and BCLK. The $\overline{ADV}$ signal is asserted according to RADVA or WADVA bit fields programming, and is negated according to the formula mentioned in RADVN and WADVN bit fields description. The BCLK signal runs with a 50% duty cycle until the end of access is reached.

If BCM = 1, the BCLK runs at frequency according to GBCD bit field settings on every async memory access, regardless of the SWR and SRD bits configuration. Caution should be exercised when using BCM bit; GBCD bit field should be updated once and should not change when BCLK is toggling. The BCM bit is used mainly for system debug mode. It has no functional use of the EIM in normal mode.

23.6.6 Burst Clock Start (BCS)

In an effort to allow greater flexibility in achieving the minimum number of wait states on burst accesses, you can determine when you want the BCLK to start toggling after the start of access. This allows the BCLK to be skewed from point of data capture on the EIM clock by any number of EIM clock cycles.

Care must be exercised when setting BCS bit field in conjunction with the BCD and RWSC/WWSC bit fields. See the external timing diagrams in "Burst Memory Accesses Timing Diagrams" for examples of how to use the BCS, BCD and RWSC/WWSC bit fields together.

23.6.7 Multiplexed Address/Data Mode Support

The control bit MUM allows support memory with multiplexed address/data bus both in asynchronous and in synchronous modes.

Caution should be exercised for using OEA/WEA & ADH bit fields. They should be configured according to the external device requirements, as it determines the time point of end of address phase and start of data phase.

23.6.8 Mixed Master/Memory Burst Modes Support

To provide mixed sequential/wrap accesses with different length, EIM interprets burst signal and generate additional $\overline{ADV}$ signals whenever there appear unequal address or burst boundary crossing condition.

BL bit field is used to notify EIM about current memory burst and wrap condition for properly external address generation. In case of non-matching boundaries in both the memory and Master access, EIM starts a new memory burst access by updating address from Master on address bus and generating $\overline{\text{ADV}}$ signal.

23.6.9 AXI (Master) Bus Cycles Support

The EIM uses an ARM AXI slave interface. It has a 32-bit bus and supports one access (one ID) at a time. No out of order or parallel accesses are supported.

The following AXI protocol signals are not supported:

- AWLOCK
- AWCACHE
- ARLOCK
- ARCACHE

ARID bus is sampled when:

- new read access is valid on the read address channel and is reflected on the RID bus output toward the master.

AWID bus is sampled when:

- new write access is valid on the write address channel and is reflected on the WID/ BID bus output toward the master.

ARPROT and AWPROT signal are partially used. ARPROT[0] and AWPROT[0] bits are used for normal/privileged access detection. ARPROT[2:1] and AWPROT[2:1] are not used.

When sampling a valid access on both of the address channels, the read access will be performed first while write access is pending. After last data transfer completed, the pending write will be executed.

A new access may be executed one cycle after sampling a valid access on the read or write address channels. Assuming there is no current access (back to back) which can cause a recovery or end of access penalty cycles; for write access, data should be present at write buffer for fast execution.

NOTE

- Only 32-bit word size accesses are supported for burst mode accesses.
- Only 8-bit (1 byte), 16-bit (2 byte) and 32-bit (4 byte) word size supported for single access.

- Maximum number of burst length is 16.
- According to AXI protocol, burst access should not cross 4 KB blocks. In case EIM gets an access that crosses the 4 KB, memory address calculation is invalid.

AXI transfers shown in the table below are also supported. These AXI cycles will be translated into the necessary cycles on the memory side. For example, for optimal operation in case ARM cache is configured to 8 beat burst with wrap, a synchronous flash and cellular RAM memory should be configured in 16 word wrap burst mode when using a 16-bit data port, and in 8 word wrap burst mode when using a 32-bit data port. EIM uses BL bit field to support different memory configurations. The controller splits the transaction when needed in some cases. See Table 23-9.

Table 23-8. AXI Burst Cycles Supported

Burst Length - Number of data transfers	Burst size - Bytes in transfer	Burst type	Description
1	1	INCR	Single transfer
1	2	INCR	Single transfer
1	4	INCR	Single transfer
2	4	WRAP	2-beat wrapping burst
4	4	WRAP	4-beat wrapping burst
8	4	WRAP	8-beat wrapping burst
16	4	WRAP	16-beat wrapping burst
2	4	INCR	2-beat incrementing burst
3	4	INCR	3-beat incrementing burst
4	4	INCR	4-beat incrementing burst
5	4	INCR	5-beat incrementing burst
6	4	INCR	6-beat incrementing burst
7	4	INCR	7-beat incrementing burst
8	4	INCR	8-beat incrementing burst
9	4	INCR	9-beat incrementing burst
10	4	INCR	10-beat incrementing burst
11	4	INCR	11-beat incrementing burst
12	4	INCR	12-beat incrementing burst
13	4	INCR	13-beat incrementing burst
14	4	INCR	14-beat incrementing burst
15	4	INCR	15-beat incrementing burst
16	4	INCR	16-beat incrementing burst

Table 23-9. AXI to Memory Burst Splits Number

AXI Burst Type	Memory Burst Type Config.	# of accesses to X8 Memory Port size	# of accesses to X16 Memory Port size	# of accesses to X32 Memory Port size
INC16 Aligned Addr.	WRAP4	16	8	4
	Cont.	1	1	1

WRAP8 Unaligned Addr.	WRAP16	2 or 3	1	2
	Cont.	2	2	2

23.6.10 WAIT_B Signal, RWSC and WWSC bit fields Usage

Most of the external devices supporting burst mode for write or read accesses providing signal which indicates for data valid on the memory bus (a.k.a. handshake mode). For this mode, RFL and WFL bits should be cleared and RWSC/ WWSC bit fields indicate when the controller should start sampling this signal from the external device or, in other words, how many BCLK cycles should be masked.

For devices which are not using this signal or have a fixed latency ability, the RFL and WFL bits may be set for internal calculation regarding BCLK cycles penalty until data is valid (memory initial access time). For this mode, RWSC/ WWSC indicates when the data is ready for sampling by the controller (read access) or the external device (write access). There is separation between read and write accesses wait-state control. For read access, RWSC bit field is valid and WWSC bit field is ignored; for write access, WWSC is valid and RWSC is ignored.

23.6.11 IPS Register Interface

Access to the registers of the EIM, read or write, is made with IPS protocol signals. The system should avoid changing the registers while master/memory transaction is valid, as this can cause an unknown behavior of the controller.

Register access size is 32-bit as the register size definition, other size of access (byte or half word) is not supported.

23.6.12 MRS Set for PSRAM

Memory registers of PSRAM devices can be configured according to external signal, which indicates whether the access is to a memory array or memory register domain.

When the CRE bit is set, the following transactions to the external device will assert the CRE signal. The polarity of this signal is determined by the CREP bit for active low or active high assertion of the signal.

23.6.13 EIM Access Termination

EIM is monitoring the corresponding CSx control signal every time variable latency access or dtack access is performed toward the external device.

In variable latency accesses, the Watchdog Timer (WDOG-1) counts BCLK cycles. If it reaches the wdog_limit (according to the WDOG_LIMIT bit field in the WCR) before the device signals can drive/sample new data, the controller will terminate the access and generate an error response transfer toward the Master.

In dtack access, WDOG-1 counts ACLK cycles instead of BCLK and it reaches the wdog_limit before the device asserts the dtack signal, the controller will terminate the access and generate an error response transfer toward the Master.

WDOG-1 can by disabled by WDOG_EN bit in the WCR.

23.6.14 Error Conditions

The following conditions cause an error (AXI error or IPS error) response signal:

- AXI errors
  - Access to a disabled chip select - access to a mapped chip select address space where the CSEN bit in the corresponding chip select Configuration Register is clear

- Access to a non mapped address - access to an address that is not mapped to any CS.
- User access to a supervisor-protected chip select address space (the SP bit in the corresponding chip select Configuration Register is set)
- User access in fixed mode access
- User preform write access to write protected chip select
- First write data ID and write address ID do not match. (No data is written to the memory.)
- First Write Data ID and write address ID match but one or more of the other Write data IDs does not match the First Write data ID (data is written to memory according)
- Access duration to external device from CSx signal assertion is 128/256/512/1024 cycles (access is terminated by the controller) - This error can be disabled be software.

- IPS errors
  - User read or write access to a reserved/non-valid address in the EIM Configuration Register

23.6.15 DTACK Mode

In DTACK mode, the EIM uses DTACK signal as an indication of when to end the access.

DTACK is an asynchronous edge/level sensitive signal. DTACK polarity is configurable by the DAP bit in CsxGCR2 (default value is 0).

In this case, EIM begins the access and after a few cycles (according DAPS field) and waits until DTACK (after synchronization) becomes asserted, then samples the data in read access and completes the current data access (see Figure 23-13, Figure 23-14 & Figure 23-15).

If more than one data is needed, CS will be negated between access (csrec field is not zero) and the AXI burst access will be split into single accesses (see Figure 23-17).

23.6.16 RDY_INT Signal as Interrupt

The EIM has an external interrupt support. When INTEN bit in the WCR is set, signal RDY_INT is used as interrupt; its status is being reflected by INT bit and output signal.

It is cleared by writing one to the INT bit. When INTEN is cleared, the interrupt is disabled. This interrupt is a level interrupt and its polarity can be configured by the INTPOL bit in the WCR.

23.6.17 RDY_INT Signal as Ready After Reset Indication

This feature is used for boot propose from external devices based on NANDFlash array memory with NORFlash interface.

When ERRST bit is set, RDY_INT signal is monitored to determine ready after reset of the external device located on CS0.

The monitoring is taking place when CS0 is accessed for the first time. The access will be pending until assertion of the signal is detected. When detection occurs, ERRST bit is self-cleared and pending access is executed to the external device on CS0.

23.6.18 EIM_GRANT / EIM_BUSY Handshake Description

Prior to executing command to one of the external device (chip select), EIM assert EIM_BUSY signal (1'b1) and checks the EIM_GRANT signal status.

If EIM_GRANT signal is high, it indicates external data bus is not used by other slaves (NAND Flash Controller) and EIM may start to execute the access. If EIM_GRANT is low, EIM waits until it is set (1'b1) before executing the access.

EIM keeps EIM_BUSY signal set until it completes the access toward the external device.

Once EIM_GRANT signal is set, it can not be reset until EIM_BUSY signal is cleared by EIM.

NOTE

In 16-bit Muxed EIM doesn't use the data bus, therefore there is no sharing of the data bus with NFC. EIM doesn't wait for EIM_GRANT signal from NFC and doesn't assert the EIM_BUSY signal.

23.6.19 LPMD / LPACK Handshake Description

These signals are used for frequency and/or voltage change, and for entering low power mode during normal operation of the EIM. Before any change can take place, the controller and all the relevant external devices should be in idle state, which means no access or data transfer is in process.

LPMD input signal is asserted once EIM detects the assertion of LPMD, all ready signals of the AXI channels are negated, and EIM is not sampling new accesses. It finishes all the ongoing accesses and already pending ones. When EIM is in idle state, the LPACK output signal is asserted. EIM will stay in idle state and the LPACK signal will stay asserted until the LPMD signal is negated.

23.6.20 Endianness

Big and Little endianness are supported by the controller according to the following table.

Table 23-10. EIM Out/in Data in Case AXI Out/in Data is 0xB3B2B1B0

Endian mode	AXI access	AXI address [1:0]	Port size and used bits								
			Word port				Half word port			Byte port	
			[31:24]	[23:16]	[15:8]	[7:0]	External address [0]	[31:24] ([15:8])	[23:16] ([7:0])	External address [1:0]	[31:24] ([23:16]) ([15:8]) ([7:0])
Big	Word	0	0xB3	0xB2	0xB1	0xB0	0	0xB3	0xB2	0	0xB3
										1	0xB2
							1	0xB1	0xB0	2	0xB1

		2		0xB2			1		0xB2	2	0xB2
		3	0xB3					0xB3		3	0xB3

23.6.21 Strobe Signal Use

The strobe signal is toggling according to address/data valid condition on the external bus for read and write accesses, and for both synchronous and asynchronous modes.

At any time point when address/data is valid on the external bus, the strobe signal will generate a positive edge, which can be used to sample the external data and control signal.

NOTE

Strobe signal for read data is active (RL + 1) cycles after data on external bus is valid.

23.7 Initialization Information

23.7.1 Active Chip Selects and Address Space Configuration

Each chip select activation is set using VIA port configuration.

Refer to the SoC chapter for the specific EIM chip select configuration.

Chip select is determine when the corresponding bit of the ACT_CS[5:0] input is set to one, else it is in none active state.

Each one of the four chip selects address space can be determined by ADDRS0[1:0] through ADDRS5[1:0] EIM inputs. The Minimum address space size per chip select is 32MByte, maximum size is 256MByte. Overall address space for all chip select is 512MByte. Base address is {EIM_NFC_BASE,28'h0}, topmost base address is CS0 base address + 0x1FFFFFFF.

Address space order is determined from the largest space on CS0 to the smallest one on CS3. Not all the chip selects must be used (determined by the active bit per CS inputs). Equal size for several chip selects may apply. It is the user's responsibility to ensure the total space size configured is within the 512 MByte dedicated to the EIM.

NOTE

If the total address space is smaller then 512MByte, it is referred as reserved space and can not be used.

Table 23-11. Examples of Address Space Configuration

chip select #	Exmple1	Exmple2	Exmple3	Exmple4
CS0	256 MByte	128 MByte	128 MByte	256 MByte
CS1	128 MByte	128 MByte	64 MByte	64 MByte
CS2	64 MByte	128 MByte	64 MByte	64 MByte
CS3	64 Mbyte	64 Mbyte	32 Mbyte	32 Mbyte

The address space is set with the matching ADDRSx[1:0] input bus according to the table below.

Table 23-12. Address Space Configuration

ADDRSx[1:0]	Size
2'b00	32 MByte
2'b01	64 MByte
2'b10	128 MByte
2'b11	256 Mbyte

23.7.2 Booting from EIM

EIM is ready to work with CS0 after the hardware reset, but it has been configured for very slow access (for boot purposes), with additional setup and hold time.

Other CSs are disabled by hardware reset. Therefore, all CSs must be properly initialized before use in writing values to the corresponding chip select configuration registers.

DSZ[1:0] and MUM fields are set according to EIM_BOOT [2:0] block inputs.

23.8 Application Note

Application note uses next functions to illustrate EIM and memory accesses:

- WR16(address, data) is a 16 bit write access
- WR32(address, data) is a 32 bit write access
- RD16(address, data) is a 16 bit read access
- RD32(address, data) is a 32 bit read access
- WR_I(address, data, delta, counter) is a write data sequence, there data(i+1) = data(i) + delta
- COMMAND_SEQUENCE as described on page 1-53
- CHECK_STATUS as described on page 1-53

All addresses are byte address. 'CS0 is a Chip Select 0 base address. 'EIM_ is a prefix of EIM's registers. 'h is a prefix of hexadecimal constant. // is a comment beginning. csba[cs] is a dimension of CS base addresses. "addr" means an address offset in current CS address space. Examples use CS0 address space, but it may be any except boot mode functionality.

Configuration examples were checked with some below defined memory models and may require some adjustment for other family members.

23.8.1 Access to AMD Flash

Below mentioned configurations intended for AMD Simultaneous Flash Memory w/ VersatileIO^{TM} Control.

23.8.1.1 AMD Flash Asynchronous Mode Configuration

Next EIM register configuration used for AMD flash asynchronous access:

- WR32('EIM_CS0RCR1,'h0a018000);

- WR32('EIM_CS0WCR1,'h0704a240);
- WR32('EIM_CS0GCR1,'h00430081); // for 32 bit memory or
- WR32('EIM_CS0GCR1,'h00410081); // for 16 bit memory

23.8.1.2 AMD Flash Utility

```
       // Single data word programming to addr, 32-bit memory
           port_size = 32;
           WR32('CS0+('h0555<<2),'h00aa); // command sequence
           WR32('CS0+('h02aa<<2),'h0055);
           WR32('CS0+('h0555<<2),'ha0); // command code
           WR32('CS0+addr, data); // addr & data
// Polling end of programming
          edata = data; // expected data
          data = ~edata;
          errst = 0;
      while(!(data == edata) &&!errst)
             begin: BR_EN
             RD16('CS0+addr, data);          // Read status
             if(data[7]!== edata[7])
                begin
                if(data[5] == 1)
                    begin
                    RD16('CS0+addr, data3);
                    RD16('CS0+addr, data);
                    if(data[6] !== data3[6])
                        begin
                        $display("CHECK_STATUS: Error timout on single data program");
                        errst = 1;
                        disable BR_EN;
                        end
                    end
               end
             else
                begin
                RD16('CS0+addr, data3);
                if(port_size == 32)
                    RD32('CS0+addr, data);
                else
                    begin
                    RD16('CS0+addr, data);
                    edata[31:16] = 16'h0;
                    end
                if(data !== edata)
                    begin
                    $display("CHECK_STATUS: Error in data write on single data program");
                      errst =2;
                    disable BR_EN;
                    end
                end
             end
      // Single data word programming to addr, 16-bit memory
          port_size = 16;
          WR32('CS0+('h0555<<1),'h00aa); // command sequence
          WR32('CS0+('h02aa<<1),'h0055);
          WR32('CS0+('h0555<<1),'ha0); // commund code
          WR32('CS0+addr, data); // addr & data
      // Polling end of programming - the same as for 32 bit
```

23.8.2 Access to Intel Sibley Flash

Below mentioned configurations intended to Sibley family muxed and non-muxed devices.

23.8.2.1 Intel Sibley Flash Asynchronous Mode Configuration

- WR32('EIM_CS0GCR1,'h00210081);
- WR32('EIM_CS0RCR1,'h0e020000);
- WR32('EIM_CS0RCR2,'h00000000);
- WR32('EIM_CS0WCR1,'h0704a040);

23.8.2.2 Intel Sibley Flash Synchronous Mode Configuration

Next configuration used for 133 MHz synchronous access to flash:

```
// Set memory to synchronous read mode
     WR16('CS0+('h5903<<1),'h0060);
     WR16('CS0+('h5903<<1),'h0003);
     WR16('CS0+('h0000<<1),'h00ff);
// Set EIM configuration to synchronous timing
     WR32('EIM_CS0GCR1,'h50214225);                    // 133 MHz
     WR32('EIM_CS0RCR1,'h0c000000);                    // 12 cycles on memory
```

Next configuration used for 66 MHz synchronous access to muxed flash:

```
// Set memory to synchronous read mode
     WR16('CS0+('h3103<<1),'h0060);
     WR16('CS0+('h3103<<1),'h0003);
     WR16('CS0+('h0000<<1),'h00ff);
//-------------------------------------------------------------------------
// Set EIM configuration to synchronous timing
     WR32('EIM_CS0GCR1,'h5021122d);                    // 66 MHz
     WR32('EIM_CS0RCR1,'h07000000);                    // 7cycles on memory
```

23.8.2.3 Intel Sibley Flash Utility

```
// Single data word programming to addr
     WR16('CS0+addr,'h0060);                 // Unlock
     WR16('CS0+addr,'h00d0);
     WR16('CS0+addr, 'h0041);
     WR16('CS0+addr, data);
     WR16('CS0+caddr, 'h0070);                 // Read Status command
     while('CS0+data[7] == 0)                                  // Wait / Polling
         RD16('CS0+addr, data);              // Read status
     RD16('CS0+addr, data);                  // Read status
     WR16('CS0+'h0000,'h00ff);
// Write buffer programming
     WR16('CS0+addr,'h0060);                 // Unlock
     WR16('CS0+addr,'h00d0);
     data    = 0;
     WR16('CS0+addr, 'h0070);                // Read Status command
     while(data[7] == 0)                           // Wait
         RD16('CS0+addr, data);              // Read status
```

```
WR16('CS0+'h0000,'h00ff);
           WR16('CS0+addr,'h00e9);           // Write Buffer command
           WR16('CS0+addr,255);              // Word counter (<256)
           for(i=0; i<'h200; i = i + 'h40)
              WR_I('CS0+addr+i, data+((i>2)*'h0010_0001), 'h0010_0001, 16); // Data
           WR16('CS0+addr,'h00d0);           // Write Confirm command
           data  = 0;
           while(data[7] == 0)                      // Wait
              RD16('CS0+addr, data);         // Read status
           RD16('CS0+addr, data);            // Read status
           WR16('CS0+'h0000,'h00ff);
```

23.8.3 Access to MDOC Device

Below mentioned configurations intended to MDOC H3 device.

23.8.3.1 MDOC Device Boot

To boot from the MDOC device the ERRST bit should be configured to 1, so that EIM will hold the first read access to CS0 until the MDOC asserts the RDY signal.

23.8.3.2 MDOC Device Asynchronous Mode Configuration

```
// Non-muxed mode
WR32('EIM_CS0GCR1,'h00410081);
WR32('EIM_CS0RCR1,'h0e121010);
WR32('EIM_CS0RCR2,'h00000000);
WR32('EIM_CS0WCR1,'h12092492);
// Muxed mode
WR32('EIM_CS0GCR1,'h00410081);
WR32('EIM_CS0RCR1,'h0e121010);
WR32('EIM_CS0RCR2,'h00000000);
WR32('EIM_CS0WCR1,'h12092492);
```

23.8.3.3 MDOC Device Utility

```
// Read Manufacturer ID and Device ID
    RE16('CS0+'h9400,'h4833);
    RE16('CS0+'h9422,'hb7cc);
```

23.8.4 Access to Micron PSRAM

Below mentioned configurations intended to mt45w4mw16bfb_706.

23.8.4.1 Micron PSRAM Asynchronous Mode Configuration

```
// 16 bit memory
    WR32('EIM_CS0GCR1,'h403104b1);
    WR32('EIM_CS0RCR1,'h0b010000);
    WR32('EIM_CS0RCR2,'h00000008);
    WR32('EIM_CS0WCR1,'h0b040040);
// 32 bit memory
    WR32('EIM_CS0GCR1,'h403304b1);
    WR32('EIM_CS0RCR1,'h0f010000);
    WR32('EIM_CS0RCR2,'h00000008);
    WR32('EIM_CS0WCR1,'h0f040040);
```

23.8.4.2 Micron PSRAM Synchronous Mode Configuration

```
// 16 bit memory
    WR32('EIM_CS0GCR1,'h403104b1);
    WR32('EIM_CS0WCR1,'h0b040000);
    WR16('CS0+('h85947<<1),'h0040); // memory configuration
    WR32('EIM_CS0GCR1,'h4021_5487);// fixed latency memory wrap 4
    WR32('EIM_CS0RCR1,'h04000000);
    WR32('EIM_CS0RCR2,'h00000008);
    WR32('EIM_CS0WCR1,'h04000000);
// 32 bit memory
    WR32('EIM_CS0GCR1,'h6003_04f1);
    WR32('EIM_CS0WCR1,'h0b04_0000);
    WR32('CS0+('h85947<<2),'h0040); // memory configuration
    WR32('EIM_CS0GCR1,'h4003_1487); // var latency memory inc. page size 128
    WR32('EIM_CS0RCR1,'h04000000);
    WR32('EIM_CS0RCR2,'h00000008);
    WR32('EIM_CS0WCR1,'h04000000);
```

23.8.5 Access to Samsung OneNAND

Mentioned below are the configurations intended for Samsung OneNAND muxed and non-muxed devices.

23.8.5.1 Samsung OneNAND Boot

There are two ways to boot from Samsung OneNAND. In the first way, the ERRST bit is set to 0 and the user has to poll the interrupt status in the OneNAND interrupt register (or set interrupt handler there). In the second way, the ERRST bit is set to 1 and the user should enable the device interrupt output before the first read from CS0 access is issued.

Load sectors 2,3 to DataRAM, page 0 done in the next example:

- WR16('CS0+('hF241<<1),'h0); // Clear interrupt status
- WR16('CS0+('hF100<<1),'h0); // block[8:0] address
- WR16('CS0+('hF107<<1),'h2); // sector[1:0] and page[7:2] addresses
- WR16('CS0+('hF200<<1),'h802); // buffer[11:8] address and counter[1:0]

- WR16('CS0+('hF101<<1),'h0); // DDP choose
- WR16('CS0+('hF220<<1),'h0); // Set command

23.8.5.2 Samsung OneNAND Asynchronous Mode Configuration

```
// Non-muxed memory
    WR32('EIM_CS0GCR1,'h00410081);
    WR32('EIM_CS0RCR1,'h0b010000);
    WR32('EIM_CS0RCR2,'h00000000);
    WR32('EIM_CS0WCR1,'h0c092480);
// Muxed memory
    WR32('EIM_CS0GCR1,'h00410089);
    WR32('EIM_CS0RCR1,'h0b010000);
    WR32('EIM_CS0RCR2,'h00000000);
    WR32('EIM_CS0WCR1,'h0c092480);
```

23.8.5.3 Samsung OneNAND Synchronous Mode Configuration

Set memory and EIM to synchronous read mode is shown in the next example:

```
    WR16('CS0+('hF221<<1),'hc0e0); // Synchronous read, 4 clk latency
    WR32('EIM_CS0GCR1,'h50412405); // 44 MHz (non-muxed)
    WR32('EIM_CS0RCR1,'h05010000);
```

The muxed Samsung OneNAND supports synchronous write, too:

```
// Set memory & EIM to synchronous read and write mode
    WR16('CS0+('hF221<<1),'hc0f2); // Sync. read and write, 4 clk latency
    WR32('EIM_CS0GCR1,'h5041240f); // 44 MHz
    WR32('EIM_CS0RCR1,'h05010000);
    WR32('EIM_CS0WCR1,'h05040000);
```

23.8.5.4 Samsung OneNAND Utility

The following utility algorithms are used on the Samsung OneNAND:

```
// Unlock Block command
    WR16('CS0+('hF100<<1),'h0);        // DFS
    WR16('CS0+('hF100<<1),'h0);        // DBS
    WR16('CS0+('hF24c<<1),'h2);        // SBA - block number (2)
    WR16('CS0+('hF241<<1),'h0);        // Clear interrupt status
    WR16('CS0+('hF220<<1),'h23);       // Unlock command
    data ='h0;
    while(!(data &'h0004))             // Polling
       RD32('WIAR, data); // Read status
// Erase block command
    WR16('CS0+('hF100<<1),'h2);        // DFS and block ([8:0]) address
    WR16('CS0+('hF101<<1),'h0);        // DBS
    WR16('CS0+('hF241<<1),'h0);        // Clear interrupt status
              WR16('CS0+('hF220<<1),'h94);            // Erase command
    data ='h0;
    while(!(data &'h0004))                  // Wait
        RD32('WIAR, data); // Read status
// Program page command
    WR16('CS0+('hF100<<1),'h2);             // DFS and block[8:0] address
    WR16('CS0+('hF107<<1),'h0);             // sector[1:0] and page[7:2] addresses
```

```
          WR16('CS0+('hF200<<1),'h800);           // buffer[11:8] address and counter[1:0]
          WR16('CS0+('hF241<<1),'h0);             // Clear interrupt status
          WR16('CS0+('hF220<<1),'h80);            // Program command
          data ='h0;
          while(!(data &'h0004))                  // Wait
              RD32('WIAR, data); // Read status
```

23.8.6 Access to Samsung UtRAM

Below mentioned configurations are intended for Samsung UtRAM.

23.8.6.1 Samsung UtRAM Asynchronous Mode Configuration

```
          WR32('EIM_CS0GCR1,'h400104b1);
          WR32('EIM_CS0RCR1,'h0a010000);
          WR32('EIM_CS0RCR2,'h00000008);
          WR32('EIM_CS0WCR1,'h0b040040);
```

23.8.6.2 Samsung UtRAM Synchronous Mode Configuration

```
          RD16('CS0+('hff_ffff<<1),data);             // command sequence
          RD16('CS0+('hff_ffff<<1),data);
          RD16('CS0+('hff_ffff<<1),data);
          RD16('CS0+('hff_feff<<1),data);
          RD16('CS0+('h00_82a0<<1),data);             // memory sync. configuration
          WR32('EIM_CS0GCR1,'h4021_53b7);            // fixed latency memory wrap 32
          WR32('EIM_CS0RCR1,'h0500_0000);
          WR32('EIM_CS0WCR1,'h0300_0000);
```

23.8.7 Access to Spansion Flash

Below mentioned configurations are intended for Spansion Flash.

23.8.7.1 Spansion Flash Asynchronous Mode Configuration

```
          WR32('EIM_CS0GCR1,'h00410081);
          WR32('EIM_CS0RCR1,'h0a018000);
          WR32('EIM_CS0RCR2,'h00000000);
          WR32('EIM_CS0WCR1,'h0704a240);
WR16('CS0+('hF220<<1),'h94);            // Erase command
          data ='h0;
          while(!(data &'h0004))                  // Wait
              RD32('WIAR, data); // Read status
     // Program page command
          WR16('CS0+('hF100<<1),'h2);             // DFS and block[8:0] address
          WR16('CS0+('hF107<<1),'h0);             // sector[1:0] and page[7:2] addresses
          WR16('CS0+('hF200<<1),'h800);           // buffer[11:8] address and counter[1:0]
          WR16('CS0+('hF241<<1),'h0);             // Clear interrupt status
          WR16('CS0+('hF220<<1),'h80);            // Program command
          data ='h0;
```

```
            while(!(data &'h0004))                  // Wait
                RD32('WIAR, data); // Read status
```

23.8.7.2 Spansion Flash Synchronous Mode Configuration

```
            WR16('CS0+('h0555<<1),'h00aa);   // command sequence
            WR16('CS0+('h02aa<<1),'h0055);
            WR16('CS0+('h0555<<1),'hd0);
            WR16('CS0+('h0000<<1),'h1ec4);   // memory sync. configuration
            WR32('EIM_CS0GCR1,'h50411325); // 66 MHz
            WR32('EIM_CS0RCR1,'h05000000); // 5 cycles on memory
```

23.8.7.3 Spansion Flash Utility

```
        // Single word programming
            COMMAND_SEQUENCE(cs,16,'ha0);           // single word programming
            WR16('CS0+addr, data);
            CHECK_STATUS('CS0+addr,data,16,1,errst);
        // Write buffer programming
            COMMAND_SEQUENCE(0,16,'h25);              // write buffer programming
            WR16('CS0+addr,'h001f);                     // counter-1
            WR_I('CS0+addr, data, 'h0010_0001, 16); // data
            WR16('CS0+addr,'h0029);                     // write buffer to flash
            CHECK_STATUS('CS0+addr+'h3e,data[31:16]+'h00f0,16,1,errst);
```

There COMMAND_SEQUENCE and CHECK_STATUS are next functions:

```
        task COMMAND_SEQUENCE;
            input[2:0]    cs;
            input[7:0]    port_size;
            input[31:0]   code;
        begin
            if(port_size == 16)
               begin
               WR16(csba[cs]+('h0555<<1),'h00aa);
               WR16(csba[cs]+('h02aa<<1),'h0055);
               WR16(csba[cs]+('h0555<<1),code);

23.10 Programmable Registers

23.10.1 EIM Memory Map/Register Definition

The EIM includes 33 user-accessible 32-bit registers. The the EIM Configuration Register (EIM_WCR) contains control bits that configure the EIM for certain operation modes.

The 160 bits used to control Individual Chip Select are divided into five registers:

- Chip Select x General Configuration Register 1 (EIM_CSxGCR1)
- Chip Select x General Configuration Register 2 (EIM_CSxGCR2)
- Chip Select x Read Configuration Register 1 (EIM_CSxRCR1)
- Chip Select x Read Configuration Register 2 (EIM_CSxRCR2)
- Chip Select x Write Configuration Register (EIM_CSxWCR)

In addition there are 3 general registers: EIM_WCR, EIM_WIAR & EIM_EAR.

NOTE

- All EIM registers are sampled by IPG_CLK_S, therefore IPG_CLK_S must be active when accessing through IP bus.
- Read access from all registers (except EIM_WIAR & EIM_EAR) will generate one IPG_XFR_WAIT cycle.
- Read access from EIM_WIAR & EIM_EAR will generate six IPG_XFR_WAIT cycles.
- Write access to all registers (except EIM_EAR) will generate three IPG_XFR_WAIT cycles.
- Write access to EIM_EAR will generate six IPG_XFR_WAIT cycles.

EIM_CS*n*GCR1 field descriptions

Field	Description
31–28 PSZ	Page Size. This bit field indicates memory page size in words (word is defined by the DSZ field). PSZ is used when fix latency mode is applied, WFL=1 for sync. write accesses, RFL=1 for sync. Read accesses. When working in fix latency mode WAIT signal from the external device is not being monitored, PSZ is used to determine if page boundary is reached and renewal of access is preformed. This bit field is ignored when sync. Mode is disabled or fix latency mode is not being used for write or read access separately. It can be valid for both access type, read or write, or only for one type, according to configuration. PSZ is cleared by a hardware reset. 0000 8 words page size 0001 16 words page size 0010 32 words page size

Table continues on the next page...

EIM_CS*n*GCR1 field descriptions (continued)

Field	Description
	0011 64 words page size 0100 128 words page size 0101 256 words page size 0110 512 words page size 0111 1024 (1k) words page size 1000 2048 (2k) words page size 1001 - 1111 Reserved
27 WP	Write Protect. This bit prevents writes to the address range defined by the corresponding chip select. WP is cleared by a hardware reset. 0 Writes are allowed in the memory range defined by chip. 1 Writes are prohibited. All attempts to write to an address mapped by this chip select result in a error response and no assertion of the chip select output.
26–24 GBC	Gap Between Chip Selects. This bit field, according to the settings shown below, determines the minimum time between end of access to the current chip select and start of access to different chip select. GBC is cleared by a hardware reset. Example settings: 000 minimum of 0 EIM clock cycles before next access from different chip select (async. mode only) 001 minimum of 1 EIM clock cycles before next access from different chip select 010 minimum of 2 EIM clock cycles before next access from different chip select 111 minimum of 7 EIM clock cycles before next access from different chip select
23 AUS	Address UnShifted. This bit indicates an unshifted mode for address assertion for the relevant chip select accesses. AUS bit is cleared by hardware reset. **NOTE:** The reset value for EIM_CS0GCR1[AUS] = EIM_BOOT[10]. For EIM_CS1GCR1 - EIM_CS5GCR1, the reset value of AUS is 0. 0 Address shifted according to port size (DSZ config.) 1 Address unshifted
22–20 CSREC	CS Recovery. This bit field, according to the settings shown below, determines the minimum pulse width of CS, OE, and WE control signals before executing a new back to back access to the same chip select. CSREC is cleared by a hardware reset. **NOTE:** The reset value for EIM_CS0GCR1, CSREC[2:1] is EIM_BOOT[9:8], for CSREC[0] is 0. For EIM_CS1GCR1 - EIM_CS5GCR, the reset value is 0b000. Example settings: 000 0 EIM clock cycles minimum width of CS, OE and WE signals (read async. mode only) 001 1 EIM clock cycles minimum width of CS, OE and WE signals 010 2 EIM clock cycles minimum width of CS, OE and WE signals 111 7 EIM clock cycles minimum width of CS, OE and WE signals
19 SP	Supervisor Protect. This bit prevents accesses to the address range defined by the corresponding chip select when the access is attempted in the User mode. SP is cleared by a hardware reset. 0 User mode accesses are allowed in the memory range defined by chip select. 1 User mode accesses are prohibited. All attempts to access an address mapped by this chip select in User mode results in an error response and no assertion of the chip select output.

Table continues on the next page...

EIM_CS*n*GCR1 field descriptions (continued)

Field	Description
18–16 DSZ	Data Port Size. This bit field defines the width of an external device's data port as shown below. **NOTE:** Only async. access supported for 8 bit port. **NOTE:** The reset value for EIM_CS0GCR1[DSZ] = {EIM_BOOT[11], EIM_BOOT[1:0]}. For EIM_CS1GCR1 - EIM_CS5GCR1, the reset value is 0b001. 000 Reserved. 001 16 bit port resides on DATA[15:0] 010 16 bit port resides on DATA[31:16] 011 32 bit port resides on DATA[31:0] 100 8 bit port resides on DATA[7:0] 101 8 bit port resides on DATA[15:8] 110 8 bit port resides on DATA[23:16] 111 8 bit port resides on DATA[31:24]
15–14 BCS	Burst Clock Start. When SRD=1 or SWR=1,this bit field determines the number of EIM clock cycles delay from start of access before the first rising edge of BCLK is generated. When BCD=0 value of BCS=0 results in a half clock delay after the start of access. For other values of BCD a one clock delay after the start of access is applied, not an immediate assertion. BCS is cleared by a hardware reset. 00 0 EIM clock cycle additional delay 01 1 EIM clock cycle additional delay 10 2 EIM clock cycle additional delay 11 3 EIM clock cycle additional delay
13–12 BCD	Burst Clock Divisor. This bit field contains the value used to program the burst clock divisor for BCLK generation. It is used to divide the internal EIMbus frequency. BCD is cleared by a hardware reset. **NOTE:** For other then the mentioned below frequency such as 104 MHz, EIM clock (input clock) should be adjust accordingly. 00 Divide EIM clock by 1 01 Divide EIM clock by 2 10 Divide EIM clock by 3 11 Divide EIM clock by 4
11 WC	Write Continuous. The WI bit indicates that write access to the memory are always continuous accesses regardless of the BL field value. WI is cleared by hardware reset. 0 Write access burst length occurs according to BL value. 1 Write access burst length is continuous.
10–8 BL	Burst Length. The BL bit field indicates memory burst length in words (word is defined by the DSZ field) and should be properly initialized for mixed wrap/increment accesses support. Continuous BL value corresponds to continuous burst length setting of the external memory device. For fix memory burst size, type is always wrap. In case not matching wrap boundaries in both the memory (BL field) and Master access on the current address, EIM update address on the external device address bus and regenerates the access. BL is cleared by a hardware reset. When APR=1, Page Read Mode is applied, BL determine the number of words within the read page burst. BL is cleared by a hardware reset for EIM_CS0GCR1 - EIM_CS5GCR1.

Table continues on the next page...

EIM_CS*n*GCR1 field descriptions (continued)

Field	Description
	000 4 words Memory wrap burst length (read page burst size when APR = 1) 001 8 words Memory wrap burst length (read page burst size when APR = 1) 010 16 words Memory wrap burst length (read page burst size when APR = 1) 011 32 words Memory wrap burst length (read page burst size when APR = 1) 100 Continuous burst length (2 words read page burst size when APR = 1) 101 Reserved 110 Reserved 111 Reserved
7 CREP	Configuration Register Enable Polarity. This bit indicates CRE memory pin assertion state, active-low or active-high, while executing a memory register set command to the external device (PSRAM memory type). CREP is set by a hardware reset. **NOTE:** Whenever PSRAM is connected the CREP value must be correct also for accesses where CRE is disabled. For Non-PSRAM memory CREP value should be 1. 0 CRE signal is active low 1 CRE signal is active high
6 CRE	Configuration Register Enable. This bit indicates CRE memory pin state while executing a memory register set command to PSRAM external device. CRE is cleared by a hardware reset. 0 CRE signal use is disable 1 CRE signal use is enable
5 RFL	Read Fix Latency. This bit field determine if the controller is monitoring the WAIT signal from the External device connected to the chip select (handshake mode - fix or variable data latency) or if it start sampling data according to RWSC field, it only valid in synchronous mode. RFL is cleared by a hardware reset. When RFL=1 Burst access is terminated on page boundary and resume on the following page according to BL bit field configuration, because WAIT signal is not monitored from the external device. 0 the External device WAIT signal is being monitored, and it reflect the external data bus state 1 the state of the External devices is determined internally (Fix latency mode only)
4 WFL	Write Fix Latency. This bit field determine if the controller is monitoring the WAIT signal from the External device connected to the chip select (handshake mode - fix or variable data latency) or if it start data transfer according to WWSC field, it only valid in synchronous mode. WFL is cleared by a hardware reset. When WFL=1 Burst access is terminated on page boundary and resume on the following page according to BL bit field configuration, because WAIT signal is not monitored from the external device 0 the External device WAIT signal is being monitored, and it reflect the external data bus state 1 the state of the External devices is determined internally (Fix latency mode only)
3 MUM	Multiplexed Mode. This bit determines the address/data multiplexed mode for asynchronous and synchronous accesses for 8 bit, 16 bit or 32 bit devices (DSZ config. dependent). **NOTE:** The reset value for EIM_CS0GCR1[MUM] = EIM_BOOT[2]. For EIM_CS1GCR1 - EIM_CS5GCR1 the reset value is 0. 0 Multiplexed Mode disable 1 Multiplexed Mode enable

Table continues on the next page...

EIM_CS*n*GCR1 field descriptions (continued)

Field	Description
2 SRD	Synchronous Read Data. This bit field determine the read accesses mode to the External device of the chip select. The External device should be configured to the same mode as this bit implicates. SRD is cleared by a hardware reset. **NOTE:** Sync. accesses supported only for 16/32 bit port. 0 read accesses are in Asynchronous mode 1 read accesses are in Synchronous mode
1 SWR	Synchronous Write Data. This bit field determine the write accesses mode to the External device of the chip select. The External device should be configured to the same mode as this bit implicates. SWR is cleared by a hardware reset. **NOTE:** Sync. accesses supported only for 16/32 bit port. 0 write accesses are in Asynchronous mode 1 write accesses are in Synchronous mode
0 CSEN	CS Enable. This bit controls the operation of the chip select pin. CSEN is set by a hardware reset for CSGCR0 to allow external boot operation. CSEN is cleared by a hardware reset to CSGCR1-CSGCR5. **NOTE:** Reset value for EIM_CS0GCR1 for CSEN is 1. For EIM_CS1GCR1-CS1GCR5 reset value is 0. 0 Chip select function is disabled; attempts to access an address mapped by this chip select results in an error respond and no assertion of the chip select output 1 Chip select is enabled, and is asserted when presented with a valid access.

23.101.2 Chip Select n General Configuration Register 2 (EIM_CSGCR2)

Addresses: EIM_CS0GCR2 is 63FD_8000h base + 4h offset = 63FD_8004h
EIM_CS1GCR2 is 63FD_8000h base + 1Ch offset = 63FD_801Ch
EIM_CS2GCR2 is 63FD_8000h base + 34h offset = 63FD_8034h
EIM_CS3GCR2 is 63FD_8000h base + 4Ch offset = 63FD_804Ch

EIM_CS*n*GCR2 field descriptions

Field	Description
31–13 Reserved	This read-only field is reserved and always has the value zero. Reserved
12 MUX16_BYP_GRANT	Muxed 16 bypass grant. This bit when asserted causes EIM to bypass the grant/ack. arbitration with NFC (only for 16 bit muxed mode accesses). **NOTE:** The reset value for EIM_CS0GCR2[MUX16_BYP_GRANT] = EIM_BOOT[12]. For EIM_CS1GCR2 - EIM_CS5GCR2, MUX16_BYP_GRANT reset value is 1. 0 EIM waits for grant before driving a 16 bit muxed mode access to the memory. 1 EIM ignores the grant signal and immediately drives a 16 bit muxed mode access to the memory.
11–10 Reserved	This read-only field is reserved and always has the value zero. Reserved
9 DAP	Data Acknowledge Polarity. This bit indicates DTACK memory pin assertion state, active-low or active-high, while executing an async access using DTACK signal from the external device. DAP is cleared by a hardware reset. 0 DTACK signal is active high 1 DTACK signal is active low
8 DAE	Data Acknowledge Enable. This bit indicates external device is using DTACK pin as strobe/terminator of an async. access. DTACK signal may be used only in asynchronous single read (APR=0) or write accesses. DTACK poling start point is set by DAPS bit field. polarity of DTACK is set by DAP bit field. DAE is cleared by a hardware reset. 0 DTACK signal use is disable 1 DTACK signal use is enable
7–4 DAPS	Data Acknowledge Poling Start. This bit field determine the starting point of DTACK input signal polling. DAPS is used only in asynchronous single read or write accesses. **NOTE:** Since DTACK is an async. signal the start point of DTACK signal polling is at least 3 cycles after the start of access. DAPS is cleared by a hardware reset. Example settings: 0000 3 EIM clk cycle between start of access and first $\overline{\text{DTACK}}$ check 0001 4 EIM clk cycles between start of access and first $\overline{\text{DTACK}}$ check 0010 5 EIM clk cycles between start of access and first $\overline{\text{DTACK}}$ check 0111 10 EIM clk cycles between start of access and first $\overline{\text{DTACK}}$ check 1011 14 EIM clk cycles between start of access and first DTACK check 1111 18 EIM clk cycles between start of access and first DTACK check
3–2 Reserved	This read-only field is reserved and always has the value zero. Reserved
1–0 ADH	Address hold time - This bit field determine the address hold time after ADV negation when mum = 1 (muxed mode). When mum = 0 this bit has no effect. For read accesses the field determines when the pads direction will be switched. **NOTE:** Reset value for EIM_CS0GCR2 for ADH is 10. For EIM_CS1GCR2-EIM_CS5GCR2 reset value is 00.

- OEA bitfield: See field descriptions for the reset values.

EIM_CS*n*RCR1 field descriptions

Field	Description
31–30 Reserved	This read-only field is reserved and always has the value zero. Reserved
29–24 RWSC	Read Wait State Control. This bit field programs the number of wait-states, according to the settings shown below, for synchronous or asynchronous read access to the external device connected to the chip select. When SRD=1 and RFL=0, RWSC indicates the number of burst clock (BCLK) cycles from the start of an access, before the controller can start sample data.Since WAIT signal can be asserted one cycle before the first data can be sampled, the controller starts evaluating the WAIT signal state one cycle before, this is referred as handshake mode or variable latency mode. When SRD=1 and RFL=1, RWSC indicates the number of burst clock (BCLK) cycles from the start of an access, until the external device is ready for data transfer, this is referred as fix latency mode. When SRD=0, RFL bit is ignored, RWSC indicates the asynchronous access length and the number of EIM clock cycles from the start of access until the external device is ready for data transfer. RWSC is cleared by a hardware reset. **NOTE:** The reset value for EIM_CS0RCR1[RWSC[4:2]] = EIM_BOOT [7:5]. For {RWSC[5], RWSC[1:0]} the reset value is 0b000. For CG1RCR1 - CS1RCR5 the reset value is 0b000000. Example settings: 000000 Reserved

Table continues on the next page...

EIM_CS*n*RCR1 field descriptions (continued)

Field	Description
	000001 RWSC value is 1 000010 RWSC value is 2 111101 RWSC value is 61 111110 RWSC value is 62 111111 RWSC value is 63
23 Reserved	This read-only field is reserved and always has the value zero. Reserved
22–20 RADVA	ADV Assertion. This bit field determines when ADV signal is asserted for synchronous or asynchronous read modes according to the settings shown below. RADVA is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between beginning of access and ADV assertion 001 1 EIM clock cycles between beginning of access and ADV assertion 010 2 EIM clock cycles between beginning of access and ADV assertion 111 7 EIM clock cycles between beginning of access and ADV assertion
19 RAL	Read ADV Low. This bit field determine ADV signal negation time. When RAL=1, RADVN bit field is ignored and ADV signal will stay asserted until end of access. When RAL=0 negation of ADV signal is according to RADVN bit field configuration. **NOTE:** The reset value of EIM_CS0RCR1[RAL] = EIM_BOOT[3]. RAL is cleared by a hardware reset for EIM_CS1RCR1 - EIM_CS5RCR1.
18–16 RADVN	ADV Negation. This bit field determines when ADV signal to memory is negated during read accesses. When SRD=1 (synchronous read mode), ADV negation occurs according to the following formula: (RADVN + RADVA + BCD + BCS + 1) EIM clock cycles from start of access. When asynchronous read mode is applied (SRD=0) and RAL=0 ADV negation occurs according to the following formula: (RADVN + RADVA + 1) EIM clock cycles from start of access. RADVN is cleared by a hardware reset. **NOTE:** the reset value for EIM_CS0RCR1[RADVN] = 2. For EIM_CS1RCR1 - EIM_CS5RCR1, the reset value is 0b000. **NOTE:** This field should be configured so ADV negation will occur before the end of access. For ADV negation at the same time with the end of access user should RAL bit.
15 Reserved	This read-only field is reserved and always has the value zero. Reserved
14–12 OEA	OE Assertion. This bit field determines when OE signal are asserted during read cycles (synchronous or asynchronous mode), according to the settings shown below. OEA is cleared by a hardware reset. In muxed mode OE assertion occurs (OEA + RADVN + RADVA + ADH +1) EIM clock cycles from start of access. **NOTE:** The reset value for EIM_CS0RCR1[OEA] is 0b000 if EIM_BOOT[2] = 0. If EIM_BOOT[2] is 1, the reset value for EIM_CS0RCR1 is 0b010. The reset value of this field for EIM_CS1RCR1 - EIM_CS5RCR1 is 0b000. Example settings: 000 0 EIM clock cycles between beginning of access and OE assertion 001 1 EIM clock cycles between beginning of access and OE assertion

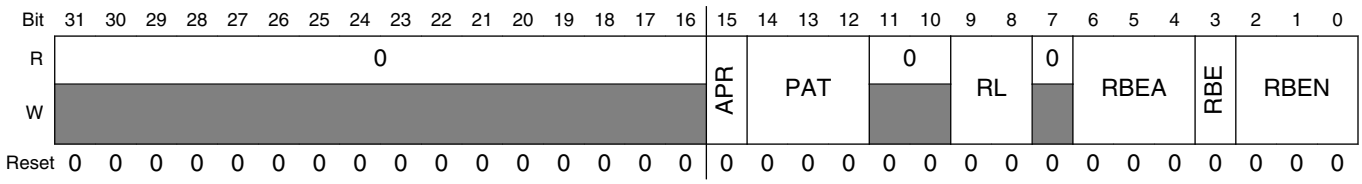
Table continues on the next page...

EIM_CS*n*RCR1 field descriptions (continued)

Field	Description
	010 2 EIM clock cycles between beginning of access and OE assertion 111 7 EIM clock cycles between beginning of access and OE assertion
11 Reserved	This read-only field is reserved and always has the value zero. Reserved
10–8 OEN	OE Negation. This bit field determines when OE signal is negated during read cycles in asynchronous single mode only (SRD=0 & APR = 0), according to the settings shown below. This bit field is ignored when SRD=1. OEN is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between end of access and OE negation 001 1 EIM clock cycles between end of access and OE negation 010 2 EIM clock cycles between end of access and OE negation 111 7 EIM clock cycles between end of access and OE negation
7 Reserved	This read-only field is reserved and always has the value zero. Reserved
6–4 RCSA	Read CS Assertion. This bit field determines when CS signal is asserted during read cycles (synchronous or asynchronous mode), according to the settings shown below. RCSA is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between beginning of read access and CS assertion 001 1 EIM clock cycles between beginning of read access and CS assertion 010 2 EIM clock cycles between beginning of read access and CS assertion 111 7 EIM clock cycles between beginning of read access and CS assertion
3 Reserved	This read-only field is reserved and always has the value zero. Reserved
2–0 RCSN	Read CS Negation. This bit field determines when CS signal is negated during read cycles in asynchronous single mode only (SRD=0 & APR = 0), according to the settings shown below. This bit field is ignored when SRD=1. RCSN is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between end of read access and CS negation 001 1 EIM clock cycles between end of read access and CS negation 010 2 EIM clock cycles between end of read access and CS negation 111 7 EIM clock cycles between end of read access and CS negation

23.101.4 Chip Select n Read Configuration Register 2 (EIM_CSRCR2)

Addresses: EIM_CS0RCR2 is 63FD_8000h base + Ch offset = 63FD_800Ch
EIM_CS1RCR2 is 63FD_8000h base + 24h offset = 63FD_8024h
EIM_CS2RCR2 is 63FD_8000h base + 3Ch offset = 63FD_803Ch
EIM_CS3RCR2 is 63FD_8000h base + 54h offset = 63FD_8054h



EIM_CS*n*RCR2 field descriptions

Field	Description
31–16 Reserved	This read-only field is reserved and always has the value zero. Reserved
15 APR	Asynchronous Page Read. This bit field determine the asynchronous read mode to the external device. When APR=0, the async. read access is done as single word (where word is defined by the DSZ field). when APR=1, the async. read access executed as page read. page size is according to BL field config., RCSN,RBEN,OEN and RADVN are being ignored. APR is cleared by a hardware reset for EIM_CS1GCR1 - EIM_CS5GCR1. **NOTE:** SRD=0 and MUM=0 must apply when APR=1
14–12 PAT	Page Access Time. This bit field is used in Asynchronous Page Read mode only (APR=1). the initial access is set by RWSC as in regular asynchronous mode. the consecutive address assertions width determine by PAT field according to the settings shown below. when APR=0 this field is ignored. PAT is cleared by a hardware reset for EIM_CS1GCR1 - EIM_CS5GCR1. 000 Address width is 2 EIM clock cycles 001 Address width is 3 EIM clock cycles 010 Address width is 4 EIM clock cycles 011 Address width is 5 EIM clock cycles 100 Address width is 6 EIM clock cycles 101 Address width is 7 EIM clock cycles 110 Address width is 8 EIM clock cycles 111 Address width is 9 EIM clock cycles
11–10 Reserved	This read-only field is reserved and always has the value zero. Reserved
9–8 RL	Read Latency. This bit field indicates cycle latency when executing a synchronous read operation. The fields holds the feedback clock loop delay in aclk cycle units. This field is cleared by a hardware reset. 00 Feedback clock loop delay is up to 1 cycle for BCD = 0 or 1.5 cycles for BCD != 0 01 Feedback clock loop delay is up to 2 cycles for BCD = 0 or 2.5 cycles for BCD != 0 10 Feedback clock loop delay is up to 3 cycles for BCD = 0 or 3.5 cycles for BCD != 0 11 Feedback clock loop delay is up to 4 cycles for BCD = 0 or 4.5 cycles for BCD != 0

Table continues on the next page...

EIM_CS*n*RCR2 field descriptions (continued)

Field	Description
7 Reserved	This read-only field is reserved and always has the value zero. Reserved
6–4 RBEA	Read BE Assertion. This bit field determines when BE signal is asserted during read cycles (synchronous or asynchronous mode), according to the settings shown below. RBEA is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between beginning of read access and BE assertion 001 1 EIM clock cycles between beginning of read access and BE assertion 010 2 EIM clock cycles between beginning of read access and BE assertion 111 7 EIM clock cycles between beginning of read access and BE assertion
3 RBE	Read BE enable. This bit field determines if BE will be asserted during read access. 0 - BE are disabled during read access. 1- BE are enable during read access according to value of RBEA & RBEN bit fields.
2–0 RBEN	Read BE Negation. This bit field determines when BE signal is negated during read cycles in asynchronous single mode only (SRD=0 & APR=0), according to the settings shown below. This bit field is ignored when SRD=1. RBEN is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between end of read access and BE negation 001 1 EIM clock cycles between end of read access and BE negation 010 2 EIM clock cycles between end of read access and BE negation 111 7 EIM clock cycles between end of read access and BE negation

23.101.5 Chip Select n Write Configuration Register 1 (EIM_CSWCR1)

Addresses: EIM_CS0WCR1 is 63FD_8000h base + 10h offset = 63FD_8010h
EIM_CS1WCR1 is 63FD_8000h base + 28h offset = 63FD_8028h
EIM_CS2WCR1 is 63FD_8000h base + 40h offset = 63FD_8040h
EIM_CS3WCR1 is 63FD_8000h base + 58h offset = 63FD_8058h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

* Notes:
- WWSC bitfield: See field descriptions for the reset values.

EIM_CS*n*WCR1 field descriptions

Field	Description
31 WAL	Write ADV Low. This bit field determine ADV signal negation time in write accesses. When WAL=1, WADVN bit field is ignored and ADV signal will stay asserted until end of access. When WAL=0 negation of ADV signal is according to WADVN bit field configuration. **NOTE:** The reset value of CS0WCR1[WAL] = EIM_BOOT[3]. This field is cleared by a hardware reset for CS1WCR1 - CS5WCR1.
30 WBED	Write Byte Enable Disable. When asserted this bit prevent from IPP_DO_BE_B[x] to be asserted during write accesses.This bit is cleared by hardware reset.
29–24 WWSC	Write Wait State Control. This bit field programs the number of wait-states, according to the settings shown below, for synchronous or asynchronous write access to the external device connected to the chip select. When SWR=1 and WFL=0, WWSC indicates the number of burst clock (BCLK) cycles from the start of an access, before the memory can sample the first data.Since WAIT signal can be asserted one cycle before the first data can be sampled, the controller starts evaluating the WAIT signal state one cycle before, this is referred as handshake mode or variable latency mode. When SWR=1 and WFL=1, WWSC indicates the number of burst clock (BCLK) cycles from the start of an access, until the external device is ready for data transfer, this is referred as fix latency mode. When SWR=0, WFL bit is ignored, WWSC indicates the asynchronous access length and the number of EIM clock cycles from the start of access until the external device is ready for data transfer. WWSC is cleared by a hardware reset. **NOTE:** The reset value for EIM_CS0WCR1[WWSC[4:2]] = EIM_BOOT [7:5], {WWSC[5], WWSC[1:0]} = 0b000. For EIM_CS1WCR1 - EIM_CS5WCR1, the reset value of this field is 0b000000. Example settings: 000000 Reserved 000001 WWSC value is 1 000010 WWSC value is 2 000011 WWSC value is 3 111111 WWSC value is 63
23–21 WADVA	ADV Assertion. This bit field determines when ADV signal is asserted for synchronous or asynchronous write modes according to the settings shown below. WADVA is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between beginning of access and ADV assertion 001 1 EIM clock cycles between beginning of access and ADV assertion 010 2 EIM clock cycles between beginning of access and ADV assertion 111 7 EIM clock cycles between beginning of access and ADV assertion
20–18 WADVN	ADV Negation. This bit field determines when ADV signal to memory is negated during write accesses. When SWR=1 (synchronous write mode), ADV negation occurs according to the following formula: (WADVN + WADVA + BCD + BCS + 1) EIM clock cycles. When asynchronous read mode is applied (SWR=0) ADV negation occurs according to the following formula: (WADVN + WADVA + 1) EIM clock cycles. **NOTE:** Reset value for EIM_CS0WCR for WADVN is 2. For EIM_CS1WCR - EIM_CS5WCR reset value is 000. **NOTE:** This field should be configured so ADV negation will occur before the end of access. For ADV negation at the same time as the end of access, S/W should set the WAL bit.

Table continues on the next page...

EIM_CS*n*WCR1 field descriptions (continued)

Field	Description
17–15 WBEA	BE Assertion. This bit field determines when BE signal is asserted during write cycles in async. mode only (SWR=0), according to the settings shown below. BEA is cleared by a hardware reset. **NOTE:** Reset value for EIM_CS0WCR for WBEA is 2. For EIM_CS1WCR - EIM_CS5WCR reset value is 000. Example settings: 000 0 EIM clock cycles between beginning of access and BE assertion 001 1 EIM clock cycles between beginning of access and BE assertion 010 2 EIM clock cycles between beginning of access and BE assertion 111 7 EIM clock cycles between beginning of access and BE assertion
14–12 WBEN	BE[3:0] Negation. This bit field determines when BE[3:0] bus signal is negated during write cycles in async. mode only (SWR=0), according to the settings shown below. This bit field is ignored when SWR=1. BEN is cleared by a hardware reset. **NOTE:** Reset value for EIM_CS0WCR for WBEN is 2. For EIM_CS1WCR - EIM_CS5WCR reset value is 000. Example settings: 000 0 EIM clock cycles between end of access and WE negation 001 1 EIM clock cycles between end of access and WE negation 010 2 EIM clock cycles between end of access and WE negation 111 7 EIM clock cycles between end of access and WE negation
11–9 WEA	WE Assertion. This bit field determines when WE signal is asserted during write cycles (synchronous or asynchronous mode), according to the settings shown below. This bit field is ignored when executing a read access to the external device. WEA is cleared by a hardware reset. **NOTE:** Reset value for EIM_CS0WCR for WEA is 2. For EIM_CS1WCR - EIM_CS5WCR reset value is 000. Example settings: 000 0 EIM clock cycles between beginning of access and WE assertion 001 1 EIM clock cycles between beginning of access and WE assertion 010 2 EIM clock cycles between beginning of access and WE assertion 111 7 EIMclock cycles between beginning of access and WE assertion
8–6 WEN	WE Negation. This bit field determines when WE signal is negated during write cycles in asynchronous mode only (SWR=0), according to the settings shown below. This bit field is ignored when SWR=1. WEN is cleared by a hardware reset. **NOTE:** Reset value for EIM_CS0WCR for WEN is 2. For EIM_CS1WCR - EIM_CS5WCR reset value is 000. Example settings: 000 0 EIM clock cycles between beginning of access and WE assertion 001 1 EIM clock cycles between beginning of access and WE assertion 010 2 EIM clock cycles between beginning of access and WE assertion 111 7 EIM clock cycles between beginning of access and WE assertion

Field	Description
5–3 WCSA	Write CS Assertion. This bit field determines when CS signal is asserted during write cycles (synchronous or asynchronous mode), according to the settings shown below.this bit field is ignored when executing a read access to the external device. WCSA is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between beginning of write access and CS assertion 001 1 EIM clock cycles between beginning of write access and CS assertion 010 2 EIM clock cycles between beginning of write access and CS assertion 111 7 EIMclock cycles between beginning of write access and CS assertion
2–0 WCSN	Write CS Negation. This bit field determines when CS signal is negated during write cycles in asynchronous mode only (SWR=0), according to the settings shown below. This bit field is ignored when SWR=1. WCSN is cleared by a hardware reset. Example settings: 000 0 EIM clock cycles between end of read access and CS negation 001 1 EIM clock cycles between end of read access and CS negation 010 2 EIM clock cycles between end of read access and CS negation 111 7 EIM clock cycles between end of read access and CS negation

23.101.6 Chip Select n Write Configuration Register 2 (EIM_CSWCR2)

Addresses: EIM_CS0WCR2 is 63FD_8000h base + 14h offset = 63FD_8014h
EIM_CS1WCR2 is 63FD_8000h base + 2Ch offset = 63FD_802Ch
EIM_CS2WCR2 is 63FD_8000h base + 44h offset = 63FD_8044h
EIM_CS3WCR2 is 63FD_8000h base + 5Ch offset = 63FD_805Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

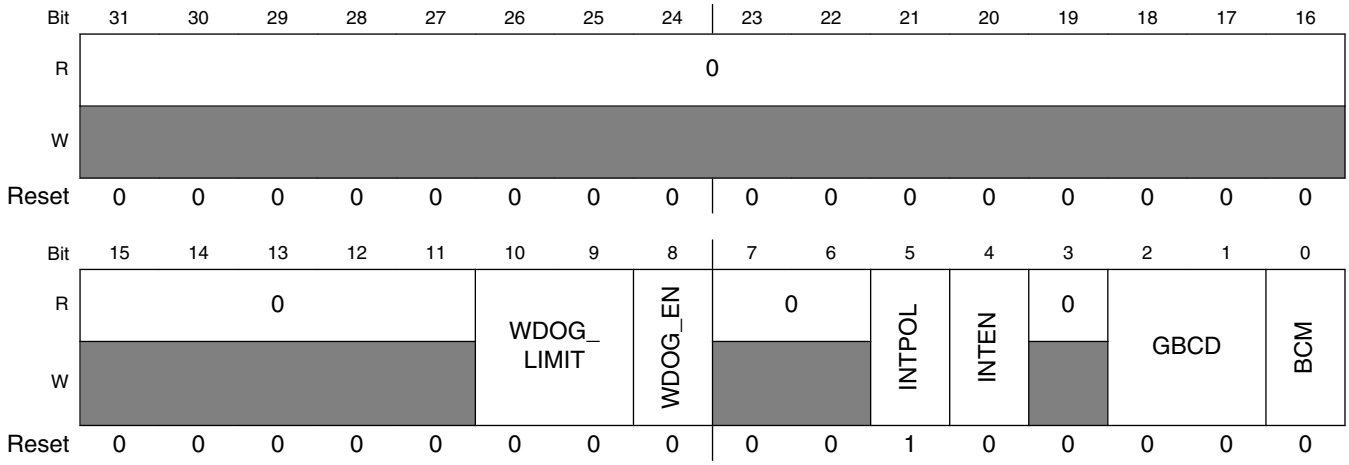
EIM_CS*n*WCR2 field descriptions

Field	Description
31–1 Reserved	This read-only field is reserved and always has the value zero. Reserved
0 WBCDD	Write Burst Clock Divisor Decrement. If this bit is asserted and BCD value is 0 sync. write access will be preformed as if BCD value is 1.When this bit is negated or BCD value is not 0 this bit has no affect. This bit is cleared by hardware reset.

23.101.7 EIM Configuration Register (EIM_WCR)

Address: EIM_WCR is 63FD_8000h base + 90h offset = 63FD_8090h



EIM_WCR field descriptions

Field	Description
31–11 Reserved	This read-only field is reserved and always has the value zero. Reserved
10–9 WDOG_LIMIT	Memory Watch Dog (WDog) cycle limit. This bit field determines the number of BCLK cycles (ACLK cycles in dtack mode) before the wdog counter terminates the access and send an error response to the master. 00 128 BCLK cycles 01 256 BCLK cycles 10 512 BCLK cycles 11 1024 BCLK cycles
8 WDOG_EN	Memory WDog enable. This bit controls the operation of the wdog counter that terminates the EIM access. 0 Memory WDog is Disabled 1 Memory WDog is Enabled
7–6 Reserved	This read-only field is reserved and always has the value zero. Reserved
5 INTPOL	Interrupt Polarity. This bit field determines the polarity of the external device interrupt. 0 External interrupt polarity is active low 1 External interrupt polarity is active high
4 INTEN	Interrupt Enable. When this bit is set the External signal RDY_INT as active interrupt. When interrupt occurs, INT bit at the WCR will be set and t EIM_EXT_INT signal will be asserted correspondingly. This bit is cleared by a hardware reset. 0 External interrupt Disable 1 External interrupt Enable

Table continues on the next page...

EIM_WCR field descriptions (continued)

Field	Description
3 Reserved	This read-only field is reserved and always has the value zero. Reserved
2–1 GBCD	General Burst Clock Divisor. When BCM bit is set, this bit field contains the value used to program the burst clock divisor for Continuos BCLK generation. The other BCD bit fields for each chip select are ignored. It is used to divide the internal AXI bus frequency. When BCM=0 GBCD bit field has no influence. GBCD is cleared by a hardware reset. 00 Divide EIM clock by 1 01 Divide EIM clock by 2 10 Divide EIM clock by 3 11 Divide EIM clock by 4
0 BCM	Burst Clock Mode. This bit selects the burst clock mode of operation. It is used for system debug mode. BCM is cleared by a hardware reset. **NOTE:** The BCLK frequency in this mode is according to GBCD bit field. **NOTE:** The BCLK phase is opposite to the EIM clock in this mode if GBCD is 0. **NOTE:** This bit should be used only in async. accesses. No sync access can be executed if this bit is set. **NOTE:** When this bit is set bcd field shouldn't be configured to 0. 0 The burst clock runs only when accessing a chip select range with the SWR/SRD bits set. When the burst clock is not running it remains in a logic 0 state. When the burst clock is running it is configured by the BCD and BCS bit fields in the chip select Configuration Register. 1 The burst clock runs whenever ACLK is active (independent of chip select configuration)

23.101.8 EIM IP Access Register (EIM_WIAR)

Address: EIM_WIAR is 63FD_8000h base + 94h offset = 63FD_8094h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0											ACLK_EN	ERRST	INT	IPS_ACK	IPS_REQ
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	1	0	0	0	0

EIM_WIAR field descriptions

Field	Description
31–5 Reserved	This read-only field is reserved and always has the value zero. Reserved
4 ACLK_EN	ACLK enable. This bit gates the ACLK for the EIM except from FFs that get ipg_aclk_s. After reset ACLK is enabled. 0 ACLK is disabled 1 ACLK is enabled
3 ERRST	READY After Reset. This bit controls the initial ready/busy status for external devices on CS0 immediately after hardware reset. This is a sticky bit which is cleared once the RDY_INT signal is asserted by the external device. When ERRST = 1 the first fetch access from EIM to the external device located on CS0 will be pending until RDY_INT signal indicates that the external device is ready, then EIM will execute the access. **NOTE:** Reset value for ERRST is EIM_BOOT[4]. 0 RDY_INT After Reset Disable 1 RDY_INT After Reset Enable
2 INT	Interrupt. This bit indicates interrupt assertion by an external device according to RDY_INT signal. When polling this bit, INT=0 indicates interrupt not occurred and INT=1 indicates assertion of the external device interrupt. This bit is cleared by a hardware reset.
1 IPS_ACK	IPS ACK. The EIM is ready for ips access. There is no active AXI access and no new AXI access is accepted till this bit is cleared. This bit is cleared by the master after it completes the ips accesses. 0 Master cannot access ips. 1 Master can access ips.
0 IPS_REQ	IPS request. The Master requests to access one of the IPS registers.Dutring such access the EIM should not preform any AXI/memory accesses. The EIM finishes the AXI accesses that already starts and asserts the IPS_ACK bit. 0 No Master requests ips access 1 Master requests ips access

23.101.9 Error Address Register (EIM_EAR)

Address: EIM_EAR is 63FD_8000h base + 98h offset = 63FD_8098h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

EIM_EAR field descriptions

Field	Description
31–0 Error-ADDR	Error Address. This bit field holds the AXI address of the last access that caused error. This register is read only register.

Chapter 24
Electrophoretic Display Controller (EPDC)

24.1 Overview

This chapter describes the detailed architecture of the EPDC. It provides a detailed description of the the block for digital design and software driver development.

The EPDC is a feature-rich, low power and high-performance direct-drive active matrix EPD controller. It is specifically designed to drive E•INK^{TM} EPD panels supporting a wide variety of TFT backplanes. The goal of the EPDC is to provide an efficient SoC integration of this functionality for e-paper applications, allowing a significant BOM cost saving over an external solution while reaching much higher levels of performance and lower power. The EPDC module is defined in the context of an optimized HW/SW partitioning and works in conjunction with the ePXP IP module to form a complete display processing solution.

The key features of the EPDC are as follows:

- TFT resolutions up to 4096 x 4096 pixels with 20 Hz refresh (programmable up to 8191 x 8191)
- TFT resolutions up to 2048 x 1536 pixels at 106 Hz refresh
- Industry standard bus interfaces (AMBA AXI and APB)
- Up to 5-bit pixel representation for up to 32 pixel levels
- Up to 16 concurrent updates with partial update support
- Automatic collision handling when used in conjunction with the i.MX driver
- Dual-scan TFT drive mode to support ultra-high resolution/refresh-rate displays
- Flexible direct-drive TFT interface supporting next generation source-drive, gate-driver and panel architectures, including LVDS, DDR and multi-level source drivers
- High-performance pixel pipeline architecture to guarantee refresh performance at high pixel-rates without the need for high internal clocking
- Ability to process multiple updates asynchronously to refresh/update operations with ability to intercept each frame scan will multiple update requests
- Performance tuning capabilities which can interface with SoC level memory arbitration mechanisms further guaranteeing frame refresh operation

- Decoupled clocking architecture allowing for independent and asynchronous clock sources for memory bus, peripheral bus and pixel-clock domains
- Full and partial update mode support
- Support for up to 256 waveform modes
- Low-power mode operation via architectural clock gating

24.2 Block Diagram and Overview

The top-level view of the EPDC is shown in Figure 24-1.

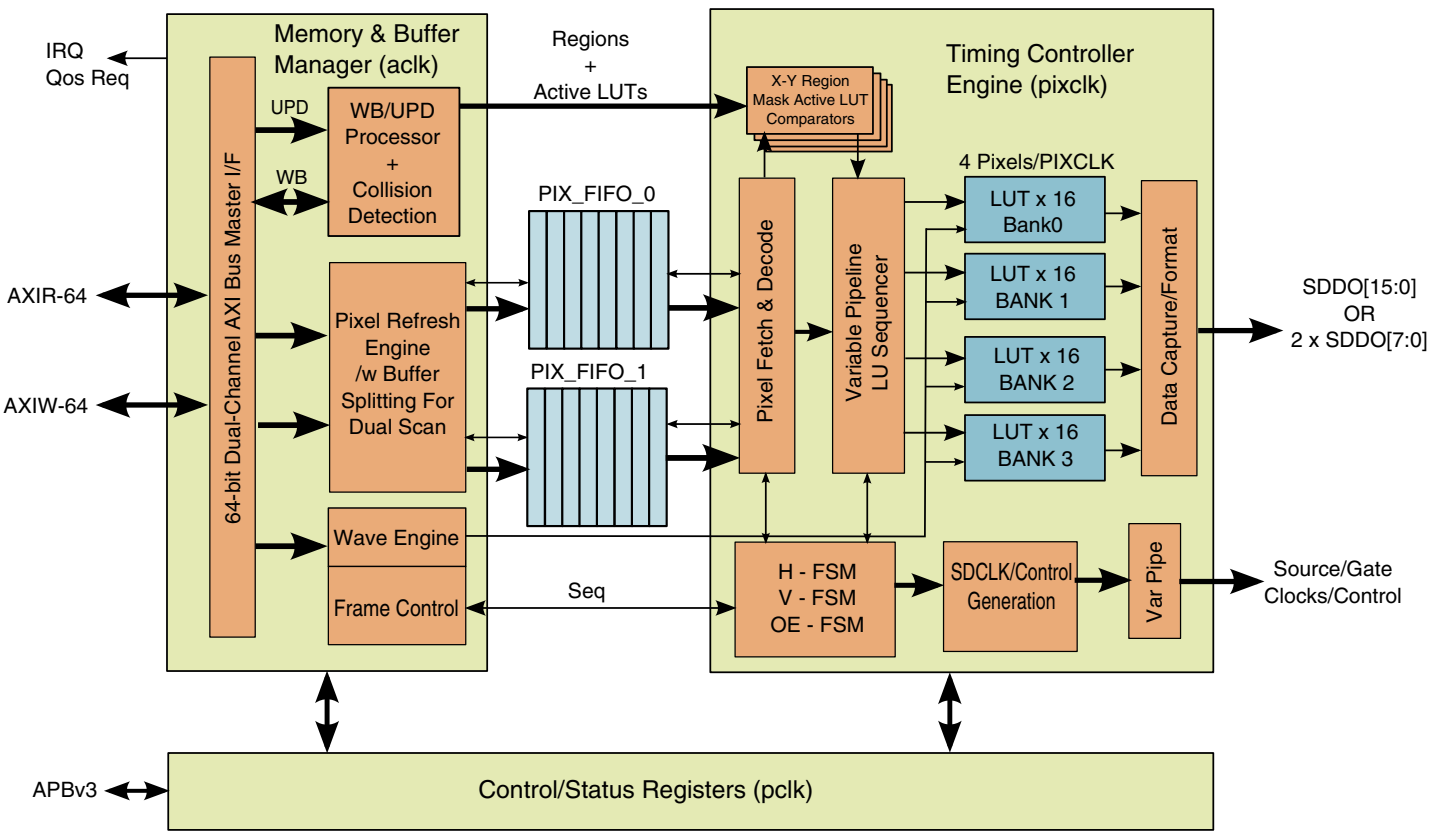

Figure 24-1. EPDC Top-Level Block Diagram

The EPD function can be separated into two major asynchronous processes. The first is the front-end portion which is responsible for processing display updates. The second is the function of driving waveforms to the TFT panel in order to update the screen contents (the refresh operation). The EPDC is comprised of two major submodules (MBM and TCE) to mirror this architectural split in the EPD algorithm. These submodules communicate through a number of control/sequencing signals and data (through the pixel FIFOs and LUT memories):

- Memory and Buffer Manager (MBM): This submodule is responsible for all memory related operations and LUT life cycle control, which involves the frame-count management for all updates. This module is clocked by both *aclk* and *pixclk*. It also encapsulates the APB register interface which is clocked by *apb_clk*.
- Timing Control Engine (TCE): This submodule is responsible for performing TFT scan frame refreshes. Its clocked by *pixclk*. It also houses the LUT memory system.

24.3 Programming Model

From an application perspective, the EPDC HW/SW solution aims to abstract much of the detail of driving an EPD display from the user space.

This is achieved through a blend of HW features and the kernel-level SW driver implementation of the EPD frame buffer. The scope of this chapter mostly pertains to EPDC HW but in order to correctly define the context of the programming model, certain assumptions about the driver architecture (including use of the ePXP IP) are described below.

24.3.1 Assumptions

The scope of the EPDC does not entail certain functions performed by the driver and application layer.

These features are as follows:

- Maintenance of update and collision lists. This includes, but is not limited to, responsibility for managing update order. Updates are processed in the order they are received by the EPDC. Actual start times of multiple updates can occur on the same frame scan. All pixels contained within an update will always begin on the same frame scan.
- Border control. This function is assumed to be performed by a GPIO functionality.
- EPD Panel Power Management. It is assumed that the driver and application layers will control the panel PMIC functions including relevant interfaces such as I^2C and 4-wire power sequencing signals.
- Reading and decompression of the waveform file. This is assumed to be unpacked, reformatted and written to system memory into a form that is easily accessed by the EPDC.
- Waveform mode selection. The ePXP provides a mechanism through its histogram analysis feature (which can be run as part of any frame/region processing operations) to allow the SW driver to characterize the region/buffer in terms of gray-map content. For example, the ePXP can determine if the update region only contains 2, 4,

8 or 16 gray levels, allowing the SW driver to choose the appropriate waveform update mode. Alternatively, the driver will also allow the application level SW to manually choose an update mode (which may be the case for ghosting artifacts clean-up, for example).

24.3.2 Register Space (Write/Set/Clear/Toggle)

The EPDC registers utilize four word address locations per 32-bit register.

For control registers (especially interrupts), this provides for a unique address for the following operations:

- Write (0x0). The base address of the register allows full writes to the 32-bit register.
- Set (0x4). This address allows a set operation on the register or its fields; writing a 1 to a register bit/field with the set address will set that bit. Writing a 0 to the set address has no effect.
- Clear (0x8). This address allows a clear operation on the register or its fields; writing a 1 to a register bit/field with the clear address will clear that bit or field.

NOTE

Interrupt status bits (such as those contained in EPDC_IRQ) must be cleared with the clear address only. Writing to the EPDC_IRQ register with a 0 will not clear the interrupt status/source. Writing a 0 to the clear address has no effect.

- Toggle (0xc). This address allows a toggle operation on the register or its fields; writing a 1 to a register bit/field with the toggle address will invert the state of that bit/field. This address is especially useful because it provides the ability to perform a read-modify-write operation with a single write operation. Writing a 0 to the toggle address has no effect.

24.3.3 Interrupts

24.3.3.1 Interrupt Sources

The EPDC contains 22 unique interrupt sources. Each interrupt source has an interrupt status bit captured in EPDC_IRQ.

When an interrupt event happens, the appropriate bit within the EPDC_IRQ register is set by the EPDC. Each of the bits in EPDC_IRQ is first AND'ed with its enable bit (in EPDC_IRQ_MASK), and then all the masked bits are logically OR'ed together to generate the final output.

24.3.3.2 Enabling/Masking Interrupts

Each of the EPDC interrupt sources can be individually enabled through the bits in the EPDC_IRQ_MASK register.

Even if an interrupt source is masked out (IRQ_EN bit set to 0), its status will still be available in the EPDC_IRQ register. The difference is that it does not result in the interrupt line being asserted.

24.3.3.3 Handling/Clearing Interrupts

When the software driver is entered as a result of an EPDC interrupt it should read the EPDC_IRQ interrupt status register.

Because multiple interrupts may have fired, in the case of a collision for example, both WB_CMPLT_IRQ and LUT_COL IRQ fields of EPDC_IRQ will be set. Once the interrupt has been handled, the driver should clear the interrupt source by writing to the CLEAR address (see Register Space (Write/Set/Clear/Toggle) for details).

It should be noted that for cases where a collision has occurred and the LUT_COL_IRQ bit is set, once the collision is handled and LUT_COL_IRQ is cleared this also clears the entire EPDC_STATUS_COL register.

24.3.4 Controller Setup

Before screen update operations can be performed the EPDC should be configured appropriately.

These rudimentary setup operations include:

- Waveform data must be present in memory (in a format that is consistent with the method in which the EPDC accesses it). Because the format of the waveform data is supplier proprietary information, it is not discussed in this chapter.
- Configuring the panel architecture parameters (source and gate-driver configuration)
- Configuring line and frame timing parameters
- Initializing the working buffer and display

24.3.4.1 Memory Requirements

At any point in time, the EPDC requires access to the un-packed waveform data, the update-region buffer, and its working buffer.

These are all expected to reside in system memory (typically external DRAM). As such, each has particular requirements:

- The Working Buffer (WB), which is pointed to by EPDC_WB_ADDR, must have EPDC_RES[HORIZONTAL] x EPDC_RES[VERTICAL] x 2 bytes allocated. This buffer is used by the EPDC to process updates and perform TFT refresh operations.
  - EPDC_RES[HORIZONTAL] mod 4 must equal 0 for memory allocation calculations because the EPDC constructs each line of the working buffer at a 64-bit boundary.
- The Update Buffer, which is pointed to by EPDC_UPD_ADDR (and can be re-defined with a different address for each update), must have the following allocation in memory:
  a. when stride feature not enabled
     - EPDC_UPD_SIZE[HEIGHT] x EPDC_UPD_SIZE[WIDTH] bytes
     - Note that EPDC_UPD_SIZE[WIDTH] mod 8 must equal to 0 (for memory allocation purposes). This means that for the address size allocation, the WIDTH field must be rounded up to the nearest number so that it can be divided by 8. This is because the EPDC reads each line of the update buffer at a 64-bit boundary (it should be noted that this is consistent with the ePXP IP output). The actual value programmed for the update can be at the pixel granularity.
- The waveform data set size is a function of mode-count, number of temperature tables and number of frames required for each temperature compensated mode.

In summary, the memory requirements are as follows (in bytes):

- WB-roundup4(EPDC_RES[HORIZONTAL]) x EPDC_RES[VERTICAL] x 2
- UPD-N x roundup8(EPDC_UPD_SIZE[WIDTH]) x EPDC_UPD_SIZE[HEIGHT]
  - N = the number of update requests currently being managed by the i.MX EPD driver (that is, the driver may maintain a list of updates in memory which it uses to feed the EPDC).

24.3.4.2 Panel Architecture Configuration

The EPDC is designed to directly drive EPD panels which typically expose the source and gate driver IC interfaces (these are typically abstracted in traditional displays such as TFT-LCD).

The source and gate driver ICs are responsible for driving the TFT matrix. There are variations in both the panel architectures and the underlying source and gate driver IC functionality.

All the key configuration parameters are defined in EDPC_RES, EPDC_FORMAT, EPDC_TCE_CTRL, EPDC_TCE_SDCFG and EPDC_TCE_GDCFG registers as follows.

- EPDC_RES:
  - HORIZONTAL: The panel horizontal resolution (in pixels). It must be noted that horizontal resolution must be an integer multiple of the source driver PIXELS_PER_SDCLK value. It also must be an integer multiple of the PIXELS_PER_CE value.
  - VERTICAL: The panel vertical resolution (in pixels). This can be any integer value.
- EPDC_FORMAT:
  - DEFAULT_TFT_PIXEL: This field should almost always be left at 0 x 00. This register is used as the value for the TFT pixel during a frame scan when a pixel location is not being updated. This condition is commonplace especially when using partial updates or updates which do not encompass the entire screen resolution. This value must always correspond to the state the source driver should see when no voltage change is needed. Incorrectly setting this value will damage the EPD material.
  - TFT_PIXEL_FORMAT: This enumerated field defines the width of the TFT pixel. The TFT pixel is defined as the per-pixel voltage control value. The most common pixel format is 2B (2 bits per pixel). Panels which support source-driver voltage modulation (multi-level voltage control) should use the 4B format. For source drivers that support 7 levels, the 4B format can be used and the unused SDDO output pins should be left floating at the board level connection (specifically SDDO3, 7, 11, 15). It should be noted that the 2BV and 4BV are variations which require the waveform data to supply a 2-bit VCOM value for each pixel.
- EPDC_TCE_CTRL:
  - SDDO_WIDTH: This selects 8- or 16-bit SDDO operation using enumerations 8-bit and 16-bit. This field is used to describe useful data, that is, for panels which support LVDS, ipp_epdc_sddo[15:8] would be used to drive differential data. In these modes, SDDO_WIDTH would be set to 8-bit.

- VCOM_MODE, VCOM_VAL: This high-level mode bit allows the EPDC to either use the VCOM value supplied in the waveform or a software programmable value defined in the VCOM_VAL field, for panels which support VCOM modulation.
- DDR_MODE: This mode-bit should be set for panels which expect source-driver data to be available on both edges of the SDCLK. This is common place for panels that support differential signaling, but the feature is not limited to LVDS panels. For example, the EPDC supports DDR modes which make full use of SDDO[15:0]. In these modes, DDR_MODE = 1 and LVDS_MODE = 0.
- LVDS_MODE: This mode always requires DDR_MODE to be set. When this mode bit is set, differential signaling is enabled such that SDDO[15:8] always drives the inverse of the pixel data which is presented on SDDO[7:0]. Because LVDS source-drivers use 2 pins per data-bit, they are typically configured to work in DDR mode. Differential signaling is also supported on the SDCE pins (as an option selected by LVDS_MODE_CE). In this mode SDCE[9:5] are used to drive the inverse differential signals for SDCE[4:0].
- LVDS_MODE_CE: When LVDS_MODE is set, this bit can also be set to allow SDCE[9:5] to act as differential pairs for each SDCE[4:0].
- DUAL_SCAN: Setting this field enables the dual scan function. When this field is set, all other parameters (except resolution) should be programmed in reference to each half of the panel. Because DUAL_SCAN modes require 2x the pixel-generation capability, there are limitations to the available TFT modes supported in this configuration (see Table 24-1 for details).
- SCAN_DIR0, SCAN_DIR1: These fields determine the vertical scan direction of the panel.
  - SCAN_DIR0: Determines the vertical scan direction of the panel when DUAL_SCAN = 0. When DUAL_SCAN = 1, this field determines the vertical scan direction of the top-half of the panel (0 means scan down and 1 means scan up).
  - SCAN_DIR1 only has meaning when DUAL_SCAN = 1. It defines the vertical scan direction of the bottom-half of the panel.
- PIXELS_PER_SDCLK: This is a key configuration and also timing parameter. Each source-driver latches a number of TFT pixels per shift-clock period (SDCLK). This register defines how many pixels are driven per SDCLK period. It must be noted that when DDR_MODE = 1, pixels are driven on both edges of the clock, so this value must be adjusted accordingly. See Table 24-1 for the required values per mode.

- EPDC_TCE_SDCFG:
  - SDCLK_HOLD: This holds the SDCLK low during the LINE_BEGIN time. The purpose of this field is to allow the user to set a LINE_BEGIN time which is not an integer multiple of SDCLKs (for fine tuning the line-time). In order to avoid

shortened pulses on SDCLK, this can be used to hold SDCLK low during the LINE_BEGIN time.
    - SDSHR: This defines the value of the SDSHR output signal which determines the source-driver output order mapping.
    - NUM_CE: This defines the total number of source-driver chip-enables (must be 1-0). It should be noted that this number does not always correspond to the number of source drivers in the panel. Many panels, only require a single chip-enable signal which is active during the entire line-data time. This signal is often called SPH in such cases.
    - PIXELS_PER_CE: This register defines the span of each chip-enable expressed in pixels. Note that for panels which utilize a single global CE, this value should be set to the horizontal resolution of the panel.
    - SDDO_REFORMAT: This enumerated field allows for TFT-pixel level re-ordering within SDDO. For most panels it is recommended to set SDDO_REFORMAT to the REVERSE_PIXELS enumeration.
    - SDDO_INVERT: When this field is set, the values on SDDO are inverted relative to the values extracted from the waveform LUT operations.
- EPDC_TCE_GDCFG:
    - GDRL: This defines the value of the GDRL output signal which determines the gate-driver pulse shift direction.
    - GDOE_MODE: This field selects between two possible methods for driving the GDOE signal. When GDOE_MODE = 0, the GDOE output is always driven during the frame-scan time except during FRAME_SYNC when it is driven low. When GDOE_MODE = 1, the GDOE signal mimics the GDCLK signal but is only active during the frame-data time (FD). For most panels this is recommended to be set at 0.
    - GDSP_MODE: This field selects between two possible methods for driving the GDSP signal. When GDSP_MODE = 0, the GDSP signal is driven on the first line-clock time of the FRAME_BEGIN time. The signal is driven for one GDCLK period (same as line-time), and can be shifted using the GDSP_OFFSET control. When GDSP_MODE = 1, GDSP is active during the entire FRAME_SYNC time, and in this mode GDSP_OFFSET has not effect.

24.3.4.3 TFT Panel Timing Configuration

The EPDC provides a simple primary set of registers to define TFT line and frame (refresh) timing.

In addition to these, there are also low-level timing and polarity registers to provide additional flexibility in dealing with future TFT architectures.

The following figure shows how the horizontal and vertical timing is defined in terms of the various timing parameters. When configuring the TFT timing, the following goals should be met:

- Arrive at a refresh rate that matches the waveform requirement (for example, 50 Hz for 50 Hz waveform). The refresh rate is defined as the time between each Frame-Sync event which can be expressed as a multiple of the line timing and the total number of vertical lines.
- Meet the various timing requirements of the gate and source driver clock and control signals (the blanking period provide an infrastructure for controlling these).
- Stay below the maximum source-driver clock (usually referred to as CL) frequency.
- Arrive at a source-driver clock frequency which in turn defines the exact pixclk frequency. In most cases, E-INK™ shall provide the expected SDCLK frequency.
- Meet the line-timing (LT) requirements of the E-INK panels and their associated waveforms.

For proper waveform performance, it is critical to match the refresh frequency to that required by the waveform and associated panel. Deviation from this frequency results in short term inaccuracy of color and in the long term, complete loss of coherency between the EPDC's internal representation of color and the physical representation on the screen.

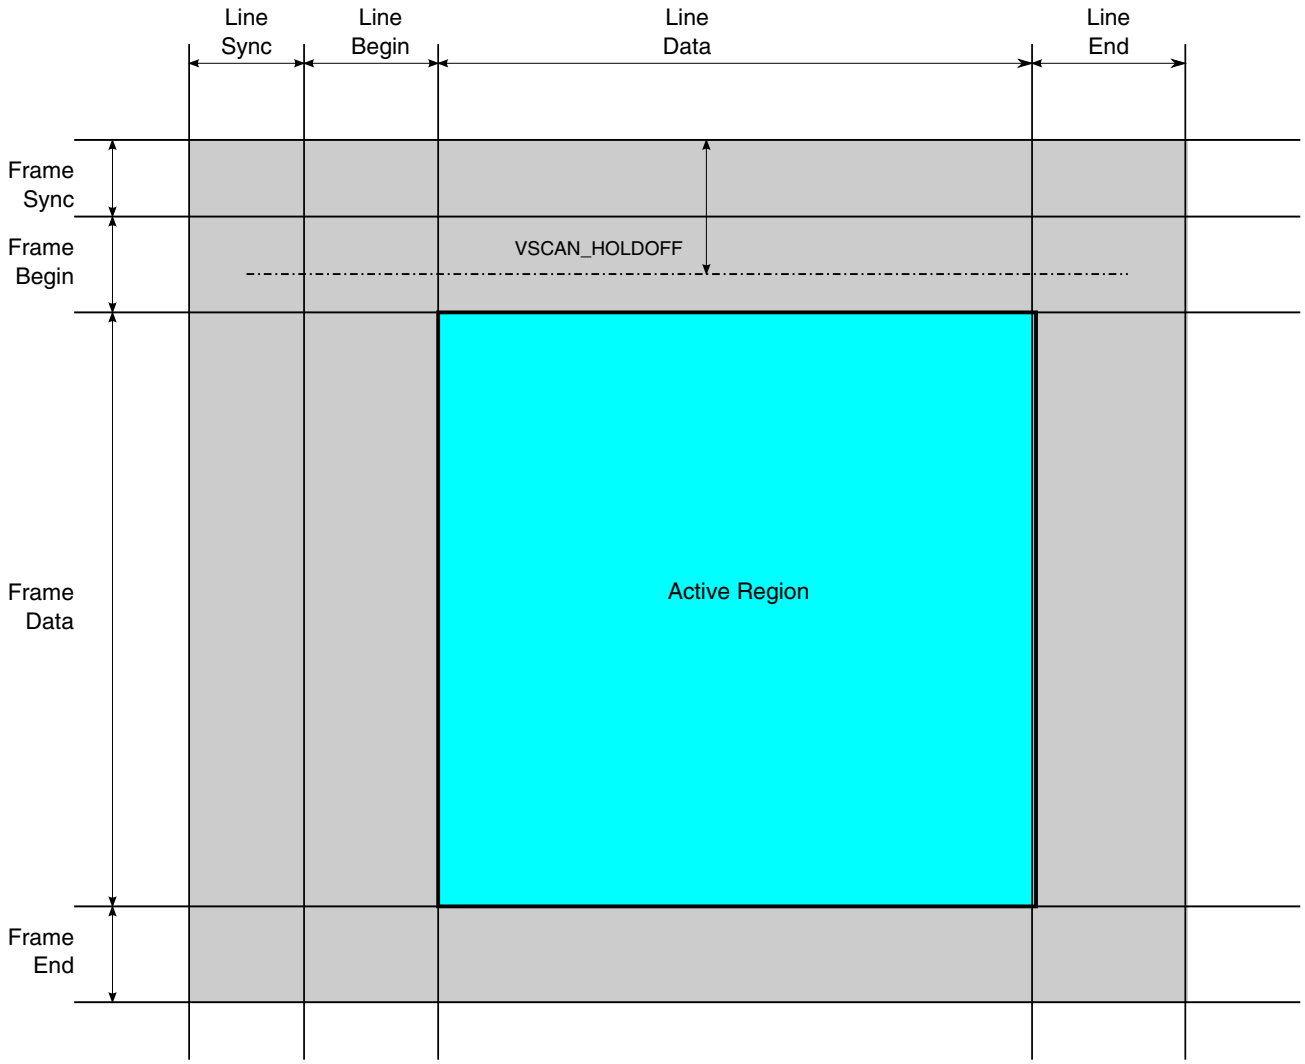

Figure 24-2. Frame Timing

The following equations define the timing of the panel scan frame (where LT = line-timing and FT = frame-timing):

$$LT = T_{PIXCLK}\,(LS + LB + (HRES \times \left(\frac{Ratio}{PIXELSPERSDCLK}\right) + LE)$$

$$FT = LT \times (FS + FB + VRES + LE)$$

Ratio is defined between the internal PIXCLK and the external source driver clock SDCLK. The ratio is automatically determined by the EPDC according to Table 24-1. A simple method to determine the ratio is as follows:

- When DDR_MODE = 1, RATIO = 4
- When DDR_MODE = 0
  - If PIXELS_PER_SDCLK = 8, RATIO = 4
  - Else, RATIO = 2

Typically it is recommended to seed these equations with an estimated (or provided) SDCLK frequency and adjust the various timings until the desired refresh rate is attained.

The following figure shows line timing for cases, where DDR_MODE = 0 (that is, those cases where data is only sampled by the source driver on the rising edge of SDCLK). Depending on the mode (see Table 24-1), the ratio is a function of TFT pixel width and PIXELS_PER_SDCLK, so the timings are shown generically, that is, for this diagram RATIO can either be 2 or 4.

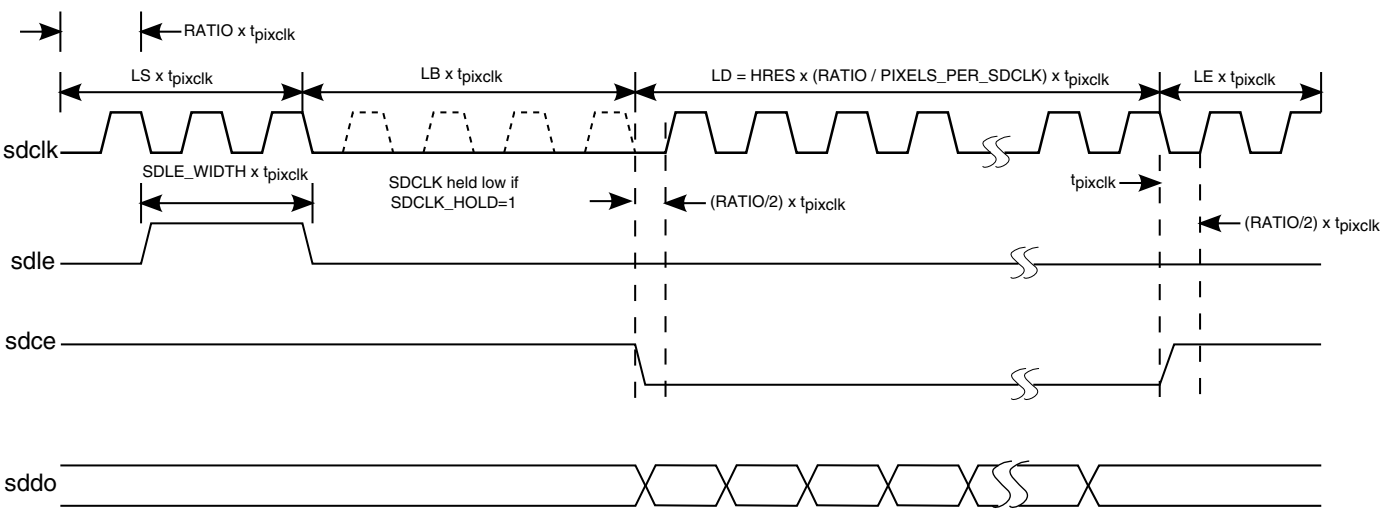

Figure 24-3. Line Timing (DDR_MODE = 0)

As per Table 24-1, when DDR_MODE=1 (for example, for source drivers that require data to be driven on each edge of SDCLK), the RATIO is always set to 4. The timing for such cases is shown in the figure below.

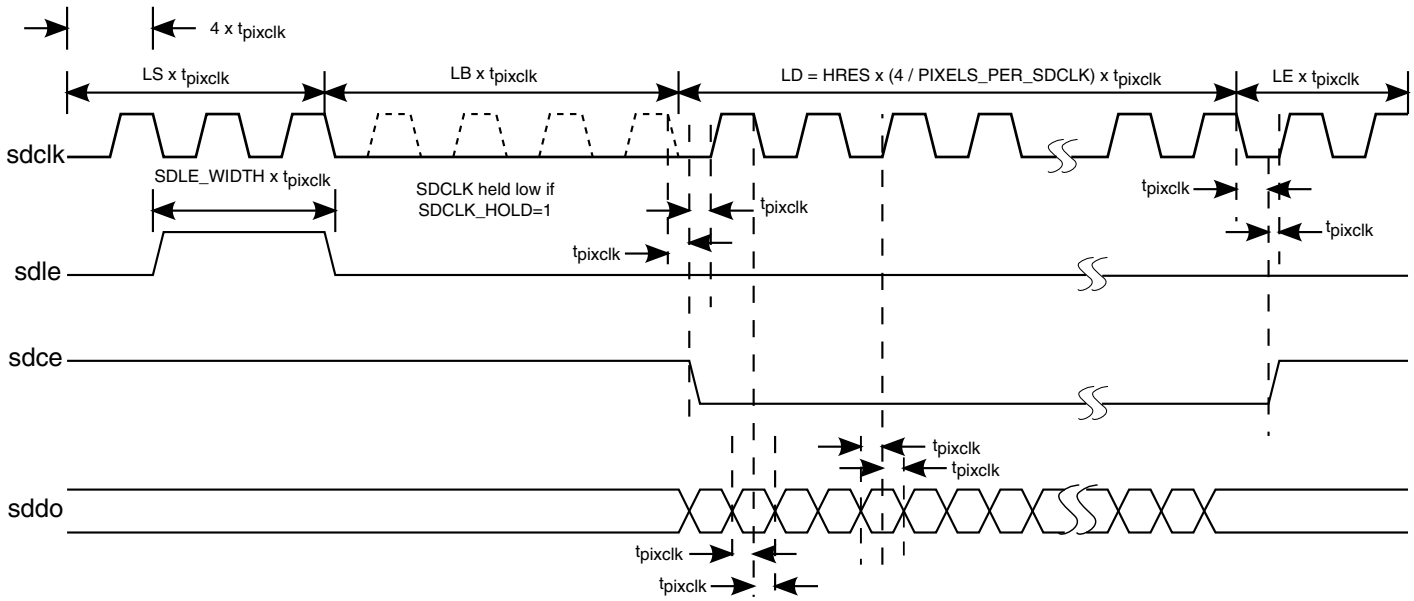

Figure 24-4. Line Timing (DDR_MODE = 1) - RATIO = 4

Vertical timing or frame timing (FT) is always expressed in terms of line timing (LT). This is shown in the following figure, followed by a detailed view of the GDCLK timing (which has programmable duty cycle to allow programming of gate-on/gate-off time) in Figure 24-6. The following important points should be noted in regard to gate-driver timing:

- All gate driver timing signals are independently referenced to the LINE_SYNC leading edge (this includes GDCLK_OFFSET, GDSP_OFFSET, and GDOE_OFFSET).
- GDSP_OFFSET is only supported for GDSP_MODE = 1
- For GDOE_MODE = 1, if GDOE is expected to be delayed relative to GDCLK, the GDOE_OFFSET value should be set at a value appropriately greater than GDCLK_OFFSET.
- All offset settings are programmed in terms of PIXCLK cycles.
- By default, if all offset values are set to 0, the gate-driver signals are always one PIXCLK cycle delayed from the LINE_SYNC leading edge.
- The LINE_SYNC leading edge does not depend on the LINE_SYNC_WIDTH value. In cases, where LINE_SYNC_WIDTH is set to some value that is less than LINE_SYNC, a virtual leading edge which determines the line start time still exists.

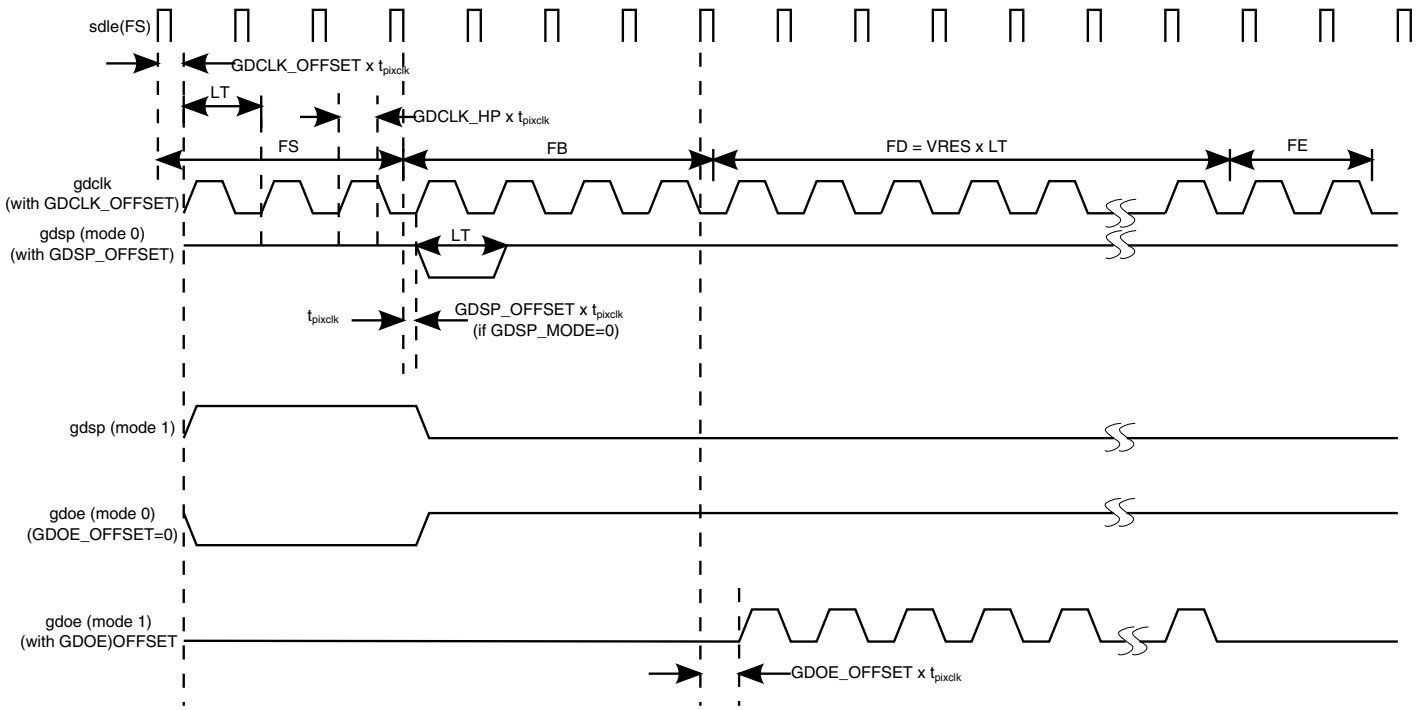

Figure 24-5. Frame Timing (Vertical)

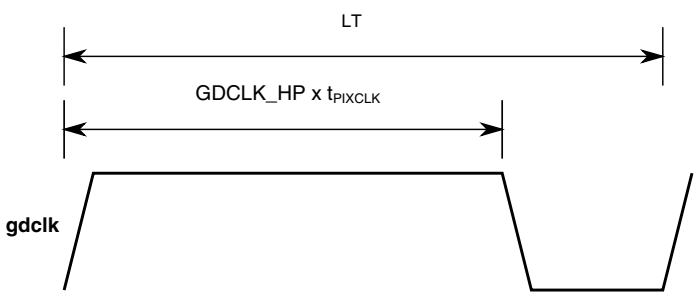

Figure 24-6. GDCLK Duty Cycle

An example calculation based on the 800 x 600 E-INK 6" panel with 50 Hz waveforms is shown be:

- PIXELS_PER_SDCLK = 4
- Ratio = 2 (2 bpp, 8-bit single-ended, SDR per Table 24-1)
- tPIXCLK = 17.64 MHz (assuming available chip clock frequency)
- LS = 20 x tPIXCLK
- LB = 8 x tPIXCLK
- LD = 800 x (2/4) x tPIXCLK = 400 x tPIXCLK
- LE = 142 x tPIXCLK
- LT = (20 + 8 + 400 + 142) x tPIXCLK = 32.31293 uS

It is seen that LINE_SYNC_WIDTH does not affect line-timing. It is recommended set the same value as LINE_SYNC, unless LB and LE are short and it is used to shorten the width of SDLE whilst still maintaining the same line-timing.

Note that it is important to meet the target line time of the panel which was 32.312 uS. Now, the frame-rate can be calculated, given the vertical timings:

- FS = 4 x LT
- FB = 4 x LT
- FD = 600 x LT
- FE = 10 x LT
- FT = (4 + 4 + 600 + 10) x LT = 50.07665 Hz

In addition to this, E-INK panels require a particular duty cycle for the GDCLK signal which is specified as gate-on-time and gate-off-time. The sum of gate-off and gate-on should equal LT and the value of gate-on can be programmed through HW_EPDC_TCE_TIMING2[GDCLK_HP], that is, GDCLK High-Pulse time.

24.3.4.4 Source-Driver and Pixel-Clock Configuration

The EPDC supports a number of source-driver architectures. Each architecture forces a particular shift-clock pixel rate.

In addition to this, the selection of the architecture requires a particular clock ratio between the internal pixel clock (pixclk) and external shift clock (ipp_epdc_sdclk). The table below outlines the various configurations and clock ratios. It also lists the relevant register settings for this configuration.

Table 24-1. Interface Modes

High-Level Mode		HW_EPDC_CTRL [DUAL_SCAN]	ipp_epdc_sddo pins used	HW_EPDC_FORMAT [TFT_PIXEL_FORMAT]	HW_EPDC_TCE_CTRL [PIXELS_PER_SDCLK]	HW_EPDC_TCE_CTRL [LVDS_MODE]	HW_EPDC_TCE_CTRL [DDR_MODE]	HW_EPDC_TCE_CTRL [SDDO_WIDTH]	Required PIXCLK (RATIO)
Single Scan	2bpp, 8-bit single-ended, SDR	0	[7:0]	2B[V]	FOUR	0	0	8BIT	SDCLK x 2
	2bpp, 16-bit single-ended, SDR	0	[15:0]	2B[V]	EIGHT	0	0	16BIT	SDCLK x 4
	2bpp, 8-bit, DDR (LVDS option)	0	[7:0],[15:8]	2B[V]	EIGHT	1|0	1	8BIT	SDCLK x 4
	4bpp, 8-bit single-ended, SDR	0	[7:0]	4B[V]	TWO	0	0	8BIT	SDCLK x 2
	4bpp, 16-bit, single-ended SDR	0	[15:0]	4B[V]	FOUR	0	0	16BIT	SDCLK x 2
	4bpp, 8-bit, DDR (LVDS option)	0	[7:0],[15:8]	4B[V]	FOUR	1|0	1	8BIT	SDCLK x 4
	4bpp, 16-bit, single-ended, DDR	0	[15:0]	4B[V]	EIGHT	0	1	16BIT	SDCLK x 4

Table continues on the next page...

Table 24-1. Interface Modes (continued)

High-Level Mode		HW_EPDC_CTRL [DUAL_SCAN]	ipp_epdc_sddo pins used	HW_EPDC_FORMAT [TFT_PIXEL_FORMAT]	HW_EPDC_TCE_CTRL [PIXELS_PER_SDCLK]	HW_EPDC_TCE_CTRL [LVDS_MODE]	HW_EPDC_TCE_CTRL [DDR_MODE]	HW_EPDC_TCE_CTRL [SDDO_WIDTH]	Required PIXCLK (RATIO)
Dual Scan	2bpp, 8-bit single-ended, SDR	1	[7:0],[15:8]	2B[V]	FOUR	0	0	8BIT	SDCLK x 2
	2bpp, 8-bit, DDR	1	[7:0],[15:8]	2B[V]	EIGHT	0	1	8BIT	SDCLK x 4
	4bpp, 8-bit single-ended, SDR	1	[7:0],[15:8]	4B[V]	TWO	0	0	8BIT	SDCLK x 2
	4bpp, 8-bit, DDR	1	[7:0],[15:8]	4B[V]	FOUR	0	1	8BIT	SDCLK x 4

24.3.4.5 Initializing the Display

Because of the nature of the EPD technology, a typical scenario would involve the EPDC's working buffer (WB) being maintained in system memory. In such power states (where memory is maintained), it is not required to initialize the display (even if the EPD panel had been powered off for example).

In low-power modes where system memory is not maintained, there are two possible methods to initialize the display.

The first method includes initialization from an unknown state and the second mode simply requires software to load the last state of the WB into memory and configure the EPDC to point to it.

24.3.4.5.1 Reset/Clocks and Buffer Preparation

In cases where the user wants to initialize the screen to a new known state, the following sequence should be followed. Assume that all relevant display power supplies are active.

First, the user must complete a soft-reset sequence which also includes enabling the main EPDC block-level clock-gate. This sequence is described in the example code below. It should be noted that setting SFTRST enables the CLKGATE. In order to correctly cycle reset values through pipeline registers, the CLKGATE bit stays asserted for some finite amount of time before it sets. After this time, it is safe to clear both the SFTRST and CLKGATE. The example below shows a typical use of these registers.

```
EPDC_CTRL_SET(BM_EPDC_CTRL_SFTRST);
while (!EPDC_CTRL.B.CLKGATE);
EPDC_CTRL_CLR(BM_EPDC_CTRL_SFTRST | BM_EPDC_CTRL_CLKGATE);
while (EPDC_CTRL_RD() & (BM_EPDC_CTRL_SFTRST | BM_EPDC_CTRL_CLKGATE));
```

Before any display update is performed, the waveform address and working buffer (WB) pointers must be set (both must be aligned to a 64-bit double long word address):

- EPDC_WVADDR-Must point to the base address of the waveform data (managed by the i.MX driver)
- EPDC_WB_ADDR-An area of memory must be assigned for the EPDC's working buffer (WB). Once assigned, this memory space should be reserved purely for the use of the EPDC. The requirements for the memory allocation are described in Memory Requirements.

After this, the various panel-configuration parameters must be set including resolutions, source and gate-driver formats, TFT and buffer pixel formats and so on.

24.3.4.5.2 Performing an Initialization Display Update

Once all the panel timing and format parameters are defined a command sequence must be sent to the EPDC with the following properties:

- Update size must be full screen resolution
- HW_EPDC_UPD_CTRL[UPDATE_MODE] must be set to FULL
- HW_EPDC_UPD_CTRL[WAVEFORM_MODE] must be set to the INIT waveform (typically 0x00)
- HW_EPDC_UPD_CTRL[USE_FIXED] must be set
- HW_EPDC_UPD_FIXED[FIXNP_EN], FIXCP_EN must be set to 1, and FIXNP and FIXCP must be set to 0xFF

The use of HW_EPDC_UPD_FIXED allows the EPDC working buffer to be primed to a state that matches the result of the initialization waveform.

If the application loads the previous WB of the EPDC, these steps are not necessary.

24.3.5 Dual-Scan Configuration

The EPDC supports ultra-high resolution/refresh rate EPD panels.

At certain resolutions/refresh-rates there exist electrical limitations of the TFT devices and TFT driver ICs such as source drivers. In order to still support driving such displays, the EPDC supports the method of the dual-scan driver method.

The specific method involves driving a TFT configuration where there are two sets of source drivers. All source driver control signals are expected to be shared across all source drivers (except the SDCE signals unless a unified CE is presented by the panel).

In this mode, ipp_epdc_sddo[7:0] is reserved to drive the upper-half of the display and ipp_epdc_sddo[15:8] is reserved to drive the lower-half of the panel. The update and working buffers do not have to be aware of the dual-scan operation since the MBM knows how to access the WB for refresh operations based on the settings of the EPDC_TCE_CTRL[SCAN_DIR_0,1]. The EPDC support four scan configurations for dual scan which are shown in the following figures. Each figure shows an example configuration (that is, the EPDC is not limited to supporting only 2 source drivers per side).

It should be noted that the dual-scan drive method allows the SDCLK frequency to be halved relative to a single-scan method for the same resolution and refresh rate. In addition to this, each TFT is only charged half as frequently (since for any given SDCLK cycle, twice as many pixels are being driven per frame scan).

Because all 16 SDDO signals must be utilized for dual-scan, there is no support for the LVDS_MODE. The supported source-driver modes for dual scan are shown in Table 24-1. From this table, it can be seen that for the 2bpp DDR mode, the EPDC is capable of generating a total of 16 pixels per SDCLK cycle.

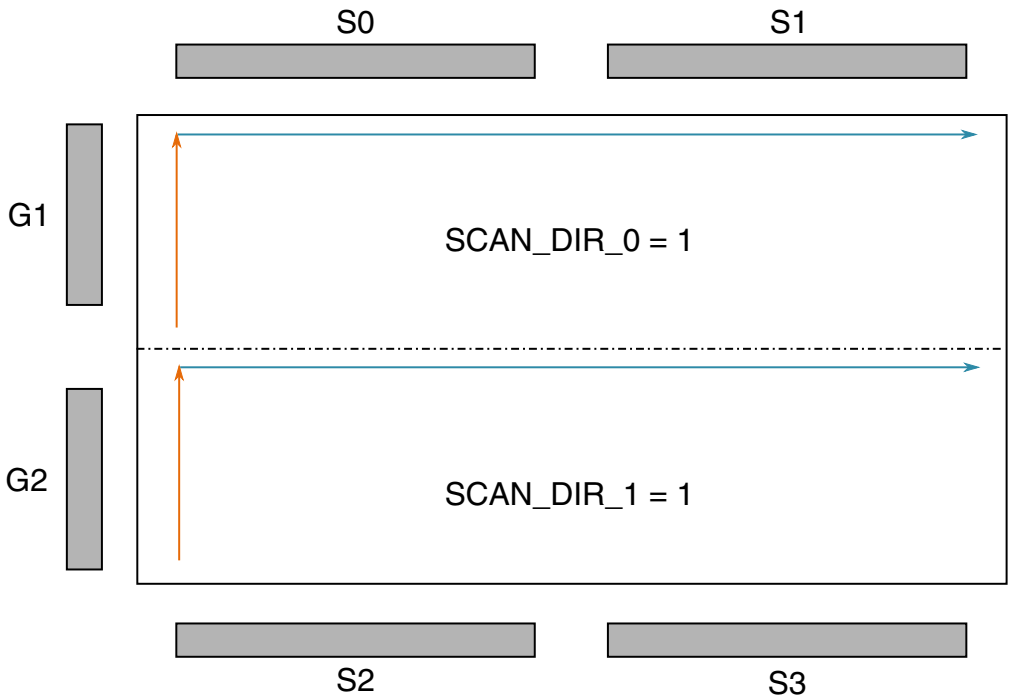

Figure 24-10. Dual-Scan Method (Scan = 11)

24.3.6 Display Update Programming

The EPDC is designed to communicate with the kernel driver through the interrupts and status registers.

The driver entry is always assumed to occur as a result of an interrupt.

24.3.6.1 Initiating a Display Update

The typical flow for in performing a display update involves the following:

- EPDC_STATUS[WB_BUSY] must be 0. The EPDC cannot process new updates if it is currently processing an update.
- EPDC_STATUS[LUTS_BUSY] must be 0. The EPDC cannot accept new updates if all LUT resources are currently active.

Assuming both conditions above are met, an update request is programmed in the following manner (it is important to note that the last step must be writing to EPDC_UPD_CTRL which initiates the display update).

The following steps can be performed before WB_BUSY and LUTS_BUSY are clear:

- At this time it is assumed that the correct temperature is selected and written to EPDC_TEMP.
- EPDC_UPD_ADDR must be set to the 8-bit buffer for the update. This buffer must be aligned to a 64-bit word address. In addition, each line address must begin at a 64-bit word address. Both criteria can be met buy utilizing the ePXP pixel processing engine which always aligns lines at a 64-bit raster (see Memory Requirements for details).
- EPDC_UPD_CORD-defines the insertion co-ordinate into the panel resolution.
- EPDC_UPD_SIZE-defines the dimension of the update (pixels).
- EPDC_UPD_FIXED-used for panel initialization or rectangular fill operations.

Writing the EPDC_UPD_CTRL register initiates a display update:

- USE_FIXED-This field is set when EPDC_UPD_FIXED is used.
- LUT_SEL-The driver should read EPDC_STATUS_NEXLUT[NEXT_LUT] (qualified by NEXT_LUT_VALID) to select an available LUT to assign this update.
- WAVEFORM_MODE-Selects the E-INK waveform mode (for example, INIT, DU, GC16 and so on). The number corresponds to the waveform number in the waveform specification document.
- UPDATE_MODE-This selects one of two enumerated updated modes.
  - FULL-In this mode, all pixels defined in the update rectangle have the waveform applied.
  - PARTIAL-In this mode, the EPDC shall only apply the waveform to pixels which are changing, otherwise the EPDC_FORMAT[DEFAULT_TFT_PIXEL] is applied to the pixels which are not changing.

24.3.6.2 Update Processing and Collisions

After the update is initiated (by writing EPDC_UPD_CTRL), the EPDC performs update-buffer processing. This involves processing this update region into it's working buffer (WB).

It is also during this time that the EPDC performs collision detection. At the end of the WB processing, the EPDC asserts the WB_CMPLT_IRQ interrupt. If a collision is detected, the LUT_COL_IRQ interrupt status bit will also be asserted.

The EPDC performs image updates to the EPD by applying waveforms to individual pixels. Waveforms are applied to groups of pixels (ranging from a single pixel to the entire display). Each individual update request is bound to a rectangle. Each pixel within this rectangle shall have a waveform applied to it using the waveform and update mode specified in EPDC_UPD_CTRL. After this process is initiated, a waveform take a finite

amount of time to complete (usually specified within the specification of the waveform mode). For proper display operation and optimum performance, a waveform must not be interrupted once it has begun

A collision is defined simply as the interruption of the application of waveform to a pixel or group of pixels. As such, it must be avoided. Because the waveforms take a finite amount of time to complete, the EPDC provides mechanism to automatically manage collisions. This allows the application to perform multiple updates resulting in a more rich user-experience without having to be cognizant of the panel and waveform characteristics.

Depending on the update mode (FULL or PARTIAL) a collision is defined as follows:

- For a full-update mode, a collision is defined as the temporal and spatial union of rectangles pertaining to unique update requests which are active. An active update is one which is still in the process of being updated (that is, a waveform is being applied).
- For a partial-update mode, a collision is defined as the temporal, spatial and differential union of pixels pertaining to unique update requests which are active. The difference between a full-updated and a partial-updated collision is that in the latter case, the collision state occurs only if the next-pixel states differ between the updates. Thus, two partial-update rectangles may intersect, but if all of the pixels in the intersecting update regions are being updated to the same gray-state, the original update and associated LUT/waveform are not disturbed and the intersection does not constitute a collision.
- It should be noted that collisions may be a one-to-many effect. In the case of partial updates, there may be a spatial and temporal union of rectangles with no differential pixel-level union. A subsequent update however might form such a pixel-level differential union to all active updates. Since each update pertains to an active LUT, these many collided updates is refered as victim LUTs in the subsequent sections. The update/LUT which caused the collision is referred to as the aggressor LUT.

An example of a partial-update mode collision is shown in the following figure. Each update encompasses the outer rectangle which meets the criteria of the spatial union. The red areas show the pixels which are currently transitioning to gray (from update 1) but need to transition to white (in update 2), these pixels meet the criteria of the differential union and lastly in the temporal domain, the period of time where LUT0 and LUT1 overlap is the temporal union. The pixels which did not change (grey and green areas in the LUT assignment box) are not part of the collision area. In the case of the gray overlapping pixels, LUT0 can continue to update. In the case of the white pixels (which were previously in-active) a new LUT (if available can be assigned) and forms the green region. Note that a subsequent update could potentially collide with the green pixels in update 2.

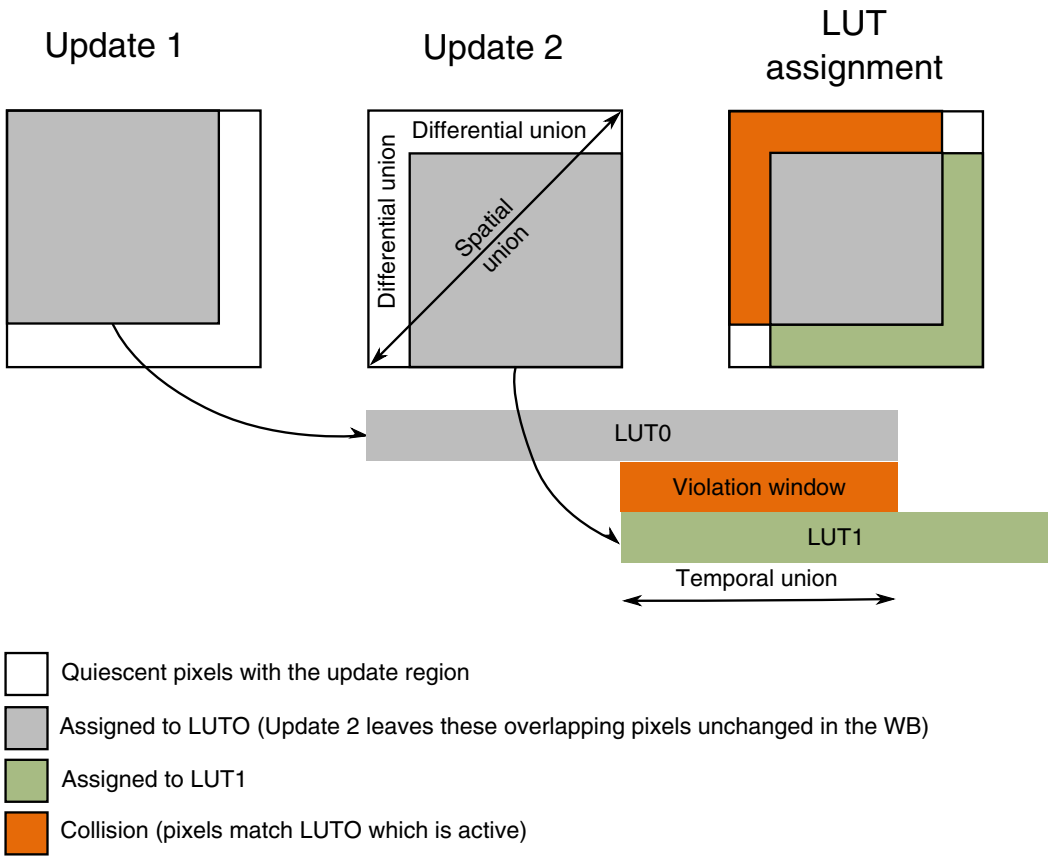

Figure 24-11. Partial Update Collision Handling

NOTE

For FULL update modes, a collision occurs at any intersection of active rectangles/LUTs because in FULL update mode, all pixels within the update rectangle have the waveform applied (even if pixel values are not changing).

It can be seen that when collision is detected (during the WB update process), the EPDC shall "block" the collided pixels being updated, and any pixels which are not collided will be assigned to the requested LUT process. When a collision occurs, the EPDC shall raise the LUT_COL_IRQ interrupt status bit (this will always happen in conjunction with WB_CMPLT_IRQ).

Because the driver is always entered via an interrupt, when the EPDC interrupt fires, it should not only check for WB_CMPLT_IRQ but also for the LUT_COL_IRQ status bit within the EPDC_IRQ register. If LUT_COL_IRQ is set, this means that a collision has occurred. If this is the case the driver should check the value of the EPDC_STATUS_COL register. This register contains one bit for each LUT that has been collided with, that is, it holds the vector of the "victim" LUTs as a result of the last update LUT. Since the driver knows the value of the LUT of the last update, it can store this update LUT value along with this associated "victim" LUT vector in a collision list.

Because the EPDC can drive up to 16 concurrent updates (which can be overlapping when using PARTIAL mode updates), a unique interrupt status bit is provided per LUT so that when an update completes (physically completes the waveform), the SW driver can know which LUT completed. In addition to the LUT completion interrupts (which are mapped into the EPDC_IRQ[LUTn_CMPLT_IRQ] interrupt status bits, the current state of each LUT can also be read from the EPDC_STATUS_LUTS status register.

The i.MX driver can use the LUT status interrupts in conjunction with EPDC_STATUS_LUTS to perform regular checks on the completion of "victim" LUTs against the vectors stored for each colliding LUT in the collision list. The driver may also choose to serialize updates such that it might wait until all victim LUTs have completed before re-issuing the colliding update.

The figure below shows a more extended sequence of a collision. In this case there are a series of updates coming from the application layer. These are A,B,C and D. Updates A, B, and C are set without any collision. When update D is requested a collision is detected. Using the interrupt status collision registers, the SW-driver stores D in a "collision-list". For that list entry it also store B which is the "victim LUT". It uses this information to check when a LUT completes to see if the victim LUTs for any update in the collision list have completed. If they have completed (through a LUT completion interrupt), the SW-driver then sends this update (D in this case) again to the EPDC. It should be noted that from the application perspective it appears that all updates A,B,C and D have been accepted, that is, the collision handling is completely hidden from user-space. Using the collision detection and LUT status interrupts, the application (in conjunction with the driver) could also choose to completely serialize the request (such that between the first and second D update, no other update is accepted).

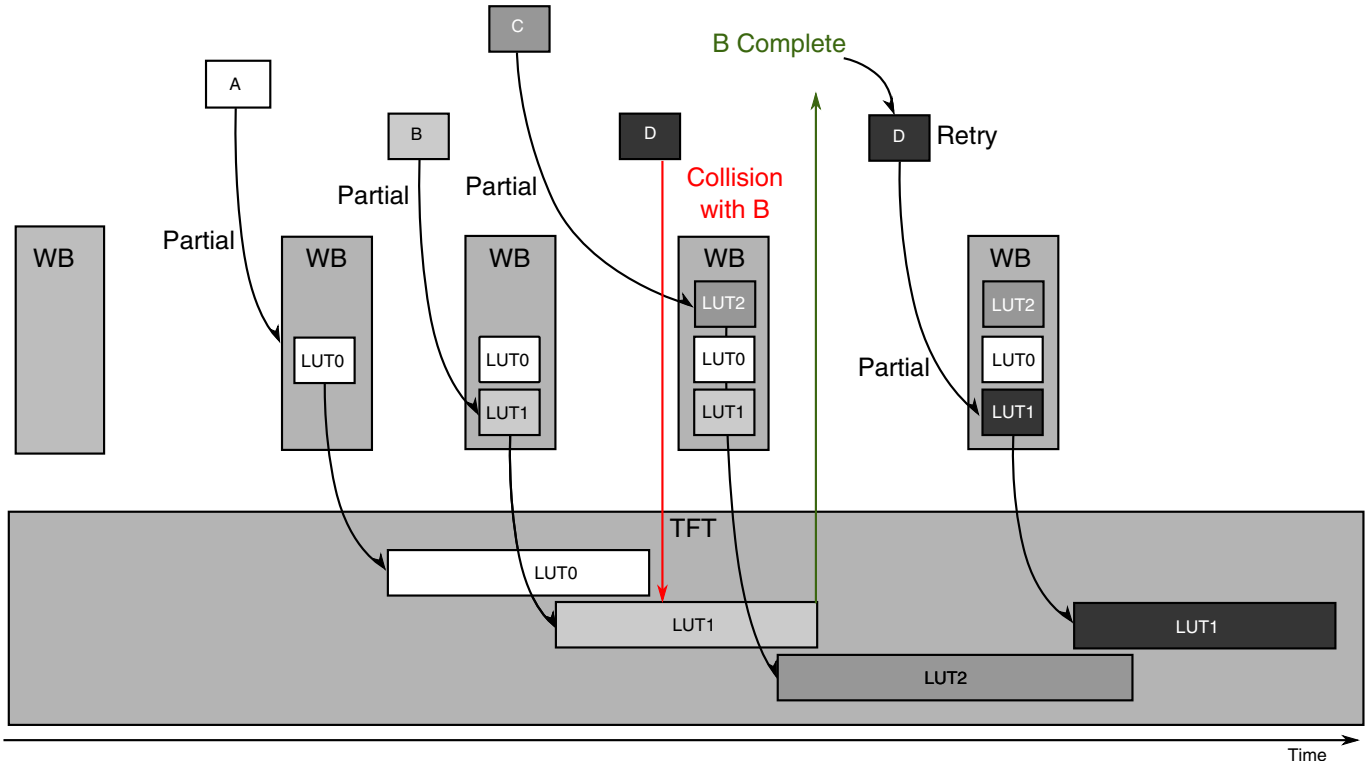

Figure 24-12. Collision Sequence

24.3.6.3 Multiple Update Flow

In most applications, such as e-book readers, besides full-screen page turns, user-interfaces require multiple updates to be performed.

Examples of this include cursors, pen-input, drop-down menus (with highlighting) and other movable graphical objects. As previously mentioned, each update takes a finite amount of time to complete (up to 1 second depending on the waveform mode). As such, it would be too prohibitive to only process one update at a time (serialization)-except in cases where a direct update waveform is used for B&W content.

As described in Initiating a Display Update, there are two conditions that must be met before the SW driver can issue a new update request:

- The Working buffer (WB) update process must be complete
- There must be an available LUT.

Assuming a free LUT is available, the EPDC is designed to have the capability to start new updates at each TFT frame scan (even being able to commence multiple updates within a frame scan blanking period). The general flow for sequential updates (concurrent or serialized) is shown in the following figure.

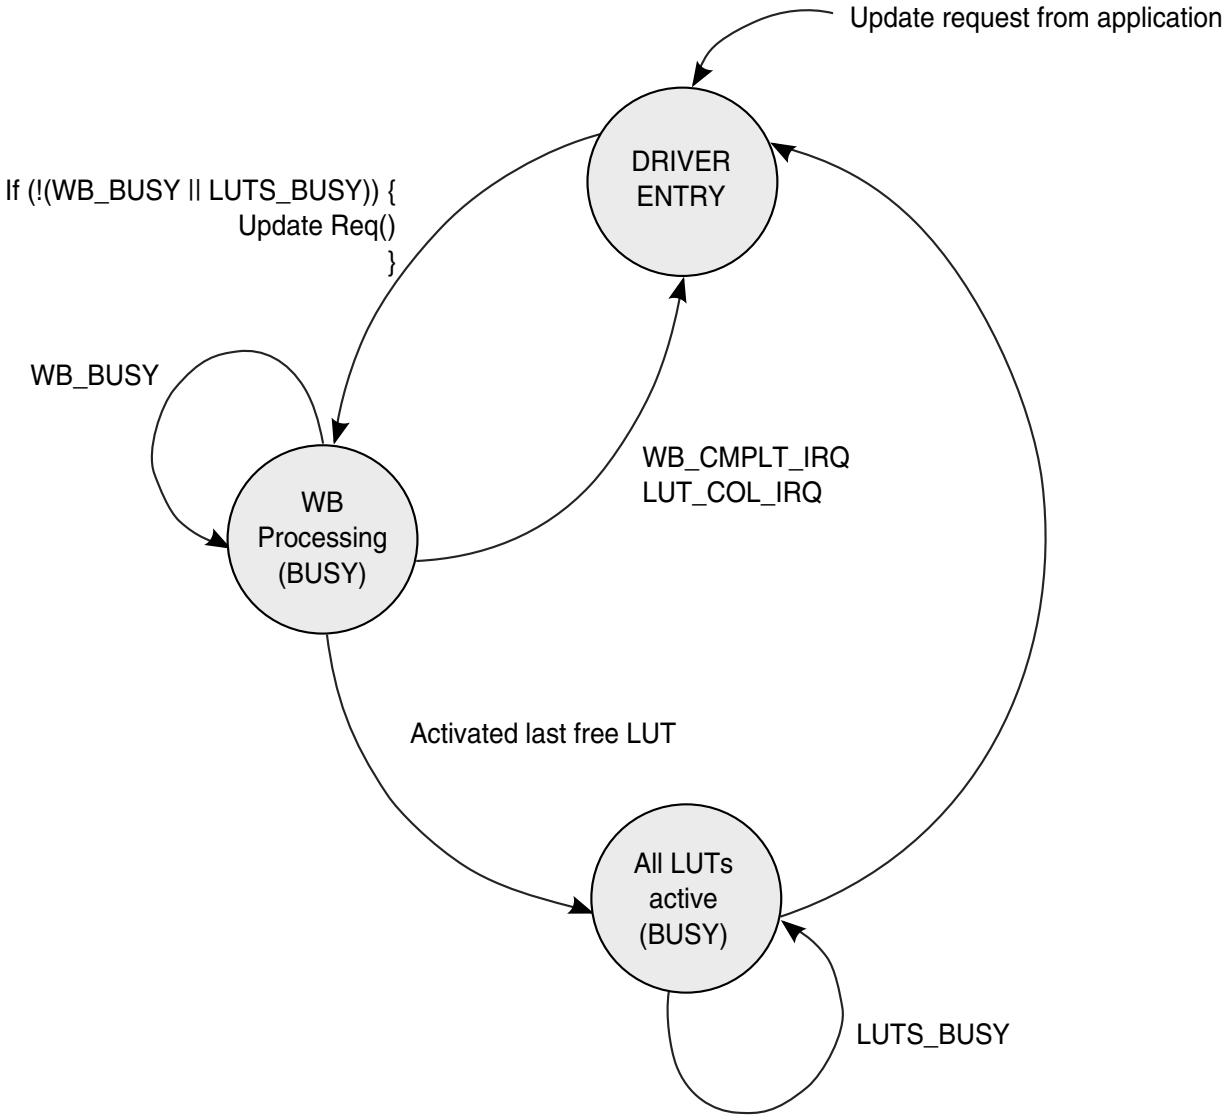

Figure 24-13. Driver Update Flow

This flow assumes that the driver is entered via interrupts. The two busy states are shown to illustrate the conditions under which the driver shall not issue new updates. In general, the driver should be throttled by the WB_CMPLT_IRQ interrupt. Because the EPDC can support up to 16 concurrent updates, its possible to re-enter the update-request (show as Update_Req() in the figure above) any-time that the WB is not busy (even though LUTs are active and the display is being updated). Its possible that if there are 15 LUTs currently active and a new update is sent, there will be a WB_CMPLT_IRQ interrupt issued, but the driver at that time would be in a busy state (because LUTS_BUSY is signaled). The driver shall be re-entered on the next LUTn_CMPLT_IRQ interrupt during which time it can issue a new update (since WB_BUSY and LUTS_BUSY status bits are low).

The update-processing process (which is controlled by the MBM module) is asynchronous to the actual TFT refresh operations (which carry out the physical screen updates), that is, there is no particular relationship between the WB_BUSY status and the state of the screen update. In contrast, the LUTn_CMPLT_IRQ interrupt status and EPDC_STATUS_LUTS provide the status of the physical waveform update. This means that when LUTn_CMPLT_IRQ interrupt fires, it means that the last physical TFT frame scan just completed for that update/LUT.

The EPDC implements proprietary methods to efficiently process the WB such that the WB processing time (the time from the SW driver writing EPDC_UPD_CTRL to the time EPDC_IRQ[WB_CMPLT_IRQ] fires), is dependent on the size of the update rectangle. This allows smaller updates to be processed faster. In most EPD applications, this is ideal because its typically smaller sprites that require the fastest performance. In addition to this the EPDC implements methods to allow store pending updates and activate them on the next available frame-scan. This means for example, that if the TFT scanning is currently in the active region and that during this time a series of small update requests are sent, the EPDC can begin all of those updates on the next available blanking period.

The figure below shows an example of two larger update request, one to LUT4 and one to LUT5. These update request are shown in the context of already active LUTs and thus active frame scan times. The times during which WB_BUSY is high and LUT_BUSY is high are defined as "blocking" because no new updates can be accepted. It should also be noted that new updates are physically commenced by the EPDC on blanking periods. From a SW programming model perspective, the EPDC_STATUS_LUTS[LUTn_STATUS] is activated immediately upon the update request being written to the EPDC. The physical frame-scanning for this particular update does not being commenced until the next available frame scan.

It should be noted that updates and WB processing can actually occur during the blanking period (or can begin in the active scan time and continue into the blanking period). For this reason, the EPDC provides some tuning controls via EPDC_TCE_CTRL[VSCAN_HOLDOFF] such that more time can be given to finish processing update request and less time to "locking down" the set of LUTs that will be activated for the upcoming active scan. The EPDC will start to pre-fill its refresh pixel FIFOs after the VSCAN_HOLDOFF period. Its possible to tune this value to allow the minimum time for the pixel FIFO pre-fill operation (making sure that refresh under-runs do not occur). If a pixel-FIFO under-run occurs, EPDC_IRQ[TCE_UNDERRUN_IRQ] will fire.

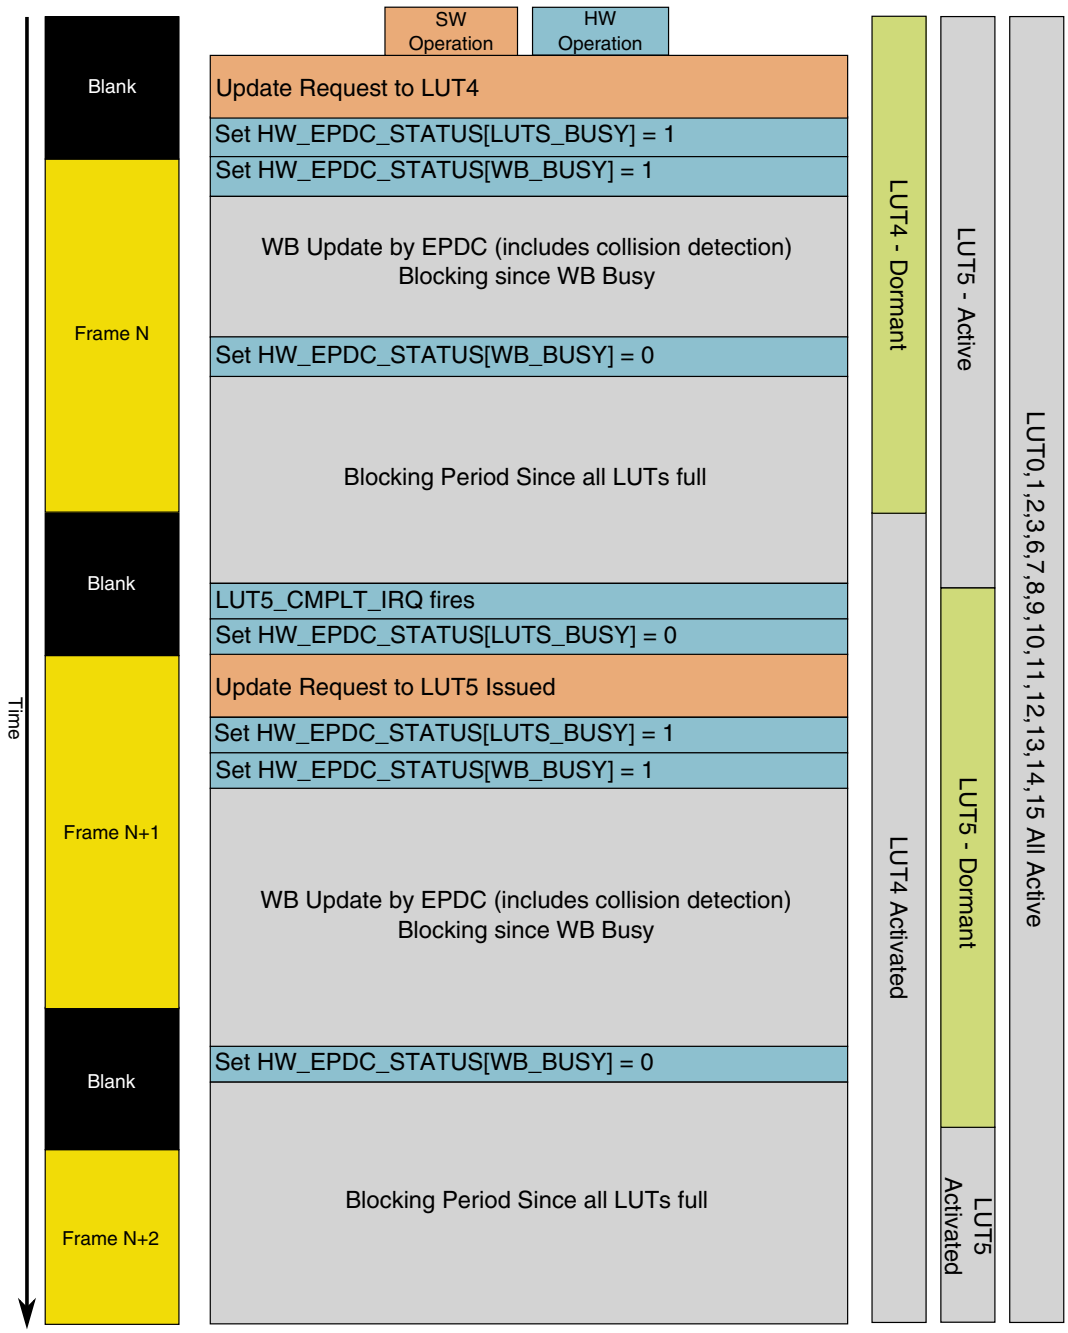

Figure 24-14. Temporal Flow of Update Processing

24.3.7 Architectural Clock Gating (Low Power Mode)

As with most modern IP, the EPDC contains low-level hardware controlled automatic clock gating throughout the design.

These clock gating elements typically gate clocks locally for individual or groups of sequential elements (flip-flops) when these registers are not currently active.

This tier of clock gating is useful for reducing power during active operation of the EPDC.

Most e-paper applications utilizing EPDs involve the processor and display controller to be in a low-power inactive state most of the time. This is because EPD displays only require refresh operations when the display content is being updated. As such, in between update operations, the EPDC provides a module level clock-gating feature that can be controlled by the driver SW as part of a higher-level power management solution.

The EPDC module can have all its clocks completely gated-off by the setting of EPDC_CTRL[CLKGATE]. There a couple of considerations that the SW driver must adhere to before placing the EPDC into this low power state:

- All active LUTs (updates) must be complete
- Any TFT operations must be complete (including any final blanking operations)

In order to maximize display update frequency (that is, the ability intercept new updates during each frame-scan), the LUT completion interrupts fire on the very end of the last frame's active scan period for that update. This means that the TCE still must compete the final "FRAME_END" blanking time to guarantee coherency of its state machines with the panel state (that is, receiving the final LUT completion IRQ is not enough to determine that the EPDC can have all its clocks shut down). Based on this, the EPDC provides the necessary interrupt and status bits allow the driver to correctly perform the clock-gating operation, but using the following method:

- Once the final EPDC_IRQ[LUTn_CMPLT_IRQ] is reached, the driver should enable the TCE_IDLE interrupt mask bit via EPDC_IRQ_MASK[TCE_IDLE_IRQ_EN], un-mask interrupts and return.
- Once the final blanking time of the last LUT (FRAME_END time) is completed and the TCE reaches its idle state, the EPDC shall assert the EPDC_IRQ[TCE_IDLE_IRQ] interrupt which will cause the driver to re-enter. At this point, the SW knows that the EPDC is in a completely idle state and can perform a set on EPDC_CTRL[CLKGATE]

Alternative implementations of the driver could simply involve polling for the EPDC_IRQ[TCE_IDLE_IRQ] interrupt status bit (which operates regardless of the interrupt being masked or not) before setting the clock-gate (this avoids two iterations of interrupt based driver-entry, but does require a wait loop in the interrupt handler which may be undesirable).

It should be noted that the time interval between the last LUTs LUTn_CMPLT_IRQ time and TCE_IDLE_IRQ interrupt is equal to the FRAME_END time.

When the application is ready to send more updates, the driver can immediately re-enable the EPDC by un-gating the module-level clock by clearing the EPDC_CTRL[CLKGATE] field. This un-gating of the clock is instant and the driver is free to immediately send update requests.

24.3.8 Performance Tuning and Considerations

The EPDC is designed to meet the performance requirements of the most demanding e-paper applications. These performance targets must be met in the context of highly integrated SoCs. In such a context, system memory is typically shared across multiple masters including the ARM platform. Because of this, there is no guarantee of latency from system memory and as such the EPDC provides a number of mechanisms to help deal with this as well as providing some ability to tune various parameters allowing the user to trade-off update processing performance with refresh functionality.

24.3.8.1 Memory and Bus Bandwidth Requirements

The EPDC MBM module contains up to 6 internal AXI requesting functions (5 read and 1 write). These are arbitrated internally before being sent to the SoC memory system. The EPDC interfaces to the SoC bus system via a dual-channel 64-bit AXI bus master port. Table 24-2 shows the various internal requesters and their properties. Note that there are two round-robin loops. Because there is only one write source, and the EPDC supports dual-channel AXI, there is no arbitration on the WB write operations.

Table 24-2. EPDC Bus Requestor Profiles

Operation	Priority	Burst Length (x8 Bytes)	Maximum Outstanding Transactions	FIFO size
Wavefor LUT read	0	8	2	16x68
WB pixel read FIFO0 (refresh)	RR 1	8 or 16	8	256x64
WB pixel read FIFO1 (refresh)	RR 1	8 or 16	8	256x64
WB read for update processing	RR 2	8	2	16x64
WB write for update processing	N/A	8	2	16x64
UPD read for update processing	RR 2	8	2	16x64

As described in Memory Requirements, it can be seen that all lines in a buffer are padded to the nearest 8 byte boundary. This is important to note for the bandwidth calculations. The maximum bandwidth scenario involves processing a full-screen update while

performing refresh operations, but refresh operations always have the highest priority. Based on this, the memory bandwidth required by the EPDC is a function of the refresh pixel rate which in turn is a function of resolution, frame-rate and blanking/active time.

The refresh bandwidth can be calculated as follows:

Active Time = Active time of the frame-scan time as a fraction (for example, 0.8)

Frame Rate = TFT frame refresh rate (Hz) (for example, 106 Hz)

Bandwidth (MB/S) = roundup4(EPDC_RES[HORIZONTAL]) x EPDC_RES[VERTICAL] x Frame Rate x (1/Active Time) x 2 x$(1/1024^2)$

As an example, for a panel with resolution 2048 x 1536 with 106 Hz refresh and estimated 80% active time, 20% blanking time, the refresh bandwidth is:

BW (MB/S) = 2048 x1536 x 106 x (1/0.8) x 2 x $(1/1024^2)$ = 795 MB/s

(note that 2048 mod 4 = 0), that is, as per 7.4.1, the WB requires 2 bytes per pixel.

Remaining bandwidth is used for other operations. Because update processing operations are not real-time (that is, do not necessarily have to occur at the refresh frame-rate), the time required to perform the update can be calculated as a function of the available bandwidth (actual bandwidth minus refresh bandwidth) and the update size.

24.3.8.2 Pixel Latency FIFOs

The EPDC contains two working buffer latency FIFOs which are used to load working buffer pixel data which is used by the TCE to perform the panel refresh operations. These FIFOs are sized at 1024 pixels each in order to provide significant system-memory latency tolerance. One pixel FIFO is dedicated for the main screen and the second is in dual-scan cases for the second half of the screen.

Under no circumstance should the EPDC pixel FIFOs reach an under-run condition. The EPDC provides an interrupt status bit to flag such as condition (TCE_UNDERRUN_IRQ). During development, this interrupt must be enabled. The pixel values stored in the FIFOs are using by the TCE to perform look-up operations (from the LUTs) to generate TFT voltage control pixels. If an under-run occurs, the result will be unknown data being used as the source for the look-ups which can damage the panel.

24.3.8.3 Basic Watermarking Control

The EPDC provides a basic pixel pre-fetching control mechanism that is applied to the beginning of a new update (i.e. from an idle state). This control is provided by EPDC_FIFOCTRL[FIFO_INIT_LEVEL]. The control allows the value to be set between 0-255, with a reset value of 128. Because the internal width of the FIFO holds 4-pixels per entry, the actual number of pixels is (FIFO_INIT_LEVEL+1) x 4.

The EPDC uses this value to pre-fill the pixel latency FIFO(s) to this level before the TCE commences the refresh operations which drive the update to the panel. This control has no effect on the FIFO(s) when the EPDC is performing sequential frame-scans. Please refer to 7.8.4 for details on influencing FIFO pre-fill operations during active scan times.

It must be noted that this value must be set less than (EPDC_RES[VERTICAL] x EPDC_RE[HORIZONTAL]) / 4.

24.3.8.4 Update/Refresh Tuning (VSCAN_HOLDOFF)

During active frame-scan time, the EPDC provides the ability to process and display new update requests. Because all pixels in the WB pertaining to a particular update are bound to a single LUT. Until all pixels pertaining to that update have been processed in the WB, its LUT cannot be activated. Referring to Figure 24-14, it can be seen that the blanking period provides time to pre-load the pixel FIFOs, but also allows time for completing WB processing updates and loading the associated frame's worth of waveform data into LUT memories.

The EPDC_TCE_CTRL[VSCAN_HOLDOFF] control field allows control over the vertical blanking period allotment for working buffer processing and pre-loading of the pixel FIFO. The time-window defined by VSCAN_HOLDOFF is allotted for working-buffer processing and LUT loading (of newly processed updates). The remainder of the time is allotted for pre-filling the pixel FIFO

It must be noted that aggressive use of VSCAN_HOLDOFF can result in pixel FIFO under-run (since the FIFO pre-fill time is compromised).

24.3.8.5 System-Level Arbitration Control

As previously mentioned, the TCE refresh operation is time critical. Because the EPDC is designed to be integrated into a multi-master SoC, system-memory is shared between multiple requesters in the system. The EPDC provides a dynamic Quality of Service (QoS) priority elevation mechanism that can be leveraged at the SoC level.

The EPDC_FIFOCTRL registers can be used in to drive the epdc_panic output signal during times when the EPDC requests require priority elevation. The expectation from the EPDC, is that as long as epdc_panic is asserted, transaction requests from the EPDC shall have their priority elevated at the SoC-level bus arbitration control points.

Referring to Figure 24-15, the registers and associated functionality are as follows:

- EPDC_FIFOCTRL[ENABLE_PRIORITY]-This must be set to enable epdc_panic functionality.
- EPDC_FIFOCTRL[FIFO_L_LEVEL]-Determines FIFO threshold which when crossed causes epdc_panic to assert.
- EPDC_FIFOCTRL[FIFO_H_LEVEL]-Once epdc_panic has been asserted (due to the pixel FIFO(s) crossing FIFO_L_LEVEL, this value (which must be set higher than FIFO_L_LEVEL), determines the point at which epdc_panic shall de-assert as the FIFO(s) fills.

It should be noted that the delta between FIFO_H_LEVEL and FIFO_L_LEVEL is intended as a "de-bounce" mechanism. The purpose is to avoid being in a constant "panic" situation which would cause thrashing of the epdc_panic signal.

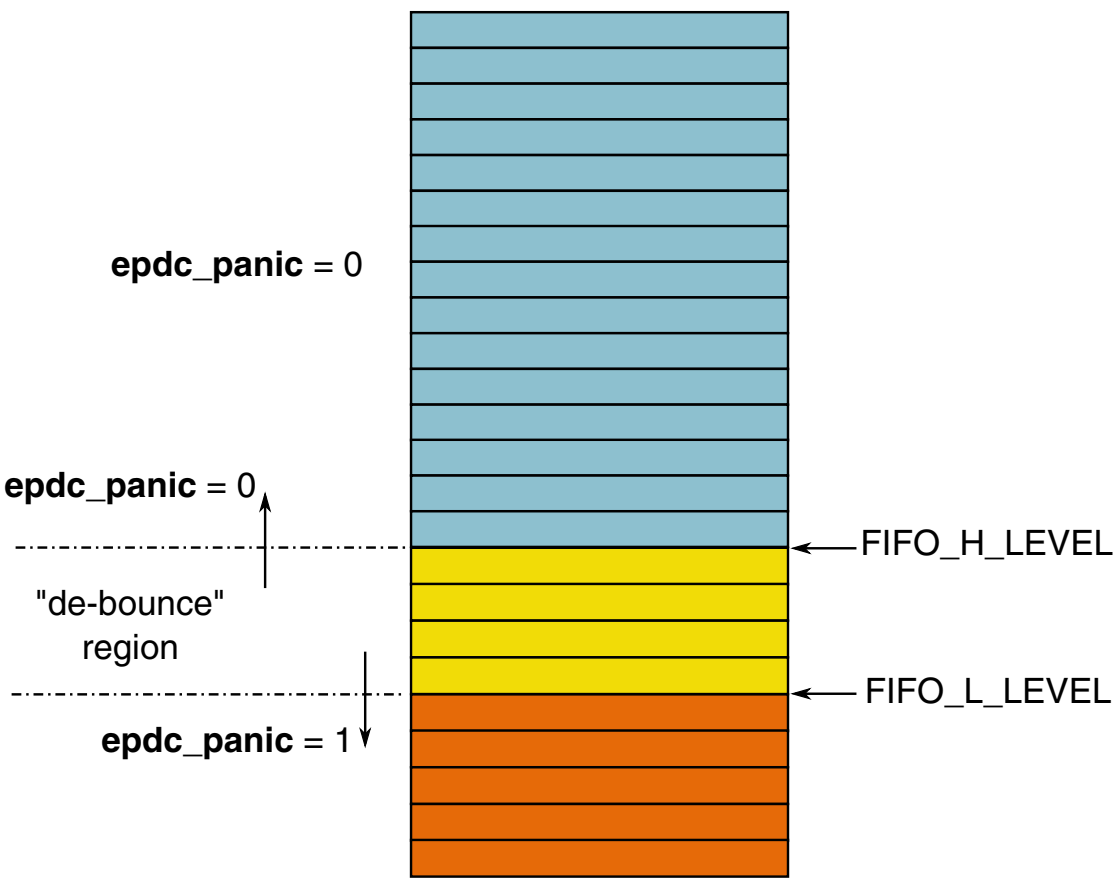

Figure 24-15. FIFO Priority Elevation

24.4 Programmable Registers

EPDC Register Format Summary

EPDC memory map

Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
4101_0000	EPDC Control Register (EPDC_CTRL)	32	R/W	C000_0000h	24.4.1/ 1193

24.4.1 EPDC Control Register (EPDC_CTRL*n*)

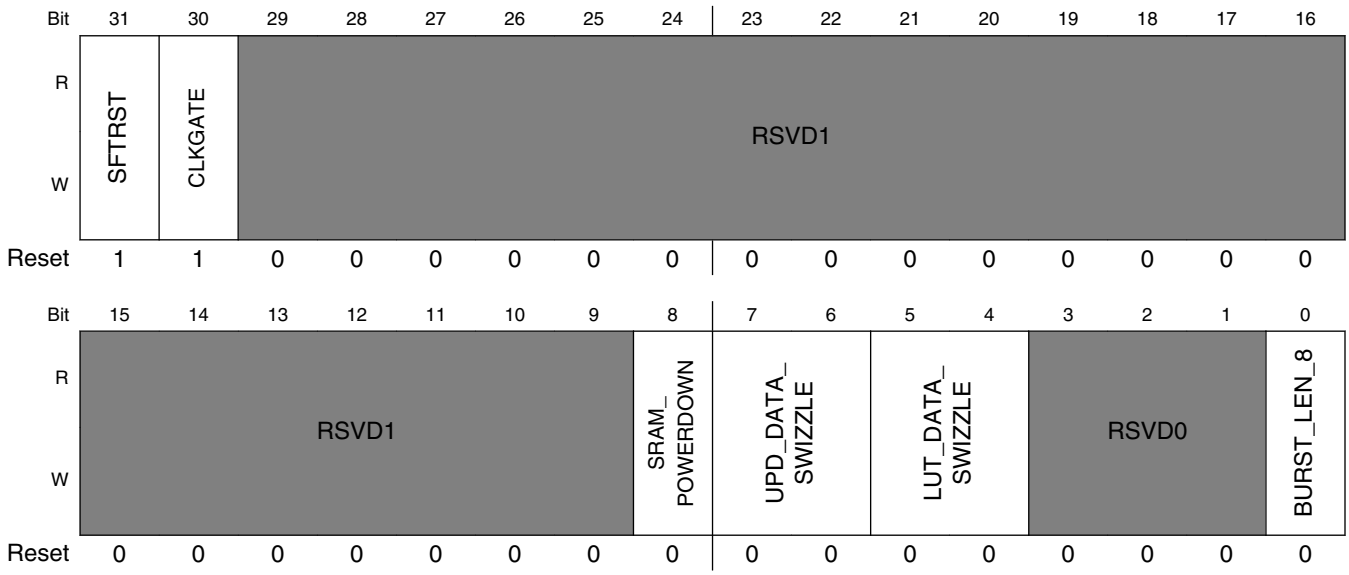
EPDC Main control register. This register controls various high-level functions of the EPDC.

Addresses: EPDC_CTRL is 4101_0000h base + 0h offset = 4101_0000h

EPDC_CTRL_SET is 4101_0000h base + 4h offset = 4101_0004h

EPDC_CTRL_CLR is 4101_0000h base + 8h offset = 4101_0008h

EPDC_CTRL_TOG is 4101_0000h base + Ch offset = 4101_000Ch



EPDC_CTRL*n* field descriptions

Field	Description
31 SFTRST	Set this bit to zero to enable normal EPDC operation. Set this bit to one (default) to disable clocking with the EPDC and hold it in its reset (lowest power) state. This bit can be turned on and then off to reset the EPDC block to its default state. Software is initialized by asserting SFTRST, the driver polls until CLKGATE is back to '0'.
30 CLKGATE	This bit must be set to zero for normal operation. When set to one it gates off the clocks to the block.
29–9 RSVD1	Reserved.
8 SRAM_ POWERDOWN	Enable Power-down of embedded SRAM memories
7–6 UPD_DATA_ SWIZZLE	Specifies how to swap the bytes for the UPD data before the WB construction. Supported configurations: 0x0 **NO_SWAP** — No byte swapping.(Little endian) 0x1 **ALL_BYTES_SWAP** — Swizzle all bytes, swap bytes 0,3 and 1,2 (aka Big Endian). 0x2 **HWD_SWAP** — Swap half-words. 0x3 **HWD_BYTE_SWAP** — Swap bytes within each half-word.

Table continues on the next page...

EPDC_CTRL*n* field descriptions (continued)

Field	Description
5–4 LUT_DATA_ SWIZZLE	Specifies how to swap the bytes for the LUT data before store to LUTRAM. Supported configurations: 0x0 **NO_SWAP** — No byte swapping.(Little endian) 0x1 **ALL_BYTES_SWAP** — Swizzle all bytes, swap bytes 0,3 and 1,2 (aka Big Endian). 0x2 **HWD_SWAP** — Swap half-words. 0x3 **HWD_BYTE_SWAP** — Swap bytes within each half-word. 0x3 **HWD_BYTE_SWAP** — Swap bytes within each half-word.
3–1 RSVD0	Reserved.
0 BURST_LEN_8	0- EPDC display fifo logic will issue AXI bursts of length 16. When set to 1, the block will issue bursts of length 8.

24.4.2 EPDC Waveform Address Pointer (EPDC_WVADDR)

Address: EPDC_WVADDR is 4101_0000h base + 20h offset = 4101_0020h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

EPDC_WVADDR field descriptions

Field	Description
31–0 ADDR	Start address of waveform tables. This address needs to be aligned to a 64-bit double word boundary.

24.4.3 EPDC Working Buffer Address (EPDC_WB_ADDR)

EPDC Working Buffer Address register controls various functions throughout the digital portion of the chip.

Address: EPDC_WB_ADDR is 4101_0000h base + 30h offset = 4101_0030h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

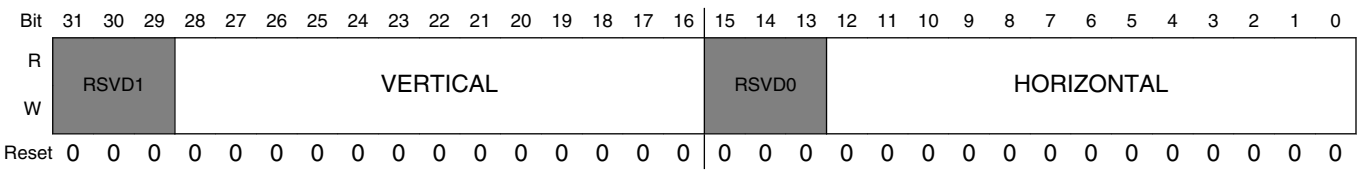
EPDC_WB_ADDR field descriptions

Field	Description
31–0 ADDR	Address for EPDC working buffer. This address must be a aligned to a 64-bit double-word boundary.

24.4.4 EPDC Screen Resolution (EPDC_RES)

EPDC Screen Resolution register defines the horizontal and vertical resolution of the target display panel.

Address: EPDC_RES is 4101_0000h base + 40h offset = 4101_0040h



EPDC_RES field descriptions

Field	Description
31–29 RSVD1	Reserved.
28–16 VERTICAL	Vertical Resoltion (in pixels)
15–13 RSVD0	Reserved.
12–0 HORIZONTAL	Horizontal Resolution (in pixels)

24.4.5 EPDC Format Control Register (EPDC_FORMAT*n*)

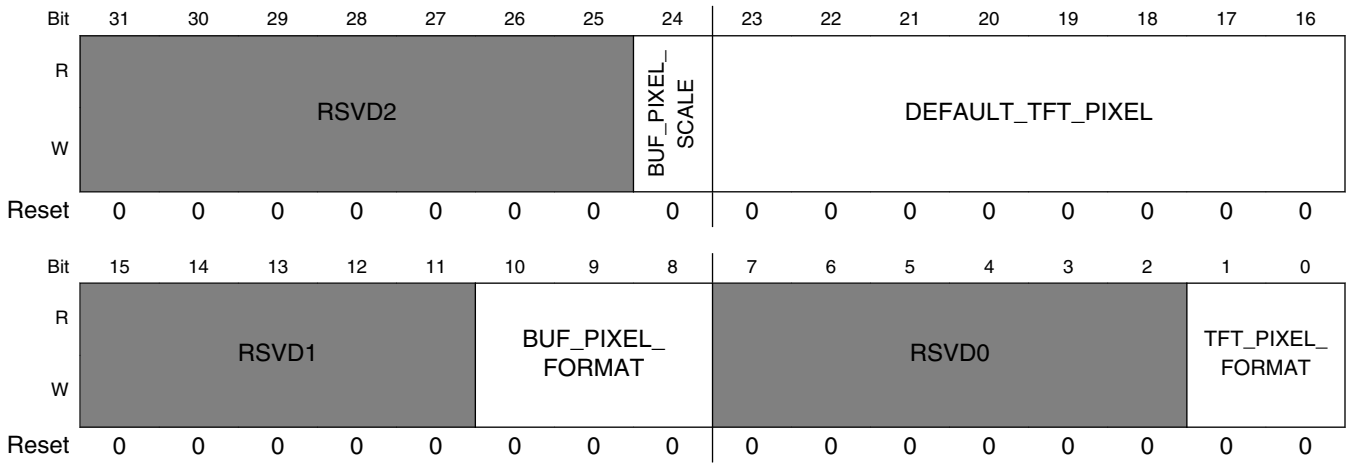
EPDC Pixel format control register defines formats for buffer and TFT pixels and controls various functions throughout the digital portion of the chip.

Addresses: EPDC_FORMAT is 4101_0000h base + 50h offset = 4101_0050h

EPDC_FORMAT_SET is 4101_0000h base + 54h offset = 4101_0054h

EPDC_FORMAT_CLR is 4101_0000h base + 58h offset = 4101_0058h

EPDC_FORMAT_TOG is 4101_0000h base + 5Ch offset = 4101_005Ch



EPDC_FORMAT*n* field descriptions

Field	Description
31–25 RSVD2	Reserved.
24 BUF_PIXEL_ SCALE	Selects method of conversion from 8-bit input. 0x0 **TRUNCATE** — Use Truncate method (LSB) 0x1 **ROUND** — Use rounding method (with saturation)
23–16 DEFAULT_TFT_ PIXEL	Default TFT pixel value. This value is used as the source-driver voltage value (TFT-pixel) for either partial-updates where a pixel has not changed or for any part of the screen which is not being updated during active frame scans.
15–11 RSVD1	Reserved.
10–8 BUF_PIXEL_ FORMAT	EPDC Input Buffer Pixel format. All update buffers are expected to have 8-bit grayscale pixels. This register defines which MSBs of those pixels are used. It must be noted that this format must match the waveform (P4N is not compatible with 3-bit waveforms) 0x2 **P2N** — 2-bit pixel 0x3 **P3N** — 3-bit pixel 0x4 **P4N** — 4-bit pixel 0x5 **P5N** — 5-bit pixel
7–2 RSVD0	Reserved.

Table continues on the next page...

EPDC_FORMAT*n* field descriptions (continued)

Field	Description
1–0 TFT_PIXEL_ FORMAT	EPDC TFT Pixel Format. This defines how many bits of the SDDO bus are required per pixel. This field must be consistent with the waveform and panel architecture. 0x0 **2B** — 2-bit 0x1 **2BV** — 2-bit and VCOM 0x2 **4B** — 4-bit 0x3 **4BV** — 4-bit and VCOM

24.4.6 EPDC FIFO Control Register (EPDC_FIFOCTRL*n*)

The EPDC FIFO Control Register allows for programmability of pixel FIFO watermarks used in conjunction with system arbitration hardware. This register houses FIFO control bits.

Addresses: EPDC_FIFOCTRL is 4101_0000h base + A0h offset = 4101_00A0h

EPDC_FIFOCTRL_SET is 4101_0000h base + A4h offset = 4101_00A4h

EPDC_FIFOCTRL_CLR is 4101_0000h base + A8h offset = 4101_00A8h

EPDC_FIFOCTRL_TOG is 4101_0000h base + ACh offset = 4101_00ACh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	ENABLE_ PRIORITY	RSVD1							FIFO_INIT_LEVEL							
Reset	0	0	0	0	0	0	0	0	1	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	FIFO_H_LEVEL								FIFO_L_LEVEL							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

EPDC_FIFOCTRL*n* field descriptions

Field	Description
31 ENABLE_ PRIORITY	Enable watermark-based priority elevation mechanism. 1=Enabled, 0=Disabled. (Only applies to FIFO_H_LEVEL and FIFO_L_LEVEL)
30–24 RSVD1	Reserved.
23–16 FIFO_INIT_ LEVEL	This register sets the watermark for the pixel-fifo.

Table continues on the next page...

EPDC_FIFOCTRL*n* field descriptions (continued)

Field	Description
15–8 FIFO_H_LEVEL	Upper level value of FIFO watermark. Must be greater than FIFO_L_LEVEL. When the pixel FIFO reaches this level or above, the priority elevation request is negated
7–0 FIFO_L_LEVEL	Lower level value of FIFO watermark. When the pixel FIFO reaches this level or below, the priority elevation request is asserted.

24.4.7 EPDC Update Region Address (EPDC_UPD_ADDR)

Address: EPDC_UPD_ADDR is 4101_0000h base + 100h offset = 4101_0100h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	ADDR																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

EPDC_UPD_ADDR field descriptions

Field	Description
31–0 ADDR	Address for incoming region update. This address points to update region which will be processed into the working buffer. This address must be a aligned to a 64-bit double-word boundary. In addition the start address of each line must be a aligned to a 64-bit double-word boundary.

24.4.8 EPDC Update Command Co-ordinate (EPDC_UPD_CORD)

Address: EPDC_UPD_CORD is 4101_0000h base + 120h offset = 4101_0120h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	RSVD1			YCORD													RSVD0			XCORD												
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

EPDC_UPD_CORD field descriptions

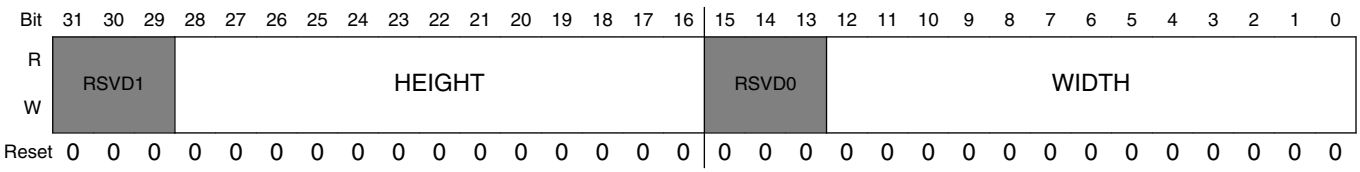
Field	Description
31–29 RSVD1	Reserved.
28–16 YCORD	Y co-ordinate for incoming region update
15–13 RSVD0	Reserved.
12–0 XCORD	X co-ordinate for incoming region update

24.4.9 EPDC Update Command Size (EPDC_UPD_SIZE)

EPDC Update Command Size register controls various functions throughout the digital portion of the chip.

-->

Address: EPDC_UPD_SIZE is 4101_0000h base + 140h offset = 4101_0140h



EPDC_UPD_SIZE field descriptions

Field	Description
31–29 RSVD1	Reserved.
28–16 HEIGHT	Height (in pixels)
15–13 RSVD0	Reserved.
12–0 WIDTH	Width (in pixels)

24.4.10 EPDC Update Command Control (EPDC_UPD_CTRL*n*)

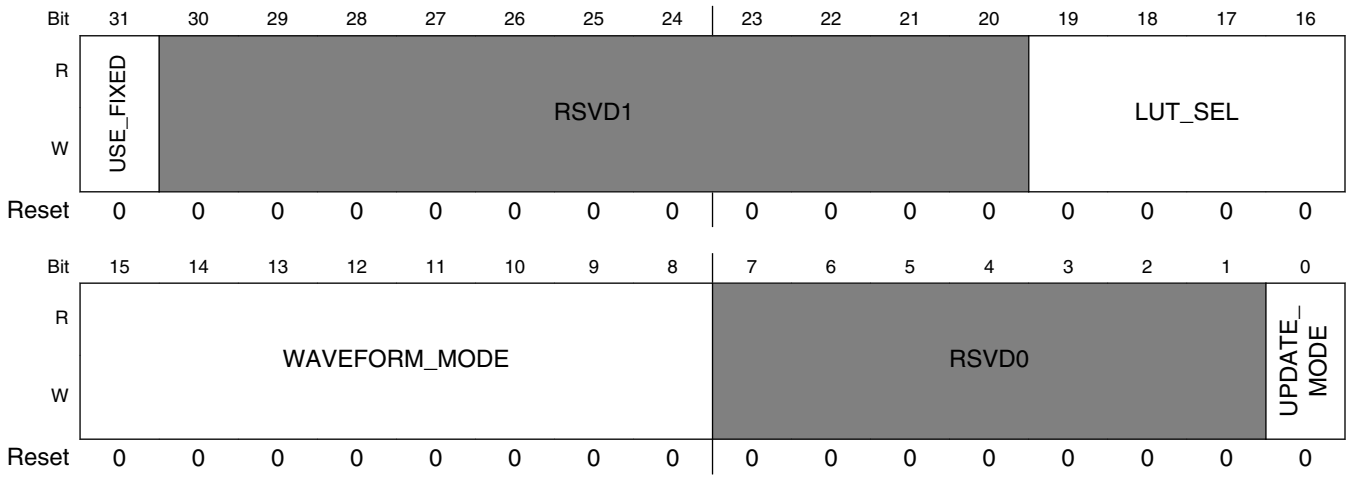
Writing to EPDC Update Command Control register triggers and update request operation.

Addresses: EPDC_UPD_CTRL is 4101_0000h base + 160h offset = 4101_0160h

EPDC_UPD_CTRL_SET is 4101_0000h base + 164h offset = 4101_0164h

EPDC_UPD_CTRL_CLR is 4101_0000h base + 168h offset = 4101_0168h

EPDC_UPD_CTRL_TOG is 4101_0000h base + 16Ch offset = 4101_016Ch



EPDC_UPD_CTRL*n* field descriptions

Field	Description
31 USE_FIXED	Use fixed pixel values (requires programming of EPDC_UPD_FIXED).
30–20 RSVD1	Reserved.
19–16 LUT_SEL	LUT select 0-15
15–8 WAVEFORM_ MODE	Waveform Mode 0-255
7–1 RSVD0	Reserved.
0 UPDATE_MODE	Update Mode 0x0 **PARTIAL** — Partial Update : only process changed pixels in region 0x1 **FULL** — Full Update : process all pixels in region

24.4.11 EPDC Update Fixed Pixel Control (EPDC_UPD_FIXED*n*)

EPDC Update Control register for fixed-pixel updates (enabled via EPDC_UPD_CTRL[USE_FIXED]).

Addresses: EPDC_UPD_FIXED is 4101_0000h base + 180h offset = 4101_0180h
EPDC_UPD_FIXED_SET is 4101_0000h base + 184h offset = 4101_0184h
EPDC_UPD_FIXED_CLR is 4101_0000h base + 188h offset = 4101_0188h
EPDC_UPD_FIXED_TOG is 4101_0000h base + 18Ch offset = 4101_018Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	FIXNP_EN	FIXCP_EN	RSVD0													
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	FIXNP								FIXCP							
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

EPDC_UPD_FIXED*n* field descriptions

Field	Description
31 FIXNP_EN	If set to 1, current updated region has the NP value defined by FIXNP
30 FIXCP_EN	If set to 1, current updated region has the CP value defined by FIXCP
29–16 RSVD0	Reserved.
15–8 FIXNP	NP value if fixenp_en is set to 1. Data in Y8 format.
7–0 FIXCP	CP value if fixecp_en is set to 1. Data in Y8 format.

24.4.12 EPDC Temperature Register (EPDC_EPDC_TEMP)

Address: EPDC_EPDC_TEMP is 4101_0000h base + 1A0h offset = 4101_01A0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	TEMPERATURE																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

EPDC_EPDC_TEMP field descriptions

Field	Description
31–0 TEMPERATURE	Temperature Value. This value is simply an index (not a temperature value). The index is used by the EPDC to access the correct temperature compensated waveform.

24.4.13 EPDC Timing Control Engine Control Register (EPDC_EPDC_TCE_CTRL*n*)

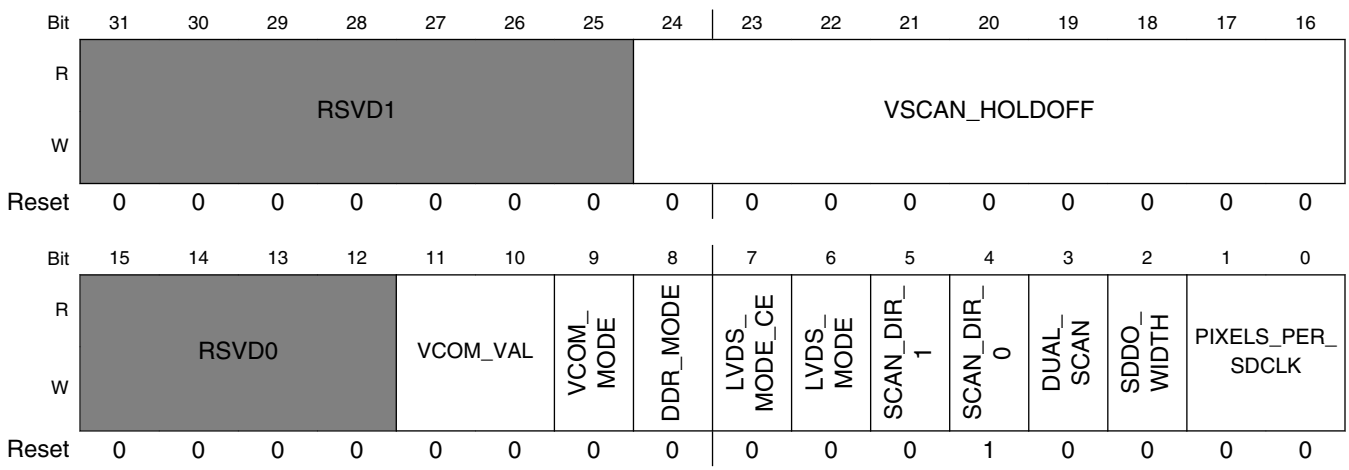
The EPDC Timing Control Engine Control Register houses Horizontal scan timing. Note that line data length is derived from EPDC_RES.

Addresses: EPDC_EPDC_TCE_CTRL is 4101_0000h base + 200h offset = 4101_0200h

EPDC_EPDC_TCE_CTRL_SET is 4101_0000h base + 204h offset = 4101_0204h

EPDC_EPDC_TCE_CTRL_CLR is 4101_0000h base + 208h offset = 4101_0208h

EPDC_EPDC_TCE_CTRL_TOG is 4101_0000h base + 20Ch offset = 4101_020Ch



EPDC_EPDC_TCE_CTRL*n* field descriptions

Field	Description
31–25 RSVD1	Reserved.
24–16 VSCAN_ HOLDOFF	This period (expressed in vertical lines), sets the portion of the vertical blanking available for new LUTs to be activated. The remainder of the blanking period is reserved for pre-filling the TCE pixel FIFOs. Increasing this value allows for multiple smaller updates to be intercepted by the current frame scan. This number should not exceed FRAME_END+FRAME_SYNC+FRAME_BEGIN. Increasing this value can improve the ability for any given update to intercept the next available frame-scan. Excessive values can result in TCE FIFO under-runs.
15–12 RSVD0	Reserved.
11–10 VCOM_VAL	When VCOM_MODE = MANUAL, this value is used to manually set the VCOM value for the VCOM[1:0] pins

Table continues on the next page...

EPDC_EPDC_TCE_CTRL*n* field descriptions (continued)

Field	Description
9 VCOM_MODE	This field determines the method used to drive the VCOM signal. 0x0 **MANUAL** — VCOM Value is set manually using VCOM_VAL field 0x1 **AUTO** — VCOM Value is used from waveform
8 DDR_MODE	If set, SDDO data is driven on both positive and negative edges of SDCLK. Note that this mode is not supported when SDDO_BUS_FORMAT=16BIT and LVDS is not used. This must always be set when LVDS_MODE is set.
7 LVDS_MODE_CE	If set (together with LVDS_MODE=1), SDCE[9:5] shall be driven as the differential inverse of SDCE[4:0]. In this mode the EPDC only supports 5 CE lines.
6 LVDS_MODE	If set, the upper 8-bit of the SDDO bus are used for LVDS differential signalling. Note that this can only be used when SDDO_BUS_FORMAT is set to 16BIT, i.e. LVDS signaling is not supported with an 8-bit SDDO interface. Note that for LVDS_MODE, DDR_MODE must also be set.
5 SCAN_DIR_1	Determines scan direction for each half of the TFT panel 0x1 **UP** — Scan this region from bottom to top 0x0 **DOWN** — Scan this region from top to bottom
4 SCAN_DIR_0	Determines scan direction for each half of the TFT panel 0x1 **UP** — Scan this region from bottom to top 0x0 **DOWN** — Scan this region from top to bottom
3 DUAL_SCAN	Enables dual scan-mode. Note in this mode, SDDO_BUS_FORMAT=16BIT must be selected. and PIXELS_PER_CLK applies to each 8-bit segment of the SDDO bus.
2 SDDO_WIDTH	Selects either 8 or 16 bit SDDO bus format 0x0 **8BIT** — Connect to 8-bit source driver 0x1 **16BIT** — Connct to 16-bit source driver
1–0 PIXELS_PER_SDCLK	Number of TFT pixels per SDCLK period. Note that this value forms the division of the PIXLK to generate the SDCLK such that SDCLK = PIXCLK/PIXELS_PER_SDCLK. For dual-scan mode (DUAL_SCAN=1), this applies to 8-bit half of the 16-bit SDDO. It should be noted that when DDR_MODE is enabled, both edges of the clock have to be accounted for in this value, so for example with an 8-bit SDDO, 2-bit TFT pixel, this field should be set to EIGHT (four pixels on the pos-edge and 4-pixels on the neg-edge) 0x0 **RESERVED** — Reserved 0x1 **TWO** — Two TFT-pixels per SDCLK 0x2 **FOUR** — Four TFT-pixels per SDCLK 0x3 **EIGHT** — Eight TFT-pixels per SDCLK

24.4.14 EPDC Timing Control Engine Source-Driver Config Register (EPDC_TCE_SDCFG*n*)

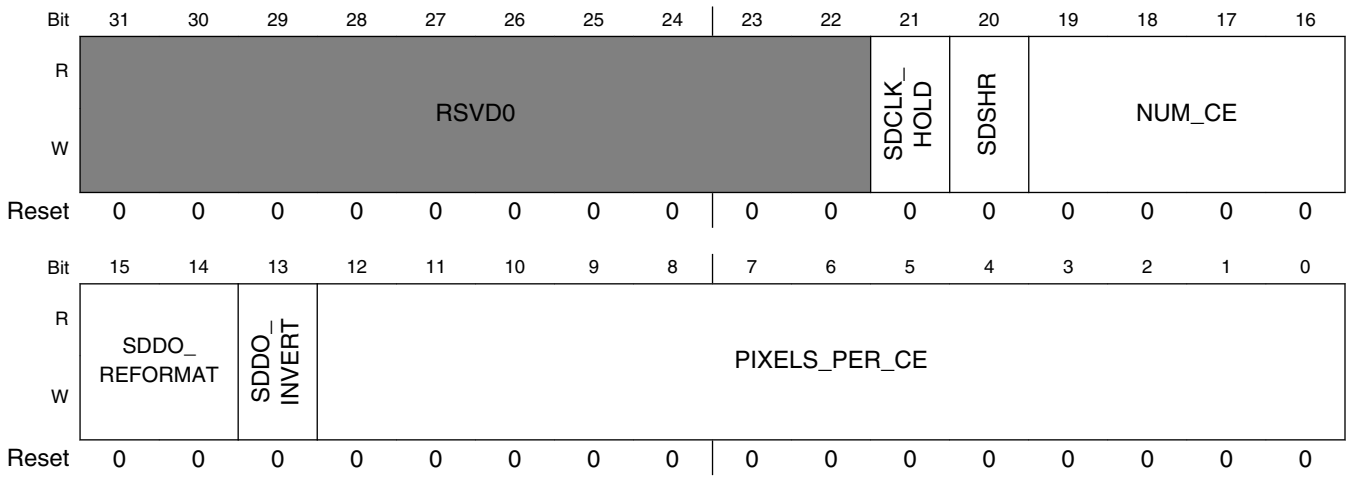
EPDC Timing Control Engine Source-Driver Config Register houses source-driver configuration.

Addresses: EPDC_TCE_SDCFG is 4101_0000h base + 220h offset = 4101_0220h

EPDC_TCE_SDCFG_SET is 4101_0000h base + 224h offset = 4101_0224h

EPDC_TCE_SDCFG_CLR is 4101_0000h base + 228h offset = 4101_0228h

EPDC_TCE_SDCFG_TOG is 4101_0000h base + 22Ch offset = 4101_022Ch



EPDC_TCE_SDCFG*n* field descriptions

Field	Description
31–22 RSVD0	Reserved.
21 SDCLK_HOLD	Setting this bit to 1 holds the SDCLK low during LINE_BEGIN
20 SDSHR	Value for source-driver shift direction output port
19–16 NUM_CE	Number of source driver IC chip-enables. Must be 1-10
15–14 SDDO_ REFORMAT	This register defines the various re-formatting options to enable more flexibility in the source-driver interface: 0x0 **STANDARD** — No change. 0x1 **FLIP_PIXELS** — Reverses the order of the pixels on SDDO. This register setting is sensitive to the TFT pixel width (TFT_PIXEL_FORMAT), e.g. for TFT_PIXEL_FORMAT=2B on an 8-bit bus P3,P2,P1,P0 becomes P0,P1,P2,P3, whereas with TFT_PIXEL_FORMAT=4B, on an 8-bit bus, P1,P0 becomes P0,P1
13 SDDO_INVERT	Setting this bit to 1 reverses the polarity of each SDDO bit so 0xAAAA in 16-bit mode for example becomes 0x5555. This setting can be made in addition to the SDDO_REFORMAT register setting.

Table continues on the next page...

EPDC_TCE_SDCFG*n* field descriptions (continued)

Field	Description
12–0 PIXELS_PER_CE	Number of pixels (outputs) per source-driver IC. Please note that EPDC_RES[HORIZONTAL] must be an integer multiple of PINS_PER_CE.

24.4.15 EPDC Timing Control Engine Gate-Driver Config Register (EPDC_TCE_GDCFG*n*)

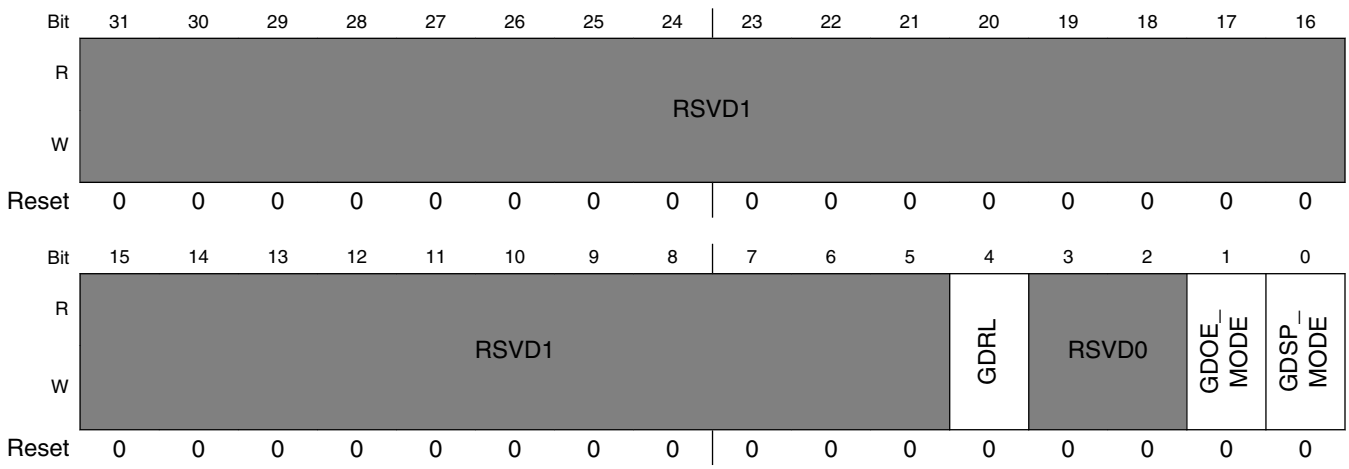
EPDC Timing Control Engine Gate-Driver Config Register houses gate-driver configuration.

Addresses: EPDC_TCE_GDCFG is 4101_0000h base + 240h offset = 4101_0240h

EPDC_TCE_GDCFG_SET is 4101_0000h base + 244h offset = 4101_0244h

EPDC_TCE_GDCFG_CLR is 4101_0000h base + 248h offset = 4101_0248h

EPDC_TCE_GDCFG_TOG is 4101_0000h base + 24Ch offset = 4101_024Ch



EPDC_TCE_GDCFG*n* field descriptions

Field	Description
31–5 RSVD1	Reserved.
4 GDRL	Value for gate-driver right/left shift output port
3–2 RSVD0	Reserved.
1 GDOE_MODE	Selects method for driving GDOE signal. When set to 0, GDOE is driven at all times during the frame-scan except FRAME_SYNC. When set to 1, GDOE is driven as a delayed version of GDCLK delayed by EPDC_TCE_TIMING3[GDOE_OFFSET].
0 GDSP_MODE	Selects method for driving GDSP pulse. When set to 0, GDSP is is always fixed to have a pulse width of one line-time. When set to 1, GDSP has a pulse-width determined by the FRAME_SYNC setting. Note that GDSP_MODE=1 is not compatible with the GDSP_OFFSET function

24.4.16 EPDC Timing Control Engine Horizontal Timing Register 1 (EPDC_TCE_HSCAN1*n*)

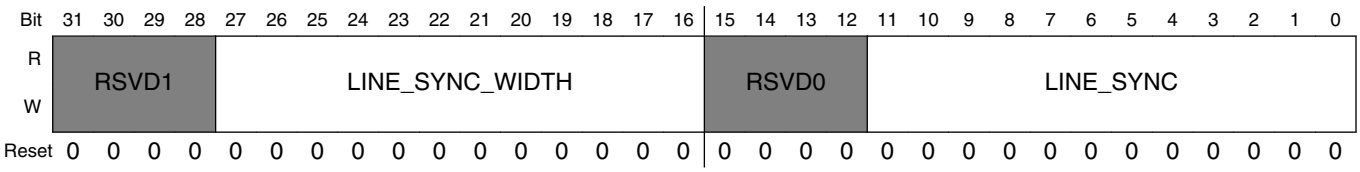
Horizontal scan timing registers. All timing values are expressed in terms of the EPDC's internal PIXCLK, which depending on the PIXELS_PER_SDCLK register setting is either 2:1 or 4:1. Note that line data length is derived from EPDC_RES.

Addresses: EPDC_TCE_HSCAN1 is 4101_0000h base + 260h offset = 4101_0260h

EPDC_TCE_HSCAN1_SET is 4101_0000h base + 264h offset = 4101_0264h

EPDC_TCE_HSCAN1_CLR is 4101_0000h base + 268h offset = 4101_0268h

EPDC_TCE_HSCAN1_TOG is 4101_0000h base + 26Ch offset = 4101_026Ch



EPDC_TCE_HSCAN1*n* field descriptions

Field	Description
31–28 RSVD1	Reserved.
27–16 LINE_SYNC_ WIDTH	Number of PIXCLK cycles for the SDLE active time. Note that this value cannot be larger than LINE_SYNC and must be greater than 0. Typically it is recommended to set this value to be the same as LINE_SYNC
15–12 RSVD0	Reserved.
11–0 LINE_SYNC	Number of PIXCLK cycles for line sync duration. Note that this value encompasses the LINE_SYNC_WIDTH duration. This value must be programmed to a multiple of SDCLK cycles

24.4.17 EPDC Timing Control Engine Horizontal Timing Register 2 (EPDC_TCE_HSCAN2*n*)

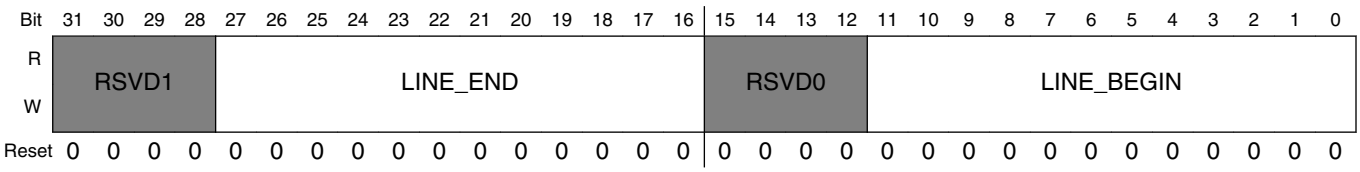
Horizontal scan timing registers. All timing values are expressed in terms of the EPDC's internal PIXCLK, which depending on the PIXELS_PER_SDCLK register setting is either 2:1 or 4:1. Note that line data length is derived from EPDC_RES.

Addresses: EPDC_TCE_HSCAN2 is 4101_0000h base + 280h offset = 4101_0280h

EPDC_TCE_HSCAN2_SET is 4101_0000h base + 284h offset = 4101_0284h

EPDC_TCE_HSCAN2_CLR is 4101_0000h base + 288h offset = 4101_0288h

EPDC_TCE_HSCAN2_TOG is 4101_0000h base + 28Ch offset = 4101_028Ch



EPDC_TCE_HSCAN2*n* field descriptions

Field	Description
31–28 RSVD1	Reserved.
27–16 LINE_END	Number of PIXCLK cycles for line end duration. This defines the duration from the de-assertion of SDCE and assertion of the next SDLE.
15–12 RSVD0	Reserved.
11–0 LINE_BEGIN	Number of PIXCLK cycles for line begin duration. This defines the interval between de-assertion of SDLE and assertion of the SDCE signals. This value must be programmed to a multiple of SDCLK cycles

24.4.18 EPDC Timing Control Engine Vertical Timing Register (EPDC_TCE_VSCAN*n*)

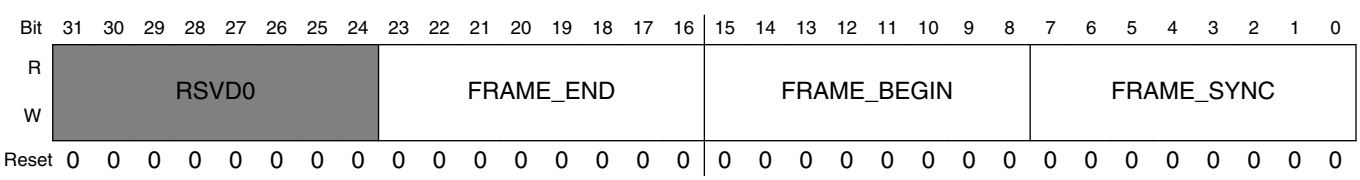
This register houses vertical scan timing. Note that frame data length is derived from EPDC_RES.

Addresses: EPDC_TCE_VSCAN is 4101_0000h base + 2A0h offset = 4101_02A0h

EPDC_TCE_VSCAN_SET is 4101_0000h base + 2A4h offset = 4101_02A4h

EPDC_TCE_VSCAN_CLR is 4101_0000h base + 2A8h offset = 4101_02A8h

EPDC_TCE_VSCAN_TOG is 4101_0000h base + 2ACh offset = 4101_02ACh



EPDC_TCE_VSCAN*n* field descriptions

Field	Description
31–24 RSVD0	Reserved.
23–16 FRAME_END	Number of lines for frame end duration.
15–8 FRAME_BEGIN	Number of lines for frame begin duration.
7–0 FRAME_SYNC	Number of lines for frame sync duration.

24.4.19 EPDC Timing Control Engine OE timing control Register (EPDC_TCE_OE*n*)

This register contains delay programming values for the SDOEZ and SDOED source driver control signals.

Addresses: EPDC_TCE_OE is 4101_0000h base + 2C0h offset = 4101_02C0h

EPDC_TCE_OE_SET is 4101_0000h base + 2C4h offset = 4101_02C4h

EPDC_TCE_OE_CLR is 4101_0000h base + 2C8h offset = 4101_02C8h

EPDC_TCE_OE_TOG is 4101_0000h base + 2CCh offset = 4101_02CCh

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

EPDC_TCE_OE*n* field descriptions

Field	Description
31–24 SDOED_WIDTH	Number of PIXCLK cycles from SDOED high to SDOED falling (Must be greater than 0)
23–16 SDOED_DLY	Number of PIXCLK cycles from SDOEZ low to SDOED rising (Must be greater than 0)
15–8 SDOEZ_WIDTH	Number of PIXCLK cycles from SDOEZ high to SDOEZ falling (Must be greater than 0)
7–0 SDOEZ_DLY	Number of PIXCLK cycles from SDLE falling edge to SDOEZ rising (Must be greater than 0)

24.4.20 EPDC Timing Control Engine Driver Polarity Register (EPDC_TCE_POLARITY*n*)

This register allows for programming the polarity of source/gate driver control signals. This register houses FIFO control bits.

Addresses: EPDC_TCE_POLARITY is 4101_0000h base + 2E0h offset = 4101_02E0h
EPDC_TCE_POLARITY_SET is 4101_0000h base + 2E4h offset = 4101_02E4h
EPDC_TCE_POLARITY_CLR is 4101_0000h base + 2E8h offset = 4101_02E8h
EPDC_TCE_POLARITY_TOG is 4101_0000h base + 2ECh offset = 4101_02ECh

EPDC_TCE_POLARITY*n* field descriptions

Field	Description
31–5 RSVD0	Reserved.
4 GDSP_POL	0 = Active Low, 1 = Active High. Applies to the GDSP output
3 GDOE_POL	0 = Active Low, 1 = Active High. Applies to the GDOE output
2 SDOE_POL	0 = Active Low, 1 = Active High. Applies to the SDOE. Does not apply to SDOEZ and SDOED outputs
1 SDLE_POL	0 = Active Low, 1 = Active High. Applies to the SDLE output
0 SDCE_POL	0 = Active Low, 1 = Active High. Applies to all 10 SDCE outputs

24.4.21 EPDC Timing Control Engine Timing Register 1 (EPDC_TCE_TIMING1*n*)

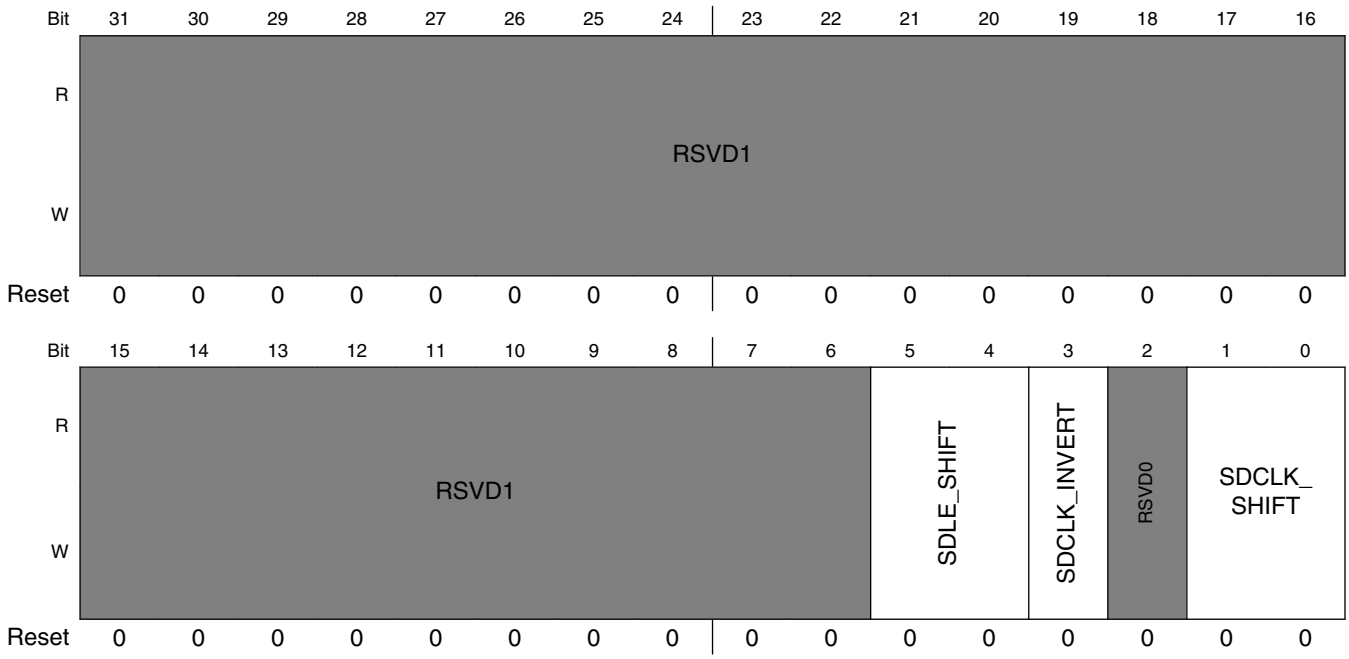
This register contains various timing adjustment controls.

Addresses: EPDC_TCE_TIMING1 is 4101_0000h base + 300h offset = 4101_0300h

EPDC_TCE_TIMING1_SET is 4101_0000h base + 304h offset = 4101_0304h

EPDC_TCE_TIMING1_CLR is 4101_0000h base + 308h offset = 4101_0308h

EPDC_TCE_TIMING1_TOG is 4101_0000h base + 30Ch offset = 4101_030Ch



EPDC_TCE_TIMING1*n* field descriptions

Field	Description
31–6 RSVD1	Reserved.
5–4 SDLE_SHIFT	This register can be used to implement additional timing setup/hold adjustment of source driver signals by adjusting the SDCLK up to 3 PIXCLK cycles 0x0 **NONE** — No shift of SDLE 0x1 **ONE** — Shift SDLE 1 pixclk cycle 0x2 **TWO** — Shift SDLE 2 pixclk cycles 0x3 **THREE** — Shift SDLE 3 pixclk cycles
3 SDCLK_INVERT	Invert phase of SDCLK
2 RSVD0	Reserved.
1–0 SDCLK_SHIFT	This register can be used to implement additional timing setup/hold adjustment of source driver signals by adjusting the SDCLK up to 4 cycles

Table continues on the next page...

EPDC_TCE_TIMING1*n* field descriptions (continued)

Field	Description
	0x0 **NONE** — No shift of SDCLK 0x1 **ONE** — Shift SDCLK 1 pixclk cycle 0x2 **TWO** — Shift SDCLK 2 pixclk cycles 0x3 **THREE** — Shift SDCLK 3 pixclk cycles

24.4.22 EPDC Timing Control Engine Timing Register 2 (EPDC_TCE_TIMING2*n*)

This register contains various timing adjustment controls and houses general purpose timing adjustment registers.

Addresses: EPDC_TCE_TIMING2 is 4101_0000h base + 310h offset = 4101_0310h
EPDC_TCE_TIMING2_SET is 4101_0000h base + 314h offset = 4101_0314h
EPDC_TCE_TIMING2_CLR is 4101_0000h base + 318h offset = 4101_0318h
EPDC_TCE_TIMING2_TOG is 4101_0000h base + 31Ch offset = 4101_031Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

EPDC_TCE_TIMING2*n* field descriptions

Field	Description
31–16 GDCLK_HP	This register controls the GDCLK high-pulse width. It is expressed by N PIXCLKs where N=1 to 65535. Note that GDCLK will always have a period equal to the line-clock timing. A value of 0 is not supported. It is recommended that this value be set to at least a half line-clock time. For panels which use GDCLK to drive GDOE, this high-pulse width should be set to cover tha majority of the line timing
15–0 GDSP_OFFSET	This register allows the user to shift the GDSP pulse by N PIXCLKs where N=1 to 65535. Note that GDSP will always have a pulse width equivalent to the line-clock timing. A value of 0 is not supported.

24.4.23 EPDC Timing Control Engine Timing Register 3 (EPDC_TCE_TIMING3*n*)

This register contains various timing adjustment controls and houses general purpose timing adjustment registers.

Addresses: EPDC_TCE_TIMING3 is 4101_0000h base + 320h offset = 4101_0320h
EPDC_TCE_TIMING3_SET is 4101_0000h base + 324h offset = 4101_0324h
EPDC_TCE_TIMING3_CLR is 4101_0000h base + 328h offset = 4101_0328h
EPDC_TCE_TIMING3_TOG is 4101_0000h base + 32Ch offset = 4101_032Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	GDOE_OFFSET																GDCLK_OFFSET

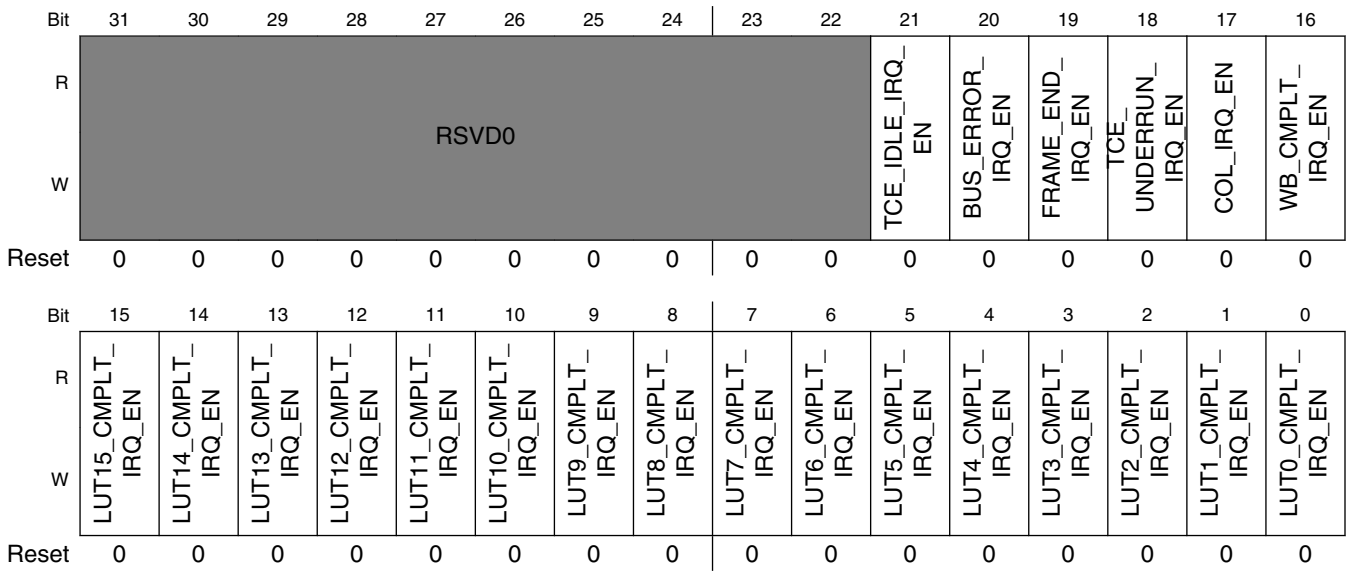
EPDC_TCE_TIMING3*n* field descriptions

Field	Description
31–16 GDOE_OFFSET	When using GDOE_MODE=1, this register sets the delay from GDCLK to the GDOE in terms of N PIXCLK cycles
15–0 GDCLK_ OFFSET	This register allows the user to shift the GDCLK from the line time by N PIXCLK cycles.

24.4.24 EPDC IRQ Mask Register (EPDC_IRQ_MASK*n*)

This register controls IRQ masking for all EPDC interrupts.

Addresses: EPDC_IRQ_MASK is 4101_0000h base + 400h offset = 4101_0400h
EPDC_IRQ_MASK_SET is 4101_0000h base + 404h offset = 4101_0404h
EPDC_IRQ_MASK_CLR is 4101_0000h base + 408h offset = 4101_0408h
EPDC_IRQ_MASK_TOG is 4101_0000h base + 40Ch offset = 4101_040Ch



EPDC_IRQ_MASK*n* field descriptions

Field	Description
31–22 RSVD0	Reserved.
21 TCE_IDLE_IRQ_EN	Enable TCE Idle interrupt detection.
20 BUS_ERROR_IRQ_EN	Enable AXI BUS ERROR interrupt detection.
19 FRAME_END_IRQ_EN	If this bit is set, EPDC will assert the current frame end interrupt. This irq is only available during updating period.
18 TCE_UNDERRUN_IRQ_EN	Enable pixel FIFO under-run condition detection.
17 COL_IRQ_EN	Enable collision detection interrupts for all LUTs

Table continues on the next page...

EPDC_IRQ_MASK*n* field descriptions (continued)

Field	Description
16 WB_CMPLT_ IRQ_EN	Enable WB complete interrupt
15 LUT15_CMPLT_ IRQ_EN	LUT15 Complete Interrupt Enable

0 LUT0_CMPLT_IRQ_EN	LUT0 Complete Interrupt Enable

24.4.25 EPDC Interrupt Register (EPDC_IRQ*n*)

This register houses the interrupt bits for the LUT Completions. The IRQ for a specific LUT is triggered when its corrrsponding physical update is competed on the screen. Each interrupt has a corresponding mask register in EPDC_IRQ_MASK.

Addresses: EPDC_IRQ is 4101_0000h base + 420h offset = 4101_0420h

EPDC_IRQ_SET is 4101_0000h base + 424h offset = 4101_0424h

EPDC_IRQ_CLR is 4101_0000h base + 428h offset = 4101_0428h

EPDC_IRQ_TOG is 4101_0000h base + 42Ch offset = 4101_042Ch

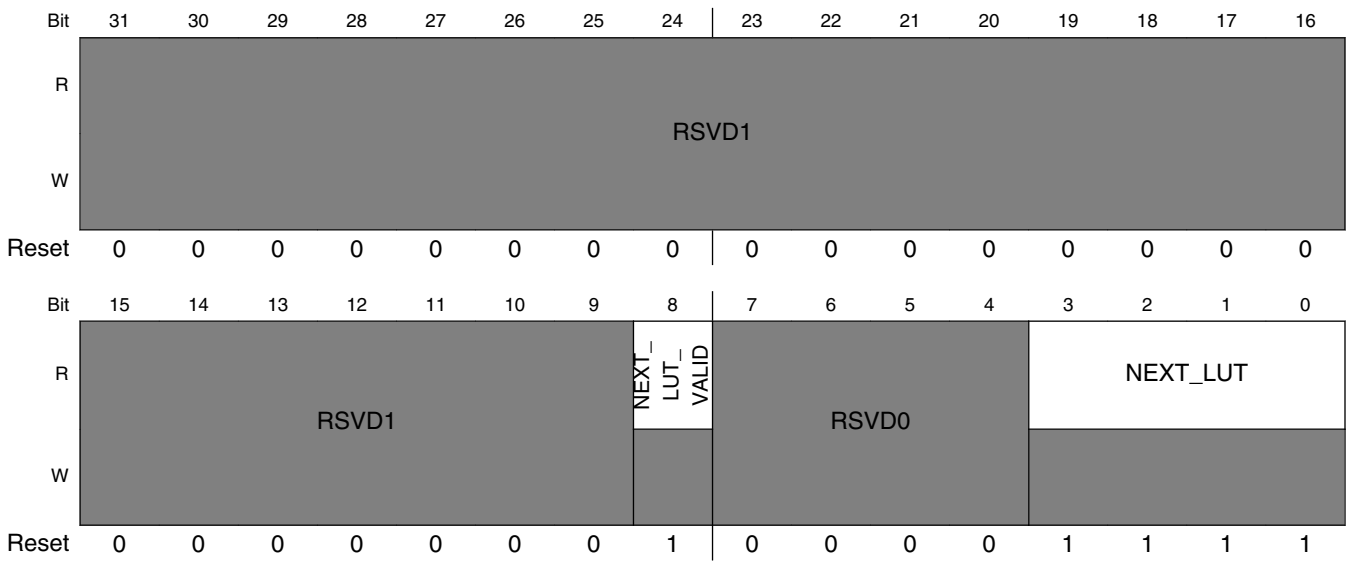
24.4.27 EPDC Status Register - Next Available LUT (EPDC_STATUS_NEXTLUT)

The EPDC Status Register provides a read-only view to various input conditions and internal states. It holds the value of next available LUT and can be used for fast LUT assignment. This value can be read and then used in an update command as part of the EPDC_UPD_CTRL register write.

Address: EPDC_STATUS_NEXTLUT is 4101_0000h base + 460h offset = 4101_0460h



EPDC_STATUS_NEXTLUT field descriptions

Field	Description
31–9 RSVD1	Reserved.
8 NEXT_LUT_ VALID	This bitfield can be used to check against a LUTs full condition.
7–4 RSVD0	Reserved.
3–0 NEXT_LUT	Next available LUT value

24.4.28 EPDC LUT Collision Status (EPDC_STATUS_COL*n*)

EPDC LUT Collision Status Register and EPDC_IRQ[WB_CMPLT_IRQ] works in conjuction with EPDC_IRQ[LUT_COL_IRQ]. When a collision occurs, the interrupt is set and all status bits are set for LUTs which were touched by the collision. It does not set the bit for the LUT that caused the collision. There is a single interrupt mask which is used to control all the IRQ bits in this register (in EPDC_IRQ_MASK).

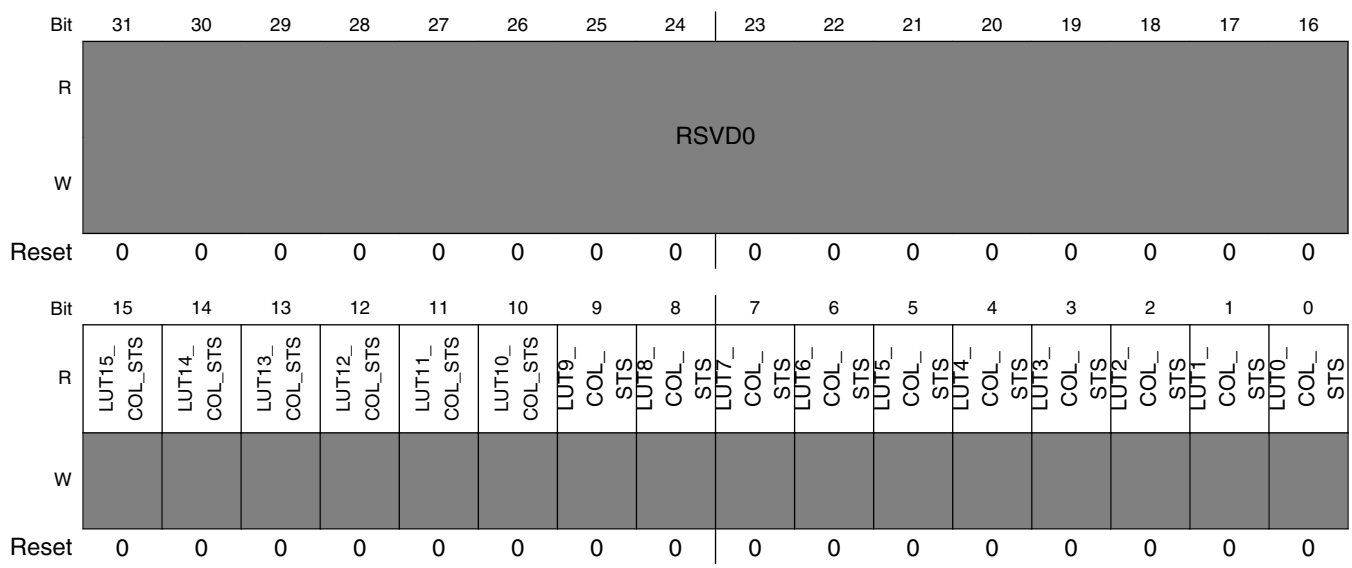
NOTE

A collision caused by a LUT which was set-up for no collision detection (according to EPDC_IRQ_MASKn[COL_IRQ_EN]) will not trigger any collision LUT IRQ or status update.

NOTE

Clearing the interrupt bit EPDC_IRQ[LUT_COL_IRQ] clears this register.

Addresses: EPDC_STATUS_COL is 4101_0000h base + 480h offset = 4101_0480h
EPDC_STATUS_COL_SET is 4101_0000h base + 484h offset = 4101_0484h
EPDC_STATUS_COL_CLR is 4101_0000h base + 488h offset = 4101_0488h
EPDC_STATUS_COL_TOG is 4101_0000h base + 48Ch offset = 4101_048Ch



EPDC_STATUS_COL*n* field descriptions

Field	Description
31–16 RSVD0	Reserved.

Table continues on the next page...

EPDC_STATUS_COL*n* field descriptions (continued)

Field	Description
15 LUT15_COL_STS	LUT15 Collision Status
14 LUT14_COL_STS	LUT14 Collision Status

1 LUT1_COL_STS	LUT1 Collision Status
0 LUT0_COL_STS	LUT0 Collision Status

24.4.29 EPDC General Status Register (EPDC_STATUS*n*)

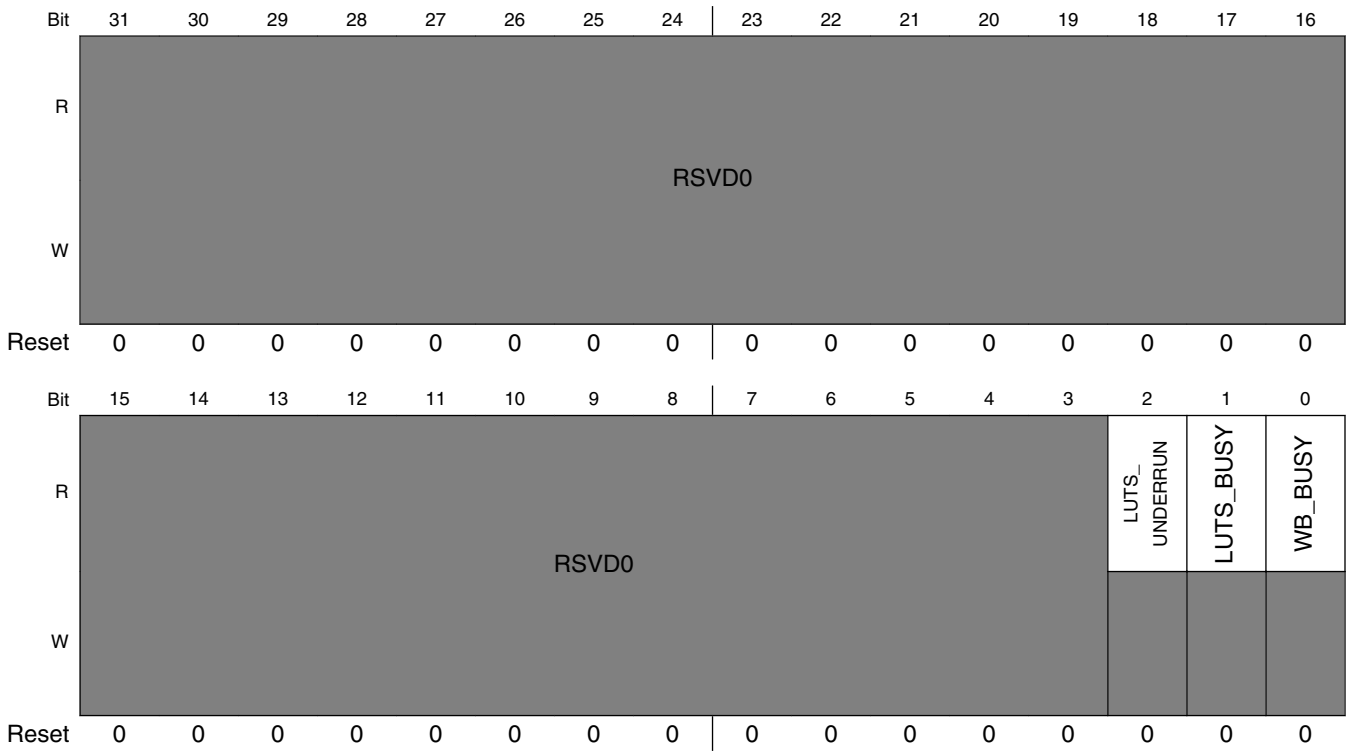
This register houses non-LUT-specific status bits.

Addresses: EPDC_STATUS is 4101_0000h base + 4A0h offset = 4101_04A0h

EPDC_STATUS_SET is 4101_0000h base + 4A4h offset = 4101_04A4h

EPDC_STATUS_CLR is 4101_0000h base + 4A8h offset = 4101_04A8h

EPDC_STATUS_TOG is 4101_0000h base + 4ACh offset = 4101_04ACh



EPDC_STATUS*n* field descriptions

Field	Description
31–3 RSVD0	Reserved.
2 LUTS_ UNDERRUN	Provides a summary status of LUT fill. 1= not enough time for active luts read during blanking period before vscan_holdoff. 0=complete all active luts fill during blanking period before VSCAN_HOLDOFF.
1 LUTS_BUSY	Provides a summary status of LUTs. 1= All LUTs are busy, 0= LUTs are available
0 WB_BUSY	Working buffer process is busy cannot accept new update requests. When WB_BUSY is 1, software should wait for the WB_CMPLT_IRQ interrupt. When this interrupt occurs WB_BUSY is cleared immediately. This is a real-time status of the process.

24.4.30 EPDC Debug register (EPDC_DEBUG*n*)

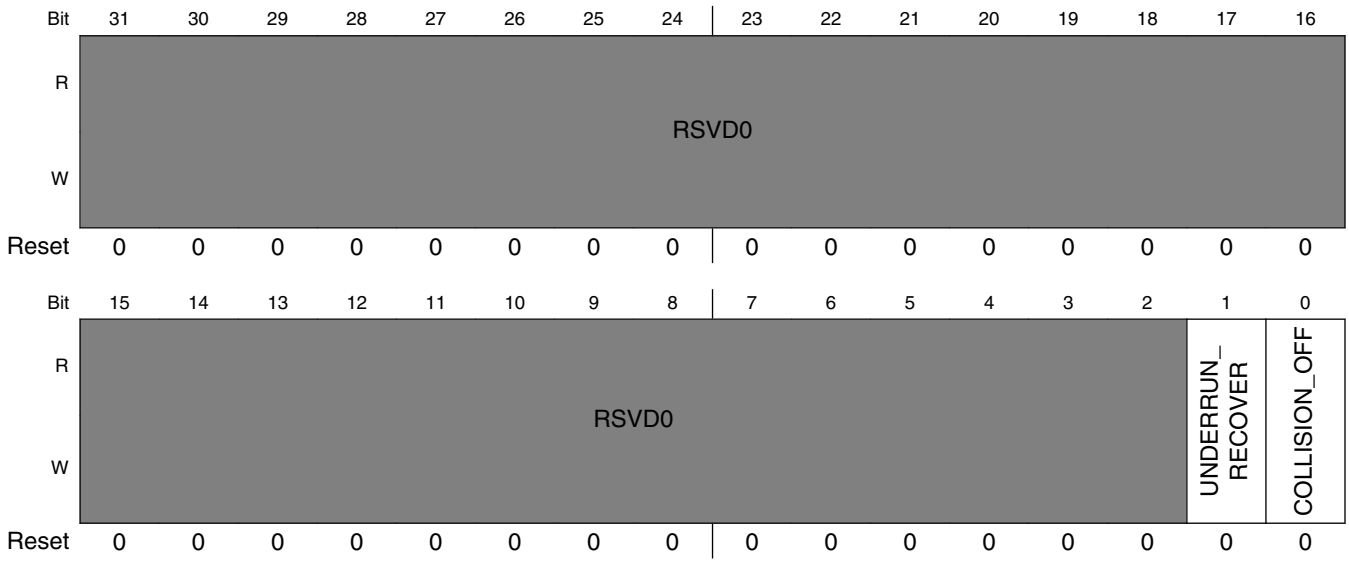
This register is for debug/testing purposes only. Writing one to this register may damage the display panel.

Addresses: EPDC_DEBUG is 4101_0000h base + 500h offset = 4101_0500h

EPDC_DEBUG_SET is 4101_0000h base + 504h offset = 4101_0504h

EPDC_DEBUG_CLR is 4101_0000h base + 508h offset = 4101_0508h

EPDC_DEBUG_TOG is 4101_0000h base + 50Ch offset = 4101_050Ch



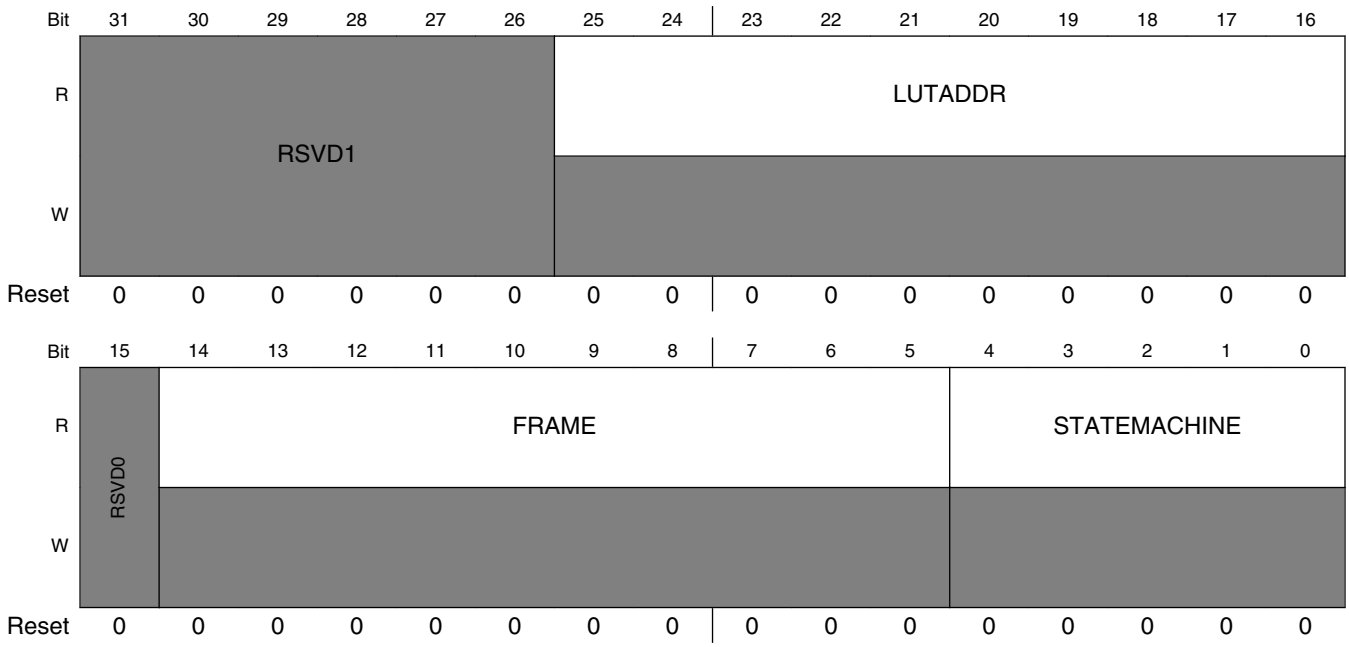
EPDC_DEBUG*n* field descriptions

Field	Description
31–2 RSVD0	Reserved.
1 UNDERRUN_ RECOVER	Set 1 to enable EPDC to recover the display at the next vsync when display fifo underrun happens.
0 COLLISION_ OFF	Set 1 to allow update to take effect even when collision is detected.

24.4.31 EPDC LUTn Debug Information register (EPDC_DEBUG_LUT*n*)

This register gives debug visibility for LUTn and houses LUTn debug bits.

Addresses: 4101_0000h base + 540h offset + (16d × *n*), where *n* = 0d to 15d



EPDC_DEBUG_LUT*n* field descriptions

Field	Description
31–26 RSVD1	Reserved.
25–16 LUTADDR	LUT address to be filled.
15 RSVD0	Reserved..
14–5 FRAME	The remaining number of frames for this update.
4–0 STATEMACHINE	LUTn state machine

24.4.32 EPDC General Purpose I/O Debug register (EPDC_GPIO*n*)

GPIO register to control ipp_epdc_bdr[1:0], ipp_epdc_pwr[3:0] and ipp_epdc_pwrcom output signals. This register houses software control signal registers.

Addresses: EPDC_GPIO is 4101_0000h base + 700h offset = 4101_0700h
EPDC_GPIO_SET is 4101_0000h base + 704h offset = 4101_0704h
EPDC_GPIO_CLR is 4101_0000h base + 708h offset = 4101_0708h
EPDC_GPIO_TOG is 4101_0000h base + 70Ch offset = 4101_070Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R W	RSVD0

EPDC_GPIO*n* field descriptions

Field	Description
31–7 RSVD0	Reserved.
6 PWRCOM	Controls ipp_epdc_pwrcom output
5–2 PWRCTRL	Controls ipp_epdc_pwrctrl[3:0] output
1–0 BDR	Controls ipp_epdc_bdr[1:0] output

24.4.33 EPDC Version Register (EPDC_VERSION)

This register reflects the version number for the EPDC.

Address: EPDC_VERSION is 4101_0000h base + 7F0h offset = 4101_07F0h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

EPDC_VERSION field descriptions

Field	Description
31–24 MAJOR	Fixed read-only value reflecting the MAJOR field of the RTL version.
23–16 MINOR	Fixed read-only value reflecting the MINOR field of the RTL version.
15–0 STEP	Fixed read-only value reflecting the stepping of the RTL version.

Chapter 25
Enhanced Periodic Interrupt Timer (EPIT)

25.1 Overview

The EPIT is a 32-bit set-and-forget timer that begins counting after the EPIT is enabled by software. It is capable of providing precise interrupts at regular intervals with minimal processor intervention.

The following figure illustrates the block diagram of the EPIT.

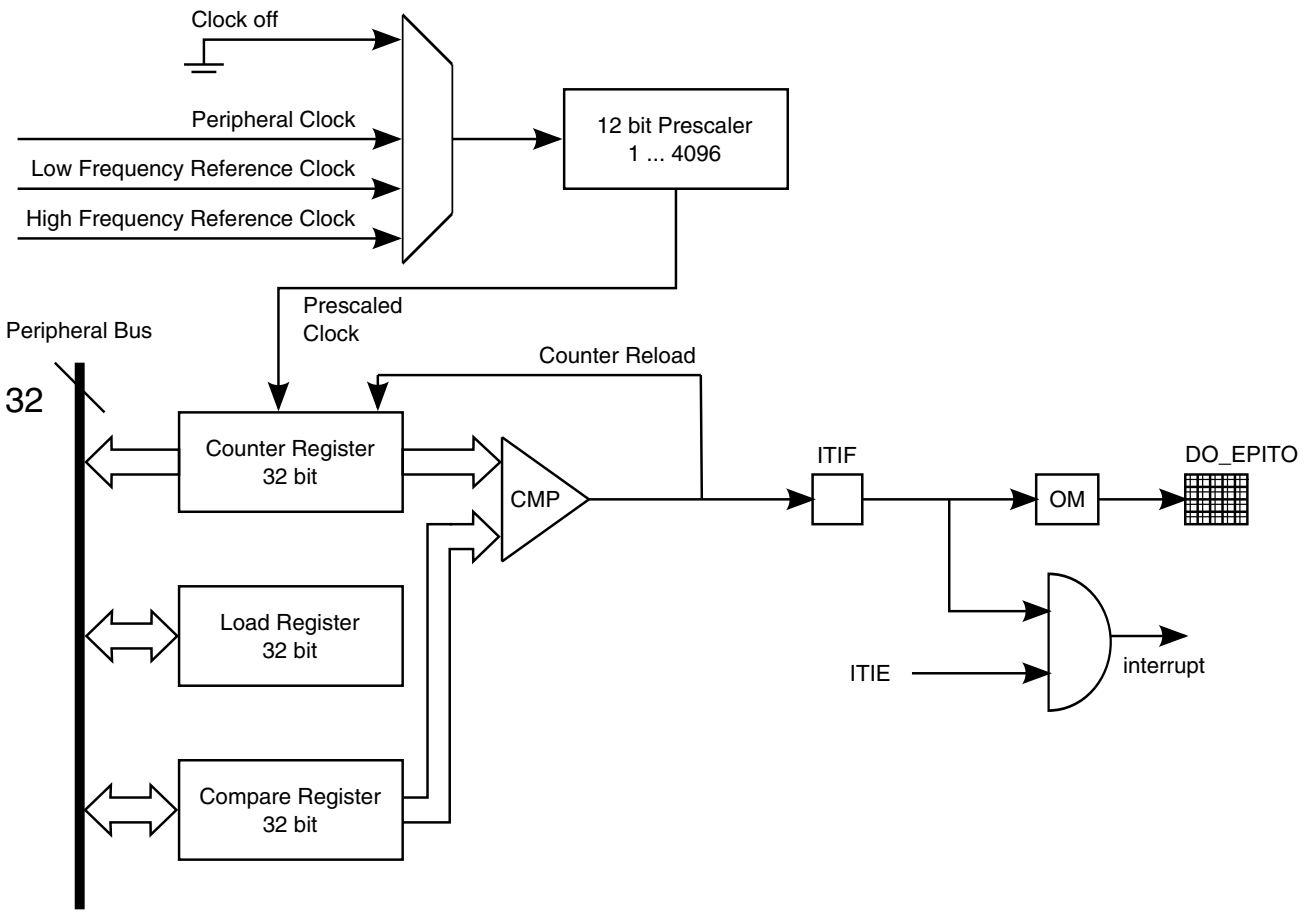

Figure 25-1. EPIT Block Diagram

25.1.1 Features

Key features of the EPIT include:

- 32-bit down counter with clock source selection
- 12-bit prescaler for division of input clock frequency
- Counter value can be programmed on the fly

- Can be programmed to be active during low-power and debug modes
- Interrupt generation when counter reaches the Compare value

25.1.2 Modes and Operations

EPIT supports the modes described in the indicated sections:

- Operating Modes
  - Set-and-Forget Mode
  - Free-Running Mode

EPIT supports the operations as described in Operations.

25.2 External Signals

The following table describes all EPIT's I/O Signals.

Table 25-1. Block I/O Signals

Name	I/O	Description	Reset State	Pull Up
DO_EPITO	O	Output pin at chip boundary for indication of occurrence of output compare event through a specified transition.	0	-

25.3 Functional Description

This section provides a complete functional description of the block.

25.3.1 Operating Modes

This section describes all functional operation modes of the block.

The EPIT can be programmed to function in set-and-forget or free-running modes.

25.3.1.1 Set-and-Forget Mode

This mode of operation is selected when the RLD bit in control register (EPIT_EPITCR) is set to a value of one.

The counter cannot be directly written from the block data bus. Instead, it gets its data from the load register (EPIT_EPITLR). Whenever the counter reaches a count of zero, the value in EPIT_EPITLR is loaded into the counter to be decremented toward zero. The counter may by directly initialized, without having to wait for the count to reach zero, when the EPIT_EPITLR is written with the IOVW bit in EPIT_EPITCR set.

25.3.1.2 Free-Running Mode

This mode of operation is selected when the RLD bit is cleared.

In this mode, the counter rolls over from 0x0000_0000 to 0xFFFF_FFFF without reloading from the modulus register and continues to count down. In this mode when writing to EPIT_EPITLR with the required initialization value after having set the IOVW bit, the counter can also be directly initialized.

25.3.2 Operations

The EPIT has a single 32-bit down counter which starts counting when the block is enabled by software.

The start value of the counter is loaded from the EPIT load register which can be written to at any time by the processor. The value in the compare register determines the time of occurrence of the interrupt.

When EPIT is disabled (EN=0), both the main counter and the prescaler counter freeze their count at current count values. ENMOD bit is a r/w bit which decides the counter value when the EPIT is enabled again by setting EN bit. If ENMOD bit is set, then the main counter is loaded with the load value (If RLD=1)/ 0xFFFF_FFFF (If RLD=0) and the prescaler counter is reset (0x000), when EPIT is enabled (EN=1). If ENMOD is programmed to 0 then both main counter and prescaler counter restart counting from their frozen values, when EPIT is enabled (EN=1). If EPIT is programmed to be disabled in a low-power mode (STOP/WAIT), then both the main counter and the prescaler counter freeze at their current count values when EPIT enters low-power mode. When EPIT exits the low-power mode, both the main counter and the prescaler counter start counting from their frozen values irrespective of the ENMOD bit.

A hardware reset resets all EPIT registers to their respective reset values. There is a software reset which has the same effect on all registers except for the EN, ENMOD, STOPEN and WAITEN bits in the control register. The state of these bits are not affected by software reset. A software reset can be asserted even when the EPIT is disabled.

25.3.3 Clocks

The clock that feeds the prescaler can be selected from among the following sources:

- **High-frequency reference clock**

  This clock is provided by the Clock Control Module (CCM). This clock remains on during low-power mode when the peripheral clock is turned off, allowing EPIT to use this clock in low-power mode. In normal mode, the CCM synchronizes this clock to ahb_clk; in low-power mode, CCM switches to an unsynchronized version.

- **Low-frequency reference clock**

  This 32 kHz reference clock is provided by the CCM. This clock remains on in low-power mode when the peripheral clock is turned off, so EPIT can use this clock during low-power mode. In normal mode, the CCM synchronizes this clock to ahb_clk; in low-power mode, CCM switches to an unsynchronized version. This clock is derived from the external 32kHz crystal.

- **Peripheral clock**

  This is the peripheral clock (PER Clock) which is provided (and optionally gated) by the CCM. This clock is typically used in normal operations. In low-power modes, if the EPIT is programmed to be disabled (via STOPEN or WAITEN), then the peripheral clock can be switched off.

The clock input source is determined by the CLKSRC field in the control register. The clock input to the prescaler can also be disabled by setting CLKSRC to 0b00. **This field value should only be changed after first disabling the EPIT by clearing the EN bit in the EPIT_EPITCR**. For other programming requirements that apply while changing clock source, refer section Change of Clock Source.

The PRESCALER field in the control register is used to select the divide ratio of the input clock that drives the main counter. The prescaler can divide the input clock by a value between 1 and 4096. A change in the value of the PRESCALER field is immediately reflected on its output clock frequency. The following figure shows the timing for a change in the prescaler value.

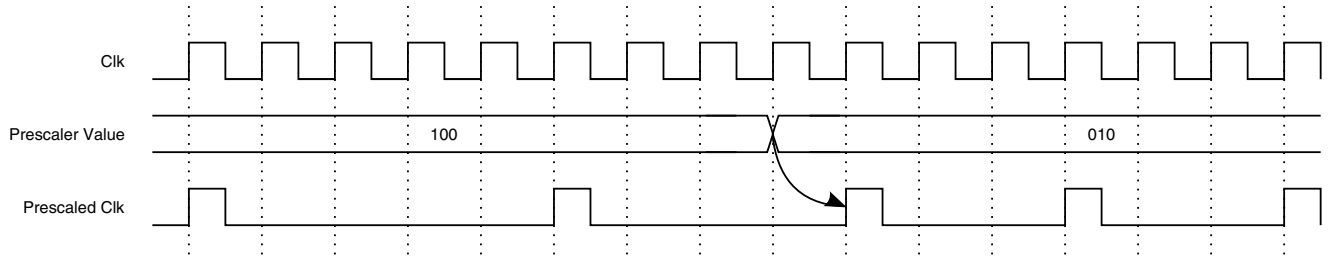

Figure 25-2. Prescaler Value Change Diagram

25.3.4 Compare Event

When the programmed value of EPIT_EPITCMPR matches the value in EPIT_EPITCNR a compare status flag is set, and an interrupt is generated if the OCIEN bit is set in the control register.

The compare output pin is set, cleared, toggled, or not affected at all depending on the setting of the output mode (OM) bits in the control register. If an interrupt is required at rollover (when the counter value reaches 0x0000_0000 and the new value is loaded) then the compare register value should be set equal to the load register value in set-and-forget mode, or equal to 0xFFFF_FFFF in free-running mode.

The following figure shows the timing for a compare event and interrupt.

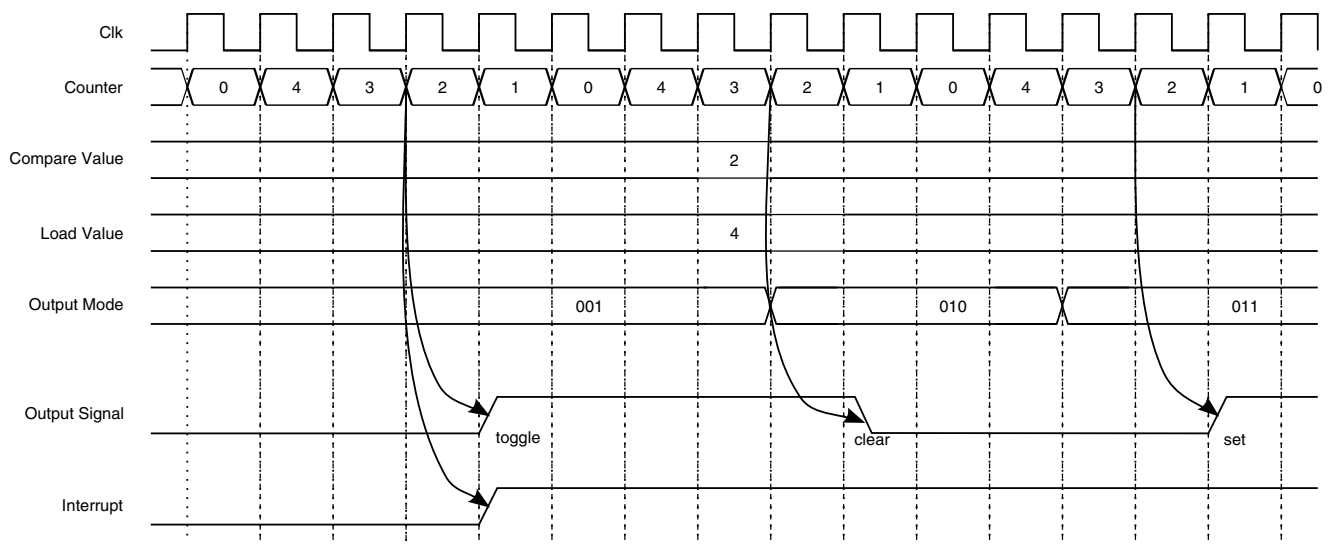

Figure 25-3. Compare Event and Interrupt Timing Diagram

25.3.4.1 Counter Value Overwrite

The EPIT counter value can be overwritten to acquire a desired value at any point of time. The procedure for this is to set the IOVW bit in the control register and then write the desired value into the load register.

This results in the load register acquiring that value and also the counter being overwritten with it. If the EPIT is running the counter resumes counting from the overwritten value.

25.3.4.2 Low-Power Mode Behavior

The EPIT timer's behavior in low-power modes depends on which clock source is being used.

If the selected clock source is available and the corresponding low-power enable bit is set, then the EPIT continues to function in the low-power mode. If the EPIT is programmed to be disabled in a low-power mode (STOP/WAIT), then main counter and the prescaler counter freeze at the current count values when the EPIT enters low-power mode. When the EPIT exits the low-power mode, both main counter and prescaler counter start counting from their frozen values irrespective of the ENMOD bit.

25.3.4.3 Debug Mode Behavior

In debug mode, the user has the option to run or halt the EPIT timers. If the DBGEN bit is reset in the EPIT Control Register, the timer is halted.

When debug mode is exited, the timer operation reverts to what it was prior to entering debug mode.

25.4 Initialization/ Application Information

25.4.1 Change of Clock Source

The CLKSRC field in EPIT_EPITCR determines the clock source. This field value should be changed only after disabling the EPIT (EN = 0).

Below is the software sequence which must be followed while changing clock source.

1. Disable the EPIT by setting EN=0 in EPIT_EPITCR.
2. Program OM=00 in the EPIT_EPITCR.

3. Disable the EPIT interrupts.
4. Program CLKSRC to desired clock source in EPIT_EPITCR.
5. Clear the EPIT status register (EPIT_EPITSR), that is, write "1" to clear (w1c).
6. Enable the EPIT interrupts.
7. Set ENMOD= 1 in the EPIT_EPITCR, to bring the EPIT Counter to defined state (EPIT_EPITLR value or 0xFFFF_FFFF).
8. Enable EPIT (EN=1) in the EPIT_EPITCR

25.5 Programmable Registers

The EPIT includes five user-accessible 32-bit registers. The following table summarizes these registers and their addresses.

Peripheral bus write access to the EPIT control register (EPITCR) and the EPIT load register (EPITLR) results in one cycle of wait state, while other valid peripheral bus accesses are with 0 wait state.

EPIT memory map

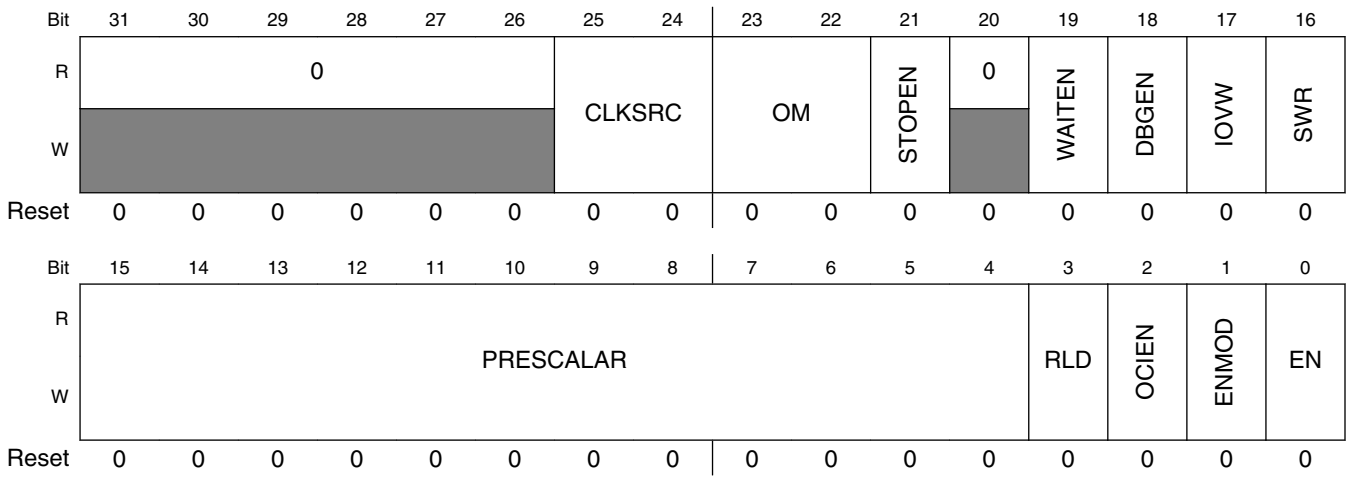
Absolute address (hex)	Register name	Width (in bits)	Access	Reset value	Section/ page
53FA_C000	Control register (EPIT_EPITCR)	32	R/W	0000_0000h	25.5.1/ 1234
53FA_C004	Status register (EPIT_EPITSR)	32	R/W	0000_0000h	25.5.2/ 1237
53FA_C008	Load register (EPIT_EPITLR)	32	R/W	FFFF_ FFFFh	25.5.3/ 1238
53FA_C00C	Compare register (EPIT_EPITCMPR)	32	R/W	0000_0000h	25.5.4/ 1238
53FA_C010	Counter register (EPIT_EPITCNR)	32	R	FFFF_ FFFFh	25.5.5/ 1239

25.5.1 Control register (EPIT_EPITCR)

The EPIT control register (EPIT_EPITCR) is used to configure the operating settings of the EPIT. It contains the clock division prescaler value and also the interrupt enable bit. Additionally it contains other control bit which are outlined below.

Peripheral Bus Write access to EPIT Control Register (EPIT_EPITCR) results in one cycle of the wait state, while other valid peripheral bus accesses are with 0 wait state.

Address: EPIT_EPITCR is 53FA_C000h base + 0h offset = 53FA_C000h



EPIT_EPITCR field descriptions

Field	Description
31–26 Reserved	This read-only field is reserved and always has the value zero. Reserved. Writing to these bits does not affect the functionality of EPIT. These bits are always read as zero.
25–24 CLKSRC	Select clock source These bits determine which clock input is to be selected for running the counter. This field value should only be changed when the EPIT is disabled by clearing the EN bit in this register. For other programming requirements while changing clock source, refer to Change of Clock Source. 00 Clock is off 01 Peripheral clock 10 High-frequency reference clock 11 Low-frequency reference clock
23–22 OM	EPIT output mode.This bit field determines the mode of EPIT output on the output pin. 00 EPIT output is disconnected from pad 01 Toggle output pin 10 Clear output pin 11 Set output pin
21 STOPEN	EPIT stop mode enable. This read/write control bit enables the operation of the EPIT during stop mode. This bit is reset by a hardware reset and unaffected by software reset. 0 EPIT is disabled in stop mode 1 EPIT is enabled in stop mode
20 Reserved	This read-only field is reserved and always has the value zero. Reserved. Writing to these bits does not affect the functionality of EPIT. These bits are always read as zero.
19 WAITEN	This read/write control bit enables the operation of the EPIT during wait mode. This bit is reset by a hardware reset. A software reset does not affect this bit. 0 EPIT is disabled in wait mode 1 EPIT is enabled in wait mode

Table continues on the next page...

EPIT_EPITCR field descriptions (continued)

Field	Description
18 DBGEN	This bit is used to keep the EPIT functional in debug mode. When this bit is cleared, the input clock is gated off in debug mode.This bit is reset by hardware reset. A software reset does not affect this bit. 0 Inactive in debug mode 1 Active in debug mode
17 IOVW	EPIT counter overwrite enable. This bit controls the counter data when the modulus register is written. When this bit is set, all writes to the load register overwrites the counter contents and the counter starts subsequently counting down from the programmed value. 0 Write to load register does not result in counter value being overwritten. 1 Write to load register results in immediate overwriting of counter value.
16 SWR	Software reset. The EPIT is reset when this bit is set to 1. It is a self clearing bit. This bit is set when the block is in reset state and is cleared when the reset procedure is over. Setting this bit resets all the registers to their reset values, except for the EN, ENMOD, STOPEN, WAITEN and DBGEN bits in this control register 0 EPIT is out of reset 1 EPIT is undergoing reset
15–4 PRESCALAR	Counter clock prescaler value. This bit field determines the prescaler value by which the clock is divided before it goes to the counter 0x000 Divide by 1 0x001 Divide by 2 0xFFFF Divide by 4096
3 RLD	Counter reload control. This bit is cleared by hardware reset. It decides the counter functionality, whether to run in free-running mode or set-and-forget mode. 0 When the counter reaches zero it rolls over to 0xFFFF_FFFF (free-running mode) 1 When the counter reaches zero it reloads from the modulus register (set-and-forget mode)
2 OCIEN	Output compare interrupt enable. This bit enables the generation of interrupt on occurrence of compare event. 0 Compare interrupt disabled 1 Compare interrupt enabled
1 ENMOD	EPIT enable mode. When EPIT is disabled (EN=0), both main counter and prescaler counter freeze their count at current count values. ENMOD bit is a r/w bit that determines the counter value when the EPIT is enabled again by setting EN bit. If ENMOD bit is set, then main counter is loaded with the load value (If RLD=1)/ 0xFFFF_FFFF (If RLD=0) and prescaler counter is reset, when EPIT is enabled (EN=1). If ENMOD is programmed to 0 then both main counter and prescaler counter restart counting from their frozen values when EPIT is enabled (EN=1). If EPIT is programmed to be disabled in a low-power mode (STOP/WAIT/ DEBUG), then both the main counter and the prescaler counter freeze at their current count values when EPIT enters low-power mode. When EPIT exits the low-power mode, both main counter and prescaler counter start counting from their frozen values irrespective of the ENMOD bit. This bit is reset by a hardware reset. A software reset does not affect this bit. 0 Counter starts counting from the value it had when it was disabled. 1 Counter starts count from load value (RLD=1) or 0xFFFF_FFFF (If RLD=0)

Table continues on the next page...

EPIT_EPITCR field descriptions (continued)

Field	Description
0 EN	This bit enables the EPIT. EPIT counter and prescaler value when EPIT is enabled (EN =1), is dependent upon ENMOD and RLD bit as described for ENMOD bit. It is recommended that all registers be properly programmed before setting this bit. This bit is reset by a hardware reset. A software reset does not affect this bit. 0 EPIT is disabled 1 EPIT is enabled

25.5.2 Status register (EPIT_EPITSR)

The EPIT status register (EPIT_EPITSR) has a single status bit for the output compare event. The bit is a write 1 to clear bit.

Address: EPIT_EPITSR is 53FA_C000h base + 4h offset = 53FA_C004h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16
R	0															
W																
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

Bit	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R	0															OCIF
W																w1c
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

EPIT_EPITSR field descriptions

Field	Description
31–1 Reserved	This read-only field is reserved and always has the value zero. Reserved. Writing to these bits does not affect the functionality of EPIT. These bits are always read as zero.
0 OCIF	Output compare interrupt flag. This bit is the interrupt flag that is set when the content of counter equals the content of the compare register (EPIT_EPITCMPR). The bit is a write 1 to clear bit. 0 Compare event hasn't occurred 1 Compare event occurred

25.5.3 Load register (EPIT_EPITLR)

The EPIT load register (EPIT_EPITLR) contains the value that is to be loaded into the counter when EPIT counter reaches zero if the RLD bit in EPIT_EPITCR is set. If the IOVW bit in the EPIT_EPITCR is set then a write to this register overwrites the value of the EPIT counter register in addition to updating this registers value. This overwrite feature is active even if the RLD bit is not set.

Address: EPIT_EPITLR is 53FA_C000h base + 8h offset = 53FA_C008h

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0

Reset	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1	1

EPIT_EPITLR field descriptions

Field	Description
31–0 LOAD	Load value. Value that is loaded into the counter at the start of each count cycle.

25.5.4 Compare register (EPIT_EPITCMPR)

The EPIT compare register (EPIT_EPITCMPR) holds the value that determines when a compare event is generated.

Address: EPIT_EPITCMPR is 53FA_C000h base + Ch offset = 53FA_C00Ch

Bit	31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1	0
R W	COMPARE																															
Reset	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0	0

EPIT_EPITCMPR field descriptions

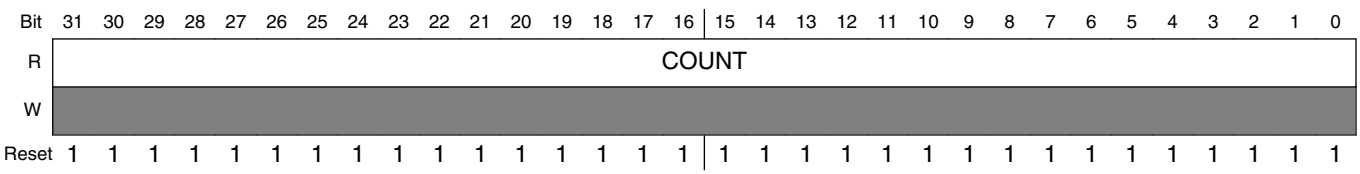
Field	Description
31–0 COMPARE	Compare Value. When the counter value equals this bit field value a compare event is generated.

25.5.5 Counter register (EPIT_EPITCNR)

The EPIT counter register (EPIT_EPITCNR) contains the current count value and can be read at any time without disturbing the counter. This is a read-only register and any attempt to write into it generates a transfer error. But if the IOVW bit in EPIT_EPITCR is set, the value of this register can be overwritten with a write to EPIT_EPITLR. This change is reflected when this register is subsequently read.

.

Address: EPIT_EPITCNR is 53FA_C000h base + 10h offset = 53FA_C010h



EPIT_EPITCNR field descriptions

Field	Description
31–0 COUNT	Counter value. This contains the current value of the counter.

Chapter 26
Enhanced Secured Digital Host Controller (eSDHCv2)

26.1 Overview

The Enhanced Secured Digital Host Controller Version 2 (ESDHCv2, referred to as ESDHC hereafter) provides the interface between the host system and the SD/SDIO/MMC cards, as depicted in Figure 26-1. The ESDHC acts as a bridge, passing host bus transactions to the SD/SDIO/MMC cards by sending commands and performing data accesses to/from the cards. It handles the SD/SDIO/MMC protocols at the transmission level.

The types of cards supported by the ESDHC are described briefly as follows:

The Multi Media Card (MMC) is a universal low cost data storage and communication media that is designed to cover a wide area of applications including mobile video and gaming. Old MMC cards are based on a 7-pin serial bus with a single data pin, while the new high speed MMC communication is based on an advanced 11-pin serial bus designed to operate in the low voltage range.

The Secure Digital Card (SD) is an evolution of the old MMC technology. It is specifically designed to meet the security, capacity, performance, and environment requirements inherent in newly emerging audio and video consumer electronic devices. The physical form factor, pin assignment and data transfer protocol are forward compatible with the old MMC (with some additions).

Under the SD protocol, it can be categorized into Memory card, I/O card and Combo card, which has both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI standard. The I/O card, which is also known as SDIO card, provides high-speed data I/O with low power consumption for mobile electronic devices. For the sake of simplicity, Figure 26-1 does not show cards with reduced size or mini cards.

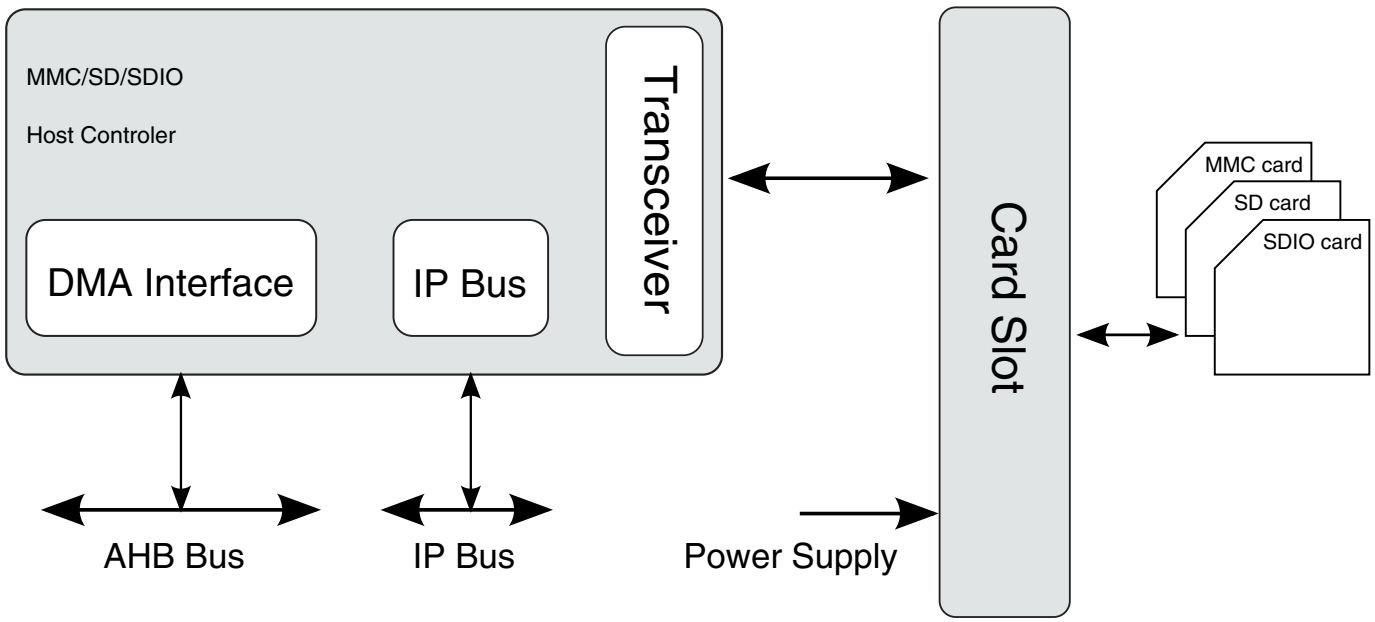


Figure 26-1. System Connection of the ESDHC

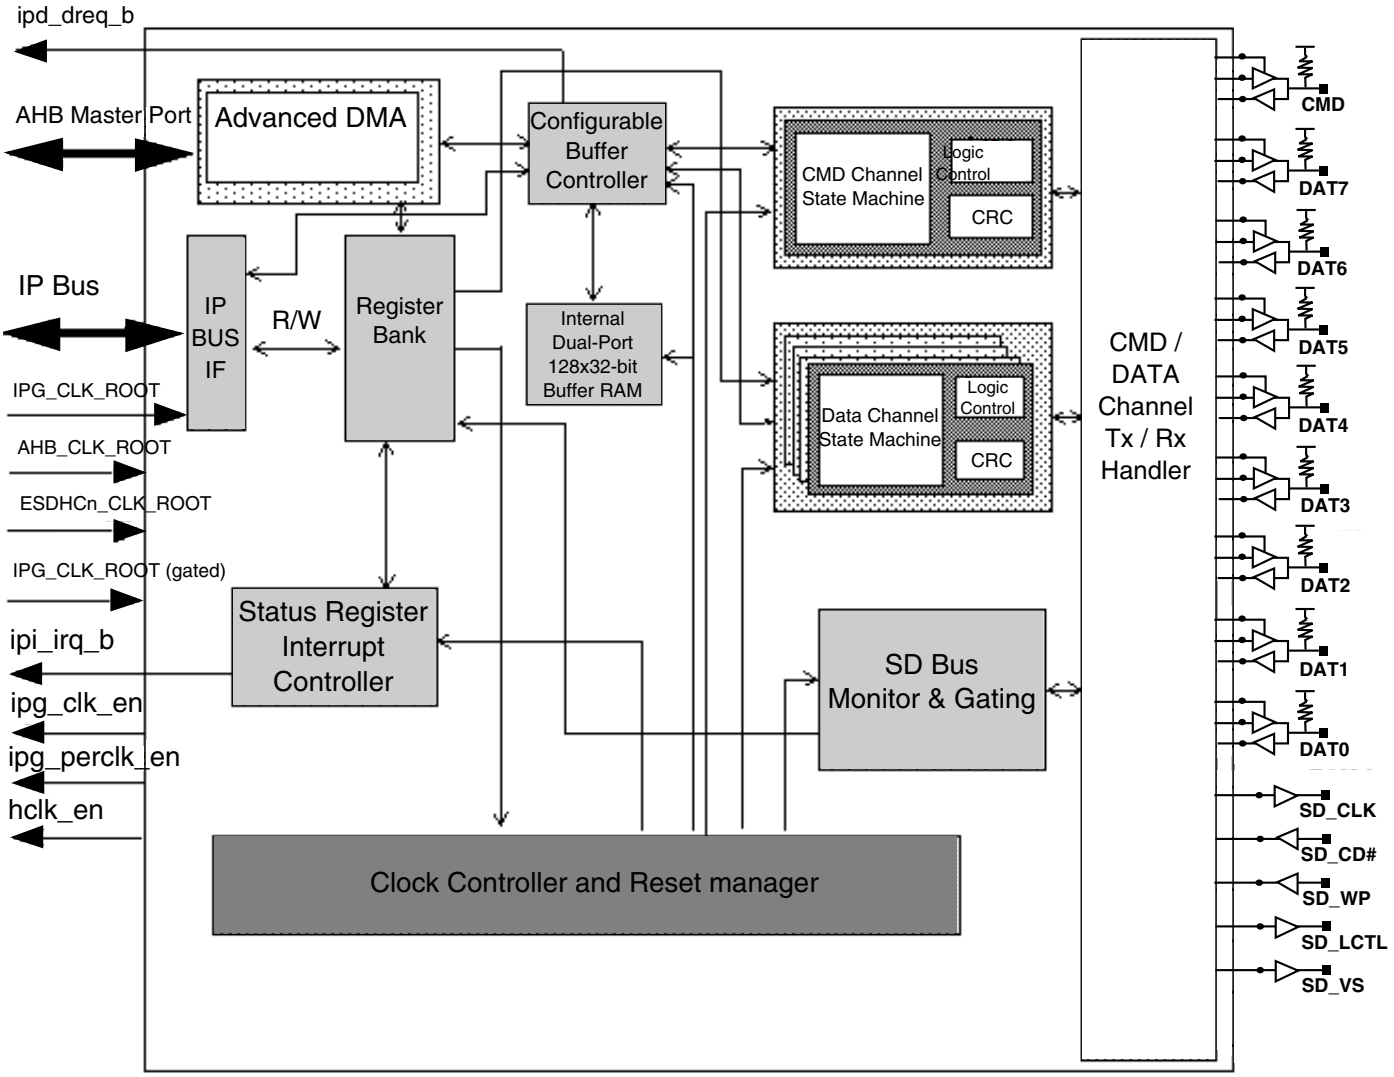

Figure 26-2. enhanced Secure Digital Host Controller Block Diagram

26.1.1 Features

The features of the ESDHC include the following:

- Conforms to the SD Host Controller Standard Specification version 2.0 including Test Event register support
- Compatible with the MMC System Specification version 4.2/4.3
- Compatible with the SD Memory Card Specification version 2.0 and supports the High Capacity SD Memory Card
- Compatible with the SDIO Card Specification version 2.0
- Designed to work with SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, MMC, MMC plus, and MMC RS cards

- Card bus clock frequency up to 52 MHz
- Supports 1-bit / 4-bit SD and SDIO modes, 1-bit / 4-bit / 8-bit MMC modes devices
  - Up to 200 Mbps of data transfer for SD/SDIO cards using 4 parallel data lines
  - Up to 416 Mbps of data transfer for MMC cards using 8 parallel data lines in SDR (Single Data Rate) mode
- Supports Single Block, Multi Block read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports the write protection switch for write operations
- Supports both synchronous and asynchronous abort
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports Auto CMD12 for multi-block transfer
- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes, also supports interrupt period
- Embodies a fully configurable 128x32-bit FIFO for read/write data
- Supports internal and external DMA capabilities
- Supports Advanced DMA to perform linked memory access

26.1.2 Modes and Operations

26.1.2.1 Data transfer Modes

The ESDHC can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- MMC 1-bit
- MMC 4-bit
- MMC 8-bit
- Identification Mode (up to 400 kHz)
- MMC full speed mode (up to 20 MHz)
- MMC high speed mode (up to 52 MHz)
- SD/SDIO full speed mode (up to 25 MHz)
- SD/SDIO high speed mode (up to 50 MHz)

26.2 External Signals

26.2.1 Signals Overview

The ESDHC has 15 associate I/O signals.

- The SD_CLK is an internally generated clock used to drive the MMC, SD, SDIO cards.
- The CMD I/O is used to send commands and receive responses to/from the card. Eight data lines (DAT7~DAT0) are used to perform data transfers between the ESDHC and the card.
- The SD_CD# and SD_WP are card detection and write protection signals directly routed from the socket. A low on SD_CD# means that a card is inserted and a high on SD_WP means that the write protect switch is active.
- SD_OD is an output signal generated in SoC level outside ESDHC and is used to select the external open drain resistor.
- SD_LCTL is an output signal used to drive an external LED to indicate that the SD interface is busy.

SD_CD#, SD_WP, SD_OD, SD_LCTL are all optional for system implementation. If the ESDHC is desired to support a 4-bit data transfer, DAT7~DAT4 can also be optional and tied to high.

26.2.2 Ports Table

See Table 26-1 for the signal properties of the I/Os.

Table 26-1. Properties of I/O Signals

Name	Port	Function	Reset State	Pull up
SD_CLK	O	Clock for MMC/SD/SDIO card	0	N/A
SD_CMD	I/O	CMD line connect to card	1	Pull up
SD_DAT7	I/O	DAT7 line in 8-bit mode Not used in other modes	1	Pull up
SD_DAT6	I/O	DAT6 line in 8-bit mode Not used in other modes	1	Pull up
SD_DAT5	I/O	DAT5 line in 8-bit mode Not used in other modes	1	Pull up
SD_DAT4	I/O	DAT4 line in 8-bit mode Not used in other modes	1	Pull up

Table continues on the next page...

Table 26-1. Properties of I/O Signals (continued)

Name	Port	Function	Reset State	Pull up
SD_DAT3	I/O	DAT3 line in 4/8-bit mode or configured as card detection pin May be configured as card detection pin in 1-bit mode	0	Should be pull-up/pull-down configurable as this port may be used for card detection
SD_DAT2	I/O	DAT2 line or Read Wait in 4-bit mode Read Wait in 1-bit mode	1	Pull up
SD_DAT1	I/O	DAT1 line in 4/8-bit mode Also used to detect interrupt in 1/4-bit mode	1	Pull up
SD_DAT0	I/O	DAT0 line in all modes Also used to detect busy state	1	Pull up
SD_CD#	I	Card detection pin If not used tie high	N/A	N/A
SD_WP	I	Card write protect detect If not used tie low	N/A	N/A
SD_OD	O	Open drain select (not generated within the ESDHC). Optional output	N/A	N/A
SD_LCTL	O	LED control used to drive an external LED Active high Fully controlled by the driver Optional output	0	N/A

26.3 Functional Description

The following sections provide a brief functional description of the major system blocks, including the Data Buffer, DMA AHB interface, register bank as well as IP Bus interface, dual-port memory wrapper, data/command controller, clock & reset manager and clock generator.

26.3.1 Data Buffer

The ESDHC uses one configurable data buffer, so that data can be transferred between the system bus (IP Bus or AHB Bus) and the SD card, with an optimized manner to maximize throughput between the two clock domains (that is, the IP peripheral clock, and the master clock). See the table below for illustration of the buffer scheme. The buffer is used as temporary storage for data being transferred between the host system and the

card. The watermark levels for read and write are both configurable, and can be any number from 1 to 128 words. The burst lengths for read and write are also configurable, and can be any number from 1 to 31 words.

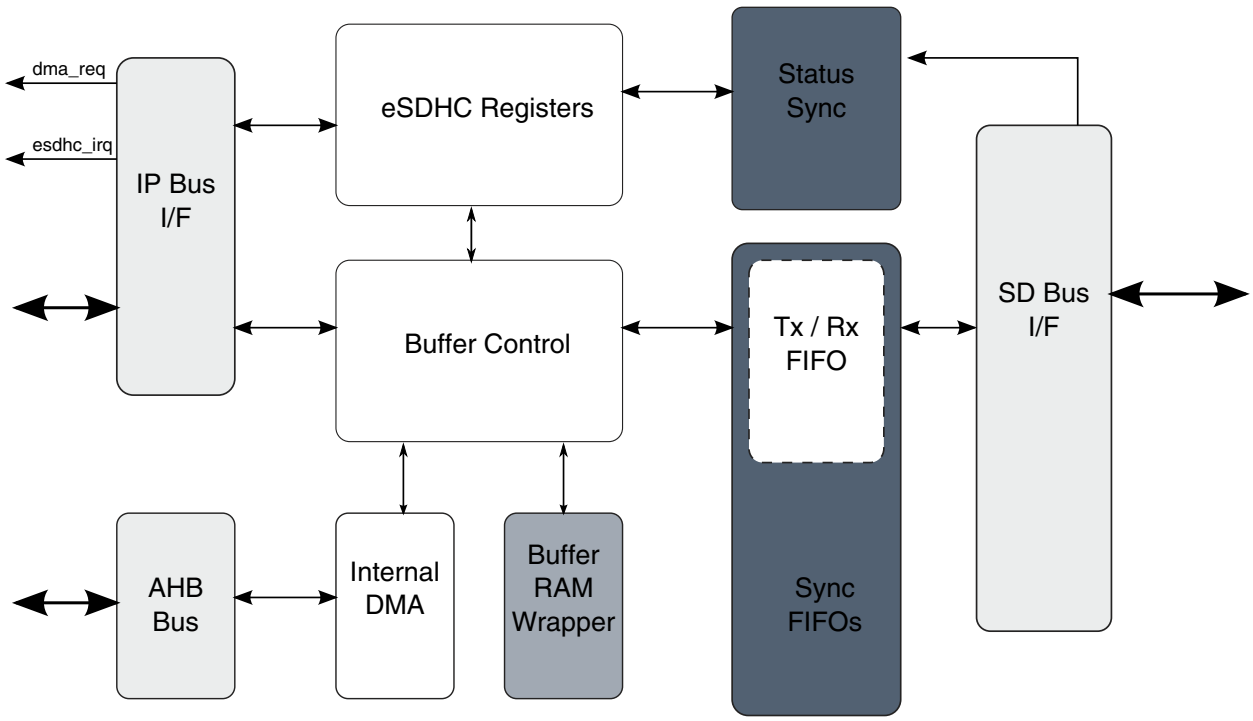

Figure 26-3. ESDHC Buffer Scheme

There are 3 transfer modes to access the data buffer:

- ARM platform polling mode:
  - For a host read operation, when the number of words received in the buffer meets or exceeds the RD_WML watermark value, then by polling the BRR bit the Host Driver can read the Buffer Data Port register to fetch the amount of words set in the RD_WML register from the buffer. The write operation is similar.
- External DMA mode:
  - For a read operation, when there are more words received in the buffer than the amount set in the RD_WML register, a DMA request is sent out to inform the external DMA to fetch the data. The request will be immediately de-asserted when there is an access on the Buffer Data Port register. If the number of words in the buffer after the current burst meets or exceeds RD_WML value, then the DMA request is asserted again. For instance, if there are twice as many words in the buffer than the RD_WML value, there are two successive DMA requests with only one cycle of de-assertion between. The write operation is similar.

NOTE

Data buffer accesses by the ARM platform polling mode and external DMA mode both use the IP Bus. In these mode, if the external DMA is enabled, an external DMA request is sent out every time the buffer is ready.

- Internal DMA mode (includes simple and advanced DMA accesses):
  - The internal DMA access, either by simple or advanced DMA, is over the AHB bus. For internal DMA access mode, the external DMA request will never be sent out.

    For a read operation, when there are more words in the buffer than the amount set in the RD_WML register, the internal DMA starts fetching data over the AHB bus. Except INCR4 and INCR8, the burst type is always INCR mode and the burst length depends on the shortest of following factors:

1. Burst length configured in the burst length field of the Watermark Level register
2. Watermark Level boundary
3. Block size boundary
4. Data boundary configured in the current descriptor (if the ADMA is active)
5. 1 Kbyte address boundary defined in the AHB protocol

Write operation is similar.

Sequential and contiguous access is necessary to ensure the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actually byte order is swapped inside the buffer, according to the endian mode configured by software. See Figure 26-4 and Figure 26-5. For a host write operation, byte order is swapped after data is fetched from the buffer and ready to send to the SD Bus. For a host read operation, byte order is swapped before the data is stored into the buffer.

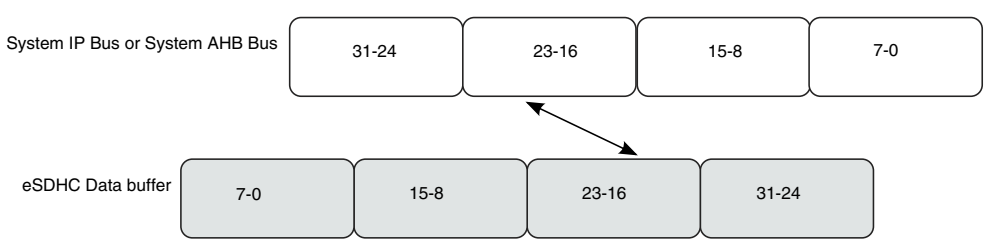

Figure 26-4. Data Swap between System Bus and ESDHC Data Buffer in Byte Little Endian Mode

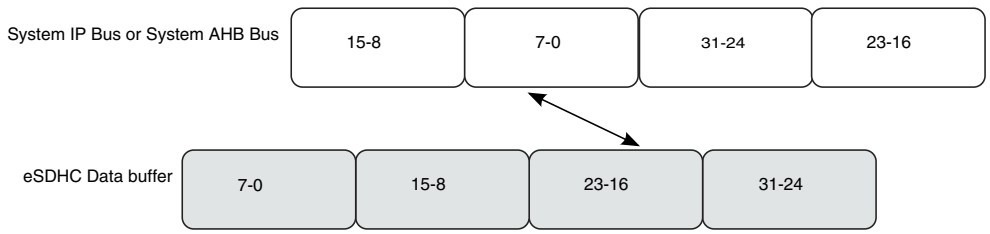

Figure 26-5. Data Swap between System Bus and ESDHC Data Buffer in Half Word Big Endian Mode

26.3.1.1 Write Operation Sequence

There are three ways to write data into the buffer when the user transfers data to the card:

1. By using external DMA through the ESDHC DMA request signal.
2. By processor core polling through the BWR bit in Interrupt Status register (interrupt or polling).
3. By using the internal DMA.

When the internal DMA is not used, (i.e. the DMAEN bit in the Transfer Type register is not set when the command is sent), the ESDHC asserts a DMA request when the amount of buffer space exceeds the value set in the WR_WML register, and is ready for receiving new data. At the same time, the ESDHC would set the BWR bit. The buffer write ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the ESDHC will not inform the system before all the required number of bytes are transferred (if no error was encountered). When an error occurs during the data transfer, the ESDHC will abort the data transfer and abandon the current block. The Host Driver should read the contents of the DMA System Address register to get the starting address of the abandoned data block. If the current data transfer is in multi block mode, the ESDHC will not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The Host Driver shall send CMD12 in this scenario and re-start the write operation from that address. It is recommended that a Software Reset for Data be applied before the transfer is re-started after error recovery.

The ESDHC will not start data transmission until the number of words set in the WR_WML register can be held in the buffer. If the buffer is empty and the Host System does not write data in time, the ESDHC will stop the SD_CLK to avoid the data buffer under-run situation.

26.3.1.2 Read Operation Sequence

There are three ways to read data from the buffer when the user transfers data from the card:

1. By using the external DMA through the ESDHC DMA request signal
2. By processor core polling through the BRR bit in Interrupt Status register (interrupt or polling)
3. By using the internal DMA

When internal DMA is not used (i.e. DMAEN bit in Transfer Type register is not set when the command is sent), the ESDHC asserts a DMA request when the amount of data exceeds the value set in the RD_WML register (that is, available and ready for system fetching data). At the same time, the ESDHC would set the BRR bit. The buffer read ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the ESDHC will not inform the system before all the required number of bytes are transferred (if no error was encountered). When an error occurs during the data transfer, the ESDHC will abort the data transfer and abandon the current block. The Host Driver should read the content of the DMA System Address register to get the starting address of the abandoned data block. If the current data transfer is in multi block mode, the ESDHC will not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The Host Driver shall send CMD12 in this scenario and re-start the read operation from that address. It is recommended that a Software Reset for Data be applied before the transfer is re-started after error recovery.

For any read transfer mode, the ESDHC will not start data transmission until the number of words set in the RD_WML register are in the buffer. If the buffer is full and the Host System does not read data in time, the ESDHC will stop the SD_CLK to avoid the data buffer over-run situation.

26.3.1.3 Data Buffer and Block Size

The user needs to know the buffer size, for the buffer operation during a data transfer, to utilize it in the most optimized way. In the ESDHC, the only data buffer can hold up to 128 words (32-bit), and the watermark levels for write and read can be configured respectively. For both read and write, the watermark level can be from 1 word to the maximum of 128 words. For both read and write, the burst length, can be from 1 word to the maximum of 31 words. The Host Driver may configure the value according to the system situation and requirement.

During a multi-block data transfer, the block length may be set to any value between 1 and 4096 bytes inclusive which satisfies the requirements of the external card. The only restriction is from the external card. It might not support that large of a block or it does not support a partial block access (which is not the integer times of 512 bytes).

For block size not times of 4, that is, not word aligned, ESDHC requires stuff bytes at the end of each block, because ESDHC treats each block individually. For example, if the block size is 7 bytes and there are 12 blocks to write, the system side must write two times for each block. For each block, the ending byte will be abandoned by ESDHC because it only sends 7 bytes to the card and picks data from the following system write, making a total of 24 beats of write access.

26.3.1.4 Dividing Large Data Transfer

This SDIO command CMD53 definition, limits the maximum data size of data transfers according to the following formula:

Max data size = Block size x Block count

The length of a multiple block transfer needs to be in block size units. If the total data length can't be divided evenly into a multiple of the block size, then there are two ways to transfer the data which depend on the function and the card design. Option 1 is for the Host Driver to split the transaction. The remainder of the block size data is then transferred by using a single block command at the end. Option 2 is to add dummy data in the last block to fill the block size. For option 2, the card must manage the removal of the dummy data.

See figure below for an example showing the dividing of large data transfers. Assuming a kind of WLAN SDIO card only supports block size up to 64 bytes. Although the ESDHC supports a block size of up to 4096 bytes, the SDIO can only accept a block size less than64 bytes, so the data must be divided (see example below).

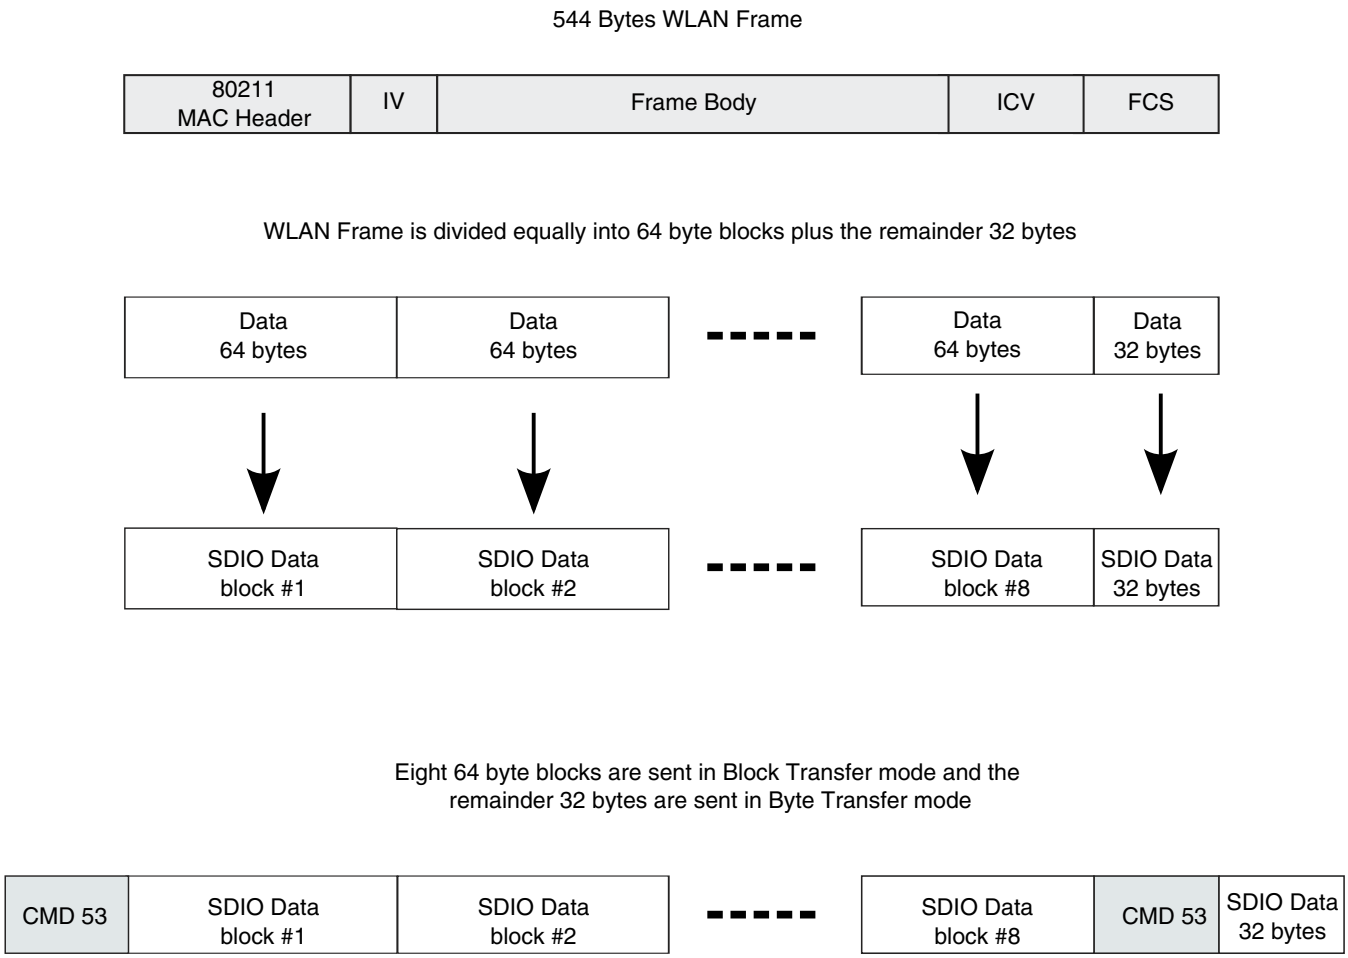

Figure 26-6. Example for Dividing Large Data Transfers

26.3.1.5 External DMA Request

When the internal DMA is not in use, and external DMA request is enabled, the Data Buffer will generate a DMA request to the system. During a write operation, when the number of WR_WML words can be held in the buffer free space, the signal esdhc_dreq_b is asserted to 0, informing the Host System of a DMA write. The BWR bit in the Interrupt Status register is also set, as long as the BWRSEN bit in the Interrupt Status Enable register is set. The DMA request is immediately de-asserted when an access to the Data Port register is made. If the buffer's free space still meets the watermark condition, the DMA request is asserted again after a cycle.

On read operation, when the number of RD_WML words are already in the buffer, the signal esdhc_dreq_b is asserted to 0, informing the Host System for a DMA read. The BRR bit in the Interrupt Status register is also set, as long as the BRRSEN bit in the

Interrupt Status Enable register is set. The DMA request is immediately de-asserted when an access to the Data Port register is made. If the buffer's data still meets the watermark condition, the DMA request is asserted again after a cycle.

Because the DMA burst length can not change during a data transfer for an external DMA transfer, the watermark level (read or write) must be a divisor of the block size. If it is not, transferring of the block may cause buffer under-run (read operation) or over-run (write operation). For example, if the block size is 512 bytes, the watermark level of read (or write) must be a power of two between 1 and 128. For processor core polling access, as the last access in the block transfer can be controlled by software, there is no such issue. The watermark level can be any value, even larger than the block size (but no greater than 128 words). This is because the actual number of bytes transferred by the software can be controlled and does not exceed the block size in each transfer.

The ESDHC also supports non-word aligned block size, as long as the card supports that block size. In this case, the watermark level should be set as the number of words. For example, if the block size is 31 bytes, the watermark level can be set to any number of word. For this case, the BLKSIZE bits of the Block Attribute register shall be set as 1fh. For the ARM platform polling access, the burst length can be 1 to 128 words, without restriction. This is because the software will transfer 8 words, and the ESDHC will also set the BWR or BRR bits when the remaining data does not violate data buffer. Refer to DMA Burst Length for more details about the dynamic watermark level of the data buffer. For the above example, even though 8 words are transferred through the Data Port register, the ESDHC will transfer only 31 bytes over the SD Bus, as required by the BLKSIZE bits. In this data transfer, with non-word aligned block size, the endian mode should be set cautiously, or invalid data will be transferred to/from the card.

26.3.2 DMA AHB Interface

The internal DMA implements a DMA engine and the AHB master. When the internal DMA is enabled, the esdhc_dreq_b will not be asserted during the transfer, but the BWR and BRR bits will be set if the BWRSEN and BRRSEN bits have been set in the Interrupt Status Enable register. See the figure below for an illustration of the DMA AHB interface block.

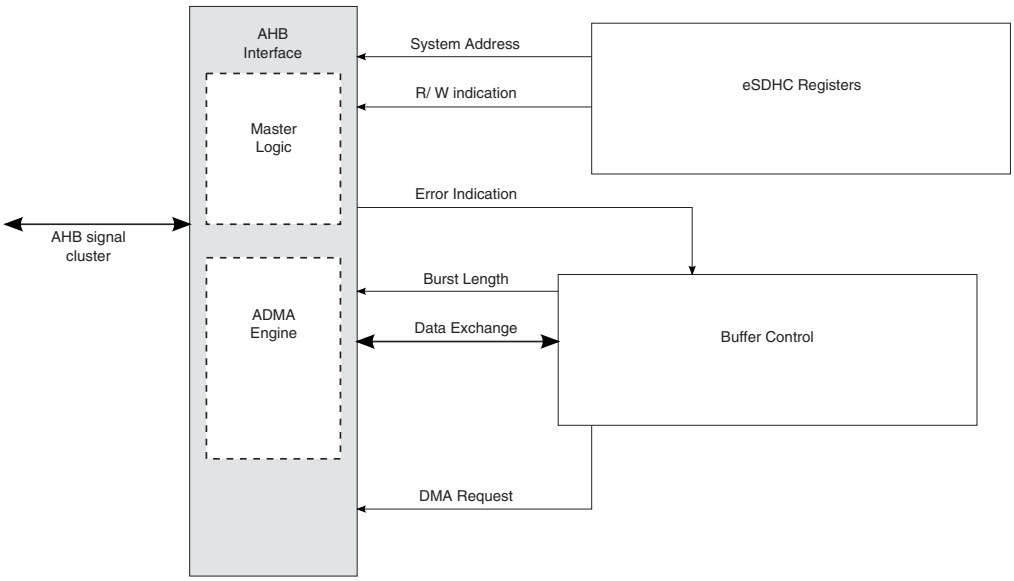

Figure 26-7. DMA AHB Interface Block

26.3.2.1 Internal DMA Request

If the watermark level requirement is met in data transfer, and the Internal DMA is enabled, the Data Buffer block will send a DMA request to AHB interface. Meanwhile, the external DMA request signal (esdhc_dreq_b) is disabled. The delay in response from the internal DMA engine depends on the system AHB bus loading and the priority assigned to the ESDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The Data Buffer de-asserts the request once an access to the buffer is made. Upon access to the buffer by internal DMA, the Data Buffer updates its internal buffer pointer, and when the watermark level is satisfied, another DMA request is sent.

The data transfer is in the block unit, and the subsequent watermark level is always set as the remaining number of words. For instance, for a multi block data read with each block size of 31 bytes, and the burst length set to 6 words. After the first burst transfer, if there are more than 2 words in the buffer (which might contain some data of the next block), another DMA request read is sent. This is because the remaining number of words to send for the current block is (31 - 6 * 4) / 4 = 2. The ESDHC will read 2 words out of the buffer, with 7 valid bytes and 1 stuff byte.

26.3.2.2 DMA Burst Length

Just like a ARM platform polling access, the DMA burst length for the internal DMA engine can be from 1 to 16 words. The actual burst length for the DMA depends on the lesser of the configured burst length or the remaining words of the current block. Take the example in Internal DMA Request again. The following burst length after 6 words are read will be 2 words, and the next burst length will be 6 words again. This is because the next block starts, which is 31 bytes, more than 6 words. The Host Driver writer may take this variable burst length into account. It is also acceptable to configure the burst length as the divisor of the block size, so that each time the burst length will be the same.

26.3.2.3 AHB Master Interface

It is possible that the internal AHB DMA engine could fail during the data transfer. When this error occurs, the DMA engine stops the transfer and goes to the idle state as well as the internal data buffer stops accepting incoming data. The DMAE bit in the Interrupt Status register is set to inform the driver.

Once the DMAE interrupt is received, the software shall send a CMD12 to abort the current transfer and read the DS_ADDR bits of the DMA System Address register to get the starting address of the corrupted block. After the DMA error is fixed, the software should apply a data reset and re-start the transfer from this address to recover the corrupted block.

26.3.2.4 ADMA Engine

In the SD Host Controller Standard, the new DMA transfer algorithm called the ADMA (Advanced DMA) is defined. For Simple DMA, once the page boundary is reached, a DMA interrupt will be generated and the new system address shall be programmed by the Host Driver. The ADMA defines the programmable descriptor table in the system memory. The Host Driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. It reduces the frequency of interrupts to the host system. Therefore, higher speed DMA transfers could be realized since the Host MCU intervention would not be needed during long DMA based data transfers.

There are two types of ADMA: ADMA1 and ADMA2 in Host Controller. ADMA1 can support data transfer of 4KB aligned data in system memory. ADMA2 removes the restriction so that data of any location and any size can be transferred in system memory. Their formats of Descriptor Table are different.

ADMA engine can recognize all kinds of descriptors define in SD Host Controller Standard, and if 'End' flag is detected in the descriptor, ADMA engine will stop after this descriptor is processed.

26.3.2.4.1 ADMA Concept and Descriptor Format

For ADMA1, including the following descriptors:

- Valid/Invalid descriptor.
- Nop descriptor.
- Set data length descriptor.
- Set data address descriptor.
- Link descriptor.
- Interrupt flag and End flag in descriptor.

For ADMA2, including the following descriptors:

- Valid/Invalid descriptor.
- Nop descriptor.
- Rsv descriptor.
- Set data length & address descriptor.
- Link descriptor.
- Interrupt flag and End flag in descriptor.

ADMA2 deals with the lower 32-bit first, and then the higher 32-bit. If the 'Valid' flag of descriptor is 0, it will ignore the high 32-bit. Address field shall be set on word aligned (lower 2-bit is always set to 0). Data length is in byte unit.

ADMA will start read/write operation after it reaches the Tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last Set type descriptor before Tran type descriptor. Every Tran type will trigger a transfer, and the transfer data length is extracted from the most recent Set type descriptor. If there is no Set type descriptor after the previous Trans descriptor, the data length will be the value for previous transfer, or 0 if no Set descriptor is ever met.

For ADMA2, Tran type descriptor contains both data length and transfer data address, so only a Tran type descriptor can start a data transfer.

Address/ Page Field		Address/ Page Field		Attribute Field					
31	12	11	6	5	4	3	2	1	0
Address or Data Length		000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	31- 28	27- 12
0	0	Nop	No Operation	Don't Care	
0	1	Set	Set Data Length	0000	Data Length
1	0	Tran	Transfer Data	Data Address	
1	1	Link	Link Descriptor	Descriptor Address	

Valid	Valid = 1 indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is processed.

Figure 26-8. Format of the ADMA1 Descriptor Table

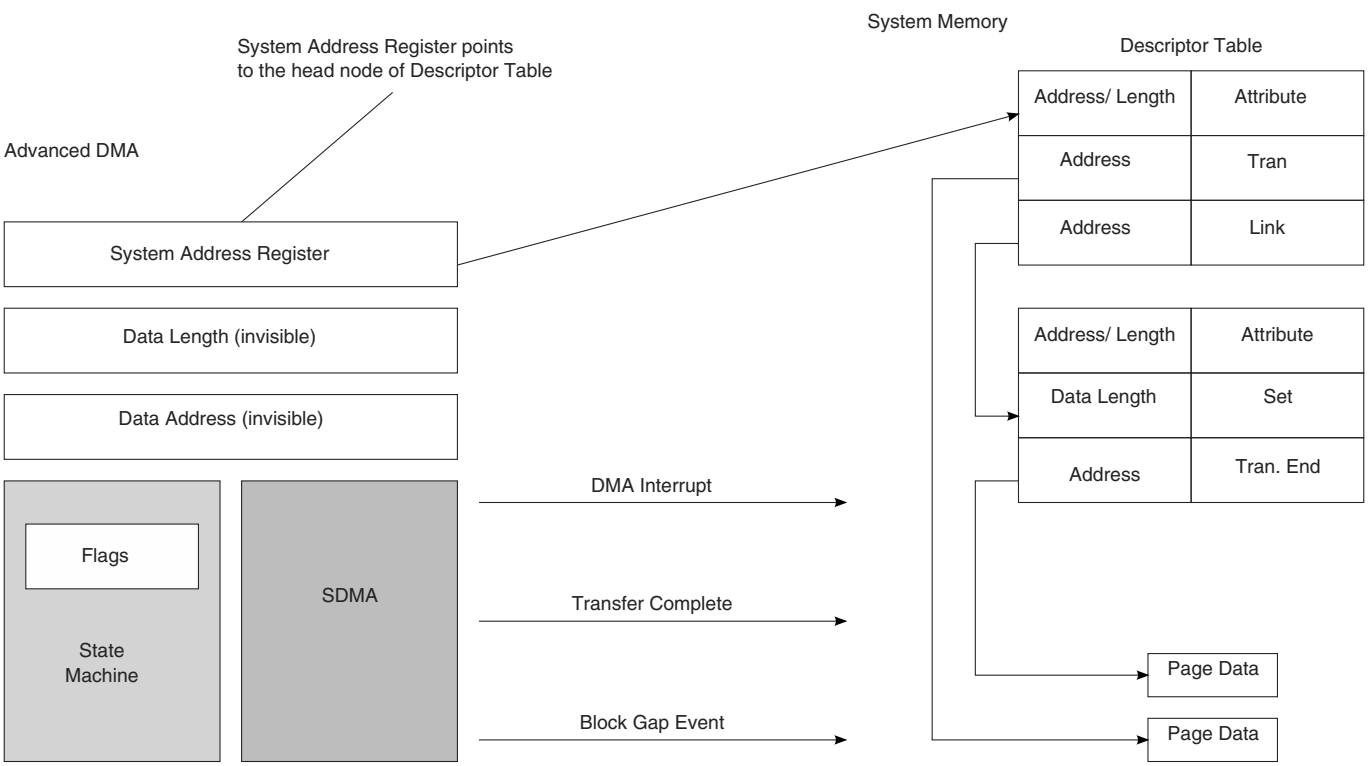

Figure 26-9. Concept and Access Method of ADMA1 Descriptor Table

Address/ Page Field		Address/ Page Field		Address/ Page Field		Attribute Field					
63	32	31	16	15	06	05	04	03	02	01	00
32-bit Address		16-bit Length		0000000000		Act 2	Act 1	0	Int	End	Valid

Act 2	Act1	Symbol	Comment	Operation
0	0	Nop	No Operation	Don't Care
0	1	Rsv	Reserved	Same as Nop. Read this line and go to next one
1	0	Tran	Transfer Data	Transfer data with address and length set in this descriptor line
1	1	Link	Link Descriptor	Link to another descriptor

Valid	Valid = 1indicates this line of descriptor is effective. If Valid = 0 generate ADMA Error Interrupt and stop ADMA.
End	End = 1 indicates current descriptor is the ending one.
Int	Int = 1 generates DMA Interrupt when this descriptor is done.

Figure 26-10. Format of the ADMA2 Descriptor Table

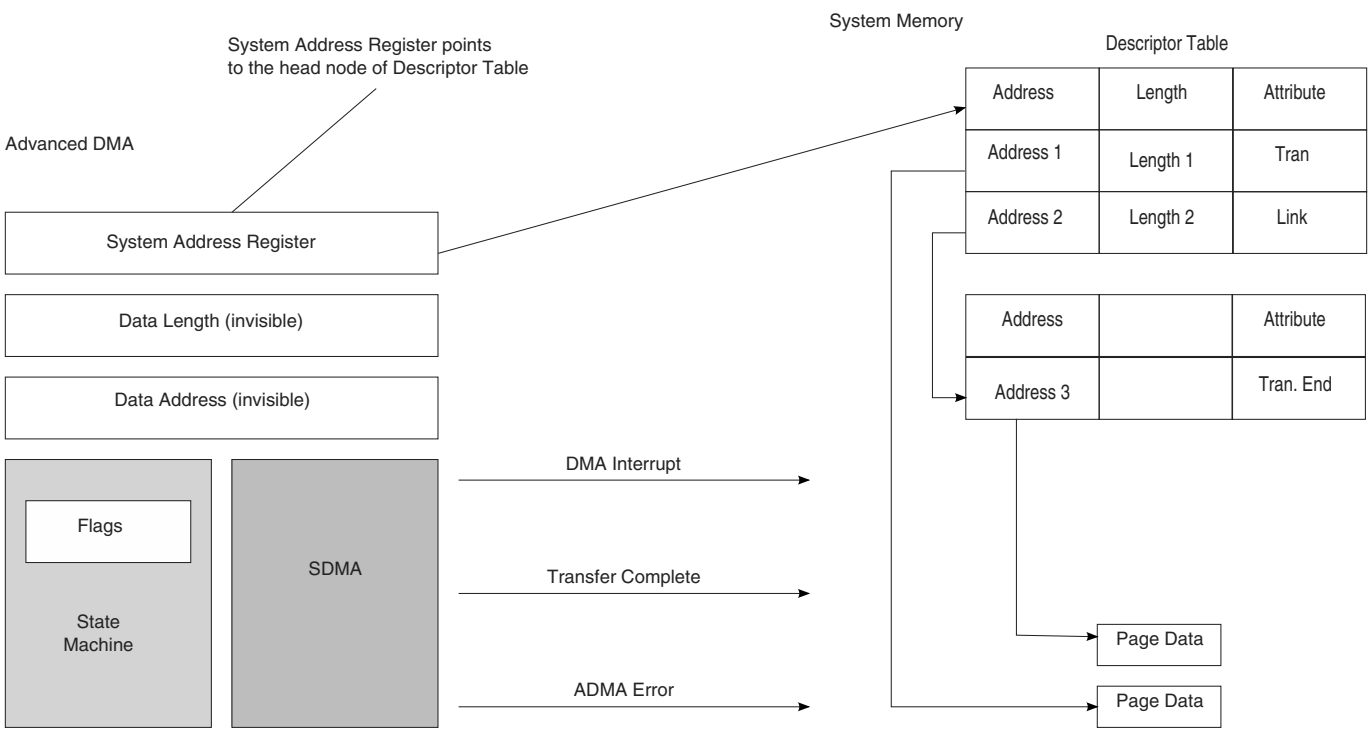

Figure 26-11. Concept and Access Method of ADMA2 Descriptor Table

26.3.2.4.2 ADMA Interrupt

If the 'Interrupt' flag of descriptor is set, ADMA will generate an interrupt according to different type descriptor:

For ADMA1:

- Set type descriptor: interrupt is generated when data length is set.
- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type descriptor: interrupt is generated when new descriptor address is set.
- Nop type descriptor: interrupt is generated just after this descriptor is fetched.

For ADMA2:

- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type descriptor: interrupt is generated when new descriptor address is set.
- Nop/Rsv type descriptor: interrupt is generated just after fetch this descriptor.

26.3.2.4.3 ADMA Error-DMA

The ADMA will stop whenever any error is encountered. These errors include:

- Fetching descriptor error
- AHB response error
- Data length mismatch error

ADMA descriptor error will be generated when it fails to detect 'Valid' flag in the descriptor. If adma descriptor error occurs, the interrupt is not generated even if the 'Interrupt' flag of this descriptor is set.

When BLKCNTEN bit is set, data length set in Block Attributes register must equal to the whole data length set in descriptor nodes, otherwise data length mismatch error will be generated.

If BLKCNTEN bit is not set, the whole data length set in descriptor should be times of block length, otherwise, when all data set in the descriptor nodes are done not at block boundary, the data mismatch error will occur.

26.3.3 Register Bank with IP Bus Interface

Register accesses via the IP Bus interface are actually on the Register Bank. See the figure below for the block diagram.

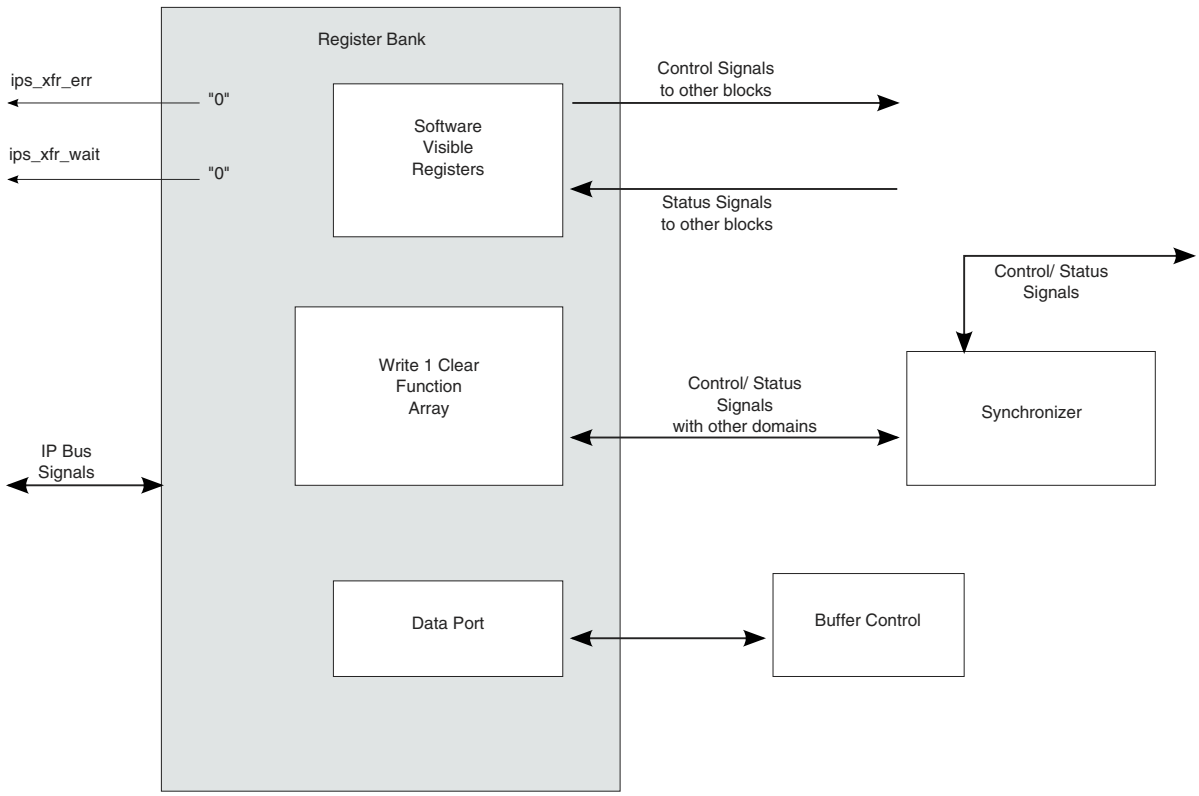

Figure 26-12. Register Bank Diagram

Only 32-bit access is allowed, and no partial read / write is supported, thus all accesses are word aligned.

26.3.4 SD Protocol Unit

The SD protocol unit deals with all SD protocol affairs.

The SD Protocol Unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into corresponding registers
- Detects the bus state on the DAT[0] line
- Monitors the interrupt from the SDIO card
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status
- Detects the write protect state

The SD Protocol Unit consists of four sub-blocks:

1. SD transceiver.

2. SD clock and monitor.
3. Command agent.
4. Data agent.

26.3.4.1 SD Transceiver

In the SD protocol unit, the transceiver is the main control sub-block. It consists of an FSM and control sub-block, from which the control signals for all other three sub-blocks are generated.

26.3.4.2 SD Clock & Monitor

This sub-block monitors the signal level on all 8 data lines, the command lines, and directly routes the level values into the Register Bank. The driver can use this for debug purposes.

The sub-block also detects the Card Detection (CD) line as well as the DAT[3] line. The transceiver reports the card insertion state according to the CD state, or the signal level on the DAT[3] line, when the D3CD bit in the Protocol Control register is set.

The sub-block detects the Write Protect (WP) line. With the information of the WP state, the Register Bank will ignore the command, accompanied by a write operation, when the WP switch is on.

If the internal data buffer is in danger, and the SD clock must be gated off to avoid buffer over/under-run, this sub-block will assert the gate of the output SD clock to shut the clock off. After the buffer danger has recovered, and when the system access of the buffer catches up, the clock gate of this sub-block will open and the SD clock will be active again.

This sub-block also drive SD_LCTL output signal when the LCTL bit is set by the driver.

26.3.4.3 Command Agent

The Command Agent deals with the transactions on the CMD line. See figure below for an illustration of the structure for the Command CRC Shift Register.

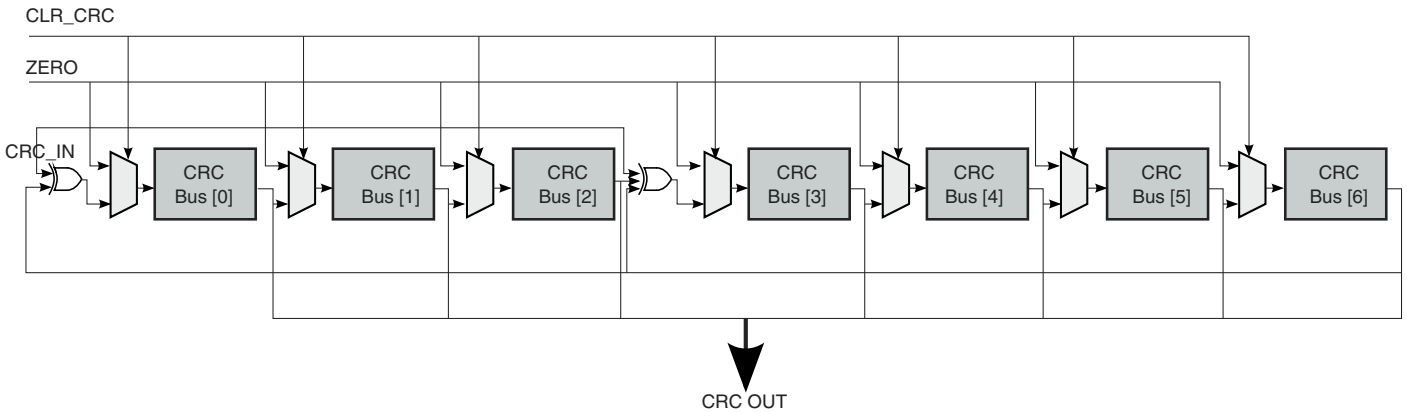

Figure 26-13. Command CRC Shift Register

The CRC polynomials for the CMD are as follows:

Generator polynomial: $G(x) = x^7 + x^3 + 1$
$M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \ldots + (\text{last bit}) * x^0$
$CRC[6:0] = \text{Remainder } [(M(x) * x^7) / G(x)]$

26.3.4.4 Data Agent

The Data Agent deals with the transactions on the eight data lines. Moreover, this sub-block also detects the busy state on the DAT[0] line, and generate the Read Wait state by the request from the Transceiver. The CRC polynomials for the DAT are as follows:

Generator polynomial: $G(x) = x^{16} + x^{12} + x^5 + 1$
$M(x) = (\text{first bit}) * x^n + (\text{second bit}) * x^{n-1} + \ldots + (\text{last bit}) * x^0$
$CRC[15:0] = \text{Remainder } [(M(x) * x^{16}) / G(x)]$

26.3.5 Clock & Reset Manager

This sub-block controls all the reset signals within the ESDHC.

There are four kinds of reset signals within ESDHC:

1. Hardware reset.
2. Software reset for all.
3. Software reset for the data part.
4. Software reset for the command part.

All these signals are fed into this sub-block and stable signals are generated inside the module to reset all other modules. The sub-block also gates off all the inside signals.

There are three clocks inside the ESDHC:

1. ipg_clk.

2. ipg_perclk.
3. hclk.

The sub-block monitors the activities of all other sub-blocks, supplies the clocks for them, and when enabled, automatically gates off the corresponding clocks.

26.3.6 Clock Generator

The Clock Generator generates the SD_CLK by peripheral source clock in two stages. Refer to Figure 26-14 for the structure of the divider. The term "Base" represents the frequency of peripheral source clock.

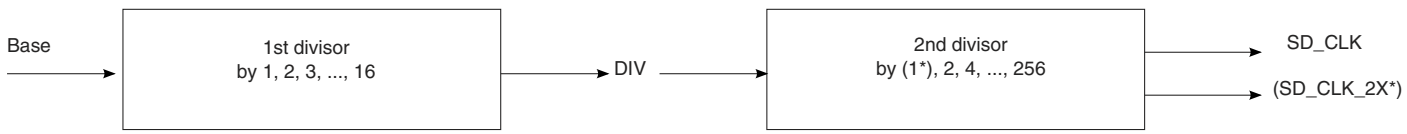

Figure 26-14. Two Stages of the Clock Divider

The first stage outputs an intermediate clock (DIV), which can be Base, Base/2, Base/3, ..., or Base/16.

The second stage is a prescaler, and outputs the actual clock (SD_CLK).This clock is the driving clock for all sub-blocks of the SD Protocol Unit, and the sync FIFOs (see Figure 26-3) to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage, can beDIV, DIV/2, DIV/4,..., or DIV/256. Thus the highest frequency of the SD_CLK is Base, and the next highest is Base/2, while the lowest frequency is Base/4096. If the Base clock is of equal duty ratio (usually true), the duty cycle of SD_CLK is also 50%, even when the compound divisor is an odd value.

26.3.7 SDIO Card Interrupt

26.3.7.1 Interrupts in 1-bit Mode

In this case the DAT[1] pin is dedicated to providing the interrupt function. An interrupt is asserted by pulling the DAT[1] low from the SDIO card, until the interrupt service is finished to clear the interrupt.

26.3.7.2 Interrupt in 4-bit Mode

Since the interrupt and data line 1 share Pin 8 in 4-bit mode, an interrupt will only be sent by the card and recognized by the host during a specific time. This is known as the Interrupt Period. The ESDHC will only sample the level on Pin 8 during the Interrupt Period. At all other times, the host will ignore the level on Pin 8, and treat it as the data signal. The definition of the Interrupt Period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the Interrupt Period becomes active two clock cycles after the completion of a data packet. This Interrupt Period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in 4-bit mode, there is only a limited period of time that the Interrupt Period can be active due to the limited period of data line availability between the multiple blocks of data. This requires a more strict definition of the Interrupt Period. For this case, the Interrupt Period is limited to two clock cycles. This begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the DAT[1] line will be held low for one clock cycle with the last clock cycle pulling DAT[1] high. On completion of the Interrupt Period, the card releases the DAT[1] line into the high Z state. The ESDHC samples the DAT[1] during the Interrupt Period when the IABG bit in the Protocol Control register is set.

Refer to SDIO Card Specification v1.10f for further information about the SDIO card interrupt.

26.3.7.3 Card Interrupt Handling

When the CINTIEN bit in the Interrupt Signal Enable Register is set to 0, the ESDHC clears the interrupt request to the Host System. The Host Driver should clear this bit before servicing the SDIO Interrupt and should set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO Status bit is cleared by resetting the SDIO interrupt. Writing to this bit would have no effects. In 1-bit mode, the ESDHC will detect the SDIO Interrupt with or without the SD clock (to support wakeup). In 4-bit mode, the interrupt signal is sampled during the Interrupt Period, so there are some sample delays between the interrupt signal from the SDIO card and the interrupt to the Host System Interrupt Controller. When the SDIO status has been set, and the Host Driver needs to service this interrupt, so the SDIO bit in the Interrupt Control Register of SDIO card will be cleared. This is required to clear the SDIO interrupt status latched in the ESDHC and to stop driving the interrupt signal to the

System Interrupt Controller. The Host Driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO Interrupt Enable bit is set to 1, and the ESDHC starts sampling the interrupt signal again.

See figure below for an illustration of the SDIO card interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

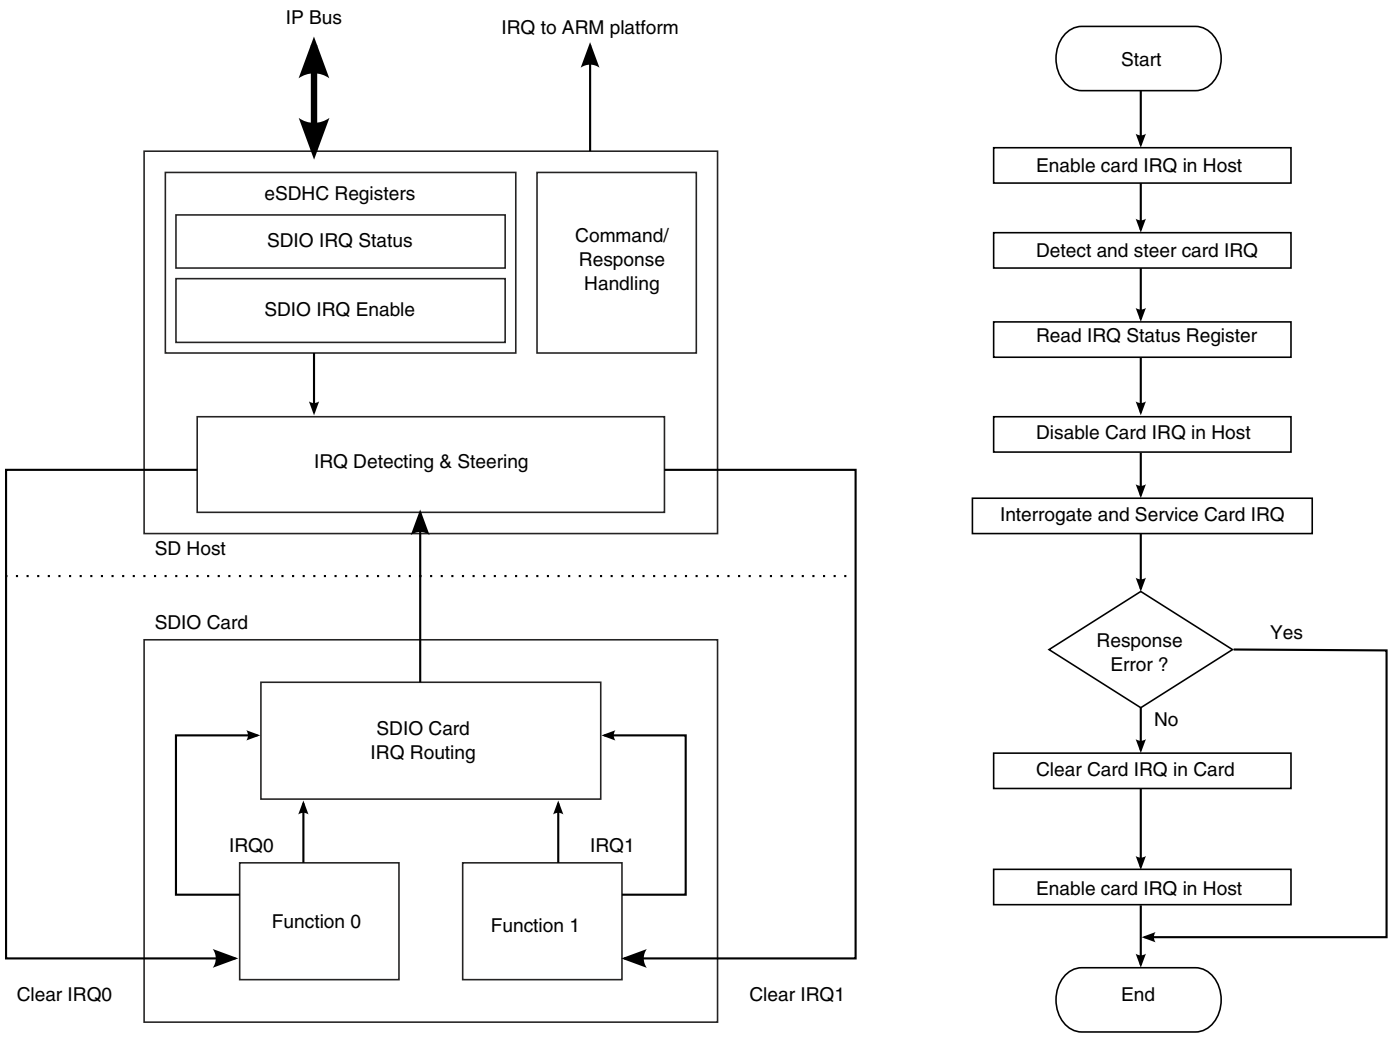

Figure 26-15. Card Interrupt Scheme and Card Interrupt Detection and Handling Procedure

26.3.8 Card Insertion and Removal Detection

The ESDHC uses either the DAT[3] pin or the CD pin to detect card insertion or removal. When there is no card on the MMC/SD bus, the DAT[3] will be pulled to a low voltage level by default. When any card is inserted to or removed from the socket, the ESDHC detects the logic value changes on the DAT[3] pin and generates an interrupt. When the DAT[3] pin is not used for card detection (for example, it is implemented in GPIO), the CD pin must be connected for card detection. Whether DAT[3] is configured for card detection or not, the CD pin is always a reference for card detection. Whether the DAT[3] pin or the CD pin is used to detect card insertion, the ESDHC will send an interrupt (if enabled) to inform the Host system that a card is inserted.

26.3.9 Power Management and Wake Up Events

When there is no operation between the ESDHC and the card through the SD bus, the user can completely disable the ipg_clk and ipg_perclk in the chip level clock control module to save power. When the user needs to use the ESDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to the ESDHC are disabled, for instance, when the system is in low power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The ESDHC can generate these interrupt even when there are no clocks enabled. The three interrupts which can be used as wake up events are:

1. Card Removal Interrupt
2. Card Insertion Interrupt
3. Interrupt from SDIO card

The ESDHC offers a power management feature. By clearing the clock enabled bits in the System Control Register (ESDHC_SYSCTL), the clocks are gated in the low position to the ESDHC. For maximum power saving, the user can disable all the clocks to the ESDHC when there is no operation in progress.

These three wake up events (or wakeup interrupts) can also be used to wake up the system from low-power modes.

NOTE

To make the interrupt a wakeup event, when all the clocks to the ESDHC are disabled or when the whole system is in low power mode, the corresponding wakeup enabled bit needs to be set. Refer to Protocol Control (ESDHCV3_PROCTL) for more information on the ESDHC Protocol Control register.

26.3.9.1 Setting Wake Up Events

For the ESDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the ARM platform enters sleep mode. Before the software disables the host clock, it should ensure that all of the following conditions have been met:

- No Read or Write Transfer is active
- Data and Command lines are not active
- No interrupts are pending
- Internal data buffer is empty

26.3.10 MMC Fast Boot

The Embedded Multimedia Card (eMMC 4.3) has a fast boot feature. In boot operation mode, the master (MultiMediaCard host) can read boot data from the slave (MMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFA (optional for slave), before issuing CMD1.

There are two types of fast boot mode in the eMMC4.3 spec: 'Boot operation' and 'Alternative boot operation.' Each type also has with acknowledge and without acknowledge modes. eSDHCv2 supports both fast boot modes.

NOTE

For the eMMC4.3 card setting, please refer to the eMMC4.3 spec.

26.3.10.1 Boot Operation

NOTE

In this block guide, this fast boot is called normal fast boot mode.

If the CMD line is held LOW for 74 clock cycles and more after power-up before the first command is issued, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within 1 second after the CMD line goes LOW, the slave starts to send the first boot data to the master on the DAT line(s). The master must keep the CMD line LOW to read all of the boot data.

If boot acknowledge is enabled, the slave has to send acknowledge pattern '010' to the master within 50ms after the CMD line goes LOW. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate boot mode with the CMD line HIGH.

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

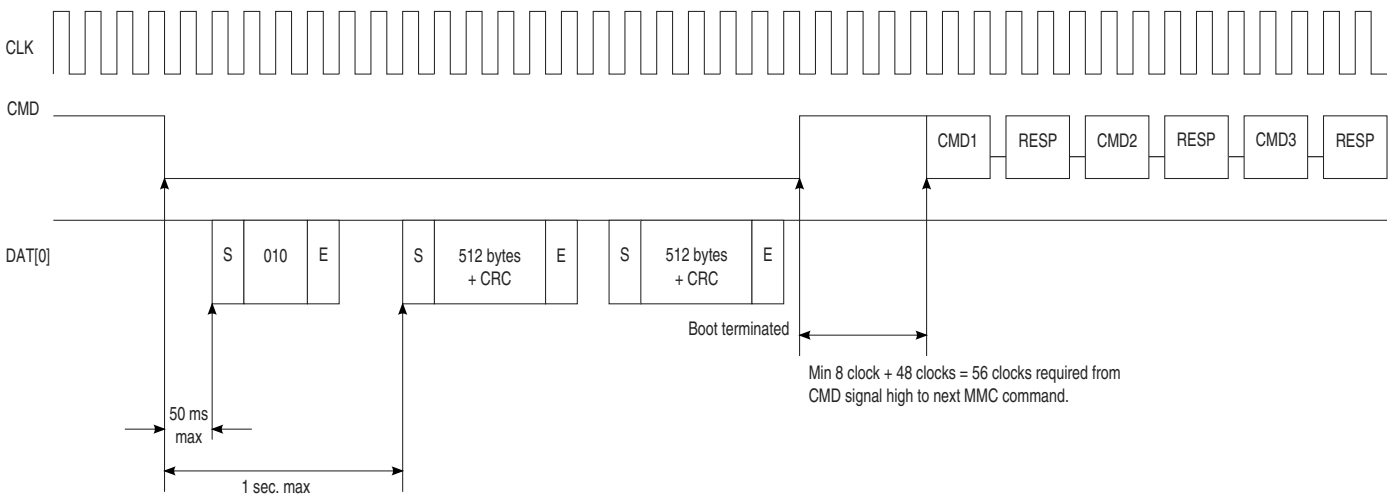

Figure 26-16. MultiMediaCard state diagram (normal boot mode)

26.3.10.2 Alternative Boot Operation

If bit 0 in the extended CSD byte[228] is set to '1', the device supports the alternative boot operation.

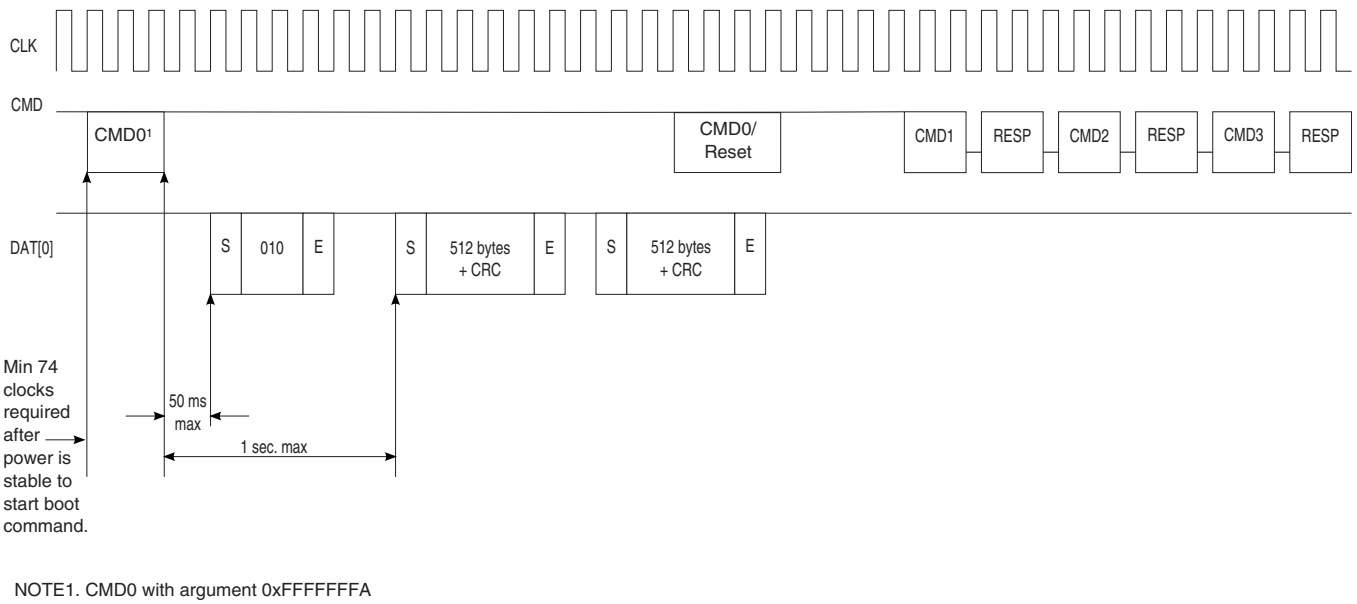
After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFA after 74 clock cycles, before CMD1is issued or the CMD line goes low, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within 1 second after CMD0 with the argument of 0xFFFFFFFA is issued, the slave starts to send the first boot data to the master on the DAT line(s).

If boot acknowledge is enabled, the slave has to send the acknowledge pattern '010' to the master within 50ms after the CMD0 with the argument of 0xFFFFFFFA is received. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate boot mode by issuing CMD0 (Reset).

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.



NOTE1. CMD0 with argument 0xFFFFFFFA

Figure 26-17. MultiMediaCard state diagram (alternative boot mode)

26.4 Initialization/Application of ESDHC

All communication between system and cards are controlled by the host. The host sends commands of two types: broadcast and addressed (point-to-point).

Broadcast commands are intended for all cards, such as "GO_IDLE_STATE", "SEND_OP_COND", "ALL_SEND_CID" and etc. In Broadcast mode, all cards are in the open-drain mode to avoid bus contention. Refer to Commands for MMC/SD/SDIO for the commands of bc and bcr categories.

After the Broadcast command CMD3 is issued, the cards enter standby mode. Addressed type commands are used from this point. In this mode, the CMD/DAT I/O pads will turn to push-pull mode, to have the driving capability for maximum frequency operation. Refer to Commands for MMC/SD/SDIO for the commands of ac and adtc categories.

26.4.1 Command Send & Response Receive Basic Operation

Assuming the data type WORD is an unsigned 32-bit integer, the below flow is a guideline for sending a command to the card(s):

```
send_command(cmd_index, cmd_arg, other requirements)
{
WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is
recommended to implement in a bit-field manner
wCmd = (<cmd_index> & 0x3f) >> 24; // set the first 8 bits as '00'+<cmd_index>
set CMDTYP, DPSEL, CICEN, CCCEN, RSTTYP, DTDSEL accorind to the command index;
if (internal DMA is used) wCmd |= 0x1;
if (multi-block transfer) {
          set MSBSEL bit;
          if (finite block number) {
                    set BCEN bit;
                    if (auto12 command is to use) set AC12EN bit;
          }
}
write_reg(CMDARG, <cmd_arg>); // configure the command argument
write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command
}
wait_for_response(cmd_index)
{
while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set
read IRQ Status register and check if any error bits about Command are set
if (any error bits are set) report error;
write 1 to clear CC bit and all Command Error bits;
}
```

For the sake of simplicity, the function wait_for_response is implemented here by means of polling. For an effective and formal way, the response is usually checked after the Command Complete Interrupt is received. By doing this, make sure the corresponding interrupt status bits are enabled.

For some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and go to the Standby State, no response to the Host when CMD2 is sent. The Host Driver shall deal with 'fake' errors like this with caution.

26.4.2 Card Identification Mode

When a card is inserted to the socket or the card was reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the Relative Card Address (RCA) or to set the RCA for the MMC cards.

26.4.2.1 Card Detect

See figure below for a flow diagram showing the detection of MMC, SD and SDIO cards using the ESDHC.

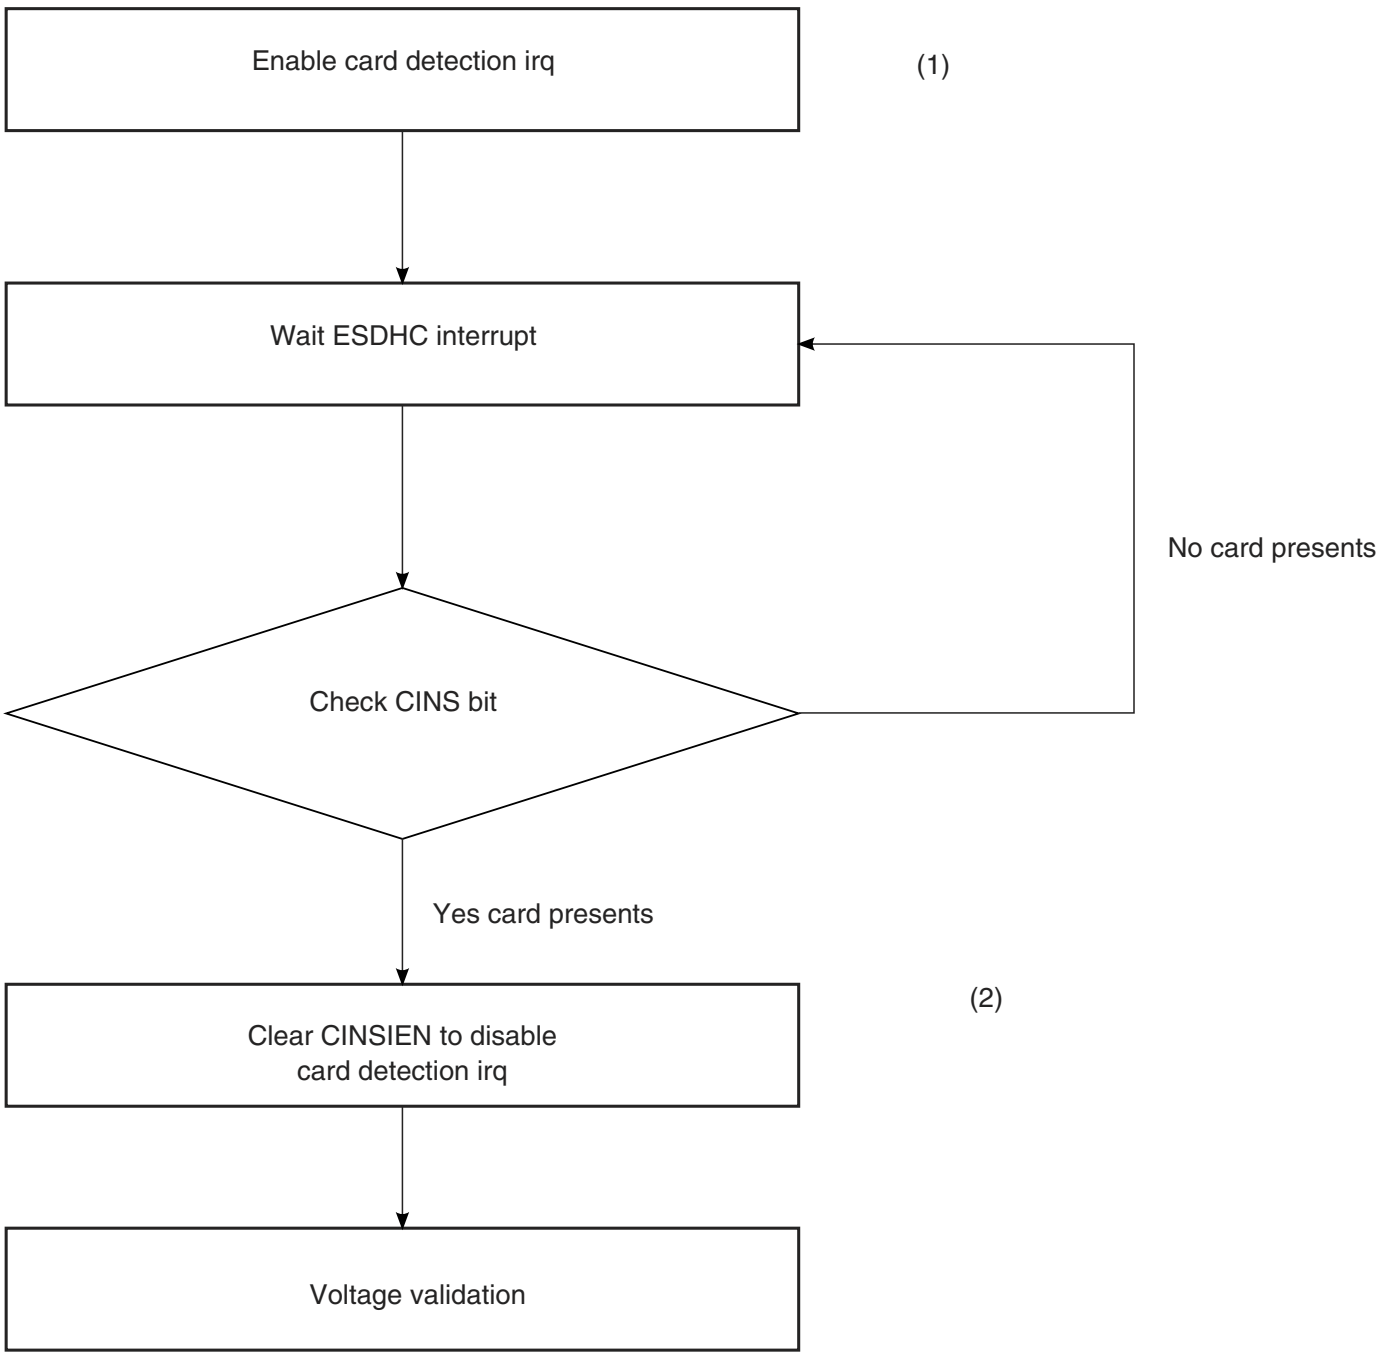


Figure 26-18. Flow Diagram for Card Detection

Here is the card detect sequence:

- Set the CINSIEN bit to enable card detection interrupt
- When an interrupt from the ESDHC is received, check the CINS bit in the Interrupt Status register to see if it was caused by card insertion
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards

26.4.2.2 Reset

The host consists of three types of resets:

- Hardware reset (Card and Host) which is driven by POR (Power On Reset)
- Software reset (Host Only) is proceed by the write operation on the RSTD, RSTC, or RSTA bits of the System Control register to reset the data part, command part, or all parts of the Host Controller, respectively
- Card reset (Card Only). The command, "Go_Idle_State" (CMD0), is the software reset command for all types of MMC cards, SD Memory cards. This command sets each card into the Idle State regardless of the current card state. For an SD I/O Card, CMD52 is used to write an I/O reset in the CCCR. The cards are initialized with a default relative card address (RCA=0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. See figure below for the software flow to reset both the ESDHC and the card.

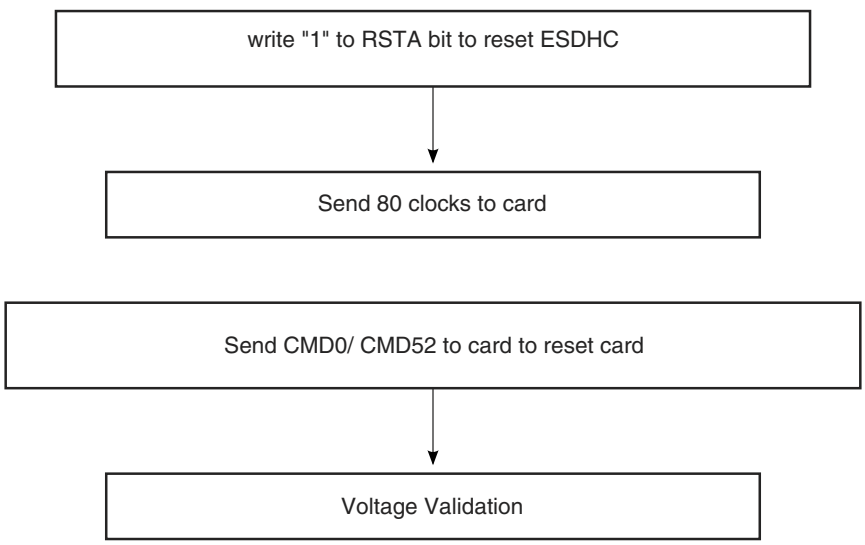

Figure 26-19. Flow Chart for Reset of the ESDHC and SD I/O Card

```
software_reset()
{
set_bit(SYSCTRL, RSTA); // software reset the Host
set DVS and SDCLKFS bit fields to get the SD_CLK of frequency around 400kHz
configure IO pad to set the power voltage of external card to around 3.0V
poll bits CIHB and CDIHB bits of PRSSTAT to wait both bits are cleared
set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
send_command(CMD_GO_IDLE_STATE, <other parameters>); // reset the card with CMD0
or send_command(CMD_IO_RW_DIRECT, <other parameters>);
}
```

26.4.2.3 Voltage Validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for Vdd are defined in the Operation Conditions Register (OCR) and may not cover the whole range. Cards that store the CID and CSD data in the preload memory are only able to communicate this information under data transfer Vdd conditions. This means if the host and card have non-common Vdd ranges, the card will not be able to complete the identification cycle, nor will it be able to send CSD data.

Therefore, a special command Send_Op_Cont (CMD1 for MMC), SD_Send_Op_Cont (ACMD41 for SD Memory) and IO_Send_Op_Cont (CMD5 for SD I/O) is used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards which do not match the Vdd range(s) desired by the host. This is accomplished by the host sending the desired Vdd voltage window as the operand of this command. Cards that can't perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive State. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before sending out-of-range cards into the Inactive State. This query should be used if the host is able to select a common voltage range or if a notification shall be sent to the system when a non-usable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```
voltage_validation(voltage_range_arguement)
{
label the card as UNKNOWN;
send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO
operation voltage, command argument is zero
if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
          if (0 < number of IO functions) {
                    label the card as SDIO;
                    IORDY = 0;
                    while (!(IORDY in IO OCR response)) { // set voltage range for each IO
function
                              send_command(IO_SEND_OP_COND, <voltage range>, <other
parameter>);
                              wait_for_response(IO_SEND_OP_COND);
                    } // end of while ...
          } // end of if (0 < ...
          if (memory part is present inside SDIO card) Label the card as SDCombo; // this is
an
SD-Combo card
} // end of if (RESP_TIMEOUT ...
if (the card is labelled as SDIO card) return; // card type is identified and voltage range
is
set, so exit the function;
send_command(APP_CMD, 0x0, <other parameters are omitted>); // CMD55, Application specific
CMD
prefix
if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55 is accepted
          send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set voltage
```

```
range
for memory part or SD card
          wait_for_response(SD_APP_OP_COND); // voltage range is set
          if (card type is UNKNOWN) label the card as SD;
          return; //
} // end of if (no error ...
else if (errors other than time-out occur) { // command/response pair is corrupted
          deal with it by program specific manner;
} // of else if (response time-out
else { // CMD55 is refuse, it must be MMC card           if (card is already labelled as
SDCombo) { // change label
                    re-label the card as SDIO;
                    ignore the error or report it;
                    return; // card is identified as SDIO card
          } // of if (card is ...
          send_command(SEND_OP_COND, <voltage range>, <...>);
          if (RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted,
either
                    label the card as UNKNOWN;
                    return;
          } // of if (RESP_TIMEOUT ...
          if (check for CE-ATA signature succeeded) { // the card is CE-ATA
                    store CE-ATA specific info from the signature;
                    label the card as CE-ATA;
          } // of if (check for CE-ATA ...
          else label the card as MMC;
} // of else
}
```

26.4.2.4 Card Registry

Card registry for the MMC and SD/SDIO/SD Combo cards are different.

For the SD Card, the Identification process starts at a clock rate lower than 400 kHz and the power voltage higher than 2.7 V (as defined by the Card spec). At this time, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host will request the card to send their valid operation conditions. The response to ACMD41 is the operation condition register of the card. The same command shall be send to all of the new cards in the system. Incompatible cards are put into the Inactive State. The host then issues the command, All_Send_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified (in the Ready State), send their CID number as the response. After the CID is sent by the card, the card goes into the Identification State.

The host then issues Send_Relative_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA will be used to address the card for future data transfer operations. Once the RCA is received, the card changes its state to the Standby State. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send_Relative_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in system.

For MMC operation, the host starts the card identification process in open-drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line allow parallel card operation during card identification. After the bus is activated the host will request the cards to send their valid operation conditions (CMD1). The response to CMD1 is the "wired OR" operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive State. The host then issues the broadcast command All_Send_CID (CMD2), asking all cards for their unique card identification (CID) number. All unidentified cards (the cards in Ready State) simultaneously start sending their CID numbers serially, while bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. Since the CID is unique for each card, only one card can be successfully send its full CID to the host. This card then goes into the Identification State. Thereafter, the host issues Set_Relative_Addr (CMD3) to assign to the card a relative card address (RCA). Once the RCA is received the card state changes to the Stand-by State, and the card does not react in further identification cycles, and its output driver switches from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a time-out condition to recognize the completion of the identification process.

For operation as MMC cards:

```
card_registry()
{
do { // decide RCA for each card until response time-out
          if(card is labelled as SDCombo or SDIO) { // for SDIO card like device
                    send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO card to
publish its
RCA
                    retrieve RCA from response;
          } // end if (card is labelled as SDCombo ...
          else if (card is labelled as SD) { // for SD card
                    send_command(ALL_SEND_CID, <...>);
                    if (RESP_TIMEOUT == wait_for_response(ALL_SEND_CID)) break;
                    send_command(SET_RELATIVE_ADDR, <...>);
                    retrieve RCA from response;
          } // else if (card is labelled as SD ...
          else if (card is labelled as MMC or CE-ATA) { // treat CE-ATA as MMC
                    send_command(ALL_SEND_CID, <...>);
                    rca = 0x1; // arbitrarily set RCA, 1 here for example, this RCA is also
the
relative address to access the CE-ATA card
                    send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper
16
bits
          } // end of else if (card is labelled as MMC ...
} while (response is not time-out);
}
```

26.4.3 Card Access

26.4.3.1 Block Write

26.4.3.1.1 Normal Write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card shall indicate the failure on the DAT line. The transferred data will be discarded and not written, and all further transmitted blocks (in multiple block write mode) will be ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE_BLK_MISALIGN is not set), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS_ERROR error bit in the status register, and while ignoring all further data transfer, waits in the Receive-data-State for a stop command. The write operation is also aborted if the host tries to write over a write protected area.

For MMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card will report an error and not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card will begin writing and hold the DAT line low if its write buffer is full and unable to accept new data from a new WRITE_BLOCK command. The host may poll the status of the card with a SEND_STATUS command (CMD13) or other means for SDIO cards at any time, and the card will respond with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 (to select a different card) to place the card into the Standby State and release the DAT line without interrupting the write operation. When re-selecting the card, it will reactivate the busy indication by pulling DAT to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card incorporates the internal DMA and the write operation is a multi-block write with the Auto CMD12 enabled. For the other two methods (by means of external DMA or ARM platform polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is described below:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:
   a. For SD/MMC cards, use SET_BLOCKLEN (CMD16)
   b. For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the ESDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the ESDHC block attribute register, block number is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the ESDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

26.4.3.1.2 Write with Pause

The write operation can be paused during the transfer. Instead of stopping the SD_CLK at any time to pause all the operations, which is also inaccessible to the Host Driver, the Driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DAT0 line is not required to de-assert to release the busy state, no suspend command is needed.

Like in the flow described in Normal Write, the write with pause is shown with the same kind of write operation:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
   a. For SD/MMC, use SET_BLOCKLEN (CMD16)
   b. For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the ESDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the ESDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the ESDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Set the SABGREQ bit.

7. Wait for the Transfer Complete interrupt.
8. Clear the SABGREQ bit.
9. Check the status bit to see if a write CRC error occurred.
10. Set the CREQ bit to continue the write operation.
11. Wait for the Transfer Complete interrupt.
12. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of the BLKCNT field in the Block Attribute register. As the data transfer and the setting of the SABGREQ bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The Driver shall read the value of BLKCNT after the transfer is paused and the Transfer Complete interrupt is received.

It is also possible the last block has begun when the Stop At Block Gap Request is sent to the buffer. In this case, the next block gap is actually the end of the transfer. These types of requests are ignored and the Driver should treat this as a non-pause transfer and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the Host System is not stopped, and the transfer is active until the data buffer is full. Because of this (if not needed), it is recommended to avoid using the Suspend Command for the SDIO card; when such a command is sent, the ESDHC thinks the System will switch to another function on the SDIO card, and flush the data buffer. The ESDHC takes the Resume Command as a normal command with data transfer, and it is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set as well as the AC12EN bit. However, the ESDHC will automatically send a CMD12 to mark the end of the multi-block transfer.

26.4.3.2 Block Read

26.4.3.2.1 Normal Read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer State. For multi blocks read, data blocks will be continuously transferred until a stop command is issued.

The software flow to read from a card incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other two methods (by means of external DMA or ARM platform polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is described below:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
   a. For SD/MMC, use SET_BLOCKLEN (CMD16)
   b. For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the ESDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the ESDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer read ready interrupt, configure the DMA settings and enable the ESDHC DMA when sending the command with data transfer. The AC12EN bit should also be set:
6. Wait for the Transfer Complete interrupt.
7. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

26.4.3.2.2 Read with Pause

The read operation is not generally able to pause. Only the SDIO card (and SDCombo card working under I/O mode) supporting the Read Wait feature can pause during the read operation. If the SDIO card supports Read Wait (SRW bit in CCCR register is 1), the Driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks. Before setting the SABGREQ bit, make sure the RWCTL bit in the Protocol Control register is set, otherwise the ESDHC will not assert the Read Wait signal during the block gap and data corruption occurs. It is recommended that the RWCTL bit be set once the Read Wait capability of the SDIO card is recognized.

Like in the flow described in Normal Read, the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on the SDIO card to confirm the card supports Read Wait.
2. Set the RWCTL bit.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:

a. For SD/MMC, use SET_BLOCKLEN (CMD16)
b. For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)

5. Set the ESDHC block length register to be the same as the block length set for the card in Step 2.
6. Set the ESDHC number block register (NOB), nob is 5 (for instance).
7. Disable the buffer read ready interrupt, configure the DMA setting and enable the ESDHC DMA when sending the command with data transfer. The AC12EN bit should also be set
8. Set the SABGREQ bit.
9. Wait for the Transfer Complete interrupt.
10. Clear the SABGREQ bit.
11. Check the status bit to see if read CRC error occurred.
12. Set the CREQ bit to continue the read operation.
13. Wait for the Transfer Complete interrupt.
14. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

Like the write operation, it is possible to meet the ending block of the transfer when paused. In this case, the ESDHC will ignore the Stop At Block Gap Request and treat it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause will be transferred to the Host System. No matter if the Suspend Command is sent or not, the internal data buffer is not flushed.

If the Suspend Command is sent and the transfer is later resumed by means of a Resume Command, the ESDHC takes the command as a normal one accompanied with data transfer. It is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit. However, the ESDHC will automatically send the CMD12 to mark the end of multi-block transfer.

26.4.3.3 Suspend Resume

The ESDHC supports the Suspend Resume operations of SDIO cards, although slightly different than the suggested implementation of Suspend in the SDIO card specification.

Suspend

After setting the SABGREQ bit, the Host Driver may send a Suspend command to switch to another function of the SDIO card. The ESDHC does not monitor the content of the response, so it doe not know whether or not the Suspend command has succeeded. Accordingly, it does not de-assert Read Wait for read pause. To solve this problem, the Driver does not set the ESDHC_XFERTYP[CMDTYP] register to 01, that is, Suspend option. Instead, the Driver sends this command as if it were a normal command (that is, sets CMDTYP to b00). Only when the command succeeds, and the BS bit is set in the response, does the Driver send another command marked as "Suspend" to inform the ESDHC that the current transfer is suspended. This is shown in the following sequence for Suspend operation:

1. Set the SABREQ bit to pause the current data transfer at block gap.
2. After the BGE bit is set, send the Suspend command to suspend the active function. The CMDTYP bit field must be 2'b00.
3. Check the BS bit of the CCCR in the response. If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.
4. Send another normal I/O command to the suspended function. The CMDTYP of this command must be 2'b01, so the ESDHC can detect this special setting and be informed that the paused operation has successfully suspended. If the paused transfer is a read operation, the ESDHC stops driving DAT2 and goes to the idle state.
5. Save the context registers in the system memory for later use, including the DMA System Address Register (for internal DMA operation), and the Block Attribute Register.
6. Begin operation for another function on the SDIO card.

26.4.3.3.1 Resume

To resume the data transfer, a Resume command shall be issued:

1. To resume the suspended function, restore the context register with the saved value in step #5 of the Suspend operation above.
2. Send the Resume command. In the Transfer Type register, all bit fields are set to the value as if this were another ordinary data transfer, instead of a transfer resume (except the CMDTYP is set to 2'b10).
3. If the Resume command has responded, the data transfer will be resumed.

26.4.3.4 ADMA1 Usage

To use the ADMA1 in a data transfer, the Host Driver must prepare the correct descriptor chain prior to sending the read/write command. The steps to accomplish this are:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4kB address aligned).
3. If necessary, create a Link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1 ~ 3.
4. Repeat steps 1 ~ 3 until all descriptors are created.
5. In the last descriptor, set the End flag to 1 and make sure the total length of all descriptors match the product of the block size and block number configured in the Block Attribute Register.
6. Set the ADMA System Address Register to the address of the first descriptor and set the DMAS field in the Protocol Control Register to 01 to select the ADMA.
7. Issue a write or read command with the DMAEN bit set to 1 in the Transfer Type Register.

Steps 1 ~ 5 are independent of step 6, so step 6 can finish before steps 1 ~ 5. Regarding the descriptor configuration, it is recommended not to use the Link descriptor as it requires extra system memory access.

26.4.3.5 Transfer Error

26.4.3.5.1 CRC Error

It is possible at the end of a block transfer, that a write CRC status error or read CRC error occurs. For this type of error the latest block received shall be discarded. This is because the integrity of the data block is not guaranteed. It is recommended to discard the following data blocks and re-transfer the block from the corrupted one. For a multi-block transfer, the Host Driver shall issue a CMD12 to abort the current process and start the transfer by a new data command. In this scenario, even when the AC12EN and BCEND bits are set, the ESDHC does not automatically send a CMD12 because the last block is not transferred. On the other hand, if it is within the last block that the CRC error occurs, an Auto CMD12 will be sent by the ESDHC. In this case, the Driver shall re-send or re-obtain the last block with a single block transfer.

26.4.3.5.2 Internal DMA Error

During the data transfer with internal Simple DMA, if the DMA engine encounters some error on the AHB bus, the DMA operation is aborted and DMA Error interrupt is sent to the Host System. When acknowledged by such an interrupt, the Driver shall calculate the start address of data block in which the error occurs. The start address can be calculated by either:

1. Read the DMA System Address register. The error occurs during the previous burst. Taking the block size, the previous burst length and the start address of the next burst transfer into account, it is straight forward to obtain the start address of the corrupted block.
2. Read the BLKCNT field of the Block Attribute register. By the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined. When the BCEN bit is not set, the contents of the Block Attribute register does not change, so this method does not work.

When a DMA error occurs, it is recommended to abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and re-start the transfer from the corrupted block to recover from the error.

26.4.3.5.3 ADMA Error-Card Access

There are three kinds of possible ADMA errors. The AHB transfer, invalid descriptor, and data-length mismatch errors. When these errors occur, the DMA transfer stops and the corresponding error status bit is set. For acknowledging the status, the Host Driver should recover the error as shown below and re-transfer from the place of interruption.

1. AHB transfer error: Such errors may occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and re-transfer the block that was corrupted, or the next block if no block is corrupted.
2. Invalid descriptor error: For such errors, it is recommended to retrieve the transfer context, reset for the data part and re-create the descriptor chain from the invalid descriptor and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
3. Data-length mismatch error: It is similar to recover from this error. The Host Driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain, and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

26.4.3.5.4 Auto CMD12 Error

After the last block of the multi block transfer is sent or received, and the AC12EN bit is set when the data transfer is initiated by the data command, the ESDHC automatically sends a CMD12 to the card to stop the transfer. When errors with this command occur, it is recommended to the Driver to deal with the situations in the following manner:

1. Auto CMD12 response time-out. It is not certain whether the command is accepted by the card or not. The Driver should clear the Auto CMD12 error status bits and re-send the CMD12 until it is accepted by the card.
2. Auto CMD12 response CRC error. Since card responds to the CMD12, the card will abort the transfer. The Driver may ignore the error and clear the error status bit.
3. Auto CMD12 conflict error or not sent. The command is not sent, so the Driver shall send a CMD12 manually.

26.4.3.6 Card Interrupt

The external cards can inform the Host Controller by means of some special signals. For the SDIO card, it can be the low level on the DAT[1] line during some special period. The ESDHC only monitors the DAT[1] line and supports the SDIO interrupt.

When the SDIO interrupt is captured by the ESDHC, and the Host System is informed by the ESDHC asserting the ESDHC interrupt line, the interrupt service from the Host Driver is called.

As the interrupt factor is controlled by the external card, the interrupt from the SDIO card must be served before the CINT bit is cleared by written 1. Refer to Card Interrupt Handling for the card interrupt handling flow.

26.4.4 Switch Function

MMC cards transferring data at bus widths other than 1-bit is a feature in MMC spec. The high speed timing mode for all card devices, was also defined in various card specifications. To enable these features, a "switch" command shall be issued by the Host Driver.

For SDIO cards, the high speed mode is enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed. For SD cards, the high speed mode is queried and enabled by a CMD6 (with the mnemonic symbol as SWITCH_FUNC). For MMC cards, the high speed mode is queried by a CMD8 and enabled by a CMD6 (with the mnemonic symbol as SWITCH).

The 4-bit and 8-bit bus width of the MMC is also enabled by the SWITCH command, but with a different argument.

DDR mode is also selected by setting ddr mode bus width via SWITCH.

These new functions can also be disabled by a software reset. For SDIO cards it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following flowcharts do not show current capability check, which is recommended in the function switch process.

26.4.4.1 Query, Enable and Disable SDIO High Speed Mode

```
enable_sdio_high_speed_mode(void)
{
send CMD52 to query bit SHS at address 0x13;
if (SHS bit is '0') report the SDIO card does not support high speed mode and return;
send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
change clock divisor value or configure the system clock feeding into ESDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is
cleared;
change clock divisor value or configure the system clock feeding into ESDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

26.4.4.2 Query, Enable and Disable SD High Speed Mode

```
enable_sd_high_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0xFFFFF1 and read 64 bytes of data accompanying the R1 response;
wait data transfer done bit is set;
check if the bit 401 of received 512 bit is set;
if (bit 401 is '0') report the SD card does not support high speed mode and return;
send CMD6, with argument 0x80FFFFF1 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into ESDHC to generate the
card_clk of around 50MHz;
(data transactions like normal peers)
}
disable_sd_high_speed_mode(void)
{
set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
check if the bit field 379~376 is 0xF;
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into ESDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)
}
```

26.4.4.3 Query, Enable and Disable MMC High Speed Mode

```
enable_mmc_high_speed_mode(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support high speed mode and
return;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
extract the value of CARD_TYPE field to check the 'high speed mode' in this MMC is 26MHz or
52MHz;
send CMD6 with argument 0x1B90100;
send CMD13 to wait card ready (busy line released);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 1;
if (HS_TIMING is not 1) report MMC switching to high speed mode failed and return;
change clock divisor value or configure the system clock feeding into ESDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
(data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
send CMD6 with argument 0x2B90100;
set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
send CMD8 to get EXT_CSD value of MMC;
check if HS_TIMING byte (byte number 185) is 0;
if (HS_TIMING is not 0) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into ESDHC to generate the
card_clk of the desired value below 20MHz;
(data transactions like normal peers)
}
```

26.4.4.4 Set MMC Bus Width

```
change_mmc_bus_width(void)
{
send CMD9 to get CSD value of MMC;
check if the value of SPEC_VER field is 4 or above;
if (SPEC_VER value is less than 4) report the MMC does not support multiple bit width and
return;
send CMD6 with argument 0x3B70x00; (8-bit, x=2; 4-bit, x=1; 1-bit, x=0)
send CMD13 to wait card ready (busy line released);
(data transactions like normal peers)
}
```

26.4.5 ADMA Operation

26.4.5.1 ADMA1 Operation

```
Set_adma1_descriptor
{
if (to start data transfer) {
// Make sure the address is 4KB align.
Set 'Set' type descriptor;
{
```

```
Set Act bits to 01;
Set [31:12] bits data length (byte unit);
}
Set 'Tran' type descriptor;
{
Set Act bits to 10;
Set [31:12] bits address (4KB align);
}
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to 11;
Set [31:12] bits the next descriptor address (4KB align);
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set End bit to 1;
}
if (to generate interrupt for this descriptor) {
Set Int bit to 1;
}
Set Valid bit to 1;
}
```

26.4.5.2 ADMA2 Operation

```
Set_adma2_descriptor
{
if (to start data transfer) {
// Make sure the address is 32-bit boundary (lower 2-bit are always '00').
Set higher 32-bit of descriptor for this data transfer initial address;
Set [31:16] bits data length (byte unit);
Set Act bits to '10';
}
else if (to fetch descriptor at non-continuous address) {
Set Act bits to '11';
// Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
Set higher 32-bit of descriptor for the next descriptor address;
}
else { // other types of descriptor
Set Act bits accordingly
}
if (this descriptor is the last one) {
Set 'End' bit '1';
}
if (to generate interrupt for this descriptor) {
Set 'Int' bit '1';
}
Set the 'Valid' bit to '1';
}
```

26.4.6 Fast Boot Operation

26.4.6.1 Normal fast boot flow

1. Software must configure INITA bit ESDHC_SYSCTL[27] to make sure 74 card clocks are finished.

2. Software must configure MMC Boot Register (ESDHC_MMCBOOT) (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 0 (normal fast boot), and bit 4 to select the ack mode or not. If it is necessary to send through DMA mode, bit 7 must be configured to enable automatic stop at block gap feature. And need to configure bit 3-bit0 must be configured to select the ack timeout value according to the sd clk frequence.
3. Software must then configure Block Attributes Register to set block size/no.
4. Software must configure Protocol control register to set DTW (data transfer width).
5. Software must configure Command Argument Register to set argument if needed (no need in normal fast boot).
6. Software must configure Transfer Type Register to start the boot process. In normal boot mode, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1.

NOTE

DMAEN should be configured as 0 in polling mode. If BCEN is configured as 1, it is best to configure blk no in Bock Attributes Register to the max value.

7. When step 6 is configured, the boot process will begin. Software must poll the data buffer ready status to read the data from buffer in time. If boot time-out happens (ack time out or the first data read time out), interrupt will be triggered, and software must configure MMC Boot Register, bit 6 to 0 to disable boot. This will make CMD high, and after at least 56 clocks, it is ready to begin normal initialization process.
8. If no time out occurs, the software must decide if the data read is finished and then configure MMC Boot Register bit 6 to 0 to disable boot. This will make CMD line high and command completed is asserted. After at least 56 clock cycles, it is ready to begin normal initialization process.
9. Reset the host and then can begin the normal process.

26.4.6.2 Alternative fast boot flow

1. Software must configure init_active bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software must configure MMC Boot Register (ESDHC_MMCBOOT) (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 1 (alternative boot), and bit 4 to select the ack mode or not. If it is necessary to send through DMA mode, bit 7 must be configured to enable automatic stop at block gap feature. Bit 3 through bit0 must be configured to select the ack timeout value according to the sd clk frequence.
3. Software must then configure Block Attributes Register to set block size/no.
4. Software mustconfigure Protocol control register to set DTW (data transfer width).

5. Software must configure Command Argument Register to set argument to 0xFFFFFFFA.
6. Software must configure Transfer Type Register to start the boot process by CMD0 with 0xFFFFFFFA argument . In alternative boot, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1.

NOTE

DMAEN should be configured as 0 in polling mode. And if BCEN is configured as 1 in polling mode, it is best to configure blk no in Bock Attributes Register to the max value.

7. When the step 6 is configured, boot process begins. Software must poll the data buffer ready status to read the data from buffer in time. If boot time out (acknowledge data time out in 50ms or data time out in 1s), host will send out the interrupt and software need to send CMD0 with reset and then configure boot enable bit to 0 to stop this process. After command completed, configure MMC Boot Register bit 6 to 0 to disable boot. After at least 8 clocks from command completed, card is ready for identification step.
8. If no time out occurs, software must decide when to stop the boot process, and send out the CMD0 with reset. After this command is completed, configure MMC Boot Register bit 6 to stop the process. After 8 clocks from command are completed, the slave (card) is ready for the identification step.
9. Reset the host and then can begin the normal process.

26.4.6.3 Fast boot application case (in DMA mode)

In the boot application case, because the image destination and the image size are contained in the

beginning of the image, DMA parameters must be switched on the fly during MMC fast boot.

In fast boot, host can use ADMA2 (Advanced DMA2) with two destinations.

The detail flow:

1. Software must configure init_active bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software must configure MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot), to 1 (alternative boot); and bit 4 to select the acknowledge mode or not. In DMA mode, configure bit 7 to 1 for enable

automatically stop at block gap feature. Also configure bit31-bit16 to set the VALUE1 (value of block count that need to transfer first time), that host will stop at block gap when card block counter is equal to this value. Bit 3 through bit0 must be configured to select the acknowledge timeout value according to the SD clock frequency.

3. Software must then configure Block Attributes Register to set block size/no. In DMA mode, it is better to set block number to the max value (16'hFFFF).
4. Software must configure Protocol control register to set DTW (data transfer width).
5. Software enbables ADMA2 by configuring protocol control register bit9-bit8.
6. Software must set at least three pairs ADMA2 descriptor in boot memory (i.e. in IRAM, at least 6 words). The first pair descriptor define the start address (i.e. IRAM) and data length (that is, 512 bytes*VALUE1) of first part boot code. Software also must set the second pair descriptor, the second start address (any value that is writeable), data length is suggest to set 1~2word (record as VAULE2).

NOTE

The second couple descriptor also transfers useful data. (At lease 1 word because the ADMA2 can't support a 0 data_length data transfer descriptor.)

7. Software must configure Command Argument Register to set argument to 0xFFFFFFFA in alternative fast boot, and do not need set in normal fast boot.
8. Software must configure Transfer Type Register to start the boot process. CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, and MSBSEL is set to 1. DMAEN is configured as 1 in DMA mode. And if BCEN is configured as 1, it is best to configure block no in Bock Attributes Register to the max value.
9. When the step 8 is configured, boot process will begin. The first VAULE1 block number data has transfer. Software must poll TC bit (bit1 in Interrupt Status Register) to determine if the first transfer has ended. Software must poll BGE bit (bit2 in Interrupt Status Register) to determine if first transfer has stopped at block gap.
10. When TC, BGE bit is 1, SW can analyze the first code of VAULE1 block, initialize the new memory device, if required, and set the third pair of descriptors to define the start address and length of the remaining part of boot code (VAULE3 the remain boot code block). Remember to set the last descriptor with END.
11. Software must configure MMC Boot Register (ESDHC_MMCBOOT) (offset 0xc4) again. Set bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot), to 1 (alternative boot); and bit 4 to select the acknowledge mode or not. In DMA mode, configure bit 7 to 1 to enable automatic stop at block gap feature. Bit31-bit16 must be configured to set the (VAULE1+1+VAULE3) so that host will stop at block gap when card

block counter is equal to this value. And must configure bit 3-bit0 to select the acknowledge timeout value according to the SD clock frequency.

12. Software must clear TC and BGE bit. It must also clear SABGREQ (bit 16 in Protocol control register), and set CREQ (bit17 Protocol control register) to 1 to resume the data transfer. Host will transfer the VALUE2 and VAULE3 data to the destination that is set by descriptor.
13. Software must poll BGE bit to determine if the fast boot is over.

NOTE

When ADMA boot flow is started, for ESDHC, it is like a normal ADMA read operation. In order to keep descriptor, must have a memory length of at least a few words.For the 1~2 word data in second descriptor setting, it is the useful data, so software need to deal the data due to the application case.

26.5 Commands for MMC/SD/SDIO

See table below for the list of commands for the MMC/SD/SDIO cards.

Refer to the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the MultiMediaCard:

1. broadcast commands (bc), no response.
2. broadcast commands with response (bcr), response from all cards simultaneously.
3. addressed (point-to-point) commands (ac), no data transfer on the DAT.
4. addressed (point-to-point) data transfer commands (adtc).

The Access Bits for the EXT_CSD Access Modes are shown in table below.

Table 26-2. Commands for MMC/SD/SDIO Cards

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD0	bc	[31:0] stuff bits	-	GO_IDLE_STATE	Resets all MMC and SD memory cards to idle state.
CMD1	bcr	[31:0] OCR without busy	R3	SEND_OP_COND	Asks all MMC and SD Memory cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD2	bcr	[31:0] stuff bits	R2	ALL_SEND_CID	Asks all cards to send their CID numbers on the CMD line.

Table continues on the next page...

Table 26-2. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD3[1]	ac	[31:6] RCA [15:0] stuff bits	R1 R6 (SDIO)	SET/ SEND_RELATIVE_ADDR	Assigns relative address to the card.
CMD4	bc	[31:0] DSR [15:0] stuff bits	-	SET_DSR	Programs the DSR of all cards.
CMD5	bc	[31:0] OCR without busy	R4	IO_SEND_OP_COND	Asks all SDIO cards in idle state to send their operation conditions register contents in the response on the CMD line.
CMD6[2]	adtc	[31] Mode 0: Check function 1: Switch function [30:8] Reserved for function groups 6 ~ 3 (All 0 or 0xFFFF) [7:4] Function group1 for command system [3:0] Function group2 for access mode	R1	SWITCH_FUNC	Checks switch ability (mode 0) and switch card function (mode 1). Refer to "SD Physical Specification V1.1" for more details.
CMD6[3]	ac	[31:26] Set to 0 [25:24] Access [23:16] Index [15:8] Value [7:3] Set to 0 [2:0] Cmd Set	R1b	SWITCH	Switches the mode of operation of the selected card or modifies the EXT_CSD registers. Refer to "The MultiMediaCard System Specification Version 4.0 Final draft 2" for more details.
CMD7	ac	[31:6] RCA [15:0] stuff bits	R1b	SELECT/ DESELECT_CARD	Toggles a card between the stand-by and transfer states or between the programming and disconnect states. In both cases, the card is selected by its own relative address and gets deselected by any other address. Address 0 deselects all.
CMD8	adtc	[31:0] stuff bits	R1	SEND_EXT_CSD	The card sends its EXT_CSD register as a block of data, with a block size of 512 bytes.
CMD9	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CSD	Addressed card sends its card-specific data (CSD) on the CMD line.
CMD10	ac	[31:6] RCA [15:0] stuff bits	R2	SEND_CID	Addressed card sends its card-identification (CID) on the CMD line.

Table continues on the next page...

Table 26-2. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD11	adtc	[31:0] data address	R1	READ_DAT_UNTIL_STOP	Reads data stream from the card, starting at the given address, until a STOP_TRANSMISSION follows.
CMD12	ac	[31:0] stuff bits	R1b	STOP_TRANSMISSION	Forces the card to stop transmission.
CMD13	ac	[31:6] RCA [15:0] stuff bits	R1	SEND_STATUS	Addressed card sends its status register.
CMD14	Reserved				
CMD15	ac	[31:6] RCA [15:0] stuff bits	-	GO_INACTIVE_STATE	Sets the card to inactive state in order to protect the card stack against communication breakdowns.
CMD16	ac	[31:0] block length	R1	SET_BLOCKLEN	Sets the block length (in bytes) for all following block commands (read and write). Default block length is specified in the CSD.
CMD17	adtc	[31:0] data address	R1	READ_SINGLE_BLOCK	Reads a block of the size selected by the SET_BLOCKLEN command.
CMD18	adtc	[31:0] data address	R1	READ_MULTIPLE_BLOCK	Continuously transfers data blocks from card to host until interrupted by a stop command.
CMD19	Reserved				
CMD20	adtc	[31:0] data address	R1	WRITE_DAT_UNTIL_STOP	Writes data stream from the host, starting at the given address, until a STOP_TRANSMISION follows.
CMD21-23	Reserved				
CMD24	adtc	[31:0] data address	R1	WRITE_BLOCK	Writes a block of the size selected by the SET_BLOCKLEN command.
CMD25	adtc	[31:0] data address	R1	WRITE_MULTIPLE_BLOCK	Continuously writes blocks of data until a STOP_TRANSMISSION follows.
CMD26	adtc	[31:0] stuff bits	R1	PROGRAM_CID	Programming of the card identification register. This command shall be issued only once per card. The card contains hardware to prevent this operation after the first programming. Normally this command is reserved for the manufacturer.
CMD27	adtc	[31:0] stuff bits	R1	PROGRAM_CSD	Programming of the programmable bits of the CSD.

Table continues on the next page...

Table 26-2. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD28	ac	[31:0] data address	R1b	SET_WRITE_PROT	If the card has write protection features, this command sets the write protection bit of the addressed group. The properties of write protection are coded in the card specific data (WP_GRP_SIZE).
CMD29	ac	[31:0] data address	R1b	CLR_WRITE_PROT	If the card provides write protection features, this command clears the write protection bit of the addressed group.
CMD30	adtc	[31:0] write protect data address	R1	SEND_WRITE_PROT	If the card provides write protection features, this command asks the card to send the status of the write protection bits.
CMD31	Reserved				
CMD32	ac	[31:0] data address	R1	TAG_SECTOR_START	Sets the address of the first sector of the erase group.
CMD33	ac	[31:0] data address	R1	TAG_SECTOR_END	Sets the address of the last sector in a continuous range within the selection of a single sector to be selected for erase.
CMD34	ac	[31:0] data address	R1	UNTAG_SECTOR	Removes one previously selected sector from the erase selection.
CMD35	ac	[31:0] data address	R1	TAG_ERASE_GROUP_START	Sets the address of the first erase group within a range to be selected for erase.
CMD36	ac	[31:0] data address	R1	TAG_ERASE_GROUP_END	Sets the address of the last erase group within a continuous range to be selected for erase.
CMD37	ac	[31:0] data address	R1	UNTAG_ERASE_GROUP	Removes one previously selected erase group from the erase selection.
CMD38	ac	[31:0] stuff bits	R1b	ERASE	Erase all previously selected sectors.
CMD39	ac	[31:0] RCA [15] register write flag [14:8] register address [7:0] register data	R4	FAST_IO	Used to write and read 8-bit (register) data fields. The command addresses a card, and a register, and provides the data for writing if the write flag is set. The R4 response contains data read from the address register. This command accesses application dependent registers which are not defined in the MMC standard.
CMD40	bcr	[31:0] stuff bits	R5	GO_IRQ_STATE	Sets the system into interrupt mode.

Table continues on the next page...

Table 26-2. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
CMD41	Reserved				
CDM42	adtc	[31:0] stuff bits	R1b	LOCK_UNLOCK	Used to set/reset the password or lock/unlock the card. The size of the data block is set by the SET_BLOCK_LEN command.
CMD43~51	Reserved				
CMD52	ac	[31:0] stuff bits	R5	IO_RW_DIRECT	Access a single register within the total 128k of register space in any I/O function.
CMD53	ac	[31:0] stuff bits	R5	IO_RW_EXTENDED	Accesses a multiple I/O register with a single command. Allows the reading or writing of a large number of I/O registers.
CMD54	Reserved				
CMD55	ac	[31:16] RCA [15:0] stuff bits	R1	APP_CMD	Indicates to the card that the next command is an application specific command rather that a standard command.
CMD56	adtc	[31:1] stuff bits [0]: RD/WR	R1b	GEN_CMD	Used either to transfer a data block to the card or to get a data block from the card for general purpose / application specific commands. The size of the data block is set by the SET_BLOCK_LEN command.
CMD57~59	Reserved				
CMD60	adtc	[31] WR [30:24] stuff bits [23:16] address [15:8] stuff bits [7:0] byte count	R1b	RW_MULTIPLE_REGISTER	These registers are used to control the behavior of the device and to retrieve status information regarding the operation of the device. All Status and Control registers are WORD (32-bit) in size and are WORD aligned. CMD60 shall be used to read and write these registers.
CMD61	adtc	[31] WR [30:16] stuff bits [15:0] data unit count	R1b	RW_MULTIPLE_BLOCK	The host issues a RW_MULTIPLE_BLOCK (CMD61) to begin the data transfer.
CMD62~63	Reserved				
ACMD6[4]	ac	[31:2] stuff bits [1:0] bus width	R1	SET_BUS_WIDTH	Defines the data bus width ('00'=1bit or '10'=4bit bus) to be used for data transfer. The allowed data bus widths are given in SCR register.
ACMD13[4]	adtc	[31:0] stuff bits	R1	SD_STATUS	Send the SD Memory Card status.

Table continues on the next page...

Table 26-2. Commands for MMC/SD/SDIO Cards (continued)

CMD INDEX	Type	Argument	Resp	Abbreviation	Description
ACMD22[4]	adtc	[31:0] stuff bits	R1	SEND_NUM_WR_SECTORS	Send the number of the written sectors (without errors). Responds with 32-bit plus the CRC data block.
ACMD23[4]	ac		R1	SET_WR_BLK_ERASE_COUNT	-
ACMD41[4]	bcr	[31:0] OCR	R3	SD_APP_OP_COND	Asks the accessed card to send its operating condition register (OCR) contents in the response on the CMD line.
ACMD42[4]	ac		R1	SET_CLR_CARD_DETECT	-
ACMD51[4]	adtc	[31:0] stuff bits	R1	SEND_SCR	Reads the SD Configuration Register (SCR).

1. CMD3 differs for MMC and SD cards. For MMC cards, it is referred to as SET_RELATIVE_ADDR, with a response type of R1. For SD cards, it is referred to as SEND_RELATIVE_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed MMC cards and high speed SD cards. Command SWITCH_FUNC is for high speed SD cards.
3. Command SWITCH is for high speed MMC cards . The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH_ERROR status bit in the EXT_CSD register is set. The Access Bits are shown in Table 26-3.
4. ACMDs shall be preceded with the APP_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this block).

Table 26-3. EXT_CSD Access Modes

Bits	Access Name	Operation
00	Command Set	The command set is changed according to the Cmd Set field of the argument
01	Set Bits	The bits in the pointed byte are set, according to the 1 bits in the Value field.
10	Clear Bits	The bits in the pointed byte are cleared, according to the 1 bits in the Value field.
11	Write Byte	The Value field is written into the pointed byte.

26.6 Software Restrictions

26.6.1 Initialization Active

The driver cannot set INITA bit in System Control register when any of the command line or data lines is active, so the driver must ensure both CDIHB and CIHB bits are cleared. In order to auto clear the INITA bit, the SDCLKEN bit must be '1', otherwise no clocks can go out to the card and INITA will never clear.

26.6.2 Softeware Polling Procedure

For polling read or write, once the software begins a buffer read or write, it must access exactly the number of times as the values set in the Watermark Level Register; moreover, if the block size is not the times of the value in Watermark Level Register (read and write respectively), the software must access exactly the remaining number of words at the end of each block. For example, for read operation, if the RD_WML is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

26.6.3 Suspend Operation

In order to suspend the data transfer, the software must inform ESDHC that the suspend command is successfully accepted. To achieve this, after the Suspend command is accepted by the SDIO card, software must send another normal command marked as suspend command (CMDTYP bits set as '01') to inform ESDHC that the transfer is suspended.

If software needs to resume the suspended trasnfer, it should read the value in BLKCNT register to save the remaining number of blocks before sending the normal command marked as suspend, otherwise on sending a 'suspend' command, ESDHC will regard the current transfer as aborted and change BLKCNT register to its original value, rather than keeping the remaining number of blocks.

26.6.4 Data Length Setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be a multiple of 4.

26.6.5 (A)DMA Address Setting

To configure ADMA1/ADMA2/DMA address register, when TC bit is set, the register will always update itself with the internal address value to support dynamic address synchronization, so software must make sure TC bit is cleared prior to configuring ADMA1/ADMA2/DMA address register.

26.6.6 Data Port Access

Data Port does not support parallel access. For example, during an external DMA access, it is not allowed to write any data to the Data Port by ARM platform; or during a ARM read operation, it is also prohibited to write any data to the Data Port, by either ARM or external DMA. Otherwise the data would be corrupted inside the ESDHC buffer.

26.6.7 Change Clock Frequency

ESDHC does not automatically gates off the card clock when the Host Driver changes the clock frequency. To remove possible glitch on the card clock, clear SDCLKEN bit when changing clock divisor value and set SDCLKEN bit to '1' after SDSTB bit is '1' again.

26.6.8 Multi-block Read

For pre-defined multi-block read operation, that is, the number of blocks to read has been defined by previous CMD23 for MMC, or pre-defined number of blocks in CMD53 for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an abort command, either automatic or manual CMD12/CMD52, is still required by ESDHC after the pre-defined number of blocks are done, to drive the internal state machine to idle mode. In this case, the card may not respond to this extra abort command and ESDHC will get Response Timeout. It is recommended to manually send an abort command with RSPTYP[1:0] both bits cleared.

26.7 Programmable Registers

This section includes the block memory map and detailed descriptions of all registers. Each of these registers support only 32-bit accesses.

NOTE

Addresses greater than 0x44, except 0x50, 0x54, 0x58, 0x60, 0x64, 0xC0, 0xC4 and 0xFC, are reserved and read as all 0s. Write to these registers is ignored.

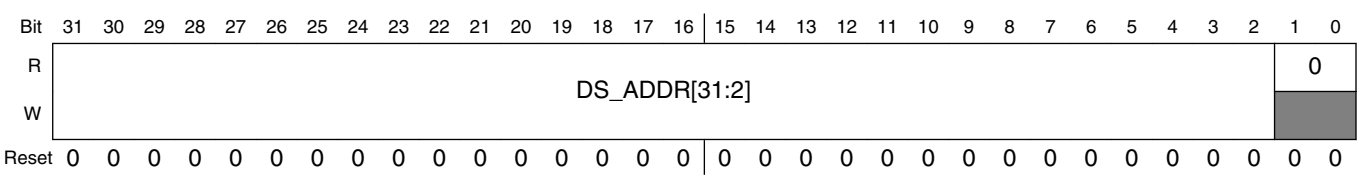
26.7.1 DMA System Address (ESDHCV2x_DSADDR)

This register contains the physical system memory address used for DMA transfers.

Addresses: ESDHCV2-1_DSADDR is 5000_4000h base + 0h offset = 5000_4000h
ESDHCV2-2_DSADDR is 5000_8000h base + 0h offset = 5000_8000h
ESDHCV2-4_DSADDR is 5002_4000h base + 0h offset = 5002_4000h



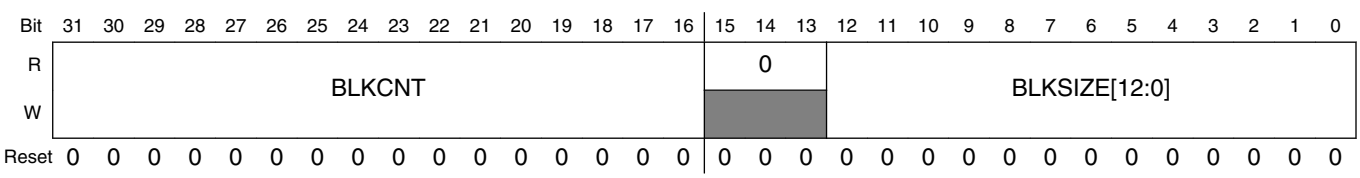
ESDHCV2x_DSADDR field descriptions

Field	Description
31–2 DS_ADDR[31:2]	DMA System Address: This register contains the 32-bit system memory address for a DMA transfer. As the address must be word (4 bytes) align, the least 2 bits are reserved, always 0. When the ESDHC stops a DMA transfer, this register points to the system address of the next contiguous data position. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operation during transfers may return an invalid value. The Host Driver shall initialize this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register. This register is protected during a data transfer. When data lines are active, write to this register is ignored. The Host driver shall wait, until ESDHCV2_PRSSTAT[DLA] bit is cleared, before writing to this register. The ESDHC internal DMA does not support a virtual memory system. It only supports continuous physical memory access. And due to AHB burst limitations, if the burst must cross the 1 KB boundary, ESDHC will automatically change SEQ burst type to NSEQ. As this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so SW cannot change this register when TC bit is set. Such restriction is also listed in Software Restrictions.
1–0 Reserved	This read-only field is reserved and always has the value zero. Reserved

26.7.2 Block Attributes (ESDHCV2x_BLKATTR)

This register is used to configure the number of data blocks and the number of bytes in each block.

Addresses: ESDHCV2-1_BLKATTR is 5000_4000h base + 4h offset = 5000_4004h
ESDHCV2-2_BLKATTR is 5000_8000h base + 4h offset = 5000_8004h
ESDHCV2-4_BLKATTR is 5002_4000h base + 4h offset = 5002_4004h



ESDHCV2x_BLKATTR field descriptions

Field	Description
31–16 BLKCNT	Blocks Count For Current Transfer: This register is enabled when ESDHCV2_XFERTYP[BCEN] bit is set to 1 and is valid only for multiple block transfers. For single block transfer, this register will always read as 1. The Host Driver shall set this register to a value between 1 and the maximum block count. The ESDHC decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to 0 results in no data blocks being transferred. This register should be accessed only when no transaction is executing (that is, after transactions have stopped). During data transfer, read operations on this register may return an invalid value and write operations are ignored.

Table continues on the next page...

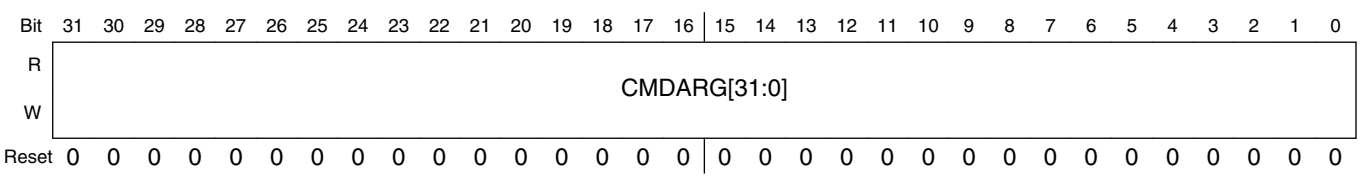
ESDHCV2x_BLKATTR field descriptions (continued)

Field	Description
	When saving transfer content as a result of a Suspend command, the number of blocks yet to be transferred can be determined by reading this register. The reading of this register should be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend. This is because when Suspend command is sent out, ESDHC will regard the current transfer is aborted and change BLKCNT register back to its original value instead of keeping the dynamical indicator of remained block count. When restoring transfer content prior to issuing a Resume command, the Host Driver shall restore the previously saved block count. 0xFFFF 65535 blocks 0x0002 2 blocks 0x0001 1 block 0x0000 Stop Count
15–13 Reserved	This read-only field is reserved and always has the value zero. Reserved
12–0 BLKSIZE[12:0]	Transfer Block Size: This register specifies the block size for block data transfers. Values ranging from 1 byte up to the maximum buffer size can be set. It can be accessed only when no transaction is executing (that is, after a transaction has stopped). Read operations during transfers may return an invalid value, and write operations will be ignored. 0x1000 4096 Bytes 0x800 2048 Bytes 0x200 512 Bytes 0x1FF 511 Bytes 0x004 4 Bytes 0x003 3 Bytes 0x002 2 Bytes 0x001 1 Byte 0x000 No data transfer

26.7.3 Command Argument (ESDHCV2x_CMDARG)

This register contains the SD/MMC Command Argument.

Addresses: ESDHCV2-1_CMDARG is 5000_4000h base + 8h offset = 5000_4008h
ESDHCV2-2_CMDARG is 5000_8000h base + 8h offset = 5000_8008h
ESDHCV2-4_CMDARG is 5002_4000h base + 8h offset = 5002_4008h



ESDHCV2x_CMDARG field descriptions

Field	Description
31–0 CMDARG[31:0]	Command Argument: The SD/MMC Command Argument is specified as bits 39-8 of the Command Format in the SD or MMC Specification.This register is write protected when the Command Inhibit (CMD) bit in the Present State register is set.

26.7.4 Command Transfer Type (ESDHCV2x_XFERTYP)

This register is used to control the operation of data transfers. The Host Driver sets this register before issuing a command followed by a data transfer, or before issuing a Resume command. To prevent data loss, the ESDHC prevents writing to the bits, that are involved in the data transfer of this register, when data transfer is active. These bits are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN and DMAEN.

The Host Driver shall check the Command Inhibit DAT bit (CDIHB) and the Command Inhibit CMD bit (CIHB) in the Present State register before writing to this register. When the CDIHB bit in the Present State register is set, any attempt to send a command with data by writing to this register is ignored; when the CIHB bit is set, any write to this register is ignored.

On sending commands with data transfer involved, it is mandatory that the block size is non-zero. Besides, block count must also be non-zero, or indicated as single block transfer (bit 5 of this register is '0' when written), or block count is disabled (bit 1 of this register is '0' when written), otherwise ESDHC will ignore the sending of this command and do nothing. For write command, with all above restrictions, it is also mandatory that the write protect switch is not active (WPSPL bit of Present State Register is '1), otherwise ESDHC will also ignore the command.

If the commands with data transfer does not receive the response in 64 clock cycles, that is, response time-out, ESDHC will regard the external device does not accept the command and abort the data transfer. In this scenario, the driver should issue the command again to re-try the transfer. It is also possible that for some reason the card responds the command but ESDHC does not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The CMDTYP field of this register is used to initiate three special commands these are:

- Suspend: ESDHC does not monitor the content of the Suspend command response and therefore assumes that the commnand succeeds when issued. It then operates assuming the card bus has been released and that it is permissible to issue the next command using the DAT line. It is the responsibility of S/W to check the status of

the Suspend command and send another command marked as Suspend to inform the ESDHC that a Suspend command was successfully issued. Refer to Suspend Resume for more details. After the end bit of command is sent, ESDHC de-asserts Read Wait for read transactions and stops checking busy for write transactions. In 4-bit mode, the interrupt cycle starts. If the Suspend command fails, the ESDHC will maintain its current state and the Host Driver shall restart the transfer by setting the Continue Request bit in the Protocol Control register.

- Resume: S/W re-starts the data transfer by restoring the registers saved before sending the Suspend Command and then sends the Resume Command. The ESDHC will check for a pending busy state before starting write transfers.
- Abort: If this command is set when executing a read transfer, ESDHC will stop reads to the buffer. If this command is set when executing a write transfer, ESDHC will stop driving the DAT line. After issuing the Abort command, the Host Driver should issue a software reset (Abort Transaction).

Command Transfer Type (ESDHCV2_XFERTYP) shows the summary of how register settings determine the type of data transfer.

Table 26-42. Transfer Type Register Setting for Various Transfer Types

Multi/Single Block Select	Block Count Enable	Block Count	Function
0	Don't Care	Don't Care	Single Transfer
1	0	Don't Care	Infinite Transfer
1	1	Positive Number	Multiple Transfer
1	1	Zero	No Data Transfer

Table below shows the relationship between the Command Index Check Enable and the Command CRC Check Enable, in regards to the Response Type bits and the name of the response type.

Table 26-43. Relationship Between Parameters and the Name of the Response Type

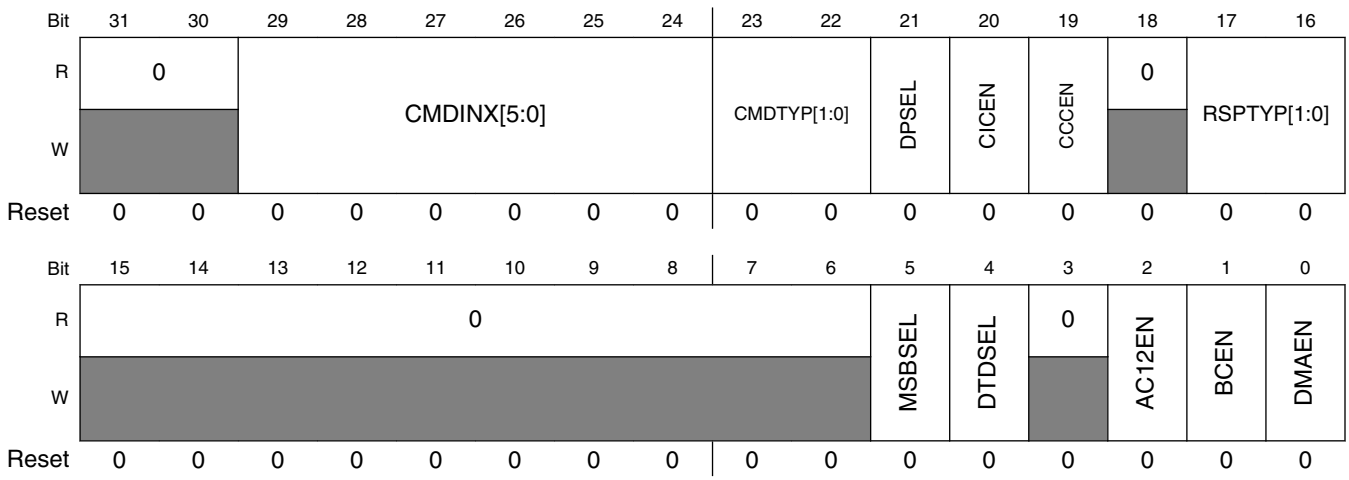
Response Type	Index Check Enable	CRC Check Enable	Name of Response Type
00	0	0	No Response
01	0	1	R2
10	0	0	R3,R4
10	1	1	R1,R5,R6
11	1	1	R1b,R5b

- In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification. But R5b is defined in this specification to indicate

that ESDHC will check the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command will be used with R5b.

- The CRC field for R3 and R4 is expected to be all 1 bits. The CRC check shall be disabled for these response types.

Addresses: ESDHCV2-1_XFERTYP is 5000_4000h base + Ch offset = 5000_400Ch
ESDHCV2-2_XFERTYP is 5000_8000h base + Ch offset = 5000_800Ch
ESDHCV2-4_XFERTYP is 5002_4000h base + Ch offset = 5002_400Ch



ESDHCV2x_XFERTYP field descriptions

Field	Description
31–30 Reserved	This read-only field is reserved and always has the value zero. Reserved
29–24 CMDINX[5:0]	Command Index: These bits shall be set to the command number that is specified in bits 45-40 of the Command-Format in the SD Memory Card Physical Layer Specification and SDIO Card Specification.
23–22 CMDTYP[1:0]	Command Type: 11 Abort CMD12, CMD52 for writing I/O Abort in CCCR 10 Resume CMD52 for writing Function Select in CCCR 01 Suspend CMD52 for writing Bus Suspend in CCCR 00 Normal mode. Used for all other commands
21 DPSEL	Data Present Select: This bit is set to 1 to indicate that data is present and shall be transferred using the DAT line. It is set to 0 for the following: • Commands using only the CMD line (for example, CMD52). • Commands with no data transfer, but using the busy signal on DAT[0] line (R1b or R5b such as, CMD38) **NOTE:** In resume command, this bit shall be set, and other bits in this register shall be set the same as when the transfer was initially launched. When the Write Protect switch is on, (that is, the WPSPL bit is active as '0'), any command with a write operation will be ignored. That is to say, when this bit is set, while the DTDSEL bit is 0, writes to the register Transfer Type are ignored.

Table continues on the next page...

ESDHCV2x_XFERTYP field descriptions (continued)

Field	Description
	1 Data Present 0 No Data Present
20 CICEN	Command Index Check Enable: If this bit is set to 1, the ESDHC will check the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this bit is set to 0, the Index field is not checked. 1 Enable 0 Disable
19 CCCEN	Command CRC Check Enable: If this bit is set to 1, the ESDHC shall check the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this bit is set to 0, the CRC field is not checked. The number of bits checked by the CRC field value changes according to the length of the response. (Refer to RSPTYP[1:0] and Command Transfer Type (ESDHCV2_XFERTYP).) 1 Enable 0 Disable
18 Reserved	This read-only field is reserved and always has the value zero. Reserved
17–16 RSPTYP[1:0]	Response Type Select: 00 No Response 01 Response Length 136 10 Response Length 48 11 Response Length 48, check Busy after response
15–6 Reserved	This read-only field is reserved and always has the value zero. Reserved
5 MSBSEL	Multi / Single Block Select: This bit enables multiple block DAT line data transfers. For any other commands, this bit shall be set to 0. If this bit is 0, it is not necessary to set the Block Count register. (See Command Transfer Type (ESDHCV2_XFERTYP).) 1 Multiple Blocks 0 Single Block
4 DTDSEL	Data Transfer Direction Select: This bit defines the direction of DAT line data transfers. The bit is set to 1 by the Host Driver to transfer data from the SD card to the ESDHC and is set to 0 for all other commands. 1 Read (Card to Host) 0 Write (Host to Card)
3 Reserved	This read-only field is reserved and always has the value zero. Reserved
2 AC12EN	Auto CMD12 Enable:

Table continues on the next page...

ESDHCV2x_XFERTYP field descriptions (continued)

Field	Description
	Multiple block transfers for memory require a CMD12 to stop the transaction. When this bit is set to 1, the ESDHC will issue a CMD12 automatically when the last block transfer has completed. The Host Driver shall not set this bit to issue commands that do not require CMD12 to stop a multiple block data transfer. In particular, secure commands defined in File Security Specification (see reference list) do not require CMD12. In single block transfer, the ESDHC will ignore this bit no matter if it is set or not. 1 Enable 0 Disable
1 BCEN	Block Count Enable: This bit is used to enable the Block Count register, which is only relevant for multiple block transfers. When this bit is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer. 1 Enable 0 Disable
0 DMAEN	DMA Enable: This bit enables DMA functionality. If this bit is set to 1, a DMA operation shall begin when the Host Driver sets the DPSEL bit of this register. Whether the Simple DMA, or the Advanced DMA, is active depends on the DMA Select field of the Protocol Control register. 1 Enable 0 Disable

26.7.5 Command Response 0 (ESDHCV2x_CMDRSP0)

This register is used to store part 0 of the response bits from the card.

Addresses: ESDHCV2-1_CMDRSP0 is 5000_4000h base + 10h offset = 5000_4010h
ESDHCV2-2_CMDRSP0 is 5000_8000h base + 10h offset = 5000_8010h
ESDHCV2-4_CMDRSP0 is 5002_4000h base + 10h offset = 5002_4010h

ESDHCV2x_CMDRSP2 field descriptions

Field	Description
31–0 CMDRSP2[31:0]	Command Response 2: Refer to Command Response 3 (ESDHCV2_CMDRSP3) for the mapping of command responses from the SD Bus to this register for each response type.

26.7.8 Command Response 3 (ESDHCV2x_CMDRSP3)

This register is used to store part 3 of the response bits from the card.

Command Response 3 (ESDHCV2_CMDRSP3) describes the mapping of command responses from the SD Bus to Command Response registers for each response type. In the table, R[] refers to a bit range within the response data as transmitted on the SD Bus.

Table 26-48. Response Bit Definition for Each Response Type

Response Type	Meaning of Response	Response Field	Response Register
R1,R1b (normal response)	Card Status	R[39:8]	ESDHCV2_CMDRSP0
R1b (Auto CMD12 response)	Card Status for Auto CMD12	R[39:8]	ESDHCV2_CMDRSP3
R2 (CID, CSD register)	CID/CSD register [127:8]	R[127:8]	{ESDHCV2_CMDRSP3[23:0], ESDHCV2_CMDRSP2, ESDHCV2_CMDRSP1, ESDHCV2_CMDRSP0}
R3 (OCR register)	OCR register for memory	R[39:8]	ESDHCV2_CMDRSP0
R4 (OCR register)	OCR register for I/O etc.	R[39:8]	ESDHCV2_CMDRSP0
R5, R5b	SDIO response	R[39:8]	ESDHCV2_CMDRSP0
R6 (Publish RCA)	New Published RCA[31:16] and card status[15:0]	R[39:9]	ESDHCV2_CMDRSP0

This table shows that most responses with a length of 48 (R[47:0]) have 32-bits of the response data (R[39:8]) stored in the ESDHCV2_CMDRSP0 register. Responses of type R1b (Auto CMD12 responses) have response data bits (R[39:8]) stored in the ESDHCV2_CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bits of the response data (R[127:8]) stored in the ESDHCV2_CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, the ESDHC only stores part of the response data in the Command Response registers. This enables the Host Driver to efficiently read 32-bits of response data in one read cycle on a 32-bit bus system. Parts of the response, the Index field and the CRC, are checked by the ESDHC (as specified by the Command Index Check Enable and the Command CRC Check Enable bits in the Transfer Type register) and generate an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, the ESDHC will check R[47:1], and if the response length is 136 the ESDHC will check R[119:1].

As ESDHC may have a multiple block data transfer executing concurrently with a CMD_wo_DAT command, the ESDHC stores the Auto CMD12 response in the ESDHCV2_CMDRSP3 register. The CMD_wo_DAT response is stored in ESDHCV2_CMDRSP0. This allows the ESDHC to avoid overwriting the Auto CMD12 response with the CMD_wo_DAT and vice versa. When the ESDHC modifies part of the Command Response registers, as shown in the table above, it preserves the unmodified bits.

Addresses: ESDHCV2-1_CMDRSP3 is 5000_4000h base + 1Ch offset = 5000_401Ch
ESDHCV2-2_CMDRSP3 is 5000_8000h base + 1Ch offset = 5000_801Ch
ESDHCV2-4_CMDRSP3 is 5002_4000h base + 1Ch offset = 5002_401Ch

ESDHCV2x_DATPORT field descriptions

Field	Description
31–0 DATCONT[31:0]	Data Content: The Buffer Data Port register is for 32-bit data access by the ARM platform or the external DMA. When the internal DMA is enabled, any write to this register is ignored, and any read from this register will always yield 0s.

26.7.10 Present State (ESDHCV2x_PRSSTAT)

The Host Driver can get status of the ESDHC from this 32-bit read only register. It issues CMD0, CMD12, CMD13 (for memory) and CMD52 (for SDIO) when the DAT lines are busy during a data transfer. These commands can be issued when Command Inhibit (CMD) is set to zero. Other commands will be issued when Command Inhibit (DAT) is set to zero. Possible changes to the SD Physical Specification may add other commands to this list in the future.

NOTE

The reset value of Present State Register depend on testbench connectivity.

Addresses: ESDHCV2-1_PRSSTAT is 5000_4000h base + 24h offset = 5000_4024h
ESDHCV2-2_PRSSTAT is 5000_8000h base + 24h offset = 5000_8024h
ESDHCV2-4_PRSSTAT is 5002_4000h base + 24h offset = 5002_4024h

ESDHCV2x_PRSSTAT field descriptions

Field	Description
31–24 DLSL[7:0]	DAT[7:0] Line Signal Level: This status is used to check the DAT line level to recover from errors, and for debugging.This is especially useful in detecting the busy signal level from DAT[0]. The reset value is effected by the external pull-up/ pull-down resistors. By default, the read value of this bit field after reset is 8'b11110111, when DAT[3] is pulled down and the other lines are pulled up. DAT[7]: Data 7 line signal level DAT[6]: Data 6 line signal level

Table continues on the next page...

ESDHCV2x_PRSSTAT field descriptions (continued)

Field	Description
	DAT[5]: Data 5 line signal level DAT[4]: Data 4 line signal level DAT[3]: Data 3 line signal level DAT[2]: Data 2 line signal level DAT[1]: Data 1 line signal level DAT[0]: Data 0 line signal level
23 CLSL	CMD Line Signal Level: This status is used to check the CMD line level to recover from errors, and for debugging. The reset value is effected by the external pull-up/pull-down resistor, by default, the read value of this bit after reset is 1'b1, when the command line is pulled up.
22–20 Reserved	This read-only field is reserved and always has the value zero. Reserved
19 WPSPL	Write Protect Switch Pin Level: The Write Protect Switch is supported for memory and combo cards.This bit reflects the inverted value of the SD_WP pin of the card socket. A software reset does not affect this bit. The reset value is effected by the external write protect switch. If the SD_WP pin is not used, it should be tied low, so that the reset value of this bit is high and write is enabled. 1 Write enabled (SD_WP=0) 0 Write protected (SD_WP=1)
18 CDPL	Card Detect Pin Level: This bit reflects the inverse value of the SD_CD# pin for the card socket. Debouncing is not performed on this bit. This bit may be valid, but is not guaranteed, because of propagation delay. Use of this bit is limited to testing As it must be debounced by software. A software reset does not effect this bit. A write to the Force Event Register does not effect this bit. The reset value is effected by the external card detection pin. This bit shows the value on the SD_CD# pin (that is, when a card is inserted in the socket, it is 0 on the SD_CD# input, and consequently the CDPL reads 1.) 1 Card present (SD_CD#=0) 0 No card present (SD_CD#=1)
17 Reserved	This read-only field is reserved and always has the value zero. Reserved
16 CINS	Card Inserted: This bit indicates whether a card has been inserted. The ESDHC debounces this signal so that the Host Driver will not need to wait for it to stabilize. Changing from a 0 to 1 generates a Card Insertion interrupt in the Interrupt Status register. Changing from a 1 to 0 generates a Card Removal interrupt in the Interrupt Status register. A write to the Force Event Register does not effect this bit. The Software Reset For All in the System Control register does not effect this bit.A software reset does not effect this bit. 1 Card Inserted 0 Power on Reset or No Card
15–12 Reserved	This read-only field is reserved and always has the value zero. Reserved

Table continues on the next page...

ESDHCV2x_PRSSTAT field descriptions (continued)

Field	Description
11 BREN	Buffer Read Enable: This status bit is used for non-DMA read transfers. The ESDHC may implement multiple buffers to transfer data efficiently. This read only flag indicates that valid data exists in the host side buffer. If this bit is high, valid data greater than the watermark level exist in the buffer. A change of this bit from 1 to 0 occurs when any read from the buffer is made. A change of this bit from 0 to1 occurs when there is enough valid data ready in the buffer and the Buffer Read Ready interrupt has been generated and enabled. 1 Read enable 0 Read disable
10 BWEN	Buffer Write Enable: This status bit is used for non-DMA write transfers. The ESDHC can implement multiple buffers to transfer data efficiently. This read only flag indicates if space is available for write data. If this bit is 1, valid data greater than the watermark level can be written to the buffer. A change of this bit from 1 to 0 occurs when any write to the buffer is made. A change of this bit from 0 to 1 occurs when the buffer can hold valid data greater than the write watermark level and the Buffer Write Ready interrupt is generated and enabled. 1 Write enable 0 Write disable
9 RTA	Read Transfer Active: This status bit is used for detecting completion of a read transfer. This bit is set for either of the following conditions: • After the end bit of the read command. • When writing a 1 to the Continue Request bit in the Protocol Control register to restart a read transfer. A Transfer Complete interrupt is generated when this bit changes to 0. This bit is cleared for either of the following conditions: • When the last data block as specified by block length is transferred to the System, that is, all data are read away from ESDHC internal buffer. • When all valid data blocks have been transferred from ESDHC internal buffer to the System and no current block transfers are being sent as a result of the Stop At Block Gap Request being set to 1. 1 Transferring data 0 No valid data
